la (12 minutes). For each of the following OCaml function definitions, give the type of the function and explain in words what the function does, from the caller's point of view. Assume the usual environment where '\*.' means 'float' multiplication as in (3.0 \*. 4.0), and where 'sin' means the 'float' trigonometric function as in (sin 1.5).

let g(f x = f x x)

let 
$$q \mid f \mid x = f \mid x \mid x$$

$$|a \mid b \mid a \mid b \mid b$$

$$|a \mid b \mid a \mid b \mid b$$

let p a b x = a (b x)

$$'\alpha \rightarrow ('0 \rightarrow ('b \rightarrow 'c))$$

let c = p s sin

1b (3 minutes). In 1a, why does s's definition use '( \*. )' and not '(fun x y -> x \*. y)' or '(\*.)' or simply '\*.'?

.. It's not a function definition that takes anyther's & y tacked it is

2. Recall that the transpose of an M×N matrix A is an N×M matrix B such that A[i][j] = B[j][i] for  $0 \le i \le M$ ,  $0 \le j \le N$ .

2a (12 minutes). Suppose we represent a matrix of items as a list of list of items. Write a function loltp that does list-of-list transposition, that is, it takes a list of list of values that represents a matrix A, and returns a list of list of values that represents the transpose of A. For example, (loltp [["a";"b";"c"];["d";"e";"f"]]) returns

[["a";"d"];["b";"e"];["c";"f"]]. If you cannot reasonably solve the problem in general, make sure that it at least succeeds on a 2×3 test case such as in the example given, and explain why a more-general

solution is not reasonable.

one and append head to new 15%. Crede a list of lists

2b (2 minutes). What is the type of your loltp function?

2c (4 minutes). Give an example value that you can pass to loltp that OCaml's type checking will accept but will cause a runtime error; or explain why no such value is possible.

3a (12 minutes). Suppose we instead represent a matrix of items in OCaml as a tuple of tuple of items. Write a function tottp that does tuple-of-tuple transposition; that is, it acts like loltp except it operates on the tuple-of-tuple representation. For example, (tottp (("a","b","c"),("d","e","f")) returns (("a","d"),("b","e"),("c","f")). Again, if you cannot reasonably solve the problem in general, make sure that it at least succeeds on a 2×3 test case such as in the example given, and explain why a more-general solution is not reasonable.

Commit to lists

3b (2 minutes). What is the type of your tottp function?

( String \* String

3c (4 minutes). Give an example value that you can pass to your tottp function that OCaml's type checking will accept but will cause a runtime error; or explain why no such value is possible.

(THEN THE WOOD REFINED TO SELECTION IS TOTTED TO THE TOTTED T

Crowen that the above definition is collect, there is providing a custopes of the value that will given an error. If it took which is a down nested tople. The time error could be caused by a typle which is a down nested tople.

4. Given a grammar, a nonterminal symbol is called "nullable" if a valid parse tree rooted at the symbol contains no terminal symbols. For example, consider the following Homework 1 style grammar:

```
let nullg =
    ["Expr", [T"("; N"Expr"; T")"];
    "Expr", [N"Expr"; N"Ops"; N"Expr"];
    "Expr", [T"ID"];
    "Ops", [N"Op"; N"Op"];
    "Ops", [N"Op"; N"Op"; N"Ops"];
    "Op", [T"+"];
    "Op", [];
    "Op", [T"*"]]
```

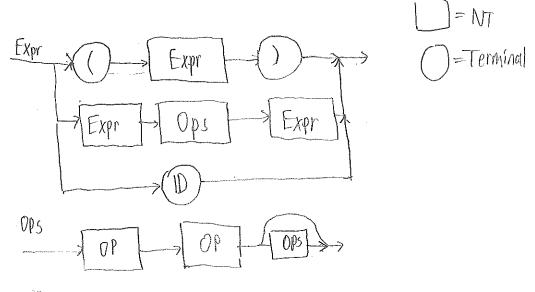

In this grammar, the nonterminal "Op" is nullable because it can produce the empty list immediately in the second-to-last rule, and the nonterminal "Ops" is nullable because it can produce two "Op" nonterminals, each of which can produce the empty list. However, "Expr" is not nullable.

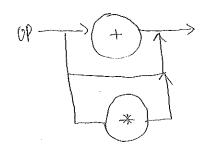

4a (12 minutes). Write an OCaml function (nullables G) that returns the set of nullable nonterminals in the grammar G, representing the set as a list. The members of the returned list can be in any order and the list can contain duplicates. For examples, (nullables nullg) might return ["Ops";"Op"]. Your function can assume the functions (subset A B), (equal\_sets A B), (set\_union A B), (set\_intersection A B), (set\_diff A B), and (computed\_fixed\_point EQ F X) that were assigned in Homework 1. However, your function should not use any functions in the OCaml standard library. You can write auxiliary functions to help implement your function.

let rec nullables grammar =

4b (5 minutes). If you translate 'nullg' to Homework 2 style, will it cause the corresponding matcher to loop in some cases? If so, give an example of how the matcher would loop; if not, explain why not.

4c (10 minutes). Convert 'nullg' to a syntax diagram that is as simple as possible.

5 (4 minutes). In OCaml, 'int list' is a subtype of ''a list'. However, in Java, 'List<Integer>' is not a subtype of 'List<Object>'. Explain the seeming discrepancy, and give some other List type that 'List<Integer>' \*is\* a subtype of in Java.

Jam is streagy typed
List(Integer) is not a subtype of List(object)
by List(Object) is actually a subtype of object along
With list (integer), but it is allot a supertype of object
of Object (which is a super of all types)
List(Object)
List(Object)
List(Object)
List(integer)

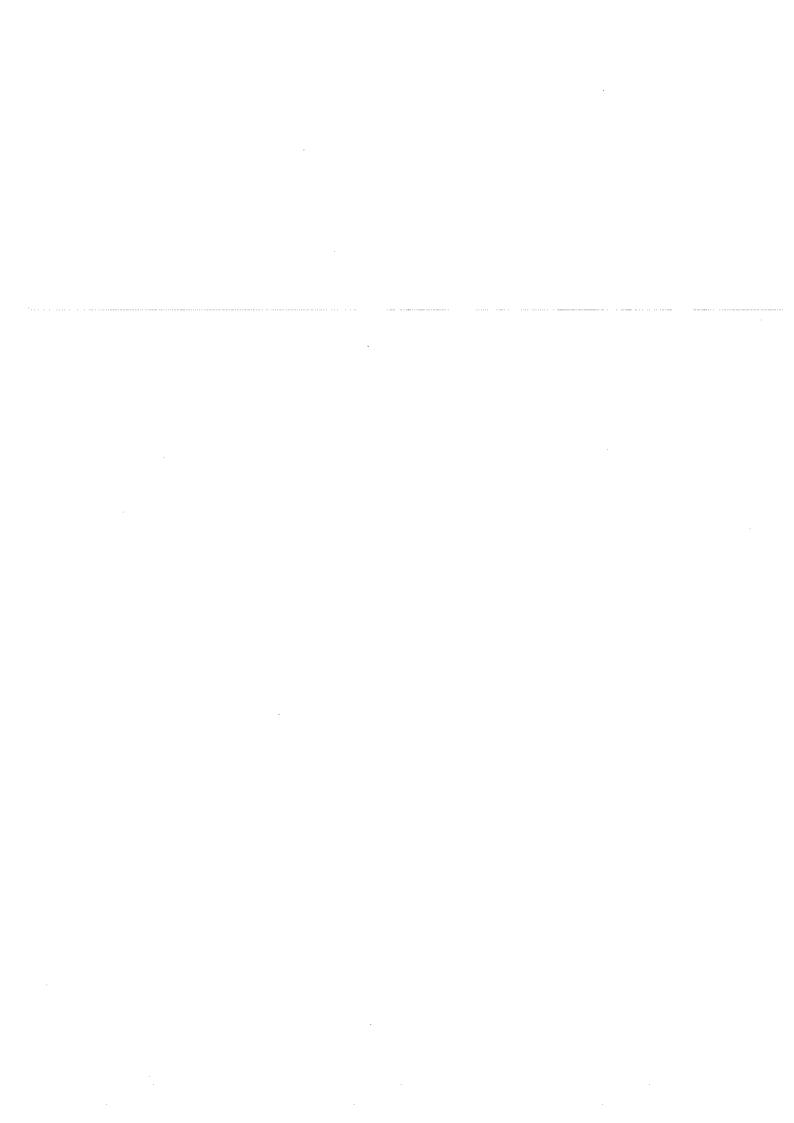

6 (6 minutes). In C, the \_Noreturn keyword marks functions that do not return; for example, the 'exit' function is declared this way:

\_Noreturn void exit(int);

because it accepts an integer argument and never returns. Compilers can optimize calls to \_Noreturn functions, e.g., by generating code that does not bother to save the call's return address (because the return address is never used).

Is a function type containing the \_Noreturn keyword a subtype of the same function type without \_Noreturn? Or vice versa? Or neither? Briefly explain.

Considering that behavior with Noveling and without Considering that behavior with Noveling and without out it pials different results, I am assess that the stance I think - Noveling is a stotype in these great it is possible to elective a function without no Deturn because it is possible to elective a function without no Deturn that has identical behavior.

7 (12 minutes). The Java designers were willing to give up some performance in exchange for reproducible results. For example, although C allows a compiler to evaluate a call's arguments in any order, Java requires the compiler to evaluate them left-to-right. Java's rule prevents some optimizations but means that code is more likely to yield the same results on different platforms. A Java compiler is still allowed to execute the arguments out of order for speed, so long as the user can't tell the difference.

A significant reliability problem in Java comes from race conditions in multithreaded programs. Couldn't the Java designers have traded performance in exchange for avoiding race conditions? That is, couldn't the Java designers have said that a Java compiler must evaluate multithreaded code as if the first runnable thread is the only running thread? (By "first" I mean the earliest-created thread.) As before, the Java compiler would still be allowed to execute code in parallel for speed, so long as the user can't tell the difference other than in performance.

If this idea is impossible, explain why that is so. Or if it is possible but impractical, explain why. Or if it is a reasonably practical suggestion, give a good reason why the Java designers did not take the suggestion.

To the bast if my understanding. I thought the designers of Java tried comething consider to this. They attempted to supplementally and methods with a complementary implement a locking mechanism on methods with a complementary because implement a locking mechanism outs have one problem thought because whole of efficiency because unlocking method. These spin locks have afterneutral effect on efficiency because they have an extended detrimental effect of a time. This is they have an extended be held at a time. This is essentially only one book may be held at a time. This is essentially only one box may be held at a time. This is essentially only one box may be held at a time.
