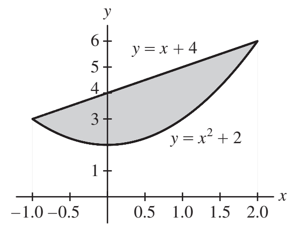
SOLUTION Let's choose to slice the region bounded by the graphs of $y = x^2 + 2$ and $y = x + 4$ (see the figure below) vertically. Because a vertical slice is perpendicular to the axis of rotation, we will use the washer method to calculate the volume of the solid of revolution. For each $x \in [-1, 2]$, the washer has outer radius $x + 4$ and inner radius $x^2 + 2$. The volume of the solid is therefore given by

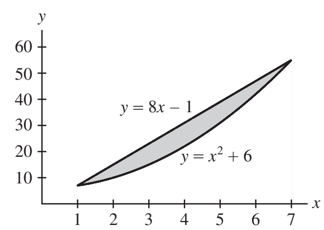
$$\begin{aligned}\pi\int_{-1}^{2}((x+4)^2 - (x^2+2)^2)\,dx &= \pi\int_{-1}^{2}(-x^4 - 3x^2 + 8x + 12)\,dx\\ &= \pi\left(-\frac{1}{5}x^5 - x^3 + 4x^2 + 12x\right)\Bigg|_{-1}^{2}\\ &= \pi\left(\frac{128}{5} + \frac{34}{5}\right) = \frac{162\pi}{5}.\end{aligned}$$



30. $y = x^2 + 6, \quad y = 8x - 1, \quad y\text{-axis}$

SOLUTION Let's choose to slice the region bounded by the graphs of $y = x^2 + 6$ and $y = 8x - 1$ (see the figure below) vertically. Because a vertical slice is parallel to the axis of rotation, we will use the shell method to calculate the volume of the solid of revolution. For each $x \in [1, 7]$, the shell has radius x and height $8x - 1 - (x^2 + 6) = -x^2 + 8x - 7$. The volume of the solid is therefore given by

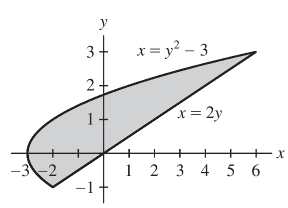
$$\begin{aligned} 2\pi \int_1^7 x(-x^2 + 8x - 7)\,dx &= 2\pi \int_1^7 (-x^3 + 8x^2 - 7x)\,dx \\ &= 2\pi \left(-\frac{1}{4}x^4 + \frac{8}{3}x^3 - \frac{7}{2}x^2 \right)\Big|_1^7 \\ &= 2\pi \left(\frac{1715}{12} + \frac{13}{12} \right) = 288\pi. \end{aligned}$$



31. $x = y^2 - 3, \quad x = 2y, \quad \text{axis } y = 4$

SOLUTION Let's choose to slice the region bounded by the graphs of $x = y^2 - 3$ and $x = 2y$ (see the figure below) horizontally. Because a horizontal slice is parallel to the axis of rotation, we will use the shell method to calculate the volume of the solid of revolution. For each $y \in [-1, 3]$, the shell has radius $4 - y$ and height $2y - (y^2 - 3) = 3 + 2y - y^2$. The volume of the solid is therefore given by

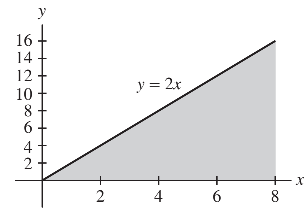
$$\begin{aligned} 2\pi \int_{-1}^3 (4 - y)(3 + 2y - y^2)\,dy &= 2\pi \int_{-1}^3 (12 + 5y - 6y^2 + y^3)\,dy \\ &= 2\pi \left(12y + \frac{5}{2}y^2 - 2y^3 + \frac{1}{4}y^4 \right)\Big|_{-1}^3 \\ &= 2\pi \left(\frac{99}{4} + \frac{29}{4} \right) = 64\pi. \end{aligned}$$



32. $y = 2x, \quad y = 0, \quad x = 8, \quad \text{axis } x = -3$

SOLUTION Let's choose to slice the region bounded by the graphs of $y = 2x$, $y = 0$ and $x = 8$ (see the figure below) vertically. Because a vertical slice is parallel to the axis of rotation, we will use the shell method to calculate the volume of the solid of revolution. For each $x \in [0, 8]$, the shell has radius $x - (-3) = x + 3$ and height $2x$. The volume of the solid is therefore given by

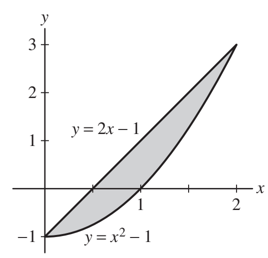
$$2\pi \int_0^8 (x + 3)(2x)\,dx = 4\pi \left(\frac{1}{3}x^3 + \frac{3}{2}x^2 \right)\Big|_0^8 = 4\pi \left(\frac{512}{3} + 96 \right) = \frac{3200\pi}{3}.$$



33. $y = x^2 - 1, \quad y = 2x - 1, \quad \text{axis } x = -2$

SOLUTION The region bounded by the graphs of $y = x^2 - 1$ and $y = 2x - 1$ is shown below. Let's choose to slice the region vertically. Because a vertical slice is parallel to the axis of rotation, we will use the shell method to calculate the volume of the solid of revolution. For each $x \in [0, 2]$, the shell has radius $x - (-2) = x + 2$ and height $(2x - 1) - (x^2 - 1) = 2x - x^2$. The volume of the solid is therefore given by

$$2\pi \int_0^2 (x + 2)(2x - x^2)\, dx = 2\pi \left(2x^2 - \frac{1}{4}x^4\right)\Big|_0^2 = 2\pi(8 - 4) = 8\pi.$$



34. $y = x^2 - 1, \quad y = 2x - 1, \quad \text{axis } y = 4$

SOLUTION Let's choose to slice the region bounded by the graphs of $y = x^2 - 1$ and $y = 2x - 1$ (see the figure in the previous exercise) vertically. Because a vertical slice is perpendicular to the axis of rotation, we will use the washer method to calculate the volume of the solid of revolution. For each $x \in [0, 2]$, the cross section is a washer with outer radius $R = 4 - (x^2 - 1) = 5 - x^2$ and inner radius $r = 4 - (2x - 1) = 5 - 2x$. The volume of the solid is therefore given by

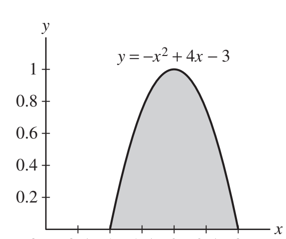
$$\pi \int_0^2 \left((5 - x^2)^2 - (5 - 2x)^2\right) dx = \pi \left(10x^2 - \frac{14}{3}x^3 + \frac{1}{5}x^5\right)\Big|_0^2 = \pi \left(40 - \frac{112}{3} + \frac{32}{5}\right) = \frac{136\pi}{15}.$$

35. $y = -x^2 + 4x - 3, \quad y = 0, \quad \text{axis } y = -1$

SOLUTION The region bounded by the graph of $y = -x^2 + 4x - 3$ and the x-axis is shown below. Let's choose to slice the region vertically. Because a vertical slice is perpendicular to the axis of rotation, we will use the washer method to calculate the volume of the solid of revolution. For each $x \in [1, 3]$, the cross section is a washer with outer radius $R = -x^2 + 4x - 3 - (-1) = -x^2 + 4x - 2$ and inner radius $r = 0 - (-1) = 1$. The volume of the solid is therefore given by

$$\pi \int_1^3 \left((-x^2 + 4x - 2)^2 - 1\right) dx = \pi \left(\frac{1}{5}x^5 - 2x^4 + \frac{20}{3}x^3 - 8x^2 + 3x\right)\Big|_1^3$$

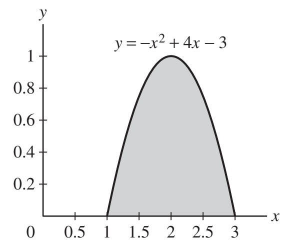
$$= \pi \left[\left(\frac{243}{5} - 162 + 180 - 72 + 9\right) - \left(\frac{1}{5} - 2 + \frac{20}{3} - 8 + 3\right)\right] = \frac{56\pi}{15}.$$



36. $y = -x^2 + 4x - 3, \quad y = 0, \quad \text{axis } x = 4$

SOLUTION The region bounded by the graph of $y = -x^2 + 4x - 3$ and the x-axis is shown in the previous exercise. Let's choose to slice the region vertically. Because a vertical slice is parallel to the axis of rotation, we will use the shell method to calculate the volume of the solid of revolution. For each $x \in [1, 3]$, the shell has radius $4 - x$ and height $-x^2 + 4x - 3$. The volume of the solid is therefore given by

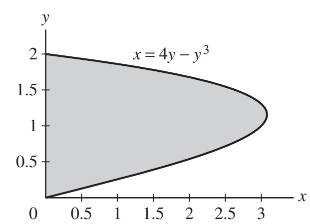
$$\begin{aligned} 2\pi \int_1^3 (4-x)(-x^2+4x-3)\,dx &= 2\pi \int_1^3 (x^3 - 8x^2 + 19x - 12)\,dx \\ &= 2\pi \left(\frac{1}{4}x^4 - \frac{8}{3}x^3 + \frac{19}{2}x^2 - 12x \right)\Bigg|_1^3 \\ &= 2\pi \left(-\frac{9}{4} + \frac{59}{12} \right) = \frac{16\pi}{3}. \end{aligned}$$



37. $x = 4y - y^3, \quad x = 0, \quad y \ge 0, \quad x\text{-axis}$

SOLUTION The region bounded by the graphs of $x = 4y - y^3$ and $x = 0$ for $y \ge 0$ is shown below. Let's choose to slice this region horizontally. Because a horizontal slice is parallel to the axis of rotation, we will use the shell method to calculate the volume of the solid of revolution. For each $y \in [0, 2]$, the shell has radius y and height $4y - y^3$. The volume of the solid is therefore given by

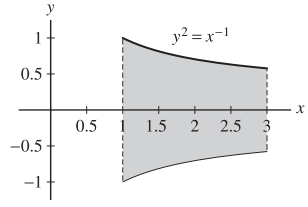
$$\begin{aligned} 2\pi \int_0^2 y(4y - y^3)\,dy &= 2\pi \int_0^2 (4y^2 - y^4)\,dy \\ &= 2\pi \left(\frac{4}{3}y^3 - \frac{1}{5}y^5 \right)\Bigg|_0^2 \\ &= 2\pi \left(\frac{32}{3} - \frac{32}{5} \right) = \frac{128\pi}{15}. \end{aligned}$$



38. $y^2 = x^{-1}, \quad x = 1, \quad x = 3, \quad \text{axis } y = -3$

SOLUTION The region bounded by the graphs of $y^2 = x^{-1}$, $x = 1$ and $x = 3$ is shown below. Let's choose to slice the region vertically. Because a vertical slice is perpendicular to the axis of rotation, we will use the washer method to calculate the volume of the solid of revolution. For each $x \in [1, 3]$, the cross section is a washer with outer radius $R = \frac{1}{\sqrt{x}} - (-3) = 3 + \frac{1}{\sqrt{x}}$ and inner radius $r = -\frac{1}{\sqrt{x}} - (-3) = 3 - \frac{1}{\sqrt{x}}$. The volume of the solid is therefore given by

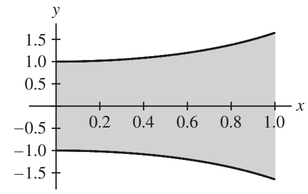
$$\pi \int_1^3 \left(\left(3 + \frac{1}{\sqrt{x}}\right)^2 - \left(3 - \frac{1}{\sqrt{x}}\right)^2 \right) dx = 12\pi \int_1^3 x^{-1/2}\,dx = 24\pi\sqrt{x}\Big|_1^3 = 24\pi(\sqrt{3} - 1).$$



39. $y = e^{-x^2/2}, \quad y = -e^{-x^2/2}, \quad x = 0, \quad x = 1, \quad y\text{-axis}$

SOLUTION Let's choose to slice the region bounded by the graphs of $y = e^{-x^2/2}$ and $y = -e^{-x^2/2}$ (see the figure below) vertically. Because a vertical slice is parallel to the axis of rotation, we will use the shell method to calculate the volume of the solid of revolution. For each $x \in [0, 1]$, the shell has radius x and height $e^{-x^2/2} - (-e^{-x^2/2}) = 2e^{-x^2/2}$. The volume of the solid is therefore given by

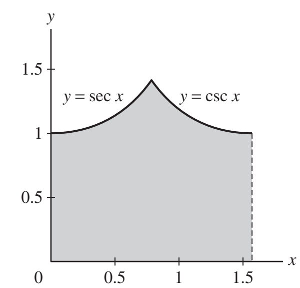
$$2\pi \int_0^1 2xe^{-x^2/2}\, dx = -4\pi e^{-x^2/2}\Big|_0^1$$
$$= -4\pi(e^{-1/2} - 1) = 4\pi(1 - e^{-1/2}).$$



40. $y = \sec x, \quad y = \csc x, \quad y = 0, \quad x = 0, \quad x = \dfrac{\pi}{2}, \quad x\text{-axis}$

SOLUTION

(a) The region in question is shown in the figure below.



(b) When the region is rotated about the x-axis, cross sections for $x \in [0, \pi/4]$ are circular disks with radius $R = \sec x$, whereas cross sections for $x \in [\pi/4, \pi/2]$ are circular disks with radius $R = \csc x$.

(c) The volume of the solid of revolution is

$$\pi \int_0^{\pi/4} \sec^2 x\, dx + \pi \int_{\pi/4}^{\pi/2} \csc^2 x\, dx = \pi\,(\tan x)\Big|_0^{\pi/4} + \pi\,(-\cot x)\Big|_{\pi/4}^{\pi/2} = \pi\,(1) + \pi\,(1) = 2\pi.$$

In Exercises 41–44, find the volume obtained by rotating the region about the given axis. The regions refer to the graph of the hyperbola $y^2 - x^2 = 1$ *in Figure 4.*

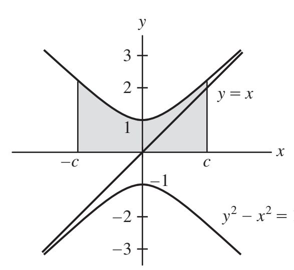


FIGURE 4

41. The shaded region between the upper branch of the hyperbola and the x-axis for $-c \le x \le c$, about the x-axis.

SOLUTION Let's choose to slice the region vertically. Because a vertical slice is perpendicular to the axis of rotation, we will use the washer method to calculate the volume of the solid of revolution. For each $x \in [-c, c]$, cross sections are circular disks with radius $R = \sqrt{1 + x^2}$. The volume of the solid is therefore given by

$$\pi \int_{-c}^{c} (1 + x^2)\, dx = \pi\,\left(x + \frac{1}{3}x^3\right)\Big|_{-c}^{c} = \pi\left[\left(c + \frac{c^3}{3}\right) - \left(-c - \frac{c^3}{3}\right)\right] = 2\pi\left(c + \frac{c^3}{3}\right).$$

42. The region between the upper branch of the hyperbola and the x-axis for $0 \le x \le c$, about the y-axis.

SOLUTION Let's choose to slice the region vertically. Because a vertical slice is parallel to the axis of rotation, we will use the shell method to calculate the volume of the solid of revolution. For each $x \in [0, c]$, the shell has radius x and height $\sqrt{1+x^2}$. The volume of the solid is therefore given by

$$2\pi \int_0^c x\sqrt{1+x^2}\,dx = \frac{2\pi}{3}(1+x^2)^{3/2}\Big|_0^c = \frac{2\pi}{3}\left((1+c^2)^{3/2}-1\right).$$

43. The region between the upper branch of the hyperbola and the line $y = x$ for $0 \le x \le c$, about the x-axis.

SOLUTION Let's choose to slice the region vertically. Because a vertical slice is perpendicular to the axis of rotation, we will use the washer method to calculate the volume of the solid of revolution. For each $x \in [0, c]$, cross sections are washers with outer radius $R = \sqrt{1+x^2}$ and inner radius $r = x$. The volume of the solid is therefore given by

$$\pi \int_0^c \left((1+x^2) - x^2\right)\,dx = \pi x\Big|_0^c = c\pi.$$

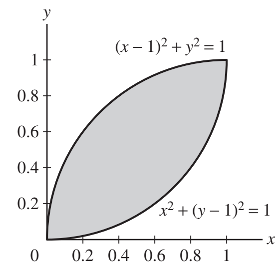
44. The region between the upper branch of the hyperbola and $y = 2$, about the y-axis.

SOLUTION The upper branch of the hyperbola and the horizontal line $y = 2$ intersect when $x = \pm\sqrt{3}$. Using the shell method, each shell has radius x and height $2 - \sqrt{1+x^2}$. The volume of the solid is therefore given by

$$2\pi \int_0^{\sqrt{3}} x\left(2 - \sqrt{1+x^2}\right)\,dx = 2\pi\left(x^2 - \frac{1}{3}(1+x^2)^{3/2}\right)\Big|_0^{\sqrt{3}} = 2\pi\left(3 - \frac{8}{3} + \frac{1}{3}\right) = \frac{4\pi}{3}.$$

45. Let R be the intersection of the circles of radius 1 centered at $(1, 0)$ and $(0, 1)$. Express as an integral (but do not evaluate): **(a)** the area of R and **(b)** the volume of revolution of R about the x-axis.

SOLUTION The region R is shown below.



(a) A vertical slice of R has its top along the upper left arc of the circle $(x-1)^2 + y^2 = 1$ and its bottom along the lower right arc of the circle $x^2 + (y-1)^2 = 1$. The area of R is therefore given by

$$\int_0^1 \left(\sqrt{1-(x-1)^2} - (1 - \sqrt{1-x^2})\right)\,dx.$$

(b) If we revolve R about the x-axis and use the washer method, each cross section is a washer with outer radius $\sqrt{1-(x-1)^2}$ and inner radius $1 - \sqrt{1-x^2}$. The volume of the solid is therefore given by

$$\pi \int_0^1 \left[(1-(x-1)^2) - (1-\sqrt{1-x^2})^2\right]\,dx.$$

46. Let $a > 0$. Show that the volume obtained when the region between $y = a\sqrt{x - ax^2}$ and the x-axis is rotated about the x-axis is independent of the constant a.

SOLUTION Setting $a\sqrt{x-ax^2} = 0$ yields $x = 0$ and $x = 1/a$. Using the washer method, cross sections are circular disks with radius $R = a\sqrt{x-ax^2}$. The volume of the solid is therefore given by

$$\pi \int_0^{1/a} a^2(x - ax^2)\,dx = \pi\left(\frac{1}{2}a^2x^2 - \frac{1}{3}a^3x^3\right)\Big|_0^{1/a} = \pi\left(\frac{1}{2} - \frac{1}{3}\right) = \frac{\pi}{6},$$

which is independent of the constant a.

47. If 12 J of work are needed to stretch a spring 20 cm beyond equilibrium, how much work is required to compress it 6 cm beyond equilibrium?

SOLUTION First, we determine the value of the spring constant k as follows:

$$\frac{1}{2}k(0.2)^2 = 12 \quad \text{so} \quad k = 600 \text{ N/m}.$$

Now, the work needed to compress the spring 6 cm beyond equilibrium is

$$W = \int_0^{0.06} 600x\,dx = 300x^2\Big|_0^{0.06} = 1.08 \text{ J}.$$

48. A spring whose equilibrium length is 15 cm exerts a force of 50 N when it is stretched to 20 cm. Find the work required to stretch the spring from 22 to 24 cm.

SOLUTION A force of 50 N is exerted when the spring is stretched 5 cm = 0.05 m from its equilibrium length; therefore, the value of the spring constant is $k = 1000$ N/m. The work required to stretch the spring from a length of 22 cm to a length of 24 cm is then

$$\int_{0.07}^{0.09} 1000x\,dx = 500x^2\Big|_{0.07}^{0.09} = 500(0.09^2 - 0.07^2) = 1.6 \text{ J}.$$

49. If 18 ft-lb of work are needed to stretch a spring 1.5 ft beyond equilibrium, how far will the spring stretch if a 12-lb weight is attached to its end?

SOLUTION First, we determine the value of the spring constant as follows:

$$\frac{1}{2}k(1.5)^2 = 18 \quad \text{so} \quad k = 16 \text{ lb/ft}.$$

Now, if a 12-lb weight is attached to the end of the spring, balancing the forces acting on the weight, we have $12 = 16d$, which implies $d = 0.75$ ft. A 12-lb weight will therefore stretch the spring 9 inches.

50. Let W be the work (against the sun's gravitational force) required to transport an 80-kg person from Earth to Mars when the two planets are aligned with the sun at their minimal distance of 55.7×10^6 km. Use Newton's Universal Law of Gravity (see Exercises 35–37 in Section 6.5) to express W as an integral and evaluate it. The sun has mass $M_s = 1.99 \times 10^{30}$ kg, and the distance from the sun to the earth is 149.6×10^6 km.

SOLUTION According to Newton's Universal Law of Gravity, the gravitational force between the person and the sun is

$$\frac{GM_s m}{r^2},$$

where $G = 6.67 \times 10^{-11}$ m^{3}kg^{-1}s^{-1} is a constant, $M_s = 1.99 \times 10^{30}$ kg is the mass of the sun, $m = 80$ kg is the mass of the person, and r is the distance between the sun and the person. The work against the sun's gravitational force required to transport the person from Earth to Mars when the two planets are aligned with the sun is therefore given by

$$W = \int_{r_{se}}^{r_{se}+r_{em}} \frac{GM_s m}{r^2}\,dr = GM_s m\left(\frac{1}{r_{se}} - \frac{1}{r_{se}+r_{em}}\right),$$

where $r_{se} = 149.6 \times 10^6$ km is the distance from the sun to Earth and $r_{em} = 55.7 \times 10^6$ km is the distance from Earth to Mars. Converting the distances to meters and substituting the known values into the formula for W yields

$$W = (6.67 \times 10^{-11})(1.99 \times 10^{30})(80)\left(\frac{1}{149.6 \times 10^9} - \frac{1}{205.3 \times 10^9}\right) \approx 1.93 \times 10^{10} \text{ J}.$$

In Exercises 51 and 52, water is pumped into a spherical tank of radius 2 m *from a source located* 1 m *below a hole at the bottom (Figure 5). The density of water is* 1000 kg/m^3.

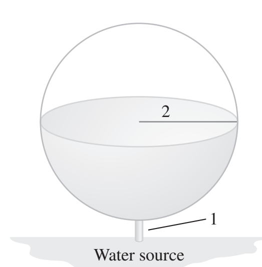


FIGURE 5

51. Calculate the work required to fill the tank.

SOLUTION Place the origin at the base of the sphere with the positive y-axis pointing upward. The equation for the great circle of the sphere is then $x^2 + (y-2)^2 = 4$. At location y, the horizontal cross section is a circle of radius $\sqrt{4-(y-2)^2} = \sqrt{4y-y^2}$; the volume of the layer is then $\pi(4y-y^2)\Delta y$ m^3, and the force needed to lift the layer is $1000(9.8)\pi(4y-y^2)\Delta y$ N. The layer of water must be lifted $y+1$ meters, so the work required to fill the tank is given by

$$\begin{aligned} 9800\pi \int_0^4 (y+1)(4y-y^2)\,dy &= 9800\pi \int_0^4 (3y^2+4y-y^3)\,dy \\ &= 9800\pi \left(y^3 + 2y^2 - \frac{1}{4}y^4 \right)\Big|_0^4 \\ &= 313{,}600\pi \approx 985{,}203.5 \text{ J}. \end{aligned}$$

52. Calculate the work $F(h)$ required to fill the tank to level h meters in the sphere.

SOLUTION Place the origin at the base of the sphere with the positive y-axis pointing upward. The equation for the great circle of the sphere is then $x^2 + (y-2)^2 = 4$. At location y, the horizontal cross section is a circle of radius $\sqrt{4-(y-2)^2} = \sqrt{4y-y^2}$; the volume of the layer is then $\pi(4y-y^2)\Delta y$ m^3, and the force needed to lift the layer is $1000(9.8)\pi(4y-y^2)\Delta y$ N. The layer of water must be lifted $y+1$ meters, so the work required to fill the tank is given by

$$\begin{aligned} 9800\pi \int_0^h (y+1)(4y-y^2)\,dy &= 9800\pi \int_0^h (3y^2+4y-y^3)\,dy \\ &= 9800\pi \left(y^3 + 2y^2 - \frac{1}{4}y^4 \right)\Big|_0^h \\ &= 9800\pi \left(h^3 + 2h^2 - \frac{1}{4}h^4 \right) \text{ J}. \end{aligned}$$

53. A tank of mass 20 kg containing 100 kg of water (density 1000 kg/m^3) is raised vertically at a constant speed of 100 m/min for one minute, during which time it leaks water at a rate of 40 kg/min. Calculate the total work performed in raising the container.

SOLUTION Let t denote the elapsed time in minutes and let y denote the height of the container. Given that the speed of ascent is 100 m/min, $y = 100t$; moreover, the mass of water in the container is

$$100 - 40t = 100 - 0.4y\text{kg}.$$

The force needed to lift the container and its contents is then

$$9.8\,(20 + (100 - 0.4y)) = 1176 - 3.92y \text{ N},$$

and the work required to lift the container and its contents is

$$\int_0^{100} (1176 - 3.92y)\,dy = (1176y - 1.96y^2)\Big|_0^{100} = 98{,}000\text{J}.$$

7 TECHNIQUES OF INTEGRATION

7.1 Integration by Parts

Preliminary Questions

1. Which derivative rule is used to derive the Integration by Parts formula?

SOLUTION The Integration by Parts formula is derived from the Product Rule.

2. For each of the following integrals, state whether substitution or Integration by Parts should be used:

$$\int x\cos(x^2)\,dx,\qquad \int x\cos x\,dx,\qquad \int x^2e^x\,dx,\qquad \int xe^{x^2}\,dx$$

SOLUTION

(a) $\int x\cos(x^2)\,dx$: use the substitution $u = x^2$.

(b) $\int x\cos x\,dx$: use Integration by Parts.

(c) $\int x^2e^x\,dx$; use Integration by Parts.

(d) $\int xe^{x^2}\,dx$; use the substitution $u = x^2$.

3. Why is $u = \cos x$, $v' = x$ a poor choice for evaluating $\int x\cos x\,dx$?

SOLUTION Transforming $v' = x$ into $v = \frac{1}{2}x^2$ increases the power of x and makes the new integral harder than the original.

Exercises

In Exercises 1–6, evaluate the integral using the Integration by Parts formula with the given choice of u and v'.

1. $\int x\sin x\,dx;\quad u = x,\ v' = \sin x$

SOLUTION Using the given choice of u and v' results in

$$\begin{aligned} u &= x & v &= -\cos x\\ u' &= 1 & v' &= \sin x \end{aligned}$$

Using Integration by Parts,

$$\int x\sin x\,dx = x(-\cos x) - \int (1)(-\cos x)\,dx = -x\cos x + \int \cos x\,dx = -x\cos x + \sin x + C.$$

2. $\int xe^{2x}\,dx;\quad u = x,\ v' = e^{2x}$

SOLUTION Using $u = x$ and $v' = e^{2x}$ gives us

$$\begin{aligned} u &= x & v &= \tfrac{1}{2}e^{2x}\\ u' &= 1 & v' &= e^{2x} \end{aligned}$$

Integration by Parts gives us

$$\int xe^{2x}\,dx = x\left(\frac{1}{2}e^{2x}\right) - \int (1)\frac{1}{2}e^{2x}\,dx = \frac{1}{2}xe^{2x} - \frac{1}{2}\left(\frac{1}{2}\right)e^{2x} + C = \frac{1}{4}e^{2x}\,(2x-1) + C.$$

3. $\int (2x+9)e^x\,dx$; $u = 2x+9$, $v' = e^x$

SOLUTION Using $u = 2x+9$ and $v' = e^x$ gives us

$$\begin{aligned} u &= 2x+9 & v &= e^x \\ u' &= 2 & v' &= e^x \end{aligned}$$

Integration by Parts gives us

$$\int (2x+9)e^x\,dx = (2x+9)e^x - \int 2e^x\,dx = (2x+9)e^x - 2e^x + C = e^x(2x+7) + C.$$

4. $\int x\cos 4x\,dx$; $u = x$, $v' = \cos 4x$

SOLUTION Using $u = x$ and $v' = \cos 4x$ gives us

$$\begin{aligned} u &= x & v &= \tfrac{1}{4}\sin 4x \\ u' &= 1 & v' &= \cos 4x \end{aligned}$$

Integration by Parts gives us

$$\begin{aligned} \int x\cos 4x\,dx &= \frac{1}{4}x\sin 4x - \int (1)\frac{1}{4}\sin 4x\,dx = \frac{1}{4}x\sin 4x - \frac{1}{4}\left(-\frac{1}{4}\cos 4x\right) + C \\ &= \frac{1}{4}x\sin 4x + \frac{1}{16}\cos 4x + C. \end{aligned}$$

5. $\int x^3\ln x\,dx$; $u = \ln x$, $v' = x^3$

SOLUTION Using $u = \ln x$ and $v' = x^3$ gives us

$$\begin{aligned} u &= \ln x & v &= \tfrac{1}{4}x^4 \\ u' &= \tfrac{1}{x} & v' &= x^3 \end{aligned}$$

Integration by Parts gives us

$$\begin{aligned} \int x^3\ \ln x\,dx &= (\ln x)\left(\frac{1}{4}x^4\right) - \int \left(\frac{1}{x}\right)\left(\frac{1}{4}x^4\right)dx \\ &= \frac{1}{4}x^4\ln x - \frac{1}{4}\int x^3\,dx = \frac{1}{4}x^4\ln x - \frac{1}{16}x^4 + C = \frac{x^4}{16}(4\ln x - 1) + C. \end{aligned}$$

6. $\int \tan^{-1}x\,dx$; $u = \tan^{-1}x$, $v' = 1$

SOLUTION Using $u = \tan^{-1}x$ and $v' = 1$ gives us

$$\begin{aligned} u &= \tan^{-1}x & v &= x \\ u' &= \frac{1}{x^2+1} & v' &= 1 \end{aligned}$$

Integration by Parts gives us

$$\int \tan^{-1}x\,dx = x\tan^{-1}x - \int \left(\frac{1}{x^2+1}\right)x\,dx.$$

For the integral on the right we'll use the substitution $w = x^2+1$, $dw = 2x\,dx$. Then we have

$$\begin{aligned} \int \tan^{-1}x\,dx &= x\tan^{-1}x - \frac{1}{2}\int \left(\frac{1}{x^2+1}\right)2x\,dx = x\tan^{-1}x - \frac{1}{2}\int \frac{dw}{w} \\ &= x\tan^{-1}x - \frac{1}{2}\ln|w| + C = x\tan^{-1}x - \frac{1}{2}\ln|x^2+1| + C. \end{aligned}$$

In Exercises 7–36, evaluate using Integration by Parts.

7. $\int (4x-3)e^{-x}\,dx$

SOLUTION Let $u = 4x - 3$ and $v' = e^{-x}$. Then we have

$$u = 4x - 3 \qquad v = -e^{-x}$$
$$u' = 4 \qquad v' = e^{-x}$$

Using Integration by Parts, we get

$$\int (4x-3)e^{-x}\,dx = (4x-3)(-e^{-x}) - \int (4)(-e^{-x})\,dx$$
$$= -e^{-x}(4x-3) + 4\int e^{-x}\,dx = -e^{-x}(4x-3) - 4e^{-x} + C = -e^{-x}(4x+1) + C.$$

8. $\int (2x+1)e^{x}\,dx$

SOLUTION Let $u = 2x + 1$ and $v' = e^{-x}$. Then we have

$$u = 2x + 1 \qquad v = -e^{-x}$$
$$u' = 2 \qquad v' = e^{-x}$$

Using Integration by Parts, we get

$$\int (2x+1)\,e^{-x}\,dx = (2x+1)(-e^{-x}) - \int (2)(-e^{-x})\,dx$$
$$= -(2x+1)e^{-x} + 2\int e^{-x}\,dx = -(2x+1)e^{-x} - 2e^{-x} + C = -e^{-x}(2x+3) + C.$$

9. $\int x\,e^{5x+2}\,dx$

SOLUTION Let $u = x$ and $v' = e^{5x+2}$. Then we have

$$u = x \qquad v = \frac{1}{5}e^{5x+2}$$
$$u' = 1 \qquad v' = e^{5x+2}$$

Using Integration by Parts, we get

$$\int xe^{5x+2}\,dx = x\left(\frac{1}{5}e^{5x+2}\right) - \int (1)\left(\frac{1}{5}e^{5x+2}\right)dx = \frac{1}{5}xe^{5x+2} - \frac{1}{5}\int e^{5x+2}\,dx$$
$$= \frac{1}{5}xe^{5x+2} - \frac{1}{25}e^{5x+2} + C = \left(\frac{x}{5} - \frac{1}{25}\right)e^{5x+2} + C$$

10. $\int x^2e^x\,dx$

SOLUTION Let $u = x^2$ and $v' = e^x$. Then we have

$$u = x^2 \qquad v = e^x$$
$$u' = 2x \qquad v' = e^x$$

Using Integration by Parts, we get

$$\int x^2\,e^x\,dx = x^2e^x - 2\int xe^x\,dx.$$

We must apply Integration by Parts again to evaluate $\int xe^x\,dx$. Taking $u = x$ and $v' = e^x$, we get

$$\int xe^x\,dx = xe^x - \int (1)e^x\,dx = xe^x - e^x + C.$$

Plugging this into the original equation gives us

$$\int x^2\,e^x\,dx = x^2e^x - 2\left(xe^x - e^x\right) + C = e^x(x^2 - 2x + 2) + C.$$

11. $\int x \cos 2x\, dx$

SOLUTION Let $u = x$ and $v' = \cos 2x$. Then we have

$$u = x \quad v = \tfrac{1}{2}\sin 2x$$
$$u' = 1 \quad v' = \cos 2x$$

Using Integration by Parts, we get

$$\int x \cos 2x\, dx = x\left(\frac{1}{2}\sin 2x\right) - \int (1)\left(\frac{1}{2}\sin 2x\right) dx$$
$$= \frac{1}{2}x\sin 2x - \frac{1}{2}\int \sin 2x\, dx = \frac{1}{2}x\sin 2x + \frac{1}{4}\cos 2x + C.$$

12. $\int x \sin(3 - x)\, dx$

SOLUTION Let $u = x$ and $v' = \sin(3 - x)$. Then we have

$$u = x \quad v = \cos(3 - x)$$
$$u' = 1 \quad v' = \sin(3 - x)$$

Using Integration by Parts, we get

$$\int x\sin(3 - x)\, dx = x\cos(3 - x) - \int (1)\cos(3 - x)\, dx = x\cos(3 - x) + \sin(3 - x) + C$$

13. $\int x^2 \sin x\, dx$

SOLUTION Let $u = x^2$ and $v' = \sin x$. Then we have

$$u = x^2 \quad v = -\cos x$$
$$u' = 2x \quad v' = \sin x$$

Using Integration by Parts, we get

$$\int x^2\sin x\, dx = x^2(-\cos x) - \int 2x(-\cos x)\, dx = -x^2\cos x + 2\int x\cos x\, dx.$$

We must apply Integration by Parts again to evaluate $\int x\cos x\, dx$. Taking $u = x$ and $v' = \cos x$, we get

$$\int x\cos x\, dx = x\sin x - \int \sin x\, dx = x\sin x + \cos x + C.$$

Plugging this into the original equation gives us

$$\int x^2\sin x\, dx = -x^2\cos x + 2(x\sin x + \cos x) + C = -x^2\cos x + 2x\sin x + 2\cos x + C.$$

14. $\int x^2 \cos 3x\, dx$

SOLUTION Let $u = x^2$ and $v' = \cos 3x$. Then we have

$$u = x^2 \quad v = \frac{1}{3}\sin 3x$$
$$u' = 2x \quad v' = \cos 3x$$

Using Integration by Parts, we get

$$\int x^2\cos 3x\, dx = \frac{1}{3}x^2\sin 3x - \int (2x)\frac{1}{3}\sin 3x\, dx = \frac{1}{3}x^2\sin 3x - \frac{2}{3}\int x\sin 3x\, dx$$

Use Integration by Parts again on this integral, with $u = x$ and $v' = \sin 3x$ to get

$$\int x^2\cos 3x\, dx = \frac{1}{3}x^2\sin 3x - \frac{2}{3}\left(-\frac{1}{3}x\cos 3x + \frac{1}{3}\int \cos 3x\, dx\right)$$
$$= \frac{1}{3}x^2\sin 3x + \frac{2}{9}x\cos 3x - \frac{2}{27}\sin 3x + C$$

15. $\int e^{-x} \sin x \, dx$

SOLUTION Let $u = e^{-x}$ and $v' = \sin x$. Then we have

$$u = e^{-x} \qquad v = -\cos x$$
$$u' = -e^{-x} \qquad v' = \sin x$$

Using Integration by Parts, we get

$$\int e^{-x} \sin x \, dx = -e^{-x} \cos x - \int (-e^{-x})(-\cos x)\, dx = -e^{-x} \cos x - \int e^{-x} \cos x \, dx.$$

We must apply Integration by Parts again to evaluate $\int e^{-x} \cos x \, dx$. Using $u = e^{-x}$ and $v' = \cos x$, we get

$$\int e^{-x} \cos x \, dx = e^{-x} \sin x - \int (-e^{-x})(\sin x)\, dx = e^{-x} \sin x + \int e^{-x} \sin x \, dx.$$

Plugging this into the original equation, we get

$$\int e^{-x} \sin x \, dx = -e^{-x} \cos x - \left[e^{-x} \sin x + \int e^{-x} \sin x \, dx \right].$$

Solving this equation for $\int e^{-x} \sin x \, dx$ gives us

$$\int e^{-x} \sin x \, dx = -\frac{1}{2} e^{-x} (\sin x + \cos x) + C.$$

16. $\int e^{x} \sin 2x \, dx$

SOLUTION Let $u = \sin 2x$ and $v' = e^{x}$. Then we have

$$u = \sin 2x \qquad v = e^{x}$$
$$u' = 2\cos 2x \qquad v' = e^{x}$$

Using Integration by Parts, we get

$$\int e^{x} \sin 2x \, dx = e^{x} \sin 2x - 2 \int e^{x} \cos 2x \, dx.$$

We must apply Integration by Parts again to evaluate $\int e^{x} \cos 2x \, dx$. Using $u = \cos 2x$ and $v' = e^{x}$, we get

$$\int e^{x} \cos 2x \, dx = e^{x} \cos 2x - \int (-2 \sin 2x) e^{x} \, dx = e^{x} \cos 2x + 2 \int e^{x} \sin 2x \, dx.$$

Plugging this into the original equation, we get

$$\int e^{x} \sin 2x \, dx = e^{x} \sin 2x - 2 \left[e^{x} \cos 2x + 2 \int e^{x} \sin 2x \, dx \right] = e^{x} \sin 2x - 2e^{x} \cos 2x - 4 \int e^{x} \sin 2x \, dx.$$

Solving this equation for $\int e^{x} \sin 2x \, dx$ gives us

$$\int e^{x} \sin 2x \, dx = \frac{1}{5} e^{x} (\sin 2x - 2\cos 2x) + C.$$

17. $\int e^{-5x} \sin x \, dx$

SOLUTION Let $u = \sin x$ and $v' = e^{-5x}$. Then we have

$$u = \sin x \qquad v = -\frac{1}{5} e^{-5x}$$
$$u' = \cos x \qquad v' = e^{-5x}$$

Using Integration by Parts, we get

$$\int e^{-5x} \sin x \, dx = -\frac{1}{5} e^{-5x} \sin x - \int \cos x \left(-\frac{1}{5} e^{-5x} \right) dx = -\frac{1}{5} e^{-5x} \sin x + \frac{1}{5} \int e^{-5x} \cos x \, dx$$

Apply Integration by Parts again to this integral, with $u = \cos x$ and $v' = e^{-5x}$ to get

$$\int e^{-5x} \cos x \, dx = -\frac{1}{5} e^{-5x} \cos x - \frac{1}{5} \int e^{-5x} \sin x \, dx$$

Plugging this into the original equation, we get

$$\begin{aligned} \int e^{-5x} \sin x \, dx &= -\frac{1}{5} e^{-5x} \sin x + \frac{1}{5} \left(-\frac{1}{5} e^{-5x} \cos x - \frac{1}{5} \int e^{-5x} \sin x \, dx \right) \\ &= -\frac{1}{5} e^{-5x} \sin x - \frac{1}{25} e^{-5x} \cos x - \frac{1}{25} \int e^{-5x} \sin x \, dx \end{aligned}$$

Solving this equation for $\int e^{-5x} \sin x \, dx$ gives us

$$\int e^{-5x} \sin x \, dx = -\frac{5}{26} e^{-5x} \sin x - \frac{1}{26} e^{-5x} \cos x + C = -\frac{1}{26} e^{-5x} (5 \sin x + \cos x) + C$$

18. $\int e^{3x} \cos 4x \, dx$

SOLUTION Let $u = \cos 4x$ and $v' = e^{3x}$. Then we have

$$\begin{aligned} u &= \cos 4x & v &= \frac{1}{3} e^{3x} \\ u' &= -4 \sin 4x & v' &= e^{3x} \end{aligned}$$

Using Integration by Parts, we get

$$\int e^{3x} \cos 4x \, dx = \frac{1}{3} e^{3x} \cos 4x - \int \frac{1}{3} e^{3x} (-4 \sin 4x) \, dx = \frac{1}{3} e^{3x} \cos 4x + \frac{4}{3} \int e^{3x} \sin 4x \, dx$$

Apply Integration by Parts again to this integral, with $u = \sin 4x$ and $v' = e^{3x}$, to get

$$\int e^{3x} \sin 4x \, dx = \frac{1}{3} e^{3x} \sin 4x - \int \frac{1}{3} e^{3x} \cdot 4 \cos 4x \, dx = \frac{1}{3} e^{3x} \sin 4x - \frac{4}{3} \int e^{3x} \cos 4x \, dx$$

Plugging this into the original equation, we get

$$\begin{aligned} \int e^{3x} \cos 4x \, dx &= \frac{1}{3} e^{3x} \cos 4x + \frac{4}{3} \left(\frac{1}{3} e^{3x} \sin 4x - \frac{4}{3} \int e^{3x} \cos 4x \, dx \right) \\ &= \frac{1}{3} e^{3x} \cos 4x + \frac{4}{9} e^{3x} \sin 4x - \frac{16}{9} \int e^{3x} \cos 4x \, dx \end{aligned}$$

Solving this equation for $\int e^{3x} \cos 4x \, dx$ gives us

$$\int e^{3x} \cos 4x \, dx = \frac{3}{25} e^{3x} \cos 4x + \frac{4}{25} e^{3x} \sin 4x = \frac{1}{25} e^{3x} (3 \cos 4x + 4 \sin 4x) + C$$

19. $\int x \ln x \, dx$

SOLUTION Let $u = \ln x$ and $v' = x$. Then we have

$$\begin{aligned} u &= \ln x & v &= \tfrac{1}{2} x^2 \\ u' &= \tfrac{1}{x} & v' &= x \end{aligned}$$

Using Integration by Parts, we get

$$\begin{aligned} \int x \ln x \, dx &= \frac{1}{2} x^2 \ln x - \int \left(\frac{1}{x} \right) \left(\frac{1}{2} x^2 \right) dx \\ &= \frac{1}{2} x^2 \ln x - \frac{1}{2} \int x \, dx = \frac{1}{2} x^2 \ln x - \frac{1}{2} \left(\frac{x^2}{2} \right) + C = \frac{1}{4} x^2 (2 \ln x - 1) + C. \end{aligned}$$

20. $\displaystyle\int \frac{\ln x}{x^2}\,dx$

SOLUTION Let $u = \ln x$ and $v' = x^{-2}$. Then we have

$$u = \ln x \qquad v = -x^{-1}$$
$$u' = \tfrac{1}{x} \qquad v' = x^{-2}$$

Using Integration by Parts, we get

$$\int \frac{\ln x}{x^2}\,dx = -\frac{1}{x}\ln x - \int \frac{1}{x}\left(\frac{-1}{x}\right)dx = -\frac{1}{x}\ln x + \int x^{-2}\,dx$$
$$= -\frac{1}{x}\ln x - \frac{1}{x} + C = -\frac{1}{x}(\ln x + 1) + C.$$

21. $\displaystyle\int x^2 \ln x\,dx$

SOLUTION Let $u = \ln x$ and $v' = x^2$. Then we have

$$u = \ln x \qquad v = \tfrac{1}{3}x^3$$
$$u' = \tfrac{1}{x} \qquad v' = x^2$$

Using Integration by Parts, we get

$$\int x^2 \ln x\,dx = \frac{1}{3}x^3 \ln x - \int \frac{1}{x}\left(\frac{1}{3}x^3\right)dx = \frac{1}{3}x^3 \ln x - \frac{1}{3}\int x^2\,dx$$
$$= \frac{1}{3}x^3 \ln x - \frac{1}{3}\left(\frac{x^3}{3}\right) + C = \frac{x^3}{3}\left(\ln x - \frac{1}{3}\right) + C.$$

22. $\displaystyle\int x^{-5}\ln x\,dx$

SOLUTION Let $u = \ln x$ and $v' = x^{-5}$. Then we have

$$u = \ln x \qquad v = -\frac{1}{4}x^{-4}$$
$$u' = \frac{1}{x} \qquad v = x^{-5}$$

Using Integration by Parts, we get

$$\int x^{-5}\ln x\,dx = -\frac{1}{4}x^{-4}\ln x + \int \frac{1}{4}x^{-4}\frac{1}{x}\,dx = -\frac{1}{4}x^{-4}\ln x + \frac{1}{4}\int x^{-5}\,dx$$
$$= -\frac{1}{4}x^{-4}\ln x - \frac{1}{16}x^{-4} + C = -\frac{1}{4x^4}\left(\ln x + \frac{1}{4}\right) + C$$

23. $\displaystyle\int (\ln x)^2\,dx$

SOLUTION Let $u = (\ln x)^2$ and $v' = 1$. Then we have

$$u = (\ln x)^2 \qquad v = x$$
$$u' = \frac{2}{x}\ln x \qquad v' = 1$$

Using Integration by Parts, we get

$$\int (\ln x)^2\,dx = (\ln x)^2(x) - \int \left(\frac{2}{x}\ln x\right)x\,dx = x(\ln x)^2 - 2\int \ln x\,dx.$$

We must apply Integration by Parts again to evaluate $\int \ln x\,dx$. Using $u = \ln x$ and $v' = 1$, we have

$$\int \ln x\,dx = x\ln x - \int \frac{1}{x}\cdot x\,dx = x\ln x - \int dx = x\ln x - x + C.$$

Plugging this into the original equation, we get

$$\int (\ln x)^2\,dx = x(\ln x)^2 - 2\,(x\ln x - x) + C = x\left[(\ln x)^2 - 2\ln x + 2\right] + C.$$

24. $\int x(\ln x)^2\,dx$

SOLUTION Let $u = (\ln x)^2$, $v' = x$. Then we have

$$u = (\ln x)^2 \qquad v = \frac{1}{2}x^2$$
$$u' = \frac{2\ln x}{x} \qquad v' = x$$

Using Integration by Parts, we get

$$\int x(\ln x)^2\,dx = \frac{1}{2}x^2(\ln x)^2 - \int x^2\frac{\ln x}{x}\,dx = \frac{1}{2}x^2(\ln x)^2 - \int x\ln x\,dx$$

Apply Integration by Parts again to this integral, with $u = \ln x$, $v' = x$, to get

$$\int x\ln x\,dx = \frac{1}{2}x^2\ln x - \frac{1}{2}\int x^2\frac{1}{x}\,dx = \frac{1}{2}x^2\ln x - \frac{1}{4}x^2$$

Plug this back into the first formula to get

$$\int x(\ln x)^2\,dx = \frac{1}{2}x^2(\ln x)^2 - \left(\frac{1}{2}x^2\ln x - \frac{1}{4}x^2\right) + C = \frac{1}{2}x^2\left((\ln x)^2 - \ln x + \frac{1}{2}\right) + C$$

25. $\int x\sec^2 x\,dx$

SOLUTION Let $u = x$ and $v' = \sec^2 x$. Then we have

$$u = x \qquad v = \tan x$$
$$u' = 1 \qquad v' = \sec^2 x$$

Using Integration by Parts, we get

$$\int x\sec^2 x\,dx = x\tan x - \int (1)\tan x\,dx = x\tan x - \ln|\sec x| + C.$$

26. $\int x\tan x\sec x\,dx$

SOLUTION Let $u = x$ and $v' = \tan x\sec x$. Then we have

$$u = x \qquad v = \sec x$$
$$u' = 1 \qquad v' = \tan x\sec x$$

Using Integration by Parts, we get

$$\int x\tan x\sec x\,dx = x\sec x - \int \sec x\,dx = x\sec x - \ln|\sec x + \tan x| + C$$

27. $\int \cos^{-1} x\,dx$

SOLUTION Let $u = \cos^{-1} x$ and $v' = 1$. Then we have

$$u = \cos^{-1} x \qquad v = x$$
$$u' = \frac{-1}{\sqrt{1-x^2}} \qquad v' = 1$$

Using Integration by Parts, we get

$$\int \cos^{-1} x\,dx = x\cos^{-1} x - \int \frac{-x}{\sqrt{1-x^2}}\,dx.$$

We can evaluate $\int \frac{-x}{\sqrt{1-x^2}}\,dx$ by making the substitution $w = 1 - x^2$. Then $dw = -2x\,dx$, and we have

$$\int \cos^{-1} x\,dx = x\cos^{-1} x - \frac{1}{2}\int \frac{-2x\,dx}{\sqrt{1-x^2}} = x\cos^{-1} x - \frac{1}{2}\int w^{-1/2}\,dw$$
$$= x\cos^{-1} x - \frac{1}{2}(2w^{1/2}) + C = x\cos^{-1} x - \sqrt{1-x^2} + C.$$

28. $\int \sin^{-1} x\, dx$

SOLUTION Let $u = \sin^{-1} x$ and $v' = 1$. Then we have

$$\begin{aligned} u &= \sin^{-1} x & v &= x \\ u' &= \frac{1}{\sqrt{1-x^2}} & v' &= 1 \end{aligned}$$

Using Integration by Parts, we get

$$\int \sin^{-1} x\, dx = x \sin^{-1} x - \int \frac{x}{\sqrt{1-x^2}}\, dx.$$

We can evaluate $\int \frac{x}{\sqrt{1-x^2}}\, dx$ by making the substitution $w = 1 - x^2$. Then $dw = -2x\, dx$, and we have

$$\begin{aligned} \int \sin^{-1} x\, dx &= x \sin^{-1} x + \frac{1}{2} \int \frac{-2x\, dx}{\sqrt{1-x^2}} = x \sin^{-1} x + \frac{1}{2} \int w^{-1/2}\, dw \\ &= x \sin^{-1} x + \frac{1}{2}(2w^{1/2}) + C = x \sin^{-1} x + \sqrt{1-x^2} + C. \end{aligned}$$

29. $\int \sec^{-1} x\, dx$

SOLUTION We are forced to choose $u = \sec^{-1} x$, $v' = 1$, so that $u' = \frac{1}{x\sqrt{x^2-1}}$ and $v = x$. Using Integration by parts, we get:

$$\int \sec^{-1} x\, dx = x \sec^{-1} x - \int \frac{x\, dx}{x\sqrt{x^2-1}} = x \sec^{-1} x - \int \frac{dx}{\sqrt{x^2-1}}.$$

Via the substitution $\sqrt{x^2-1} = \tan\theta$ (so that $x = \sec\theta$ and $dx = \sec\theta \tan\theta d\theta$), we get:

$$\begin{aligned} \int \sec^{-1} x\, dx &= x \sec^{-1} x - \int \frac{\sec\theta \tan\theta d\theta}{\tan\theta} = x \sec^{-1} x - \int \sec\theta d\theta \\ &= x \sec^{-1} x - \ln|\sec\theta + \tan\theta| + C = x \sec^{-1} x - \ln|x + \sqrt{x^2-1}| + C. \end{aligned}$$

30. $\int x 5^x\, dx$

SOLUTION Let $u = x$ and $v' = 5^x$. Then we have

$$\begin{aligned} u &= x & v &= \frac{5^x}{\ln 5} \\ u' &= 1 & v' &= 5^x \end{aligned}$$

Using Integration by Parts, we get

$$\begin{aligned} \int x\, 5^x\, dx &= x\left(\frac{5^x}{\ln 5}\right) - \int (1)\frac{5^x}{\ln 5}\, dx = \frac{x\, 5^x}{\ln 5} - \frac{1}{\ln 5}\int 5^x\, dx \\ &= \frac{x\, 5^x}{\ln 5} - \frac{1}{\ln 5}\left(\frac{5^x}{\ln 5}\right) + C = \frac{5^x}{\ln 5}\left(x - \frac{1}{\ln 5}\right) + C. \end{aligned}$$

31. $\int 3^x \cos x\, dx$

SOLUTION Let $u = \cos x$ and $v' = 3^x$. Then we have

$$\begin{aligned} u &= \cos x & v &= \frac{3^x}{\ln 3} \\ u' &= -\sin x & v' &= 3^x \end{aligned}$$

Using Integration by Parts, we get

$$\int 3^x \cos x\, dx = \frac{3^x}{\ln 3} \cos x + \frac{1}{\ln 3} \int 3^x \sin x\, dx$$

Apply Integration by Parts to the remaining integral, with $u = \sin x$ and $v' = 3^x$; then

$$\int 3^x \sin x\,dx = \frac{3^x}{\ln 3}\sin x - \frac{1}{\ln 3}\int 3^x \cos x\,dx$$

Plug this into the first equation to get

$$\begin{aligned}\int 3^x \cos x\,dx &= \frac{3^x}{\ln 3}\cos x + \frac{1}{\ln 3}\left(\frac{3^x}{\ln 3}\sin x - \frac{1}{\ln 3}\int 3^x \cos x\,dx\right)\\ &= \frac{3^x}{\ln 3}\cos x + \frac{3^x}{(\ln 3)^2}\sin x - \frac{1}{(\ln 3)^2}\int 3^x \cos x\,dx\end{aligned}$$

Solving for $\int 3^x \cos x\,dx$ gives

$$\int 3^x \cos x\,dx = \frac{3^x \ln 3 \cos x}{1 + (\ln 3)^2} + \frac{3^x \sin x}{1 + (\ln 3)^2} + C = \frac{3^x}{1 + (\ln 3)^2}(\ln 3 \cos x + \sin x) + C$$

32. $\int x \sinh x\,dx$

SOLUTION Let $u = x$, $v' = \sinh x$. Then

$$\begin{aligned} u &= x & v &= \cosh x\\ u' &= 1 & v' &= \sinh x\end{aligned}$$

Integration by Parts gives us

$$\int x \sinh x\,dx = x \cosh x - \int \cosh x\,dx = x \cosh x - \sinh x + C$$

33. $\int x^2 \cosh x\,dx$

SOLUTION Let $u = x^2$, $v' = \cosh x$. Then

$$\begin{aligned} u &= x^2 & v &= \sinh x\\ u' &= 2x & v' &= \cosh x\end{aligned}$$

Integration by Parts gives us (along with Exercise 32)

$$\int x^2 \cosh x\,dx = x^2 \sinh x - 2\int x \sinh x, dx = x^2 \sinh x - 2x \cosh x + 2 \sinh x + C$$

34. $\int \cos x \cosh x\,dx$

SOLUTION Let $u = \cos x$ and $v' = \cosh x$. Then

$$\begin{aligned} u &= \cos x & v &= \sinh x\\ u' &= -\sin x & v' &= \cosh x\end{aligned}$$

Integration by Parts gives us

$$\int \cos x \cosh x\,dx = \cos x \sinh x - \int (-\sin x) \sinh x\,dx = \cos x \sinh x + \int \sin x \sinh x\,dx.$$

We must apply Integration by Parts again to evaluate $\int \sin x \sinh x\,dx$. Using $u = \sin x$ and $v' = \sinh x$, we find

$$\int \sin x \sinh x\,dx = \sin x \cosh x - \int \cos x \cosh x\,dx.$$

Plugging this into the original equation, we have

$$\int \cos x \cosh x\,dx = \cos x \sinh x + \sin x \cosh x - \int \cos x \cosh x\,dx.$$

Solving this equation for $\int \cos x \cosh x\, dx$ yields

$$\int \cos x \cosh x\, dx = \frac{1}{2}(\cos x \sinh x + \sin x \cosh x) + C.$$

35. $\int \tanh^{-1} 4x\, dx$

SOLUTION Using $u = \tanh^{-1} 4x$ and $v' = 1$ gives us

$$u = \tanh^{-1} 4x \qquad v = x$$
$$u' = \frac{4}{1-16x^2} \qquad v' = 1$$

Integration by Parts gives us

$$\int \tanh^{-1} 4x\, dx = x \tanh^{-1} 4x - \int \left(\frac{4}{1-16x^2}\right) x\, dx.$$

For the integral on the right we'll use the substitution $w = 1 - 16x^2$, $dw = -32x\, dx$. Then we have

$$\begin{aligned}\int \tanh^{-1} 4x\, dx &= x \tanh^{-1} 4x + \frac{1}{8}\int \frac{dw}{w} = x \tanh^{-1} 4x + \frac{1}{8} \ln |w| + C\\ &= x \tanh^{-1} 4x + \frac{1}{8} \ln |1 - 16x^2| + C.\end{aligned}$$

36. $\int \sinh^{-1} x\, dx$

SOLUTION Using $u = \sinh^{-1} x$ and $v' = 1$ gives us

$$u = \sinh^{-1} x \qquad v = x$$
$$u' = \frac{1}{\sqrt{1+x^2}} \qquad v' = 1$$

Integration by Parts gives us

$$\int \sinh^{-1} x\, dx = x \sinh^{-1} x - \int \left(\frac{1}{\sqrt{1+x^2}}\right) x\, dx.$$

For the integral on the right we'll use the substitution $w = 1 + x^2$, $dw = 2x\, dx$. Then we have

$$\begin{aligned}\int \sinh^{-1} x\, dx &= x \sinh^{-1} x - \frac{1}{2}\int \frac{dw}{\sqrt{w}} = x \sinh^{-1} x - \sqrt{w} + C\\ &= x \sinh^{-1} x - \sqrt{1+x^2} + C.\end{aligned}$$

In Exercises 37 and 38, evaluate using substitution and then Integration by Parts.

37. $\int e^{\sqrt{x}}\, dx$ *Hint:* Let $u = x^{1/2}$

SOLUTION Let $w = x^{1/2}$. Then $dw = \frac{1}{2}x^{-1/2}dx$, or $dx = 2\,x^{1/2}\,dw = 2w\,dw$. Now,

$$\int e^{\sqrt{x}}\, dx = 2\int we^w\, dw.$$

Using Integration by Parts with $u = w$ and $v' = e^w$, we get

$$2\int we^w\, dw = 2(we^w - e^w) + C.$$

Substituting back, we find

$$\int e^{\sqrt{x}}\, dx = 2e^{\sqrt{x}}(\sqrt{x} - 1) + C.$$

38. $\int x^3 e^{x^2}\,dx$

SOLUTION Let $w = x^2$. Then $dw = 2x\,dx$, and

$$\int x^3 e^{x^2}\,dx = \frac{1}{2}\int we^w\,dw.$$

Using Integration by Parts, we let $u = w$ and $v' = e^w$. Then we have

$$\int we^w\,dw = we^w - \int (1)e^w\,dw = we^w - e^w + C.$$

Substituting back in terms of x, we get

$$\int x^3\,e^{x^2}\,dx = \frac{1}{2}\left(x^2e^{x^2} - e^{x^2}\right) + C.$$

In Exercises 39–48, evaluate using Integration by Parts, substitution, or both if necessary.

39. $\int x\cos 4x\,dx$

SOLUTION Let $u = x$ and $v' = \cos 4x$. Then we have

$$\begin{array}{ll} u = x & v = \frac{1}{4}\sin 4x \\ u' = 1 & v' = \cos 4x \end{array}$$

Using Integration by Parts, we get

$$\begin{aligned}\int x\cos 4x\,dx &= \frac{1}{4}x\sin 4x - \int (1)\frac{1}{4}\sin 4x\,dx = \frac{1}{4}x\sin 4x - \frac{1}{4}\left(-\frac{1}{4}\cos 4x\right) + C \\ &= \frac{1}{4}x\sin 4x + \frac{1}{16}\cos 4x + C.\end{aligned}$$

40. $\int \frac{\ln(\ln x)\,dx}{x}$

SOLUTION Let $w = \ln x$. Then $dw = dx/x$, and we have

$$\int \frac{\ln(\ln x)\,dx}{x} = \int \ln w\,dw$$

Now we can use Integration by Parts, letting $u = \ln w$ and $v' = 1$. Then $u' = 1/w$, $v = w$, and

$$\int \ln w\,dw = w\ln w - \int \frac{1}{w}(w)\,dw = w\ln w - w + C.$$

Substituting back in terms of x, we get

$$\int \frac{\ln(\ln x)\,dx}{x} = (\ln x)\ln(\ln x) - \ln x + C.$$

41. $\int \frac{x\,dx}{\sqrt{x+1}}$

SOLUTION Let $u = x + 1$. Then $du = dx$, $x = u - 1$, and

$$\begin{aligned}\int \frac{x\,dx}{\sqrt{x+1}} &= \int \frac{(u-1)\,du}{\sqrt{u}} = \int \left(\frac{u}{\sqrt{u}} - \frac{1}{\sqrt{u}}\right) du = \int (u^{1/2} - u^{-1/2})\,du \\ &= \frac{2}{3}u^{3/2} - 2u^{1/2} + C = \frac{2}{3}(x+1)^{3/2} - 2(x+1)^{1/2} + C.\end{aligned}$$

42. $\int x^2(x^3+9)^{15}\,dx$

SOLUTION Note that $(x^3 + 0)' = 3x^2$, so use substitution with $u = x^3 + 9$, $du = 3x^2\,dx$. Then

$$\int x^2(x^3+9)^{15}\,dx = \frac{1}{3}\int u^{15}\,du = \frac{1}{48}u^{16} + C = \frac{1}{48}(x^3+9)^{16} + C$$

43. $\int \cos x \ln(\sin x)\,dx$

SOLUTION Let $w = \sin x$. Then $dw = \cos x\,dx$, and

$$\int \cos x\ \ln(\sin x)\,dx = \int \ln w\,dw.$$

Now use Integration by Parts with $u = \ln w$ and $v' = 1$. Then $u' = 1/w$ and $v = w$, which gives us

$$\int \cos x\ \ln(\sin x)\,dx = \int \ln w\,dw = w \ln w - w + C = \sin x \ln(\sin x) - \sin x + C.$$

44. $\int \sin \sqrt{x}\,dx$

SOLUTION First use substitution, with $w = \sqrt{x}$ and $dw = dx/(2\sqrt{x})$. This gives us

$$\int \sin \sqrt{x}\,dx = \int \frac{(2\sqrt{x}) \sin \sqrt{x}\,dx}{(2\sqrt{x})} = 2 \int w \sin w\,dw.$$

Now use Integration by Parts, with $u = w$ and $v' = \sin w$. Then we have

$$\begin{aligned}\int \sin \sqrt{x}\,dx &= 2 \int w \sin w\,dw = 2\left(-w \cos w - \int -\cos w\,dw\right)\\ &= 2(-w \cos w + \sin w) + C = 2 \sin \sqrt{x} - 2\sqrt{x} \cos \sqrt{x} + C.\end{aligned}$$

45. $\int \sqrt{x} e^{\sqrt{x}}\,dx$

SOLUTION Let $w = \sqrt{x}$. Then $dw = \frac{1}{2\sqrt{x}}\,dx$ and

$$\int \sqrt{x} e^{\sqrt{x}}\,dx = 2 \int w^2 e^w\,dw.$$

Now, use Integration by Parts with $u = w^2$ and $v' = e^w$. This gives

$$\int \sqrt{x} e^{\sqrt{x}}\,dx = 2 \int w^2 e^w\,dw = 2w^2 e^w - 4 \int w e^w\,dw.$$

We need to use Integration by Parts again, this time with $u = w$ and $v' = e^w$. We find

$$\int w e^w\,dw = w e^w - \int e^w\,dw = w e^w - e^w + C;$$

finally,

$$\int \sqrt{x} e^{\sqrt{x}}\,dx = 2w^2 e^w - 4 w e^w + 4 e^w + C = 2x e^{\sqrt{x}} - 4\sqrt{x} e^{\sqrt{x}} + 4 e^{\sqrt{x}} + C.$$

46. $\int \frac{\tan \sqrt{x}\,dx}{\sqrt{x}}$

SOLUTION Let $u = \sqrt{x}$ and $du = \frac{1}{2} x^{-1/2}$. Then

$$\int \frac{\tan \sqrt{x}\,dx}{\sqrt{x}} = 2 \int \tan u\,du = -2 \ln|\cos u| + C = -2 \ln|\cos \sqrt{x}| + C$$

47. $\int \frac{\ln(\ln x) \ln x\,dx}{x}$

SOLUTION Let $w = \ln x$. Then $dw = dx/x$, and

$$\int \frac{\ln(\ln x) \ln x\,dx}{x} = \int w \ln w\,dw.$$

Now use Integration by Parts, with $u = \ln w$ and $v' = w$. Then,

$$\begin{aligned} u &= \ln w & v &= \frac{1}{2} w^2\\ u' &= w^{-1} & v' &= w \end{aligned}$$

and

$$\int \frac{\ln(\ln x)\ln x\,dx}{x} = \frac{1}{2}w^2\ln w - \frac{1}{2}\int w\,dw = \frac{1}{2}w^2\ln w - \frac{1}{2}\left(\frac{w^2}{2}\right) + C$$
$$= \frac{1}{2}(\ln x)^2\ln(\ln x) - \frac{1}{4}(\ln x)^2 + C = \frac{1}{4}(\ln x)^2[2\ln(\ln x) - 1] + C.$$

48. $\int \sin(\ln x)\,dx$

SOLUTION Let $u = \sin(\ln x)$ and $v' = 1$. Then we have

$$u = \sin(\ln x) \qquad v = x$$
$$u' = \frac{\cos(\ln x)}{x} \qquad v' = 1$$

Using Integration by Parts, we get

$$\int \sin(\ln x)\,dx = x\sin(\ln x) - \int (x)\frac{\cos(\ln x)}{x}\,dx = x\sin(\ln x) - \int \cos(\ln x)\,dx.$$

We must use Integration by Parts again to evaluate $\int \cos(\ln x)\,dx$. Let $u = \cos(\ln x)$ and $v' = 1$. Then

$$\int \sin(\ln x)\,dx = x\sin(\ln x) - \left[x\cos(\ln x) - \int(-\sin(\ln x))\,dx\right]$$
$$= x\sin(\ln x) - x\cos(\ln x) - \int \sin(\ln x)\,dx.$$

Solving this equation for $\int \sin(\ln x)\,dx$, we get

$$\int \sin(\ln x)\,dx = \frac{x}{2}[\sin(\ln x) - \cos(\ln x)] + C.$$

In Exercises 49–54, compute the definite integral.

49. $\int_0^3 xe^{4x}\,dx$

SOLUTION Let $u = x$, $v' = e^{4x}$. Then $u' = 1$ and $v = \frac{1}{4}e^{4x}$. Using Integration by Parts,

$$\int_0^3 xe^{4x}\,dx = \left(\frac{1}{4}xe^{4x}\right)\Big|_0^3 - \frac{1}{4}\int_0^3 e^{4x}\,dx = \frac{3}{4}e^{12} - \frac{1}{16}e^{12} + \frac{1}{16} = \frac{11}{16}e^{12} + \frac{1}{16}$$

50. $\int_0^{\pi/4} x\sin 2x\,dx$

SOLUTION Let $u = x$ and $v' = \sin 2x$. Then $u' = 1$ and $v = -\frac{1}{2}\cos 2x$. Using Integration by Parts,

$$\int_0^{\pi/4} x\sin(2x)\,dx = -\frac{1}{2}x\cos 2x\Big|_0^{\pi/4} - \int_0^{\pi/4}\left(-\frac{1}{2}\cos 2x\right)dx = \left(-\frac{1}{2}x\cos 2x + \left(\frac{1}{2}\right)\frac{\sin 2x}{2}\right)\Big|_0^{\pi/4}$$
$$= \left(-\frac{1}{2}\left(\frac{\pi}{4}\right)\cos\left(\frac{\pi}{2}\right) + \frac{1}{4}\sin\left(\frac{\pi}{2}\right)\right) - (0+0) = \frac{1}{4}.$$

51. $\int_1^2 x\ln x\,dx$

SOLUTION Let $u = \ln x$ and $v' = x$. Then $u' = \frac{1}{x}$ and $v = \frac{1}{2}x^2$. Using Integration by Parts gives

$$\int_1^2 x\ln x\,dx = \left(\frac{1}{2}x^2\ln x\right)\Big|_1^2 - \frac{1}{2}\int_1^2 x\,dx = 2\ln 2 - \frac{1}{4}x^2\Big|_1^2 = 2\ln 2 - \frac{3}{4}$$

52. $\int_1^e \frac{\ln x\,dx}{x^2}$

SOLUTION Let $u = \ln x$ and $v' = x^{-2}$. Then $u' = x^{-1}$ and $v = -x^{-1}$. Using Integration by Parts gives

$$\int_1^e \frac{\ln x\,dx}{x^2} = -\frac{\ln x}{x}\Big|_1^e + \int_1^e x^{-2}\,dx = -e^{-1} - x^{-1}\Big|_1^e = 1 - \frac{2}{e}$$

53. $\int_0^{\pi} e^x \sin x\, dx$

SOLUTION Let $u = \sin x$ and $v' = e^x$; then $u' = \cos x$ and $v = e^x$. Integration by Parts gives

$$\int_0^{\pi} e^x \sin x\, dx = e^x \sin x \Big|_0^{\pi} - \int_0^{\pi} e^x \cos x\, dx = -\int_0^{\pi} e^x \cos x\, dx$$

Apply integration by parts again to this integral, with $u = \cos x$ and $v' = e^x$; then $u' = -\sin x$ and $v = e^x$, so we get

$$\int_0^{\pi} e^x \sin x\, dx = -\left(\left(e^x \cos x\right)\Big|_0^{\pi} + \int_0^{\pi} e^x \sin x\, dx \right) = e^{\pi} + 1 - \int_0^{\pi} e^x \sin x\, dx$$

Solving for $\int_0^{\pi} e^x \sin x\, dx$ gives

$$\int_0^{\pi} e^x \sin x\, dx = \frac{e^{\pi} + 1}{2}$$

54. $\int_0^{1} \tan^{-1} x\, dx$

SOLUTION Let $u = \tan^{-1} x$ and $v' = 1$. Then we have

$$\begin{aligned} u &= \tan^{-1} x & v &= x \\ u' &= \frac{1}{x^2+1} & v' &= 1 \end{aligned}$$

Integration by Parts gives us

$$\int \tan^{-1} x\, dx = x \tan^{-1} x - \int \left(\frac{1}{x^2+1} \right) x\, dx.$$

For the integral on the right we'll use the substitution $w = x^2 + 1$, $dw = 2x\, dx$. Then we have

$$\int \tan^{-1} x\, dx = x \tan^{-1} x - \frac{1}{2} \int \frac{dw}{w} = x \tan^{-1} x - \frac{1}{2} \ln |w| + C = x \tan^{-1} x - \frac{1}{2} \ln |x^2 + 1| + C.$$

Now we can compute the definite integral:

$$\int_0^{1} \tan^{-1} x\, dx = \left(x \tan^{-1} x - \frac{1}{2} \ln |x^2 + 1| \right) \Big|_0^1 = \left((1) \tan^{-1}(1) - \frac{1}{2} \ln 2 \right) - (0) = \frac{\pi}{4} - \frac{1}{2} \ln 2.$$

55. Use Eq. (5) to evaluate $\int x^4 e^x\, dx$.

SOLUTION

$$\begin{aligned} \int x^4 e^x\, dx &= x^4 e^x - 4 \int x^3 e^x\, dx = x^4 e^x - 4 \left[x^3 e^x - 3 \int x^2 e^x\, dx \right] \\ &= x^4 e^x - 4x^3 e^x + 12 \int x^2 e^x\, dx = x^4 e^x - 4x^3 e^x + 12 \left[x^2 e^x - 2 \int x e^x\, dx \right] \\ &= x^4 e^x - 4x^3 e^x + 12x^2 e^x - 24 \int x e^x\, dx = x^4 e^x - 4x^3 e^x + 12x^2 e^x - 24 \left[x e^x - \int e^x\, dx \right] \\ &= x^4 e^x - 4x^3 e^x + 12x^2 e^x - 24 \left[x e^x - e^x \right] + C. \end{aligned}$$

Thus,

$$\int x^4 e^x\, dx = e^x (x^4 - 4x^3 + 12x^2 - 24x + 24) + C.$$

56. Use substitution and then Eq. (5) to evaluate $\int x^4 e^{7x}\,dx$.

SOLUTION Let $u = 7x$. Then $du = 7dx$, and

$$\int x^4 e^{7x}\,dx = \frac{1}{7^5}\int (7x)^4 e^{7x}(7dx) = \frac{1}{7^5}\int u^4 e^u\,du.$$

Now use the result from Exercise 55:

$$\begin{aligned}\int x^4 e^{7x}\,dx &= \frac{1}{7^5}e^u[u^4 - 4u^3 + 12u^2 - 24u + 24] + C\\ &= \frac{1}{7^5}e^{7x}[(7x)^4 - 4(7x)^3 + 12(7x)^2 - 24(7x) + 24] + C\\ &= \frac{1}{7^5}e^{7x}[2401x^4 - 1372x^3 + 588x^2 - 168x + 24] + C.\end{aligned}$$

57. Find a reduction formula for $\int x^n e^{-x}\,dx$ similar to Eq. (5).

SOLUTION Let $u = x^n$ and $v' = e^{-x}$. Then

$$\begin{array}{ll} u = x^n & v = -e^{-x} \\ u' = nx^{n-1} & v' = e^{-x} \end{array}$$

Using Integration by Parts, we get

$$\int x^n e^{-x}\,dx = -x^n e^{-x} - \int nx^{n-1}(-e^{-x})\,dx = -x^n e^{-x} + n\int x^{n-1}e^{-x}\,dx.$$

58. Evaluate $\int x^n \ln x\,dx$ for $n \neq -1$. Which method should be used to evaluate $\int x^{-1}\ln x\,dx$?

SOLUTION Let $u = \ln x$ and $v' = x^n$. Then we have

$$\begin{array}{ll} u = \ln x & v = \dfrac{x^{n+1}}{n+1} \\ u' = \dfrac{1}{x} & v' = x^n \end{array}$$

and

$$\begin{aligned}\int x^n \ln x\,dx &= \frac{x^{n+1}}{n+1}\ln x - \int \frac{1}{x}\cdot\frac{x^{n+1}}{n+1}\,dx = \frac{x^{n+1}}{n+1}\ln x - \frac{1}{n+1}\int x^n\,dx\\ &= \frac{x^{n+1}}{n+1}\ln x - \frac{1}{n+1}\cdot\frac{x^{n+1}}{n+1} = \frac{x^{n+1}}{n+1}\left(\ln x - \frac{1}{n+1}\right) + C.\end{aligned}$$

For $n = -1$, $\int x^{-1}\ln x\,dx$, use the substitution $u = \ln x$, $du = dx/x$. Then

$$\int x^{-1}\ln x\,dx = \int u\,du = \frac{u^2}{2} + C = \frac{1}{2}(\ln x)^2 + C.$$

In Exercises 59–66, indicate a good method for evaluating the integral (but do not evaluate). Your choices are algebraic manipulation, substitution (specify u and du), and Integration by Parts (specify u and v′). If it appears that the techniques you have learned thus far are not sufficient, state this.

59. $\int \sqrt{x}\ln x\,dx$

SOLUTION Use Integration by Parts, with $u = \ln x$ and $v' = \sqrt{x}$.

60. $\int \frac{x^2 - \sqrt{x}}{2x}\,dx$

SOLUTION Use algebraic manipulation:

$$\frac{x^2 - \sqrt{x}}{2x} = \frac{x}{2} - \frac{1}{2\sqrt{x}}.$$

61. $\int \frac{x^3\,dx}{\sqrt{4-x^2}}$

SOLUTION Use substitution, followed by algebraic manipulation: Let $u = 4 - x^2$. Then $du = -2x\,dx$, $x^2 = 4 - u$, and

$$\int \frac{x^3}{\sqrt{4-x^2}}dx = -\frac{1}{2}\int \frac{(x^2)(-2x\,dx)}{\sqrt{u}} = -\frac{1}{2}\int \frac{(4-u)(du)}{\sqrt{u}} = -\frac{1}{2}\int \left(\frac{4}{\sqrt{u}} - \frac{u}{\sqrt{u}}\right) du.$$

62. $\int \frac{dx}{\sqrt{4-x^2}}$

SOLUTION The techniques learned so far are insufficient. This problem requires the technique of trigonometric substitution.

63. $\int \frac{x+2}{x^2+4x+3}\,dx$

SOLUTION Use substitution. Let $u = x^2 + 4x + 3$; then $du = 2x + 4\,dx = 2(x+2)\,dx$, and

$$\int \frac{x+2}{x^2+4x+3}\,dx = \frac{1}{2}\int \frac{1}{u}\,du$$

64. $\int \frac{dx}{(x+2)(x^2+4x+3)}$

SOLUTION The techniques learned so far are insufficient. This problem requires the technique of trigonometric substitution.

65. $\int x\sin(3x+4)\,dx$

SOLUTION Use Integration by Parts, with $u = x$ and $v' = \sin(3x+4)$.

66. $\int x\cos(9x^2)\,dx$

SOLUTION Use substitution, with $u = 9x^2$ and $du = 18x\,dx$.

67. Evaluate $\int (\sin^{-1} x)^2\,dx$. *Hint:* Use Integration by Parts first and then substitution.

SOLUTION First use integration by parts with $v' = 1$ to get

$$\int (\sin^{-1} x)^2\,dx = x(\sin^{-1} x)^2 - 2\int \frac{x\sin^{-1} x\,dx}{\sqrt{1-x^2}}.$$

Now use substitution on the integral on the right, with $u = \sin^{-1} x$. Then $du = dx/\sqrt{1-x^2}$ and $x = \sin u$, and we get (using Integration by Parts again)

$$\int \frac{x\sin^{-1} x\,dx}{\sqrt{1-x^2}} = \int u\sin u\,du = -u\cos u + \sin u + C = -\sqrt{1-x^2}\,\sin^{-1} x + x + C.$$

where $\cos u = \sqrt{1-\sin^2 u} = \sqrt{1-x^2}$. So the final answer is

$$\int (\sin^{-1} x)^2\,dx = x(\sin^{-1} x)^2 + 2\sqrt{1-x^2}\sin^{-1} x - 2x + C.$$

68. Evaluate $\int \frac{(\ln x)^2\,dx}{x^2}$. *Hint:* Use substitution first and then Integration by Parts.

SOLUTION Let $w = \ln x$. Then $dw = dx/x,\ e^w = x$, and

$$\int \frac{(\ln x)^2\,dx}{x^2} = \int \frac{w^2 dw}{e^w}.$$

Now use Integration by Parts, with $u = w^2$ and $v' = e^{-w}$:

$$\begin{aligned}\int \frac{w^2 dw}{e^w} &= -w^2 e^{-w} - \int 2w(-e^{-w})\,dw = -w^2 e^{-w} + 2(-we^{-w} - e^{-w}) + C\\ &= -e^{-w}(w^2 + 2w + 2) + C = -e^{-\ln x}((\ln x)^2 + 2\ln x + 2) + C.\end{aligned}$$

The final answer is

$$\int \frac{(\ln x)^2\,dx}{x^2} = \frac{-[(\ln x)^2 + 2\ln x + 2]}{x} + C.$$

69. Evaluate $\int x^7 \cos(x^4)\,dx$.

SOLUTION First, let $w = x^4$. Then $dw = 4x^3\,dx$ and

$$\int x^7 \cos(x^4)\,dx = \frac{1}{4}\int w \cos x\,dw.$$

Now, use Integration by Parts with $u = w$ and $v' = \cos w$. Then

$$\int x^7 \cos(x^4)\,dx = \frac{1}{4}\left(w \sin w - \int \sin w\,dw\right) = \frac{1}{4} w \sin w + \frac{1}{4}\cos w + C = \frac{1}{4}x^4 \sin(x^4) + \frac{1}{4}\cos(x^4) + C.$$

70. Find $f(x)$, assuming that

$$\int f(x)e^x\,dx = f(x)e^x - \int x^{-1}e^x\,dx$$

SOLUTION We see that Integration by Parts was applied to $\int f(x)\,e^x\,dx$ with $u = f(x)$ and $v' = e^x$, and that therefore $f'(x) = u' = x^{-1}$. Thus $f(x) = \ln x + C$ for any constant C.

71. Find the volume of the solid obtained by revolving the region under $y = e^x$ for $0 \le x \le 2$ about the y-axis.

SOLUTION By the Method of Cylindrical Shells, the volume V of the solid is

$$V = \int_a^b (2\pi r)h\,dx = 2\pi \int_0^2 xe^x\,dx.$$

Using Integration by Parts with $u = x$ and $v' = e^x$, we find

$$V = 2\pi \quad (xe^x - e^x)\Big|_0^2 = 2\pi\big[(2e^2 - e^2) - (0 - 1)\big] = 2\pi(e^2 + 1).$$

72. Find the area enclosed by $y = \ln x$ and $y = (\ln x)^2$.

SOLUTION The two graphs intersect at $x = 1$ and at $x = e$, and $\ln x$ is above $(\ln x)^2$, so the area is

$$\int_1^e \ln x - (\ln x)^2\,dx = \int_1^e \ln x\,dx - \int_1^e (\ln x)^2\,dx$$

Using integration by parts for the second integral, let $u = (\ln x)^2$, $v' = 1$; then $u' = \frac{2\ln x}{x}$ and $v = x$, so that

$$\int_1^e (\ln x)^2\,dx = \left(x(\ln x)^2\right)\Big|_1^e - 2\int_1^e \ln x = e - 2\int_1^e \ln x$$

Substituting this back into the original equation gives

$$\int_1^e \ln x - (\ln x)^2\,dx = 3\int_1^e \ln x\,dx - e$$

We use integration by parts to evaluate the remaining integral, with $u = \ln x$ and $v' = 1$; then $u' = \frac{1}{x}$ and $v = x$, so that

$$\int_1^e \ln x\,dx = x\ln x\Big|_1^e - \int_1^e 1\,dx = e - (e - 1) = 1$$

and thus, substituting back in, the value of the original integral is

$$\int_1^e \ln x - (\ln x)^2\,dx = 3\int_1^e \ln x\,dx - e = 3 - e$$

73. Recall that the *present value* (PV) of an investment that pays out income continuously at a rate $R(t)$ for T years is $\int_0^T R(t)e^{-rt}\,dt$, where r is the interest rate. Find the PV if $R(t) = 5000 + 100t$ \$/year, $r = 0.05$ and $T = 10$ years.

SOLUTION The present value is given by

$$PV = \int_0^T R(t)e^{-rt}\,dt = \int_0^{10} (5000 + 100t)e^{-rt}\,dt = 5000\int_0^{10} e^{-rt}\,dt + 100\int_0^{10} te^{-rt}\,dt.$$

Using Integration by Parts for the integral on the right, with $u = t$ and $v' = e^{-rt}$, we find

$$\begin{aligned} PV &= 5000\left(-\frac{1}{r}e^{-rt}\right)\Big|_0^{10} + 100\left[\left(-\frac{t}{r}e^{-rt}\right)\Big|_0^{10} - \int_0^{10} \frac{-1}{r}e^{-rt}\,dt\right] \\ &= -\frac{5000}{r}e^{-rt}\Big|_0^{10} - \frac{100}{r}\left(te^{-rt} + \frac{1}{r}e^{-rt}\right)\Big|_0^{10} \\ &= -\frac{5000}{r}(e^{-10r} - 1) - \frac{100}{r}\left[\left(10e^{-10r} + \frac{1}{r}e^{-10r}\right) - \left(0 + \frac{1}{r}\right)\right] \\ &= e^{-10r}\left[-\frac{5000}{r} - \frac{1000}{r} - \frac{100}{r^2}\right] + \frac{5000}{r} + \frac{100}{r^2} \\ &= \frac{5000r + 100 - e^{-10r}(6000r + 100)}{r^2}. \end{aligned}$$

74. Derive the reduction formula

$$\int (\ln x)^k\,dx = x(\ln x)^k - k\int (\ln x)^{k-1}\,dx \qquad \boxed{6}$$

SOLUTION Use Integration by Parts with $u = (\ln x)^k$ and $v' = 1$. Then $u' = k(\ln x)^{k-1}/x$, $v = x$, and we get

$$\int (\ln x)^k\,dx = x(\ln x)^k - k\int \frac{(\ln x)^{k-1}x\,dx}{x} = x(\ln x)^k - k\int (\ln x)^{k-1}\,dx.$$

75. Use Eq. (6) to calculate $\int (\ln x)^k\,dx$ for $k = 2, 3$.

SOLUTION

$$\int (\ln x)^2\,dx = x(\ln x)^2 - 2\int \ln x\,dx = x(\ln x)^2 - 2(x\ln x - x) + C = x(\ln x)^2 - 2x\ln x + 2x + C;$$

$$\begin{aligned} \int (\ln x)^3\,dx &= x(\ln x)^3 - 3\int (\ln x)^2\,dx = x(\ln x)^3 - 3\left[x(\ln x)^2 - 2x\ln x + 2x\right] + C \\ &= x(\ln x)^3 - 3x(\ln x)^2 + 6x\ln x - 6x + C. \end{aligned}$$

76. Derive the reduction formulas

$$\int x^n\cos x\,dx = x^n\sin x - n\int x^{n-1}\sin x\,dx$$

$$\int x^n\sin x\,dx = -x^n\cos x + n\int x^{n-1}\cos x\,dx$$

SOLUTION For $\int x^n\cos x\,dx$, let $u = x^n$ and $v' = \cos x$. Then we have

$$\begin{array}{ll} u = x^n & v = \sin x \\ u' = nx^{n-1} & v' = \cos x \end{array}$$

Using Integration by Parts, we get

$$\int x^n\cos x\,dx = x^n\sin x - n\int x^{n-1}\sin x\,dx.$$

For $\int x^n\sin x\,dx$, let $u = x^n$ and $v' = \sin x$. Then we have

$$\begin{array}{ll} u = x^n & v = -\cos x \\ u' = nx^{n-1} & v' = \sin x \end{array}$$

Using Integration by Parts, we get

$$\int x^n\sin x\,dx = -x^n\cos x + n\int x^{n-1}\cos x\,dx.$$

77. Prove that $\int xb^x\,dx = b^x\left(\frac{x}{\ln b} - \frac{1}{\ln^2 b}\right) + C$.

SOLUTION Let $u = x$ and $v' = b^x$. Then $u' = 1$ and $v = b^x/\ln b$. Using Integration by Parts, we get

$$\int x\,b^x\,dx = \frac{xb^x}{\ln b} - \frac{1}{\ln b}\int b^x\,dx = \frac{xb^x}{\ln b} - \frac{1}{\ln b}\cdot\frac{b^x}{\ln b} + C = b^x\left(\frac{x}{\ln b} - \frac{1}{(\ln b)^2}\right) + C.$$

78. Define $P_n(x)$ by

$$\int x^n e^x\,dx = P_n(x)\,e^x + C$$

Use Eq. (5) to prove that $P_n(x) = x^n - nP_{n-1}(x)$. Use this recursion relation to find $P_n(x)$ for $n = 1, 2, 3, 4$. Note that $P_0(x) = 1$.

SOLUTION Use induction on n. Clearly for $n = 0$, we have

$$\int x^0 e^x\,dx = \int e^x\,dx = e^x + C = (1)e^x + C$$

so we may take $P_0(x) = 1 = x^0 - 0$. Now assume that

$$\int x^n e^x\,dx = P_n(x)e^x + C$$

where $P_n(x) = x^n - nP_{n-1}(x)$. Then using Eq. (5) with $n + 1$ in place of n gives

$$\int x^{n+1}e^x\,dx = x^{n+1}e^x - (n+1)\int x^n e^x\,dx = x^{n+1}e^x - (n+1)(P_n(x)e^x + C_1)$$
$$= (x^{n+1} - (n+1)P_n(x))e^x + C$$

Thus we may define $P_{n+1}(x) = x^{n+1} - (n+1)P_n(x)$ and we get

$$\int x^{n+1}e^x\,dx = P_{n+1}(x)e^x + C$$

as required.

Further Insights and Challenges

79. The Integration by Parts formula can be written

$$\int u(x)v(x)\,dx = u(x)V(x) - \int u'(x)V(x)\,dx \qquad \boxed{7}$$

where $V(x)$ satisfies $V'(x) = v(x)$.

(a) Show directly that the right-hand side of Eq. (7) does not change if $V(x)$ is replaced by $V(x) + C$, where C is a constant.

(b) Use $u = \tan^{-1}x$ and $v = x$ in Eq. (7) to calculate $\int x\tan^{-1}x\,dx$, but carry out the calculation twice: first with $V(x) = \frac{1}{2}x^2$ and then with $V(x) = \frac{1}{2}x^2 + \frac{1}{2}$. Which choice of $V(x)$ results in a simpler calculation?

SOLUTION

(a) Replacing $V(x)$ with $V(x) + C$ in the expression $u(x)V(x) - \int V(x)u'(x)\,dx$, we get

$$u(x)(V(x)+C) - \int (V(x)+C)u'(x)\,dx = u(x)V(x) + u(x)C - \int V(x)u'(x)\,dx - C\int u'(x)\,dx$$
$$= u(x)V(x) - \int V(x)u'(x)\,dx + C\left[u(x) - \int u'(x)\,dx\right]$$
$$= u(x)V(x) - \int V(x)u'(x)\,dx + C\,[u(x) - u(x)]$$
$$= u(x)V(x) - \int V(x)u'(x)\,dx.$$

(b) If we evaluate $\int x \tan^{-1} x\, dx$ with $u = \tan^{-1} x$ and $v' = x$, and if we don't add a constant to v, Integration by Parts gives us

$$\int x \tan^{-1} x\, dx = \frac{x^2}{2} \tan^{-1} x - \frac{1}{2} \int \frac{x^2 dx}{x^2+1}.$$

The integral on the right requires algebraic manipulation in order to evaluate. But if we take $V(x) = \frac{1}{2}x^2 + \frac{1}{2}$ instead of $V(x) = \frac{1}{2}x^2$, then

$$\int x \tan^{-1} x\, dx = \left(\frac{1}{2}x^2 + \frac{1}{2}\right) \tan^{-1} x - \frac{1}{2} \int \frac{x^2+1}{x^2+1}\, dx = \frac{1}{2}(x^2+1) \tan^{-1} x - \frac{1}{2}x + C$$
$$= \frac{1}{2}(x^2 \tan^{-1} x - x + \tan^{-1} x) + C.$$

80. Prove in two ways that

$$\int_0^a f(x)\, dx = af(a) - \int_0^a xf'(x)\, dx \qquad \boxed{8}$$

First use Integration by Parts. Then assume $f(x)$ is increasing. Use the substitution $u = f(x)$ to prove that $\int_0^a xf'(x)\, dx$ is equal to the area of the shaded region in Figure 1 and derive Eq. (8) a second time.

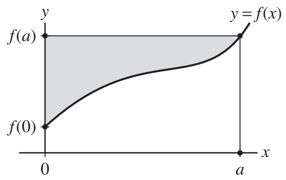

FIGURE 1

SOLUTION Let $u = f(x)$ and $v' = 1$. Then Integration by Parts gives

$$\int_0^a f(x)\, dx = xf(x)\Big|_0^a - \int_0^a xf'(x)\, dx = af(a) - \int_0^a xf'(x)\, dx.$$

Alternately, let $u = f(x)$. Then $du = f'(x)\, dx$, and if $f(x)$ is either increasing or decreasing, it has an inverse function, and $x = f^{-1}(u)$. Thus,

$$\int_{x=0}^{x=a} xf'(x)\, dx = \int_{f(0)}^{f(a)} f^{-1}(u)\, du$$

which is precisely the area of the shaded region in Figure 1 (integrating along the vertical axis). Since the area of the entire rectangle is $af(a)$, the difference between the areas of the two regions is $\int_0^a f(x)\, dx$.

81. Assume that $f(0) = f(1) = 0$ and that f'' exists. Prove

$$\int_0^1 f''(x) f(x)\, dx = -\int_0^1 f'(x)^2\, dx \qquad \boxed{9}$$

Use this to prove that if $f(0) = f(1) = 0$ and $f''(x) = \lambda f(x)$ for some constant λ, then $\lambda < 0$. Can you think of a function satisfying these conditions for some λ?

SOLUTION Let $u = f(x)$ and $v' = f''(x)$. Using Integration by Parts, we get

$$\int_0^1 f''(x) f(x)\, dx = f(x) f'(x)\Big|_0^1 - \int_0^1 f'(x)^2\, dx = f(1)f'(1) - f(0)f'(0) - \int_0^1 f'(x)^2\, dx = -\int_0^1 f'(x)^2\, dx.$$

Now assume that $f''(x) = \lambda f(x)$ for some constant λ. Then

$$\int_0^1 f''(x) f(x)\, dx = \lambda \int_0^1 [f(x)]^2\, dx = -\int_0^1 f'(x)^2\, dx < 0.$$

Since $\int_0^1 [f(x)]^2\, dx > 0$, we must have $\lambda < 0$. An example of a function satisfying these properties for some λ is $f(x) = \sin \pi x$.

82. Set $I(a,b) = \int_0^1 x^a(1-x)^b\,dx$, where a, b are whole numbers.

(a) Use substitution to show that $I(a,b) = I(b,a)$.

(b) Show that $I(a,0) = I(0,a) = \dfrac{1}{a+1}$.

(c) Prove that for $a \ge 1$ and $b \ge 0$,

$$I(a,b) = \frac{a}{b+1}\,I(a-1,b+1)$$

(d) Use (b) and (c) to calculate $I(1,1)$ and $I(3,2)$.

(e) Show that $I(a,b) = \dfrac{a!\,b!}{(a+b+1)!}$.

SOLUTION

(a) Let $u = 1-x$. Then $du = -dx$ and

$$I(a,b) = \int_{u=1}^{u=0} (1-u)^a u^b(-du) = \int_0^1 u^b(1-u)^a\,du = I(b,a).$$

(b) $I(a,0) = I(0,a)$ by part (a). Further,

$$I(a,0) = \int_0^1 x^a(1-x)^0\,dx = \int_0^1 x^a\,dx = \frac{1}{a+1}.$$

(c) Using Integration by Parts with $u = (1-x)^b$ and $v' = x^a$ gives

$$I(a,b) = (1-x)^b\frac{x^{a+1}}{a+1}\bigg|_0^1 + \frac{b}{a+1}\int_0^1 x^{a+1}(1-x)^{b-1}\,dx = \frac{b}{a+1}I(a+1,b-1).$$

The other equality arises from Integration by Parts with $u = x^a$ and $v' = (1-x)^b$.

(d)

$$I(1,1) = \frac{1}{1+1}I(1-1,1+1) = \frac{1}{2}I(0,2) = \frac{1}{2}\cdot\frac{1}{3} = \frac{1}{6}$$

$$I(3,2) = \frac{1}{2}I(4,2) = \frac{1}{2}\cdot\frac{1}{5}I(5,0) = \frac{1}{10}\cdot\frac{1}{6} = \frac{1}{60}.$$

(e) We proceed as follows:

$$\begin{aligned}
I(a,b) &= \frac{a}{b+1}I(a-1,b+1) = \frac{a}{b+1}\cdot\frac{a-1}{b+2}I(a-2,b+2)\\
&\ \ \vdots\\
&= \frac{a}{b+1}\cdot\frac{a-1}{b+2}\cdots\frac{1}{b+a}I(0,b+a)\\
&= \frac{a(a-1)\cdots(1)}{(b+1)(b+2)\cdots(b+a)}\cdot\frac{1}{b+a+1}\\
&= \frac{b!\,a!}{b!\,(b+1)(b+2)\cdots(b+a)(b+a+1)} = \frac{a!\,b!}{(a+b+1)!}.
\end{aligned}$$

83. Let $I_n = \int x^n\cos(x^2)\,dx$ and $J_n = \int x^n\sin(x^2)\,dx$.

(a) Find a reduction formula that expresses I_n in terms of J_{n-2}. *Hint:* Write $x^n\cos(x^2)$ as $x^{n-1}(x\cos(x^2))$.

(b) Use the result of (a) to show that I_n can be evaluated explicitly if n is odd.

(c) Evaluate I_3.

SOLUTION

(a) Integration by Parts with $u = x^{n-1}$ and $v' = x\cos(x^2)\,dx$ yields

$$I_n = \frac{1}{2}x^{n-1}\sin(x^2) - \frac{n-1}{2}\int x^{n-2}\sin(x^2)\,dx = \frac{1}{2}x^{n-1}\sin(x^2) - \frac{n-1}{2}J_{n-2}.$$

(b) If n is odd, the reduction process will eventually lead to either

$$\int x\cos(x^2)\,dx \quad \text{or} \quad \int x\sin(x^2)\,dx,$$

both of which can be evaluated using the substitution $u = x^2$.
(c) Starting with the reduction formula from part (a), we find

$$I_3 = \frac{1}{2}x^2\sin(x^2) - \frac{2}{2}\int x\sin(x^2)\,dx = \frac{1}{2}x^2\sin(x^2) + \frac{1}{2}\cos(x^2) + C.$$

7.2 Trigonometric Integrals

Preliminary Questions

1. Describe the technique used to evaluate $\int \sin^5 x\,dx$.

SOLUTION Because the sine function is raised to an odd power, rewrite $\sin^5 x = \sin x \sin^4 x = \sin x(1-\cos^2 x)^2$ and then substitute $u = \cos x$.

2. Describe a way of evaluating $\int \sin^6 x\; dx$.

SOLUTION Repeatedly use the reduction formula for powers of $\sin x$.

3. Are reduction formulas needed to evaluate $\int \sin^7 x\cos^2 x\,dx$? Why or why not?

SOLUTION No, a reduction formula is not needed because the sine function is raised to an odd power.

4. Describe a way of evaluating $\int \sin^6 x\cos^2 x\,dx$.

SOLUTION Because both trigonometric functions are raised to even powers, write $\cos^2 x = 1 - \sin^2 x$ and then apply the reduction formula for powers of the sine function.

5. Which integral requires more work to evaluate?

$$\int \sin^{798} x\cos x\,dx \qquad \text{or} \qquad \int \sin^4 x\cos^4 x\,dx$$

Explain your answer.

SOLUTION The first integral can be evaluated using the substitution $u = \sin x$, whereas the second integral requires the use of reduction formulas. The second integral therefore requires more work to evaluate.

Exercises

In Exercises 1–6, use the method for odd powers to evaluate the integral.

1. $\int \cos^3 x\,dx$

SOLUTION Use the identity $\cos^2 x = 1 - \sin^2 x$ to rewrite the integrand:

$$\int \cos^3 x\,dx = \int \left(1-\sin^2 x\right)\cos x\,dx.$$

Now use the substitution $u = \sin x$, $du = \cos x\,dx$:

$$\int \cos^3 x\,dx = \int \left(1-u^2\right)\,du = u - \frac{1}{3}u^3 + C = \sin x - \frac{1}{3}\sin^3 x + C.$$

2. $\int \sin^5 x\,dx$

SOLUTION Use the identity $\sin^2 x = 1 - \cos^2 x$ to rewrite the integrand:

$$\int \sin^5 x\,dx = \int \left(\sin^2 x\right)^2 \sin x\,dx = \int \left(1-\cos^2 x\right)^2 \sin x\,dx.$$

Now use the substitution $u = \cos x$, $du = -\sin x\,dx$:

$$\begin{aligned}\int \sin^5 x\,dx &= -\int \left(1-u^2\right)^2 du = -\int \left(1-2u^2+u^4\right) du = -u + \frac{2}{3}u^3 - \frac{1}{5}u^5 + C\\ &= -\cos x + \frac{2}{3}\cos^3 x - \frac{1}{5}\cos^5 x + C.\end{aligned}$$

3. $\int \sin^3\theta \cos^2\theta \, d\theta$

SOLUTION Write $\sin^3\theta = \sin^2\theta \sin\theta = (1-\cos^2\theta)\sin\theta$. Then

$$\int \sin^3\theta\cos^2\theta\,d\theta = \int \left(1-\cos^2\theta\right)\cos^2\theta\sin\theta\,d\theta.$$

Now use the substitution $u=\cos\theta$, $du = -\sin\theta\,d\theta$:

$$\int \sin^3\theta\cos^2\theta\,d\theta = -\int \left(1-u^2\right)u^2\,du = -\int \left(u^2-u^4\right)du$$
$$= -\frac{1}{3}u^3 + \frac{1}{5}u^5 + C = -\frac{1}{3}\cos^3\theta + \frac{1}{5}\cos^5\theta + C.$$

4. $\int \sin^5 x \cos x \, dx$

SOLUTION Write $\sin^5 x = \sin^4 x \sin x = (1-\cos^2 x)^2 \sin x$. Then

$$\int \cos x \sin^5 x\,dx = \int \cos x \left(1-\cos^2 x\right)^2 \sin x\,dx.$$

Now use the substitution $u=\cos x$, $du = -\sin x\,dx$:

$$\int \cos x\sin^5 x\,dx = -\int u\left(1-u^2\right)^2 du = -\int u\left(1-2u^2+u^4\right)du = \int \left(-u+2u^3-u^5\right)du$$
$$= -\frac{1}{2}u^2 + \frac{1}{2}u^4 - \frac{1}{6}u^6 + C = -\frac{1}{2}\cos^2 x + \frac{1}{2}\cos^4 x - \frac{1}{6}\cos^6 x + C.$$

5. $\int \sin^3 t \cos^3 t \, dt$

SOLUTION Write $\sin^3 t = (1-\cos^2 t)\sin t\,dt$. Then

$$\int \sin^3 t\cos^3 t\,dt = \int (1-\cos^2 t)\cos^3 t\sin t\,dt = \int \left(\cos^3 t - \cos^5 t\right)\sin t\,dt.$$

Now use the substitution $u=\cos t$, $du=-\sin t\,dt$:

$$\int \sin^3 t\cos^3 t\,dt = -\int \left(u^3-u^5\right)du = -\frac{1}{4}u^4 + \frac{1}{6}u^6 + C = -\frac{1}{4}\cos^4 t + \frac{1}{6}\cos^6 t + C.$$

6. $\int \sin^2 x \cos^5 x \, dx$

SOLUTION Write $\cos^5 x = \cos^4 x\cos x = (1-\sin^2 x)^2\cos x$. Then

$$\int \sin^2 x\cos^5 x\,dx = \int \sin^2 x\left(1-\sin^2 x\right)^2 \cos x\,dx.$$

Now use the substitution $u=\sin x$, $du = \cos x\,dx$:

$$\int \sin^2 x\cos^5 x\,dx = \int u^2\left(1-u^2\right)^2 du = \int \left(u^2-2u^4+u^6\right)du$$
$$= \frac{1}{3}u^3 - \frac{2}{5}u^5 + \frac{1}{7}u^7 + C = \frac{1}{3}\sin^3 x - \frac{2}{5}\sin^5 x + \frac{1}{7}\sin^7 x + C.$$

7. Find the area of the shaded region in Figure 1.

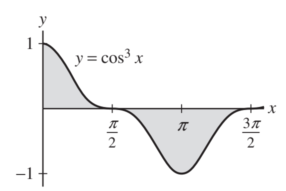

FIGURE 1 Graph of $y=\cos^3 x$.

SOLUTION First evaluate the indefinite integral by writing $\cos^3 x = (1 - \sin^2 x)\cos x$, and using the substitution $u = \sin x$, $du = \cos x\,dx$:

$$\int \cos^3 x\,dx = \int \left(1 - \sin^2 x\right)\cos x\,dx = \int \left(1 - u^2\right) du = u - \frac{1}{3}u^3 + C = \sin x - \frac{1}{3}\sin^3 x + C.$$

The area is given by

$$\begin{aligned} A &= \int_0^{\pi/2} \cos^3 x\,dx - \int_{\pi/2}^{3\pi/2} \cos^3 x\,dx = \left(\sin x - \frac{1}{3}\sin^3 x\right)\Big|_0^{\pi/2} - \left(\sin x - \frac{1}{3}\sin^3 x\right)\Big|_{\pi/2}^{3\pi/2} \\ &= \left[\left(\sin\frac{\pi}{2} - \frac{1}{3}\sin^3\frac{\pi}{2}\right) - 0\right] - \left[\left(\sin\frac{3\pi}{2} - \frac{1}{3}\sin^3\frac{3\pi}{2}\right) - \left(\sin\frac{\pi}{2} - \frac{1}{3}\sin^3\frac{\pi}{2}\right)\right] \\ &= 1 - \frac{1}{3}(1)^3 - (-1) + \frac{1}{3}(-1)^3 + 1 - \frac{1}{3}(1)^3 = 2. \end{aligned}$$

8. Use the identity $\sin^2 x = 1 - \cos^2 x$ to write $\int \sin^2 x \cos^2 x\,dx$ as a sum of two integrals, and then evaluate using the reduction formula.

SOLUTION Using the identity $\sin^2 x = 1 - \cos^2 x$, we get

$$\int \sin^2 x \cos^2 x\,d = \int \left(1 - \cos^2 x\right)\cos^2 x\,dx = \int \cos^2 x\,dx - \int \cos^4 x\,dx.$$

Using the reduction formula for $\cos^m x$, we get

$$\int \cos^4 x\,dx = \frac{\cos^3 x \sin x}{4} + \frac{3}{4}\int \cos^2 x\,dx.$$

Thus,

$$\int \sin^2 x \cos^2 x\,dx = \int \cos^2 x - \frac{1}{4}\cos^3 x \sin x - \frac{3}{4}\int \cos^2 x\,dx = -\frac{1}{4}\cos^3 x \sin x + \frac{1}{4}\int \cos^2 x\,dx.$$

Using the reduction formula again, we have

$$\int \sin^2 x \cos^2 x\,dx = -\frac{1}{4}\cos^3 x \sin x + \frac{1}{4}\left[\frac{\cos x \sin x}{2} + \frac{1}{2}\int dx\right] = -\frac{1}{4}\cos^3 x \sin x + \frac{1}{8}\cos x \sin x + \frac{1}{8}x + C.$$

In Exercises 9–12, evaluate the integral using methods employed in Examples 3 and 4.

9. $\int \cos^4 y\,dy$

SOLUTION Using the reduction formula for $\cos^m y$, we get

$$\begin{aligned} \int \cos^4 y\,dy &= \frac{1}{4}\cos^3 y \sin y + \frac{3}{4}\int \cos^2 y\,dy = \frac{1}{4}\cos^3 y \sin y + \frac{3}{4}\left(\frac{1}{2}\cos y \sin y + \frac{1}{2}\int dy\right) \\ &= \frac{1}{4}\cos^3 y \sin y + \frac{3}{8}\cos y \sin y + \frac{3}{8}y + C. \end{aligned}$$

10. $\int \cos^2\theta \sin^2\theta\,d\theta$

SOLUTION First use the identity $\cos^2\theta = 1 - \sin^2\theta$ to write:

$$\int \cos^2\theta \sin^2\theta\,d\theta = \int \left(1 - \sin^2\theta\right)\sin^2\theta\,d\theta = \int \sin^2\theta\,d\theta - \int \sin^4\theta\,d\theta.$$

Using the reduction formula for $\sin^m\theta$, we get

$$\begin{aligned} \int \cos^2\theta \sin^2\theta\,d\theta &= \int \sin^2\theta\,d\theta - \left[-\frac{1}{4}\sin^3\theta\cos\theta + \frac{3}{4}\int \sin^2\theta\,d\theta\right] = \frac{1}{4}\sin^3\theta\cos\theta + \frac{1}{4}\int \sin^2\theta\,d\theta \\ &= \frac{1}{4}\sin^3\theta\cos\theta + \frac{1}{4}\left(-\frac{1}{2}\sin\theta\cos\theta + \frac{1}{2}\int d\theta\right) = \frac{1}{4}\sin^3\theta\cos\theta - \frac{1}{8}\sin\theta\cos\theta + \frac{1}{8}\theta + C. \end{aligned}$$

11. $\int \sin^4 x \cos^2 x\, dx$

SOLUTION Use the identity $\cos^2 x = 1 - \sin^2 x$ to write:

$$\int \sin^4 x \cos^2 x\, dx = \int \sin^4 x \left(1 - \sin^2 x\right) dx = \int \sin^4 x\, dx - \int \sin^6 x\, dx.$$

Using the reduction formula for $\sin^m x$:

$$\begin{aligned}\int \sin^4 x \cos^2 x\, dx &= \int \sin^4 x\, dx - \left[-\frac{1}{6}\sin^5 x \cos x + \frac{5}{6}\int \sin^4 x\, dx\right]\\ &= \frac{1}{6}\sin^5 x \cos x + \frac{1}{6}\int \sin^4 x\, dx = \frac{1}{6}\sin^5 x \cos x + \frac{1}{6}\left(-\frac{1}{4}\sin^3 x \cos x + \frac{3}{4}\int \sin^2 x\, dx\right)\\ &= \frac{1}{6}\sin^5 x \cos x - \frac{1}{24}\sin^3 x \cos x + \frac{1}{8}\int \sin^2 x\, dx\\ &= \frac{1}{6}\sin^5 x \cos x - \frac{1}{24}\sin^3 x \cos x + \frac{1}{8}\left(-\frac{1}{2}\sin x \cos x + \frac{1}{2}\int dx\right)\\ &= \frac{1}{6}\sin^5 x \cos x - \frac{1}{24}\sin^3 x \cos x - \frac{1}{16}\sin x \cos x + \frac{1}{16}x + C.\end{aligned}$$

12. $\int \sin^2 x \cos^6 x\, dx$

SOLUTION Use the identity $\sin^2 x = 1 - \cos^2 x$ to write

$$\int \sin^2 x \cos^6 x\, dx = \int (1 - \cos^2 x)\cos^6 x\, dx = \int \cos^6 x\, dx - \int \cos^8 x\, dx$$

Now use the reduction formula for $\cos^n x$:

$$\begin{aligned}\int \cos^6 x\, dx &= \frac{\cos^5 x \sin x}{6} + \frac{5}{6}\int \cos^4 x\, dx\\ &= \frac{\cos^5 x \sin x}{6} + \frac{5}{6}\left(\frac{\cos^3 x \sin x}{4} + \frac{3}{4}\int \cos^2 x\, dx\right)\\ &= \frac{1}{6}\cos^5 x \sin x + \frac{5}{24}\cos^3 x \sin x + \frac{15}{24}\left(\frac{x}{2} + \frac{\sin 2x}{4}\right) + C\\ &= \frac{1}{6}\cos^5 x \sin x + \frac{5}{24}\cos^3 x \sin x + \frac{15}{48}x + \frac{15}{96}\sin 2x + C\end{aligned}$$

and

$$\begin{aligned}\int \cos^8 x\, dx &= \frac{1}{8}\cos^7 x \sin x + \frac{7}{8}\int \cos^6 x\, dx\\ &= \frac{1}{8}\cos^7 x \sin x + \frac{7}{8}\left(\frac{1}{6}\cos^5 x \sin x + \frac{5}{24}\cos^3 x \sin x + \frac{15}{48}x + \frac{15}{96}\sin 2x\right) + C\\ &= \frac{1}{8}\cos^7 x \sin x + \frac{7}{48}\cos^5 x \sin x + \frac{35}{192}\cos^3 x \sin x + \frac{105}{384}x + \frac{105}{768}\sin 2x + C\end{aligned}$$

so that

$$\int \sin^2 x \cos^6 x\, dx = -\frac{1}{8}\cos^7 x \sin x + \frac{1}{48}\cos^5 x \sin x + \frac{5}{192}\cos^3 x \sin x + \frac{5}{128}x + \frac{5}{256}\sin 2x + C$$

In Exercises 13 and 14, evaluate using Eq. (13).

13. $\int \sin^3 x \cos^2 x\, dx$

SOLUTION First rewrite $\sin^3 x = \sin x \cdot \sin^2 x = \sin x(1 - \cos^2 x)$, so that

$$\int \sin^3 x \cos^2 x\, dx = \int \sin x(1 - \cos^2 x)\cos^2 x\, dx = \int \sin x(\cos^2 x - \cos^4 x)\, dx$$

Now make the substitution $u = \cos x$, $du = -\sin x\, dx$:

$$\int \sin x(\cos^2 x - \cos^4 x)\, dx = -\int u^2 - u^4\, du = \frac{1}{5}u^5 - \frac{1}{3}u^3 + C = \frac{1}{5}\cos^5 x - \frac{1}{3}\cos^3 x + C$$

14. $\int \sin^2 x \cos^4 x\, dx$

SOLUTION Using the formula for $\int \sin^m x \cos^n x\, dx$, we get

$$I = \int \sin^2 x \cos^4 x\, dx = \frac{1}{6}\sin^3 x \cos^3 x + \frac{3}{6}\int \sin^2 x \cos^2 x\, dx = \frac{1}{6}\sin^3 x \cos^3 x + \frac{1}{2}\int \sin^2 x \cos^2 x\, dx.$$

Applying the formula again on the remaining integral, we get

$$\int \sin^2 x \cos^2 x\, dx = \frac{1}{4}\sin^3 x \cos x + \frac{1}{4}\int \sin^2 x \cos^0 x\, dx = \frac{1}{4}\sin^3 x \cos x + \frac{1}{4}\int \sin^2 x\, dx.$$

The final result is

$$\begin{aligned} I &= \frac{1}{6}\sin^3 x \cos^3 x + \frac{1}{2}\left(\frac{1}{4}\sin^3 x \cos x + \frac{1}{4}\int \sin^2 x\, dx\right) \\ &= \frac{1}{6}\sin^3 x \cos^3 x + \frac{1}{8}\sin^3 x \cos x + \frac{1}{8}\left(\frac{1}{2}x - \frac{1}{2}\sin x \cos x\right) + C \\ &= \frac{1}{6}\sin^3 x \cos^3 x + \frac{1}{8}\sin^3 x \cos x + \frac{1}{16}x - \frac{1}{16}\sin x \cos x + C. \end{aligned}$$

In Exercises 15–18, evaluate the integral using the method described on page 409 and the reduction formulas on page 410 as necessary.

15. $\int \tan^3 x \sec x\, dx$

SOLUTION Use the identity $\tan^2 x = \sec^2 x - 1$ to rewrite $\tan^3 x \sec x = (\sec^2 x - 1)\sec x \tan x$. Then use the substitution $u = \sec x$, $du = \sec x \tan x\, dx$:

$$\int \tan^3 x \sec x\, dx = \int (\sec^2 x - 1)\sec x \tan x\, dx = \int u^2 - 1\, du = \frac{1}{3}u^3 - u + C = \frac{1}{3}\sec^3 x - \sec x + C$$

16. $\int \tan^2 x \sec x\, dx$

SOLUTION First use the identity $\tan^2 x = \sec^2 x - 1$:

$$\int \tan^2 x \sec x\, dx = \int (\sec^2 x - 1)\sec x\, dx = \int \sec^3 x - \sec x\, dx = \int \sec^3 x\, dx - \ln|\sec x + \tan x|$$

To evaluate the remaining integral, we use the reduction formula:

$$\int \sec^3 x\, dx = \frac{1}{2}\sec x \tan x + \frac{1}{2}\int \sec x\, dx = \frac{1}{2}\sec x \tan x + \frac{1}{2}\ln|\sec x + \tan x|$$

so that finally, putting these together,

$$\int \tan^2 x \sec x\, dx = \int \sec^3 x\, dx - \ln|\sec x + \tan x| = \frac{1}{2}(\sec x \tan x - \ln|\sec x + \tan x|) + C$$

17. $\int \tan^2 x \sec^4 x\, dx$

SOLUTION First use the identity $\tan^2 x = \sec^2 x - 1$:

$$\int \tan^2 x \sec^4 x\, dx = \int (\sec^2 x - 1)\sec^4 x\, dx = \int \sec^6 x - \sec^4 x\, dx = \int \sec^6 x\, dx - \int \sec^4 x, dx$$

We evaluate the second integral using the reduction formula:

$$\begin{aligned} \int \sec^4 x\, dx &= \frac{1}{3}\tan x \sec^2 x + \frac{2}{3}\int \sec^2 x\, dx \\ &= \frac{1}{3}\tan x \sec^2 x + \frac{2}{3}\tan x \end{aligned}$$

Then

$$\int \sec^6 x\,dx = \frac{1}{5}\tan x\sec^4 x + \frac{4}{5}\int \sec^4 x\,dx$$
$$= \frac{1}{5}\tan x\sec^4 x + \frac{4}{5}\left(\frac{1}{3}\tan x\sec^2 x + \frac{2}{3}\tan x\right)$$
$$= \frac{1}{5}\tan x\sec^4 x + \frac{4}{15}\tan x\sec^2 x + \frac{8}{15}\tan x$$

so that

$$\int \tan^2 x\sec^4 x\,dx = \int \sec^6 x\,dx - \int \sec^4 x\,dx$$
$$= \frac{1}{5}\tan x\sec^4 x - \frac{1}{15}\tan x\sec^2 x - \frac{2}{15}\tan x + C$$

18. $\int \tan^8 x\sec^2 x\,dx$

SOLUTION Use the substitution $u = \tan x$, $du = \sec^2 x\,dx$; then

$$\int \tan^8 x\sec^2 x\,dx = \int u^8\,du = \frac{1}{9}u^9 = \frac{1}{9}\tan^9 x + C$$

In Exercises 19–22, evaluate using methods similar to those that apply to integral $\tan^m x\sec^n$.

19. $\int \cot^3 x\,dx$

SOLUTION Using the reduction formula for $\cot^m x$, we get

$$\int \cot^3 x\,dx = -\frac{1}{2}\cot^2 x - \int \cot x\,dx = -\frac{1}{2}\cot^2 x + \ln|\csc x| + C.$$

20. $\int \sec^3 x\,dx$

SOLUTION Using the reduction formula for $\sec^m x$, we get

$$\int \sec^3 x\,dx = \frac{1}{2}\tan x\sec x + \frac{1}{2}\int \sec x\,dx = \frac{1}{2}\tan x\sec x + \frac{1}{2}\ln|\sec x + \tan x| + C.$$

21. $\int \cot^5 x\csc^2 x\,dx$

SOLUTION Make the substitution $u = \cot x$, $du = -\csc^2 x\,dx$; then

$$\int \cot^5 x\csc^2 x\,dx = -\int u^5\,du = -\frac{1}{6}u^6 = -\frac{1}{6}\cot^6 x + C$$

22. $\int \cot^4 x\csc x\,dx$

SOLUTION Use the identity $\cot^2 x = \csc^2 x - 1$ to write

$$\int \cot^4 x\csc x\,dx = \int (\csc^2 x - 1)^2\csc x\,dx = \int \csc^5 x - 2\csc^3 x + \csc x\,dx$$

Now apply the reduction formula:

$$\int \csc^3 x\,dx = -\frac{1}{2}\cot x\csc x + \frac{1}{2}\int \csc x\,dx = -\frac{1}{2}\cot x\csc x - \frac{1}{2}\ln|\csc x + \cot x| + C$$

so that

$$\int \csc^5 x\,dx = -\frac{1}{4}\cot x\csc^3 x + \frac{3}{4}\int \csc^3 x\,dx$$
$$= -\frac{1}{4}\cot x\csc^3 x - \frac{3}{4}\left(\frac{1}{2}\cot x\csc x + \frac{1}{2}\ln|\csc x + \cot x|\right) + C$$
$$= -\frac{1}{4}\cot x\csc^3 x - \frac{3}{8}\cot x\csc x - \frac{3}{8}\ln|\csc x + \cot x| + C$$

Putting all this together, we get

$$\begin{aligned}\int \cot^4 x \csc x\,dx &= \int \csc^5 x\,dx - 2\int \csc^3 x\,dx + \int \csc x\,dx\\ &= -\frac{1}{4}\cot x\csc^3 x - \frac{3}{8}\cot x\csc x - \frac{3}{8}\ln|\csc x + \cot x| + \cot x\csc x\\ &\quad + \ln|\csc x + \cot x| - \ln|\csc x + \cot x| + C\\ &= -\frac{1}{4}\cot x\csc^3 x + \frac{5}{8}\cot x\csc x - \frac{3}{8}\ln|\csc x + \cot x| + C\end{aligned}$$

In Exercises 23–46, evaluate the integral.

23. $\int \cos^5 x \sin x\,dx$

SOLUTION Use the substitution $u = \cos x$, $du = -\sin x\,dx$. Then

$$\int \cos^5 x \sin x\,dx = -\int u^5\,du = -\frac{1}{6}u^6 + C = -\frac{1}{6}\cos^6 x + C.$$

24. $\int \cos^3(2-x)\sin(2-x)\,dx$

SOLUTION Use the substitution $u = \cos(2-x)$, $du = \sin(2-x)\,dx$. Then

$$\int \cos^3(2-x)\sin(2-x)\,dx = \int u^3\,du = \frac{1}{4}u^4 + C = \frac{1}{4}\cos^4(2-x) + C$$

25. $\int \cos^4(3x+2)\,dx$

SOLUTION First use the substitution $u = 3x+2$, $du = 3\,dx$ and then apply the reduction formula for $\cos^n x$:

$$\begin{aligned}\int \cos^4(3x+2)\,dx &= \frac{1}{3}\cos^4 u\,du = \frac{1}{3}\left(\frac{1}{4}\cos^3 u\sin u + \frac{3}{4}\int \cos^2 u\,du\right)\\ &= \frac{1}{12}\cos^3 u\sin u + \frac{1}{4}\left(\frac{u}{2} + \frac{\sin 2u}{4}\right) + C\\ &= \frac{1}{12}\cos^3(3x+2)\sin(3x+2) + \frac{1}{8}(3x+2) + \frac{1}{16}\sin(6x+4) + C\end{aligned}$$

26. $\int \cos^7 3x\,dx$

SOLUTION Use the substitution $u = 3x$, $du = 3\,dx$, and the reduction formula for $\cos^m x$:

$$\begin{aligned}\int \cos^7 3x\,dx &= \frac{1}{3}\int \cos^7 u\,du = \frac{1}{21}\cos^6 u\sin u + \frac{6}{21}\int \cos^5 u\,du\\ &= \frac{1}{21}\cos^6 u\sin u + \frac{2}{7}\left(\frac{1}{5}\cos^4 u\sin u + \frac{4}{5}\int \cos^3 u\,du\right)\\ &= \frac{1}{21}\cos^6 u\sin u + \frac{2}{35}\cos^4 u\sin u + \frac{8}{35}\left(\frac{1}{3}\cos^2 u\sin u + \frac{2}{3}\int \cos u\,du\right)\\ &= \frac{1}{21}\cos^6 u\sin u + \frac{2}{35}\cos^4 u\sin u + \frac{8}{105}\cos^2 u\sin u + \frac{16}{105}\sin u + C\\ &= \frac{1}{21}\cos^6 3x\sin 3x + \frac{2}{35}\cos^4 3x\sin 3x + \frac{8}{105}\cos^2 3x\sin 3x + \frac{16}{105}\sin 3x + C.\end{aligned}$$

27. $\int \cos^3(\pi\theta)\sin^4(\pi\theta)\,d\theta$

SOLUTION Use the substitution $u = \pi\theta$, $du = \pi\,d\theta$, and the identity $\cos^2 u = 1 - \sin^2 u$ to write

$$\int \cos^3(\pi\theta)\sin^4(\pi\theta)\,d\theta = \frac{1}{\pi}\int \cos^3 u\sin^4 u\,du = \frac{1}{\pi}\int \left(1 - \sin^2 u\right)\sin^4 u\cos u\,du.$$

Now use the substitution $w = \sin u$, $dw = \cos u\, du$:

$$\int \cos^3(\pi\theta)\sin^4(\pi\theta)\, d\theta = \frac{1}{\pi}\int \left(1 - w^2\right) w^4\, dw = \frac{1}{\pi}\int \left(w^4 - w^6\right) dw = \frac{1}{5\pi}w^5 - \frac{1}{7\pi}w^7 + C$$
$$= \frac{1}{5\pi}\sin^5(\pi\theta) - \frac{1}{7\pi}\sin^7(\pi\theta) + C.$$

28. $\int \cos^{498} y \sin^3 y\, dy$

SOLUTION Use the identity $\sin^2 y = 1 - \cos^2 y$ to write

$$\int \cos^{498} y \sin^3 y\, dy = \int \cos^{498} y \left(1 - \cos^2 y\right)\sin y\, dy.$$

Now use the substitution $u = \cos y$, $du = -\sin y\, dy$:

$$\int \cos^{498} y \sin^3 y\, dy = -\int u^{498}\left(1 - u^2\right) du = -\int \left(u^{498} - u^{500}\right) du$$
$$= -\frac{1}{499}u^{499} + \frac{1}{501}u^{501} + C = -\frac{1}{499}\cos^{499} y + \frac{1}{501}\cos^{501} y + C.$$

29. $\int \sin^4(3x)\, dx$

SOLUTION Use the substitution $u = 3x$, $du = 3\, dx$ and the reduction formula for $\sin^m x$:

$$\int \sin^4(3x)\, dx = \frac{1}{3}\int \sin^4 u\, du = -\frac{1}{12}\sin^3 u\cos u + \frac{1}{4}\int \sin^2 u\, du$$
$$= -\frac{1}{12}\sin^3 u\cos u + \frac{1}{4}\left(-\frac{1}{2}\sin u\cos u + \frac{1}{2}\int du\right)$$
$$= -\frac{1}{12}\sin^3 u\cos u - \frac{1}{8}\sin u\cos u + \frac{1}{8}u + C$$
$$= -\frac{1}{12}\sin^3(3x)\cos(3x) - \frac{1}{8}\sin(3x)\cos(3x) + \frac{3}{8}x + C.$$

30. $\int \sin^2 x\cos^6 x\, dx$

SOLUTION Use the identity $\sin^2 x = 1 - \cos^2 x$ and the reduction formula for $\cos^m x$:

$$\int \sin^2 x\cos^6 x\, dx = \int \cos^6 x\left(1 - \cos^2 x\right) dx = \int \cos^6 x\, dx - \int \cos^8 x\, dx$$
$$= \int \cos^6 x\, dx - \left(\frac{1}{8}\cos^7 x\sin x + \frac{7}{8}\int \cos^6 x\, dx\right)$$
$$= -\frac{1}{8}\cos^7 x\sin x + \frac{1}{8}\int \cos^6 x\, dx$$
$$= -\frac{1}{8}\cos^7 x\sin x + \frac{1}{8}\left(\frac{1}{6}\cos^5 x\sin x + \frac{5}{6}\int \cos^4 x\, dx\right)$$
$$= -\frac{1}{8}\cos^7 x\sin x + \frac{1}{48}\cos^5 x\sin x + \frac{5}{48}\int \cos^4 x\, dx$$
$$= -\frac{1}{8}\cos^7 x\sin x + \frac{1}{48}\cos^5 x\sin x + \frac{5}{48}\left(\frac{1}{4}\cos^3 x\sin x + \frac{3}{4}\int \cos^2 x\, dx\right)$$
$$= -\frac{1}{8}\cos^7 x\sin x + \frac{1}{48}\cos^5 x\sin x + \frac{5}{192}\cos^3 x\sin x + \frac{15}{192}\int \cos^2 x\, dx$$
$$= -\frac{1}{8}\cos^7 x\sin x + \frac{1}{48}\cos^5 x\sin x + \frac{5}{192}\cos^3 x\sin x + \frac{15}{192}\left(\frac{1}{2}\cos x\sin x + \frac{1}{2}x\right)$$
$$= -\frac{1}{8}\cos^7 x\sin x + \frac{1}{48}\cos^5 x\sin x + \frac{5}{192}\cos^3 x\sin x + \frac{5}{128}\cos x\sin x + \frac{5}{128}x + C.$$

31. $\int \csc^2(3-2x)\,dx$

SOLUTION First make the substitution $u = 3-2x$, $du = -2\,dx$, so that

$$\int \csc^2(3-2x)\,dx = \frac{1}{2}\int(-\csc^2 u)\,du = \frac{1}{2}\cot u + C = \frac{1}{2}\cot(3-2x) + C$$

32. $\int \csc^3 x\,dx$

SOLUTION Use the reduction formula for $\csc^m x$:

$$\int \csc^3 x\,dx = -\frac{1}{2}\cot x\csc x + \frac{1}{2}\int \csc x\,dx = -\frac{1}{2}\cot x\csc x + \frac{1}{2}\ln|\csc x - \cot x| + C.$$

33. $\int \tan x\sec^2 x\,dx$

SOLUTION Use the substitution $u = \tan x$, $du = \sec^2 x\,dx$. Then

$$\int \tan x\sec^2 x\,dx = \int u\,du = \frac{1}{2}u^2 + C = \frac{1}{2}\tan^2 x + C.$$

34. $\int \tan^3\theta\sec^3\theta\,d\theta$

SOLUTION Use the identity $\tan^2\theta = \sec^2\theta - 1$ to write

$$\int \tan^3\theta\sec^3\theta\,d\theta = \int\left(\sec^2\theta - 1\right)\sec^2\theta(\sec\theta\tan\theta\,d\theta).$$

Now use the substitution $u = \sec\theta$, $du = \sec\theta\tan\theta\,d\theta$:

$$\int \tan^3\theta\sec^3\theta\,d\theta = \int\left(u^2-1\right)u^2\,du = \int\left(u^4-u^2\right)du = \frac{1}{5}u^5 - \frac{1}{3}u^3 + C = \frac{1}{5}\sec^5\theta - \frac{1}{3}\sec^3\theta + C.$$

35. $\int \tan^5 x\sec^4 x\,dx$

SOLUTION Use the identity $\tan^2 x = \sec^2 x - 1$ to write

$$\int \tan^5 x\sec^4 x\,dx = \int\left(\sec^2 x - 1\right)^2\sec^3 x(\sec x\tan x\,dx).$$

Now use the substitution $u = \sec x$, $du = \sec x\tan x\,dx$:

$$\begin{aligned}\int \tan^5 x\sec^4 x\,dx &= \int\left(u^2-1\right)^2u^3\,du = \int\left(u^7 - 2u^5 + u^3\right)du\\ &= \frac{1}{8}u^8 - \frac{1}{3}u^6 + \frac{1}{4}u^4 + C = \frac{1}{8}\sec^8 x - \frac{1}{3}\sec^6 x + \frac{1}{4}\sec^4 x + C.\end{aligned}$$

36. $\int \tan^4 x\sec x\,dx$

SOLUTION Use the identity $\tan^2 x = \sec^2 x - 1$ to write

$$\int \tan^4 x\sec x\,dx = \int\left(\sec^2 x - 1\right)^2\sec x\,dx = \int \sec^5 x\,dx - 2\int\sec^3 x\,dx + \int\sec x\,dx.$$

Now use the reduction formula for $\sec^m x$:

$$\begin{aligned}\int \tan^4 x\sec x\,dx &= \left(\frac{1}{4}\tan x\sec^3 x + \frac{3}{4}\int\sec^3 x\,dx\right) - 2\int\sec^3 x\,dx + \int\sec x\,dx\\ &= \frac{1}{4}\tan x\sec^3 x - \frac{5}{4}\int\sec^3 x\,dx + \int\sec x\,dx\\ &= \frac{1}{4}\tan x\sec^3 x - \frac{5}{4}\left(\frac{1}{2}\tan x\sec x + \frac{1}{2}\int\sec x\,dx\right) + \int\sec x\,dx\\ &= \frac{1}{4}\tan x\sec^3 x - \frac{5}{8}\tan x\sec x + \frac{3}{8}\int\sec x\,dx\\ &= \frac{1}{4}\tan x\sec^3 x - \frac{5}{8}\tan x\sec x + \frac{3}{8}\ln|\sec x + \tan x| + C.\end{aligned}$$

37. $\int \tan^6 x \sec^4 x\,dx$

SOLUTION Use the identity $\sec^2 x = \tan^2 x + 1$ to write

$$\int \tan^6 x \sec^4 x\,dx = \int \tan^6 x \left(\tan^2 x + 1\right) \sec^2 x\,dx.$$

Now use the substitution $u = \tan x$, $du = \sec^2 x\,dx$:

$$\int \tan^6 x \sec^4 x\,dx = \int u^6 \left(u^2+1\right) du = \int \left(u^8 + u^6\right) du = \frac{1}{9}u^9 + \frac{1}{7}u^7 + C = \frac{1}{9}\tan^9 x + \frac{1}{7}\tan^7 x + C.$$

38. $\int \tan^2 x \sec^3 x\,dx$

SOLUTION Use the identity $\tan^2 x = \sec^2 x - 1$ to write

$$\int \tan^2 x \sec^3 x\,dx = \int \left(\sec^2 x - 1\right) \sec^3 x\,dx = \int \sec^5 x\,dx - \int \sec^3 x\,dx.$$

Now use the reduction formula for $\sec^m x$:

$$\begin{aligned}\int \tan^2 x \sec^3 x\,dx &= \frac{1}{4}\tan x \sec^3 x + \frac{3}{4}\int \sec^3 x\,dx - \int \sec^3 x\,dx \\ &= \frac{1}{4}\tan x \sec^3 x - \frac{1}{4}\int \sec^3 x\,dx \\ &= \frac{1}{4}\tan x \sec^3 x - \frac{1}{4}\left(\frac{1}{2}\tan x \sec x + \frac{1}{2}\int \sec x\,dx\right) \\ &= \frac{1}{4}\tan x \sec^3 x - \frac{1}{8}\tan x \sec x - \frac{1}{8}\ln|\sec x + \tan x| + C.\end{aligned}$$

39. $\int \cot^5 x \csc^5 x\,dx$

SOLUTION First use the identity $\cot^2 x = \csc^2 x - 1$ to rewrite the integral:

$$\int \cot^5 x \csc^5 x\,dx = \int (\csc^2 x - 1)^2 \csc^4 x(\cot x \csc x)\,dx = \int (\csc^8 x - 2\csc^6 x + \csc^4 x)(\cot x \csc x)\,dx$$

Now use the substitution $u = \csc x$ and $du = -\cot x \csc x\,dx$ to get

$$\begin{aligned}\int \cot^5 x \csc^5 x\,dx &= -\int u^8 - 2u^6 + u^4\,du = -\frac{1}{9}u^9 + \frac{2}{7}u^7 - \frac{1}{5}u^5 + C \\ &= -\frac{1}{9}\csc^9 x + \frac{2}{7}\csc^7 x - \frac{1}{5}\csc^5 x + C\end{aligned}$$

40. $\int \cot^2 x \csc^4 x\,dx$

SOLUTION First rewrite using $\cot^2 x = \csc^2 x - 1$ and then use the reduction formula:

$$\begin{aligned}\int \cot^2 x \csc^4 x\,dx &= \int (\csc^2 x - 1)\csc^4 x\,dx = \int \csc^6 x\,dx - \int \csc^4 x\,dx \\ &= -\frac{1}{5}\cot x \csc^4 x + \frac{4}{5}\int \csc^4 x\,dx - \int \csc^4 x\,dx \\ &= -\frac{1}{5}\cot x \csc^4 x - \frac{1}{5}\int \csc^4 x\,dx \\ &= -\frac{1}{5}\cot x \csc^4 x - \frac{1}{5}\left(-\frac{1}{3}\cot x \csc^2 x + \frac{2}{3}\int \csc^2 x\,dx\right) \\ &= -\frac{1}{5}\cot x \csc^4 x + \frac{1}{15}\cot x \csc^2 x + \frac{2}{15}\cot x + C\end{aligned}$$

41. $\int \sin 2x \cos 2x\,dx$

SOLUTION Use the substitution $u = \sin 2x$, $du = 2\cos 2x\,dx$:

$$\int \sin 2x \cos 2x\,dx = \frac{1}{2}\int \sin 2x(2\cos 2x\,dx) = \frac{1}{2}\int u\,du = \frac{1}{4}u^2 + C = \frac{1}{4}\sin^2 2x + C.$$

42. $\int \cos 4x \cos 6x \, dx$

SOLUTION Use the formula for $\int \cos mx \cos nx \, dx$:

$$\int \cos 4x \cos 6x \, dx = \frac{\sin(4-6)x}{2(4-6)} + \frac{\sin(4+6)x}{2(4+6)} + C = \frac{\sin(-2x)}{-4} + \frac{\sin(10x)}{20} + C$$
$$= \frac{1}{4}\sin 2x + \frac{1}{20}\sin 10x + C.$$

Here we've used the fact that $\sin x$ is an odd function: $\sin(-x) = -\sin x$.

43. $\int t \cos^3(t^2) \, dt$

SOLUTION Use the substitution $u = t^2$, $du = 2t\,dt$, followed by the reduction formula for $\cos^m x$:

$$\int t\cos^3(t^2)\,dt = \frac{1}{2}\int \cos^3 u\,du = \frac{1}{6}\cos^2 u \sin u + \frac{1}{3}\int \cos u\,du$$
$$= \frac{1}{6}\cos^2 u \sin u + \frac{1}{3}\sin u + C = \frac{1}{6}\cos^2(t^2)\sin(t^2) + \frac{1}{3}\sin(t^2) + C.$$

44. $\int \frac{\tan^3(\ln t)}{t}\,dt$

SOLUTION Use the substitution $u = \ln t$, $du = \frac{1}{t}\,dt$, followed by the reduction formula for $\tan^n x$:

$$\int \frac{\tan^3(\ln t)}{t}\,dt = \int \tan^3 u\,du = \frac{1}{2}\tan^2 u - \int \tan u\,du$$
$$= \frac{1}{2}\tan^2 u - \ln|\sec u| + C = \frac{1}{2}\tan^2(\ln t) - \ln|\sec(\ln t)| + C.$$

45. $\int \cos^2(\sin t)\cos t\,dt$

SOLUTION Use the substitution $u = \sin t$, $du = \cos t\,dt$, followed by the reduction formula for $\cos^m x$:

$$\int \cos^2(\sin t)\cos t\,dt = \int \cos^2 u\,du = \frac{1}{2}\cos u\sin u + \frac{1}{2}\int du$$
$$= \frac{1}{2}\cos u \sin u + \frac{1}{2}u + C = \frac{1}{2}\cos(\sin t)\sin(\sin t) + \frac{1}{2}\sin t + C.$$

46. $\int e^x \tan^2(e^x)\,dx$

SOLUTION Use the substitution $u = e^x$, $du = e^x\,dx$ followed by the reduction formula for $\tan^m x$:

$$\int e^x\tan^2(e^x)\,dx = \int \tan^2 u\,du = \tan u - \int 1\,du = \tan u - u + C = \tan(e^x) - e^x + C$$

In Exercises 47–60, evaluate the definite integral.

47. $\int_0^{2\pi} \sin^2 x\,dx$

SOLUTION Use the formula for $\int \sin^2 x\,dx$:

$$\int_0^{2\pi}\sin^2 x\,dx = \left(\frac{x}{2} - \frac{\sin 2x}{4}\right)\Bigg|_0^{2\pi} = \left(\frac{2\pi}{2} - \frac{\sin 4\pi}{4}\right) - \left(\frac{0}{2} - \frac{\sin 0}{4}\right) = \pi.$$

48. $\int_0^{\pi/2} \cos^3 x\,dx$

SOLUTION Use the reduction formula for $\cos^m x$:

$$\int_0^{\pi/2}\cos^3 x\,dx = \frac{1}{3}\cos^2 x\sin x\Bigg|_0^{\pi/2} + \frac{2}{3}\int_0^{\pi/2}\cos x\,dx = \left[\frac{1}{3}(0)(1) - \frac{1}{3}(1)(0)\right] + \frac{2}{3}\sin x\Bigg|_0^{\pi/2}$$
$$= 0 + \frac{2}{3}(1-0) = \frac{2}{3}.$$

49. $\int_0^{\pi/2} \sin^5 x\, dx$

SOLUTION Use the identity $\sin^2 x = 1 - \cos^2 x$ followed by the substitution $u = \cos x$, $du = -\sin x\, dx$ to get

$$\int_0^{\pi/2} \sin^5 x\, dx = \int_0^{\pi/2} (1 - \cos^2 x)^2 \sin x\, dx = \int_0^{\pi/2} (1 - 2\cos^2 x + \cos^4 x) \sin x\, dx$$
$$= -\int_1^0 (1 - 2u^2 + u^4)\, du = -\left(u - \frac{2}{3}u^3 + \frac{1}{5}u^5\right)\Big|_1^0 = 1 - \frac{2}{3} + \frac{1}{5} = \frac{8}{15}$$

50. $\int_0^{\pi/2} \sin^2 x \cos^3 x\, dx$

SOLUTION Use the identity $\sin^2 x = 1 - \cos^2 x$ followed by the substitution $u = \sin x$, $du = \cos x\, dx$ to get

$$\int_0^{\pi/2} \sin^2 x \cos^3 x\, dx = \int_0^{\pi/2} \sin^2 x (1 - \sin^2 x) \cos x\, dx = \int_0^{\pi/2} (\sin^2 x - \sin^4 x) \cos x\, dx$$
$$= \int_0^1 u^2 - u^4\, du = \left(\frac{1}{3}u^3 - \frac{1}{5}u^5\right)\Big|_0^1 = \frac{2}{15}$$

51. $\int_0^{\pi/4} \frac{dx}{\cos x}$

SOLUTION Use the definition of $\sec x$ to simplify the integral:

$$\int_0^{\pi/4} \frac{dx}{\cos x} = \int_0^{\pi/4} \sec x\, dx = \ln|\sec x + \tan x|\Big|_0^{\pi/4} = \ln\left|\sqrt{2} + 1\right| - \ln|1 + 0| = \ln\left(\sqrt{2} + 1\right).$$

52. $\int_{\pi/4}^{\pi/2} \frac{dx}{\sin x}$

SOLUTION Use the definition of $\csc x$ to simplify the integral:

$$\int_{\pi/4}^{\pi/2} \frac{dx}{\sin x} = \int_{\pi/4}^{\pi/2} \csc x\, dx = \ln|\csc x - \cot x|\Big|_{\pi/4}^{\pi/2} = \ln|1 - 0| - \ln\left|\sqrt{2} - 1\right| = -\ln\left|\sqrt{2} - 1\right|$$
$$= \ln\left(\frac{1}{\sqrt{2} - 1}\right) = \ln\left(\frac{(\sqrt{2} + 1)}{(\sqrt{2} - 1)(\sqrt{2} + 1)}\right) = \ln(\sqrt{2} + 1).$$

53. $\int_0^{\pi/3} \tan x\, dx$

SOLUTION Use the formula for $\int \tan x\, dx$:

$$\int_0^{\pi/3} \tan x\, dx = \ln|\sec x|\Big|_0^{\pi/3} = \ln 2 - \ln 1 = \ln 2.$$

54. $\int_0^{\pi/4} \tan^5 x\, dx$

SOLUTION First use the reduction formula for $\tan^m x$ to evaluate the indefinite integral:

$$\int \tan^5 x\, dx = \frac{1}{4}\tan^4 x - \int \tan^3 x\, dx = \frac{1}{4}\tan^4 x - \left(\frac{1}{2}\tan^2 x - \int \tan x\, dx\right)$$
$$= \frac{1}{4}\tan^4 x - \frac{1}{2}\tan^2 x + \ln|\sec x| + C.$$

Now compute the definite integral:

$$\int_0^{\pi/4} \tan^5 x\, dx = \left(\frac{1}{4}\tan^4 x - \frac{1}{2}\tan^2 x + \ln|\sec x|\right)\Big|_0^{\pi/4}$$
$$= \left(\frac{1}{4}\left(1^4\right) - \frac{1}{2}\left(1^2\right) + \ln\sqrt{2}\right) - (0 - 0 + \ln 1)$$
$$= \frac{1}{4} - \frac{1}{2} + \ln\sqrt{2} - 0 = \frac{1}{2}\ln 2 - \frac{1}{4}.$$

55. $\displaystyle\int_{-\pi/4}^{\pi/4} \sec^4 x\,dx$

SOLUTION First use the reduction formula for $\sec^m x$ to evaluate the indefinite integral:

$$\int \sec^4 x\,dx = \frac{1}{3}\tan x \sec^2 x + \frac{2}{3}\int \sec^2 x\,dx = \frac{1}{3}\tan x \sec^2 x + \frac{2}{3}\tan x + C.$$

Now compute the definite integral:

$$\int_{-\pi/4}^{\pi/4} \sec^4 x\,dx = \left(\frac{1}{3}\tan x \sec^2 x + \frac{2}{3}\tan x\right)\Bigg|_{-\pi/4}^{\pi/4}$$
$$= \left[\frac{1}{3}(1)\left(\sqrt{2}\right)^2 + \frac{2}{3}(1)\right] - \left[\frac{1}{3}(-1)\left(\sqrt{2}\right)^2 + \frac{2}{3}(-1)\right] = \frac{4}{3} - \left(-\frac{4}{3}\right) = \frac{8}{3}.$$

56. $\displaystyle\int_{\pi/4}^{3\pi/4} \cot^4 x \csc^2 x\,dx$

SOLUTION Use the substitution $u = \cot x$, $du = -\csc^2 x\,dx$. $x = \pi/4$ corresponds to $u = 1$, and $x = 3\pi/4$ corresponds to $u = -1$. We get

$$\int_{\pi/4}^{3\pi/4} \cot^4 x \csc^2 x\,dx = -\int_1^{-1} u^4\,du = -\frac{1}{5}u^5\Big|_1^{-1} = \frac{2}{5}$$

57. $\displaystyle\int_0^{\pi} \sin 3x \cos 4x\,dx$

SOLUTION Use the formula for $\int \sin mx \cos nx\,dx$:

$$\int_0^{\pi} \sin 3x \cos 4x\,dx = \left(-\frac{\cos(3-4)x}{2(3-4)} - \frac{\cos(3+4)x}{2(3+4)}\right)\Bigg|_0^{\pi} = \left(-\frac{\cos(-x)}{-2} - \frac{\cos 7x}{14}\right)\Bigg|_0^{\pi}$$
$$= \left(\frac{1}{2}\cos x - \frac{1}{14}\cos 7x\right)\Bigg|_0^{\pi} = \left[\frac{1}{2}(-1) - \frac{1}{14}(-1)\right] - \left[\frac{1}{2}(1) - \frac{1}{14}(1)\right] = -\frac{6}{7}.$$

58. $\displaystyle\int_0^{\pi} \sin x \sin 3x\,dx$

SOLUTION Use the formula for $\int \sin mx \sin nx\,dx$:

$$\int_0^{\pi} \sin x \sin 3x\,dx = \left(\frac{\sin(1-3)x}{2(1-3)} - \frac{\sin(1+3)x}{2(1+3)}\right)\Bigg|_0^{\pi} = \left(\frac{\sin(-2x)}{-4} - \frac{\sin 4x}{8}\right)\Bigg|_0^{\pi}$$
$$= \left(\frac{1}{4}\sin 2x - \frac{1}{8}\sin 4x\right)\Bigg|_0^{\pi} = 0 - 0 = 0.$$

59. $\displaystyle\int_0^{\pi/6} \sin 2x \cos 4x\,dx$

SOLUTION Using the formula for $\displaystyle\int \sin mx \cos nx\,dx$, we have

$$\int_0^{\pi/6} \sin 2x \cos 4x\,dx = \left(-\frac{1}{-4}\cos(-2x) - \frac{1}{2\cdot 6}\cos(6x)\right)\Bigg|_0^{\pi/6} = \left(\frac{1}{4}\cos 2x - \frac{1}{12}\cos 6x\right)\Bigg|_0^{\pi/6}$$
$$= \left(\frac{1}{4}\cdot\frac{1}{2} - \frac{1}{12}\cdot(-1)\right) - \left(\frac{1}{4} - \frac{1}{12}\right) = \frac{1}{24}$$

Here we've used the fact that $\cos x$ is an even function: $\cos(-x) = \cos x$.

60. $\displaystyle\int_0^{\pi/4} \sin 7x \cos 2x\,dx$

SOLUTION Using the formula for $\displaystyle\int \sin mx \cos nx\,dx$, we have

$$\int_0^{\pi/4} \sin 7x \cos 2x\,dx = \left(-\frac{1}{10}\cos 5x - \frac{1}{18}\cos 9x\right)\Bigg|_0^{\pi/4}$$
$$= \left(-\frac{1}{10}\cdot\left(-\frac{\sqrt{2}}{2}\right) - \frac{1}{18}\cdot\frac{\sqrt{2}}{2}\right) - \left(-\frac{1}{10} - \frac{1}{18}\right) = \frac{1}{45}(7+\sqrt{2})$$

61. Use the identities for $\sin 2x$ and $\cos 2x$ on page 407 to verify that the following formulas are equivalent.

$$\int \sin^4 x\,dx = \frac{1}{32}(12x - 8\sin 2x + \sin 4x) + C$$
$$\int \sin^4 x\,dx = -\frac{1}{4}\sin^3 x\cos x - \frac{3}{8}\sin x\cos x + \frac{3}{8}x + C$$

SOLUTION First, observe

$$\begin{aligned}\sin 4x &= 2\sin 2x\cos 2x = 2\sin 2x(1 - 2\sin^2 x)\\ &= 2\sin 2x - 4\sin 2x\sin^2 x = 2\sin 2x - 8\sin^3 x\cos x.\end{aligned}$$

Then

$$\begin{aligned}\frac{1}{32}(12x - 8\sin 2x + \sin 4x) + C &= \frac{3}{8}x - \frac{3}{16}\sin 2x - \frac{1}{4}\sin^3 x\cos x + C\\ &= \frac{3}{8}x - \frac{3}{8}\sin x\cos x - \frac{1}{4}\sin^3 x\cos x + C.\end{aligned}$$

62. Evaluate $\int \sin^2 x\cos^3 x\,dx$ using the method described in the text and verify that your result is equivalent to the following result produced by a computer algebra system.

$$\int \sin^2 x\cos^3 x\,dx = \frac{1}{30}(7 + 3\cos 2x)\sin^3 x + C$$

SOLUTION Use the identity $\cos^2 x = 1 - \sin^2 x$ to write

$$\int \sin^2 x\cos^3 x\,dx = \int \sin^2 x(1 - \sin^2 x)\cos x\,dx.$$

Now use the substitution $u = \sin x$, $du = \cos x\,dx$:

$$\int \sin^2 x\cos^3 x\,dx = \int u^2(1 - u^2)\,du = \frac{1}{3}u^3 - \frac{1}{5}u^5 + C = \frac{1}{3}\sin^3 x - \frac{1}{5}\sin^5 x + C.$$

To show that this result matches that produced by the computer algebra system, we will make use of the identity $\sin^2 x = \frac{1}{2} - \frac{1}{2}\cos 2x$. We find

$$\begin{aligned}\frac{1}{3}\sin^3 x - \frac{1}{5}\sin^5 x + C &= \sin^3 x\left(\frac{1}{3} - \frac{1}{5}\sin^2 x\right) + C = \sin^3 x\left(\frac{7}{30} + \frac{1}{10}\cos 2x\right) + C\\ &= \frac{1}{30}\sin^3 x(7 + 3\cos 2x) + C.\end{aligned}$$

63. Find the volume of the solid obtained by revolving $y = \sin x$ for $0 \le x \le \pi$ about the x-axis.

SOLUTION Using the disk method, the volume is given by

$$V = \int_0^{\pi} \pi(\sin x)^2\,dx = \pi\int_0^{\pi}\sin^2 x\,dx = \pi\left(\frac{x}{2} - \frac{\sin 2x}{4}\right)\Big|_0^{\pi} = \pi\left[\left(\frac{\pi}{2} - 0\right) - (0)\right] = \frac{\pi^2}{2}.$$

64. Use Integration by Parts to prove Eqs. (1) and (2).

SOLUTION To prove the reduction formula for $\sin^n x$, use Integration by Parts with $u = \sin^{n-1} x$ and $v' = \sin x$. Then $u' = (n-1)\sin^{n-2} x\cos x$, $v = -\cos x$, and

$$\begin{aligned}\int \sin^n x\,dx &= -\sin^{n-1} x\cos x + (n-1)\int \sin^{n-2} x\cos^2 x\,dx\\ &= -\sin^{n-1} x\cos x + (n-1)\int \sin^{n-2} x\left(1 - \sin^2 x\right)dx\\ &= -\sin^{n-1} x\cos x + (n-1)\int \sin^{n-2} x\,dx - (n-1)\int \sin^n x\,dx.\end{aligned}$$

Solving this equation for $\int \sin^n x\,dx$, we get

$$\begin{aligned}n\int \sin^n x\,dx &= -\sin^{n-1} x\cos x + (n-1)\int \sin^{n-2} x\,dx\\ \int \sin^n x\,dx &= -\frac{1}{n}\sin^{n-1} x\cos x + \frac{n-1}{n}\int \sin^{n-2} x\,dx\end{aligned}$$

To prove the reduction formula for $\cos^n x$, use Integration by Parts with $u = \cos^{n-1} x$ and $v' = \cos x$. Then $u' = -(n-1)\cos^{n-2} x \sin x$, $v = \sin x$, and

$$\begin{aligned}\int \cos^n x\,dx &= \cos^{n-1} x \sin x + (n-1)\int \cos^{n-2} x \sin^2 x\,dx \\ &= \cos^{n-1} x \sin x + (n-1)\int \cos^{n-2} x\left(1-\cos^2 x\right)dx \\ &= \cos^{n-1} x \sin x + (n-1)\int \cos^{n-2} x\,dx - (n-1)\int \cos^n x\,dx.\end{aligned}$$

Solving this equation for $\int \cos^n x\,dx$, we get

$$\begin{aligned}n\int \cos^n x\,dx &= \cos^{n-1} x \sin x + (n-1)\int \cos^{n-2} x\,dx \\ \int \cos^n x\,dx &= \frac{1}{n}\cos^{n-1} x \sin x + \frac{n-1}{n}\int \cos^{n-2} x\,dx\end{aligned}$$

In Exercises 65–68, use the following alternative method for evaluating the integral $J = \int \sin^m x \cos^n x\,dx$ when m and n are both even. Use the identities

$$\sin^2 x = \frac{1}{2}(1-\cos 2x), \qquad \cos^2 x = \frac{1}{2}(1+\cos 2x)$$

to write $J = \frac{1}{4}\int (1-\cos 2x)^{m/2}(1+\cos 2x)^{n/2}\,dx$, and expand the right-hand side as a sum of integrals involving smaller powers of sine and cosine in the variable $2x$.

65. $\int \sin^2 x \cos^2 x\,dx$

SOLUTION Using the identities $\sin^2 x = \frac{1}{2}(1-\cos 2x)$ and $\cos^2 x = \frac{1}{2}(1+\cos 2x)$, we have

$$\begin{aligned}J &= \int \sin^2 x \cos^2 x\,dx = \frac{1}{4}\int (1-\cos 2x)(1+\cos 2x)\,dx \\ &= \frac{1}{4}\int \left(1-\cos^2 2x\right)dx = \frac{1}{4}\int dx - \frac{1}{4}\int \cos^2 2x\,dx.\end{aligned}$$

Now use the substitution $u = 2x$, $du = 2\,dx$, and the formula for $\int \cos^2 u\,du$:

$$\begin{aligned}J &= \frac{1}{4}x - \frac{1}{8}\int \cos^2 u\,du = \frac{1}{4}x - \frac{1}{8}\left(\frac{u}{2} + \frac{1}{2}\sin u \cos u\right) + C \\ &= \frac{1}{4}x - \frac{1}{16}(2x) - \frac{1}{16}\sin 2x \cos 2x + C = \frac{1}{8}x - \frac{1}{16}\sin 2x \cos 2x + C.\end{aligned}$$

66. $\int \cos^4 x\,dx$

SOLUTION Using the identity $\cos^2 x = \frac{1}{2}(1+\cos 2x)$, we have

$$\begin{aligned}J &= \int \cos^4 x\,dx = \frac{1}{4}\int (1+\cos 2x)^2\,dx = \frac{1}{4}\int \left(1 + 2\cos 2x + \cos^2 2x\right)dx \\ &= \frac{1}{4}\int dx + \frac{1}{4}\int \cos 2x(2\,dx) + \frac{1}{8}\int \cos^2 2x(2\,dx)\end{aligned}$$

Using the substitution $u = 2x$, $du = 2\,dx$, we get

$$\begin{aligned}J &= \frac{1}{4}x + \frac{1}{4}\sin 2x + \frac{1}{8}\int \cos^2 u\,du = \frac{1}{4}x + \frac{1}{4}\sin 2x + \frac{1}{8}\left(\frac{u}{2} + \frac{1}{2}\sin u \cos u\right) + C \\ &= \frac{1}{4}x + \frac{1}{4}\sin 2x + \frac{1}{16}(2x) + \frac{1}{16}\sin 2x \cos 2x + C = \frac{3}{8}x + \frac{1}{4}\sin 2x + \frac{1}{16}\sin 2x \cos 2x + C.\end{aligned}$$

67. $\int \sin^4 x \cos^2 x \, dx$

SOLUTION Using the identities $\sin^2 x = \frac{1}{2}(1 - \cos 2x)$ and $\cos^2 x = \frac{1}{2}(1 + \cos 2x)$, we have

$$\begin{aligned} J = \int \sin^4 x \cos^2 x \, dx &= \frac{1}{8} \int (1 - \cos 2x)^2 (1 + \cos 2x) \, dx \\ &= \frac{1}{8} \int \left(1 - 2\cos 2x + \cos^2 2x\right)(1 + \cos 2x) \, dx \\ &= \frac{1}{8} \int \left(1 - \cos 2x - \cos^2 2x + \cos^3 2x\right) dx. \end{aligned}$$

Now use the substitution $u = 2x$, $du = 2\,dx$, together with the reduction formula for $\cos^m x$:

$$\begin{aligned} J &= \frac{1}{8}x - \frac{1}{16}\int \cos u \, du - \frac{1}{16}\int \cos^2 u \, du + \frac{1}{16}\int \cos^3 u \, du \\ &= \frac{1}{8}x - \frac{1}{16}\sin u - \frac{1}{16}\left(\frac{u}{2} + \frac{1}{2}\sin u \cos u\right) + \frac{1}{16}\left(\frac{1}{3}\cos^2 u \sin u + \frac{2}{3}\int \cos u \, du\right) \\ &= \frac{1}{8}x - \frac{1}{16}\sin 2x - \frac{1}{32}(2x) - \frac{1}{32}\sin 2x \cos 2x + \frac{1}{48}\cos^2 2x \sin 2x + \frac{1}{24}\sin 2x + C \\ &= \frac{1}{16}x - \frac{1}{48}\sin 2x - \frac{1}{32}\sin 2x \cos 2x + \frac{1}{48}\cos^2 2x \sin 2x + C. \end{aligned}$$

68. $\int \sin^6 x \, dx$

SOLUTION Using the identity $\sin^2 x = \frac{1}{2}(1 - \cos 2x)$, we have

$$\begin{aligned} J = \int \sin^6 x \, dx &= \int \left(\frac{1}{2}(1 - \cos 2x)\right)^3 dx = \frac{1}{8}\int (1 - \cos 2x)^3 \, dx \\ &= \frac{1}{8}\int 1 - 3\cos 2x + 3\cos^2 2x - \cos^3 2x \, dx \end{aligned}$$

Now use the substitution $u = 2x$, $du = 2\,dx$ together with the reduction formula for $\cos^m x$:

$$\begin{aligned} J &= \frac{1}{8}x - \frac{3}{16}\int \cos u \, du + \frac{3}{16}\int \cos^2 u \, du - \frac{1}{16}\int \cos^3 u \, du \\ &= \frac{1}{8}x - \frac{3}{16}\sin u + \frac{3}{16}\left(\frac{u}{2} + \frac{1}{2}\sin u \cos u\right) - \frac{1}{16}\left(\frac{1}{3}\cos^2 u \sin u + \frac{2}{3}\int \cos u \, du\right) \\ &= \frac{1}{8}x - \frac{3}{16}\sin u + \frac{3}{32}u + \frac{3}{32}\sin u \cos u - \frac{1}{48}\cos^2 u \sin u - \frac{1}{24}\sin u + C \\ &= \frac{1}{8}x - \frac{11}{48}\sin u + \frac{3}{32}u + \frac{3}{32}\sin u \cos u - \frac{1}{48}\cos^2 u \sin u + C \\ &= \frac{1}{8}x - \frac{11}{48}\sin 2x + \frac{3}{32}\cdot 2x + \frac{3}{32}\sin 2x \cos 2x - \frac{1}{48}\cos^2 2x \sin 2x + C \\ &= \frac{5}{16}x - \frac{11}{48}\sin 2x + \frac{3}{32}\sin 2x \cos 2x - \frac{1}{48}\cos^2 2x \sin 2x + C \end{aligned}$$

69. Prove the reduction formula

$$\int \tan^k x \, dx = \frac{\tan^{k-1} x}{k-1} - \int \tan^{k-2} x \, dx$$

Hint: $\tan^k x = (\sec^2 x - 1)\tan^{k-2} x$.

SOLUTION Use the identity $\tan^2 x = \sec^2 x - 1$ to write

$$\int \tan^k x \, dx = \int \tan^{k-2} x \left(\sec^2 x - 1\right) dx = \int \tan^{k-2} x \sec^2 x \, dx - \int \tan^{k-2} x \, dx.$$

Now use the substitution $u = \tan x$, $du = \sec^2 x \, dx$:

$$\int \tan^k x \, dx = \int u^{k-2} \, du - \int \tan^{k-2} x \, dx = \frac{1}{k-1}u^{k-1} - \int \tan^{k-2} x \, dx = \frac{\tan^{k-1} x}{k-1} - \int \tan^{k-2} x \, dx.$$

70. Use the substitution $u = \csc x - \cot x$ to evaluate $\int \csc x \, dx$ (see Example 5).

SOLUTION Using the substitution $u = \csc x - \cot x$,

$$du = \left(-\csc x \cot x + \csc^2 x\right) dx = \csc x(\csc x - \cot x)\, dx,$$

we have

$$\int \csc x \, dx = \int \frac{\csc x(\csc x - \cot x)\, dx}{\csc x - \cot x} = \int \frac{du}{u} = \ln|u| + C = \ln|\csc x - \cot x| + C.$$

71. Let $I_m = \int_0^{\pi/2} \sin^m x \, dx$.

(a) Show that $I_0 = \frac{\pi}{2}$ and $I_1 = 1$.

(b) Prove that, for $m \geq 2$,

$$I_m = \frac{m-1}{m} I_{m-2}$$

(c) Use (a) and (b) to compute I_m for $m = 2, 3, 4, 5$.

SOLUTION

(a) We have

$$I_0 = \int_0^{\pi/2} \sin^0 x \, dx = \int_0^{\pi/2} 1 \, dx = \frac{\pi}{2}$$

$$I_1 = \int_0^{\pi/2} \sin x \, dx = -\cos x \Big|_0^{\pi/2} = 1$$

(b) Using the reduction formula for $\sin^m x$, we get for $m \geq 2$

$$\begin{aligned}
I_m &= \int_0^{\pi/2} \sin^m x \, dx = -\frac{1}{m} \sin^{m-1} x \cos x \Big|_0^{\pi/2} + \frac{m-1}{m} \int_0^{\pi/2} \sin^{m-2} x \, dx \\
&= -\frac{1}{m} \sin^{m-1}\left(\frac{\pi}{2}\right) \cos\left(\frac{\pi}{2}\right) + \frac{1}{m} \sin^{m-1}(0)\cos(0) + \frac{m-1}{m} I_{m-2} \\
&= \frac{1}{m}(-1 \cdot 0 + 0 \cdot 1) + \frac{m-1}{m} I_{m-2} \\
&= \frac{m-1}{m} I_{m-2}
\end{aligned}$$

(c)

$$\begin{aligned}
I_2 &= \frac{1}{2} I_0 = \frac{1}{2} \cdot \frac{\pi}{2} = \frac{\pi}{4} \\
I_3 &= \frac{2}{3} I_1 = \frac{2}{3} \\
I_4 &= \frac{3}{4} I_2 = \frac{3}{4} \cdot \frac{\pi}{4} = \frac{3}{16}\pi \\
I_5 &= \frac{4}{5} I_3 = \frac{8}{15}
\end{aligned}$$

72. Evaluate $\int_0^{\pi} \sin^2 mx \, dx$ for m an arbitrary integer.

SOLUTION Use the substitution $u = mx$, $du = m\, dx$. Then

$$\begin{aligned}
\int_0^{\pi} \sin^2 mx \, dx &= \frac{1}{m} \int_{x=0}^{x=\pi} \sin^2 u \, du = \frac{1}{m}\left(\frac{u}{2} - \frac{\sin 2u}{4}\right)\Big|_{x=0}^{x=\pi} = \frac{1}{m}\left(\frac{mx}{2} - \frac{\sin 2mx}{4}\right)\Big|_0^{\pi} \\
&= \left(\frac{x}{2} - \frac{\sin 2mx}{4m}\right)\Big|_0^{\pi} = \left(\frac{\pi}{2} - \frac{\sin 2\pi m}{4}\right) - (0).
\end{aligned}$$

If m is an arbitrary integer, then $\sin 2m\pi = 0$. Thus

$$\int_0^{\pi} \sin^2 mx \, dx = \frac{\pi}{2}.$$

73. Evaluate $\int \sin x \ln(\sin x)\,dx$. *Hint:* Use Integration by Parts as a first step.

SOLUTION Start by using integration by parts with $u = \ln(\sin x)$ and $v' = \sin x$, so that $u' = \cot x$ and $v = -\cos x$. Then

$$I = \int \sin x \ln(\sin x)\,dx = -\cos x \ln(\sin x) + \int \cot x \cos x\,dx = -\cos x \ln(\sin x) + \int \frac{\cos^2 x}{\sin x}\,dx$$
$$= -\cos x \ln(\sin x) + \int \frac{1-\sin^2 x}{\sin x}\,dx = -\cos x \ln(\sin x) - \int \sin x\,dx + \int \csc x\,dx$$
$$= -\cos x \ln(\sin x) + \cos x + \int \csc x\,dx$$

Using the table, $\int \csc x\,dx = \ln|\csc x - \cot x| + C$, so finally

$$I = -\cos x \ln(\sin x) + \cos x + \ln|\csc x - \cot x| + C$$

74. Total Energy A 100-W light bulb has resistance $R = 144\ \Omega$ (ohms) when attached to household current, where the voltage varies as $V = V_0 \sin(2\pi f t)$ ($V_0 = 110$ V, $f = 60$ Hz). The energy (in joules) expended by the bulb over a period of T seconds is

$$U = \int_0^T P(t)\,dt$$

where $P = V^2/R$ (J/s) is the power. Compute U if the bulb remains on for 5 hours.

SOLUTION After converting to seconds (5 hours = 18,000 seconds), the total energy expended is given by

$$U = \int_0^{18{,}000} P(t)\,dt = \int_0^{18{,}000} \frac{V^2}{R}\,dt = \frac{V_0^2}{R}\int_0^{18{,}000} \sin^2(2\pi f t)\,dt = \frac{110^2}{144}\int_0^{18{,}000} \sin^2(120\pi t)\,dt.$$

Now use the substitution $u = 120\pi t$, $du = 120\pi\,dt$:

$$U = \frac{110^2}{144}\left(\frac{1}{120\pi}\right)\int_{t=0}^{t=18{,}000} \sin^2 u\,du = \frac{110^2}{144\cdot 120\pi}\left[\frac{u}{2} - \frac{1}{2}\sin u \cos u\right]_{t=0}^{t=18{,}000}$$
$$= \frac{110^2}{144\cdot 120\pi}\left[60\pi t - \frac{1}{2}\sin(120\pi t)\cos(120\pi t)\right]_0^{18{,}000} = \frac{110^2}{144\cdot 120\pi}\left[\big(60\pi(18{,}000) - 0\big) - 0\right]$$
$$= \frac{(110^2)(60\pi)(18{,}000)}{(144)(120\pi)} = 756{,}260 \text{ joules.}$$

75. Let m, n be integers with $m \neq \pm n$. Use Eqs. (23)–(25) to prove the so-called **orthogonality relations** that play a basic role in the theory of Fourier Series (Figure 2):

$$\int_0^{\pi} \sin mx \sin nx\,dx = 0$$
$$\int_0^{\pi} \cos mx \cos nx\,dx = 0$$
$$\int_0^{2\pi} \sin mx \cos nx\,dx = 0$$

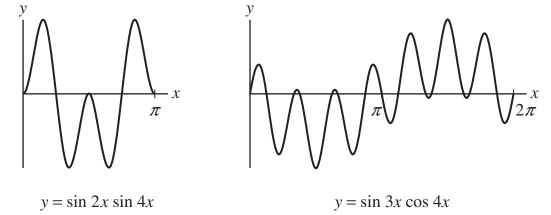

FIGURE 2 The integrals are zero by the orthogonality relations.

SOLUTION If m, n are integers, then $m-n$ and $m+n$ are integers, and therefore $\sin(m-n)\pi = \sin(m+n)\pi = 0$, since $\sin k\pi = 0$ if k is an integer. Thus we have

$$\int_0^{\pi} \sin mx \sin nx\, dx = \left(\frac{\sin(m-n)x}{2(m-n)} - \frac{\sin(m+n)x}{2(m+n)}\right)\Bigg|_0^{\pi} = \left(\frac{\sin(m-n)\pi}{2(m-n)} - \frac{\sin(m+n)\pi}{2(m+n)}\right) - 0 = 0;$$

$$\int_0^{\pi} \cos mx \cos nx\, dx = \left(\frac{\sin(m-n)x}{2(m-n)} + \frac{\sin(m+n)x}{2(m+n)}\right)\Bigg|_0^{\pi} = \left(\frac{\sin(m-n)\pi}{2(m-n)} + \frac{\sin(m+n)\pi}{2(m+n)}\right) - 0 = 0.$$

If k is an integer, then $\cos 2k\pi = 1$. Using this fact, we have

$$\begin{aligned}\int_0^{2\pi} \sin mx \cos nx\, dx &= \left(-\frac{\cos(m-n)x}{2(m-n)} - \frac{\cos(m+n)x}{2(m+n)}\right)\Bigg|_0^{2\pi}\\ &= \left(-\frac{\cos(m-n)2\pi}{2(m-n)} - \frac{\cos(m+n)2\pi}{2(m+n)}\right) - \left(-\frac{1}{2(m-n)} - \frac{1}{2(m+n)}\right)\\ &= \left(-\frac{1}{2(m-n)} - \frac{1}{2(m+n)}\right) - \left(-\frac{1}{2(m-n)} - \frac{1}{2(m+n)}\right) = 0.\end{aligned}$$

Further Insights and Challenges

76. Use the trigonometric identity

$$\sin mx \cos nx = \frac{1}{2}\big(\sin(m-n)x + \sin(m+n)x\big)$$

to prove Eq. (24) in the table of integrals on page 410.

SOLUTION Using the identity $\sin mx \cos nx = \frac{1}{2}(\sin(m-n)x + \sin(m+n)x)$, we get

$$\int \sin mx \cos nx\, dx = \frac{1}{2}\int \sin(m-n)x\, dx + \frac{1}{2}\int \sin(m+n)x\, dx = -\frac{\cos(m-n)x}{2(m-n)} - \frac{\cos(m+n)x}{2(m+n)} + C.$$

77. Use Integration by Parts to prove that (for $m \neq 1$)

$$\int \sec^m x\, dx = \frac{\tan x \sec^{m-2} x}{m-1} + \frac{m-2}{m-1}\int \sec^{m-2} x\, dx$$

SOLUTION Using Integration by Parts with $u = \sec^{m-2} x$ and $v' = \sec^2 x$, we have $v = \tan x$ and

$$u' = (m-2)\sec^{m-3} x(\sec x \tan x) = (m-2)\tan x \sec^{m-2} x.$$

Then,

$$\begin{aligned}\int \sec^m x\, dx &= \tan x \sec^{m-2} x - (m-2)\int \tan^2 x \sec^{m-2} x\, dx\\ &= \tan x \sec^{m-2} x - (m-2)\int \left(\sec^2 x - 1\right)\sec^{m-2} x\, dx\\ &= \tan x \sec^{m-2} x - (m-2)\int \sec^m x\, dx + (m-2)\int \sec^{m-2} x\, dx.\end{aligned}$$

Solving this equation for $\int \sec^m x\, dx$, we get

$$\begin{aligned}(m-1)\int \sec^m x\, dx &= \tan x \sec^{m-2} x + (m-2)\int \sec^{m-2} x\, dx\\ \int \sec^m x\, dx &= \frac{\tan x \sec^{m-2} x}{m-1} + \frac{m-2}{m-1}\int \sec^{m-2} x\, dx.\end{aligned}$$

78. Set $I_m = \displaystyle\int_0^{\pi/2} \sin^m x\, dx$. Use Exercise 71 to prove that

$$\begin{aligned}I_{2m} &= \frac{2m-1}{2m}\frac{2m-3}{2m-2}\cdots\frac{1}{2}\cdot\frac{\pi}{2}\\ I_{2m+1} &= \frac{2m}{2m+1}\frac{2m-2}{2m-1}\cdots\frac{2}{3}\end{aligned}$$

Conclude that

$$\frac{\pi}{2} = \frac{2 \cdot 2}{1 \cdot 3} \cdot \frac{4 \cdot 4}{3 \cdot 5} \cdots \frac{2m \cdot 2m}{(2m-1)(2m+1)} \frac{I_{2m}}{I_{2m+1}}$$

SOLUTION We'll use induction to show these results. Recall from Exercise 71 that

$$I_m = \frac{m-1}{m} I_{m-2}$$

when $m \geq 2$. Now, for I_{2m}, the result is true for $m = 1$ and $m = 2$ (again see Exercise 71). Now assume the result is true for $m = k - 1$:

$$I_{2(k-1)} = I_{2k-2} = \frac{2k-3}{2k-2} \cdot \frac{2k-5}{2k-4} \cdots \frac{1}{2} \cdot \frac{\pi}{2}$$

Using the relation $I_m = ((m-1)/m)I_{m-2}$, we have

$$I_{2k} = \frac{2k-1}{2k} I_{2k-2} = \frac{2k-1}{2k} \cdot \left(\frac{2k-3}{2k-2} \cdot \frac{2k-5}{2k-4} \cdots \frac{1}{2} \cdot \frac{\pi}{2} \right).$$

For I_{2m+1}, the result is true for $m = 1$. Now assume the result is true for $m = k - 1$:

$$I_{2(k-1)+1} = I_{2k-1} = \frac{2k-2}{2k-1} \cdot \frac{2k-4}{2k-3} \cdots \frac{2}{3}$$

Again using the relation $I_m = ((m-1)/m)I_{m-2}$, we have

$$I_{2k+1} = \left(\frac{2k+1-1}{2k+1} \right) I_{2k-1} = \frac{2k}{2k+1} \left(\frac{2k-2}{2k-1} \cdot \frac{2k-4}{2k-3} \cdots \frac{2}{3} \right).$$

This establishes the explicit formulas for I_{2m} and I_{2m+1}. Now, divide these two results to obtain

$$\frac{I_{2m}}{I_{2m+1}} = \frac{(2m-1)(2m+1)}{2m \cdot 2m} \cdot \frac{(2m-3)(2m-1)}{(2m-2)(2m-2)} \cdots \frac{1 \cdot 3}{2 \cdot 2} \cdot \frac{\pi}{2}.$$

Solving for $\pi/2$, we get the desired result:

$$\frac{\pi}{2} = \frac{2 \cdot 2}{1 \cdot 3} \cdot \frac{4 \cdot 4}{3 \cdot 5} \cdots \frac{2m \cdot 2m}{(2m-1)(2m+1)} \cdot \frac{I_{2m}}{I_{2m+1}}.$$

79. This is a continuation of Exercise 78.

(a) Prove that $I_{2m+1} \leq I_{2m} \leq I_{2m-1}$. *Hint:* $\sin^{2m+1} x \leq \sin^{2m} x \leq \sin^{2m-1} x$ for $0 \leq x \leq \frac{\pi}{2}$.

(b) Show that $\dfrac{I_{2m-1}}{I_{2m+1}} = 1 + \dfrac{1}{2m}$.

(c) Show that $1 \leq \dfrac{I_{2m}}{I_{2m+1}} \leq 1 + \dfrac{1}{2m}$.

(d) Prove that $\displaystyle\lim_{m\to\infty} \frac{I_{2m}}{I_{2m+1}} = 1$.

(e) Finally, deduce the infinite product for $\frac{\pi}{2}$ discovered by English mathematician John Wallis (1616–1703):

$$\frac{\pi}{2} = \lim_{m\to\infty} \frac{2}{1} \cdot \frac{2}{3} \cdot \frac{4}{3} \cdot \frac{4}{5} \cdots \frac{2m \cdot 2m}{(2m-1)(2m+1)}$$

SOLUTION

(a) For $0 \leq x \leq \frac{\pi}{2}$, $0 \leq \sin x \leq 1$. Multiplying this last inequality by $\sin x$, we obtain

$$0 \leq \sin^2 x \leq \sin x.$$

Continuing to multiply this inequality by $\sin x$, we obtain, more generally,

$$\sin^{2m+1} x \leq \sin^{2m} x \leq \sin^{2m-1} x.$$

Integrating these functions over $[0, \frac{\pi}{2}]$, we get

$$\int_0^{\pi/2} \sin^{2m+1} x\, dx \leq \int_0^{\pi/2} \sin^{2m} x\, dx \leq \int_0^{\pi/2} \sin^{2m-1} x\, dx,$$

which is the same as

$$I_{2m+1} \leq I_{2m} \leq I_{2m-1}.$$

(b) Using the relation $I_m = ((m-1)/m)I_{m-2}$, we have

$$\frac{I_{2m-1}}{I_{2m+1}} = \frac{I_{2m-1}}{\left(\frac{2m}{2m+1}\right) I_{2m-1}} = \frac{2m+1}{2m} = \frac{2m}{2m} + \frac{1}{2m} = 1 + \frac{1}{2m}.$$

(c) First start with the inequality of part (a):

$$I_{2m+1} \le I_{2m} \le I_{2m-1}.$$

Divide through by I_{2m+1}:

$$1 \le \frac{I_{2m}}{I_{2m+1}} \le \frac{I_{2m-1}}{I_{2m+1}}.$$

Use the result from part (b):

$$1 \le \frac{I_{2m}}{I_{2m+1}} \le 1 + \frac{1}{2m}.$$

(d) Taking the limit of this inequality, and applying the Squeeze Theorem, we have

$$\lim_{m\to\infty} 1 \le \lim_{m\to\infty} \frac{I_{2m}}{I_{2m+1}} \le \lim_{m\to\infty} \left(1 + \frac{1}{2m}\right).$$

Because

$$\lim_{m\to\infty} 1 = 1 \quad \text{and} \quad \lim_{m\to\infty} \left(1 + \frac{1}{2m}\right) = 1,$$

we obtain

$$1 \le \lim_{m\to\infty} \frac{I_{2m}}{I_{2m+1}} \le 1.$$

Therefore

$$\lim_{m\to\infty} \frac{I_{2m}}{I_{2m+1}} = 1.$$

(e) Take the limit of both sides of the equation obtained in Exercise 78(d):

$$\lim_{m\to\infty} \frac{\pi}{2} = \lim_{m\to\infty} \frac{2\cdot 2}{1\cdot 3} \cdot \frac{4\cdot 4}{3\cdot 5} \cdots \frac{2m\cdot 2m}{(2m-1)(2m+1)} \frac{I_{2m}}{I_{2m+1}}$$

$$\frac{\pi}{2} = \left(\lim_{m\to\infty} \frac{2\cdot 2}{1\cdot 3} \cdot \frac{4\cdot 4}{3\cdot 5} \cdots \frac{2m\cdot 2m}{(2m-1)(2m+1)}\right)\left(\lim_{m\to\infty} \frac{I_{2m}}{I_{2m+1}}\right).$$

Finally, using the result from (d), we have

$$\frac{\pi}{2} = \lim_{m\to\infty} \frac{2\cdot 2}{1\cdot 3} \cdot \frac{4\cdot 4}{3\cdot 5} \cdots \frac{2m\cdot 2m}{(2m-1)(2m+1)}.$$

7.3 Trigonometric Substitution

Preliminary Questions

1. State the trigonometric substitution appropriate to the given integral:

(a) $\int \sqrt{9-x^2}\,dx$ **(b)** $\int x^2(x^2-16)^{3/2}\,dx$

(c) $\int x^2(x^2+16)^{3/2}\,dx$ **(d)** $\int (x^2-5)^{-2}\,dx$

SOLUTION

(a) $x = 3\sin\theta$ **(b)** $x = 4\sec\theta$ **(c)** $x = 4\tan\theta$ **(d)** $x = \sqrt{5}\sec\theta$

2. Is trigonometric substitution needed to evaluate $\int x\sqrt{9-x^2}\,dx$?

SOLUTION No. There is a factor of x in the integrand outside the radical and the derivative of $9-x^2$ is $-2x$, so we may use the substitution $u = 9-x^2$, $du = -2x\,dx$ to evaluate this integral.

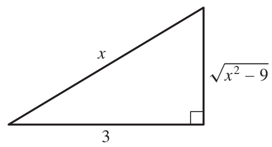
3. Express $\sin 2\theta$ in terms of $x = \sin\theta$.

SOLUTION First note that if $\sin\theta = x$, then $\cos\theta = \sqrt{1-\sin^2\theta} = \sqrt{1-x^2}$. Thus,

$$\sin 2\theta = 2\sin\theta\cos\theta = 2x\sqrt{1-x^2}.$$

4. Draw a triangle that would be used together with the substitution $x = 3\sec\theta$.

SOLUTION



Exercises

In Exercises 1–4, evaluate the integral by following the steps given.

1. $I = \displaystyle\int \frac{dx}{\sqrt{9-x^2}}$

(a) Show that the substitution $x = 3\sin\theta$ transforms I into $\displaystyle\int d\theta$, and evaluate I in terms of θ.

(b) Evaluate I in terms of x.

SOLUTION

(a) Let $x = 3\sin\theta$. Then $dx = 3\cos\theta\,d\theta$, and

$$\sqrt{9-x^2} = \sqrt{9-9\sin^2\theta} = 3\sqrt{1-\sin^2\theta} = 3\sqrt{\cos^2\theta} = 3\cos\theta.$$

Thus,

$$I = \int \frac{dx}{\sqrt{9-x^2}} = \int \frac{3\cos\theta\,d\theta}{3\cos\theta} = \int d\theta = \theta + C.$$

(b) If $x = 3\sin\theta$, then $\theta = \sin^{-1}(\frac{x}{3})$. Thus,

$$I = \theta + C = \sin^{-1}\left(\frac{x}{3}\right) + C.$$

2. $I = \displaystyle\int \frac{dx}{x^2\sqrt{x^2-2}}$

(a) Show that the substitution $x = \sqrt{2}\sec\theta$ transforms the integral I into $\displaystyle\frac{1}{2}\int \cos\theta d\theta$, and evaluate I in terms of θ.

(b) Use a right triangle to show that with the above substitution, $\sin\theta = \sqrt{x^2-2}/x$.

(c) Evaluate I in terms of x.

SOLUTION

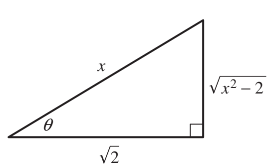
(a) Let $x = \sqrt{2}\sec\theta$. Then $dx = \sqrt{2}\sec\theta\tan\theta\,d\theta$, and

$$\sqrt{x^2-2} = \sqrt{2\sec^2\theta - 2} = \sqrt{2(\sec^2\theta - 1)} = \sqrt{2\tan^2\theta} = \sqrt{2}\tan\theta.$$

Thus,

$$I = \int \frac{dx}{x^2\sqrt{x^2-2}} = \int \frac{\sqrt{2}\sec\theta\tan\theta\,d\theta}{(2\sec^2\theta)(\sqrt{2}\tan\theta)} = \frac{1}{2}\int \frac{d\theta}{\sec\theta} = \frac{1}{2}\int \cos\theta\,d\theta = \frac{1}{2}\sin\theta + C.$$

(b) Since $x = \sqrt{2}\sec\theta$, $\sec\theta = \frac{x}{\sqrt{2}}$, and we construct the following right triangle:



From this triangle we see that $\sin\theta = \sqrt{x^2-2}/x$.

(c) Combining the results from parts (a) and (b),

$$I = \frac{1}{2}\sin\theta + C = \frac{\sqrt{x^2-2}}{2x} + C.$$

3. $I = \int \frac{dx}{\sqrt{4x^2+9}}$

(a) Show that the substitution $x = \frac{3}{2}\tan\theta$ transforms I into $\frac{1}{2}\int \sec\theta\,d\theta$.

(b) Evaluate I in terms of θ (refer to the table of integrals on page 410 in Section 7.2 if necessary).

(c) Express I in terms of x.

SOLUTION

(a) If $x = \frac{3}{2}\tan\theta$, then $dx = \frac{3}{2}\sec^2\theta\,d\theta$, and

$$\sqrt{4x^2+9} = \sqrt{4\cdot\left(\frac{3}{2}\tan\theta\right)^2+9} = \sqrt{9\tan^2\theta+9} = 3\sqrt{\sec^2\theta} = 3\sec\theta$$

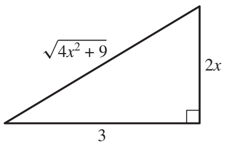
Thus,

$$I = \int \frac{dx}{\sqrt{4x^2+9}} = \int \frac{\frac{3}{2}\sec^2\theta\,d\theta}{3\sec\theta} = \frac{1}{2}\int \sec\theta\,d\theta$$

(b)

$$I = \frac{1}{2}\int \sec\theta\,d\theta = \frac{1}{2}\ln|\sec\theta+\tan\theta| + C$$

(c) Since $x = \frac{3}{2}\tan\theta$, we construct a right triangle with $\tan\theta = \frac{2x}{3}$:



From this triangle, we see that $\sec\theta = \frac{1}{3}\sqrt{4x^2+9}$, and therefore

$$\begin{aligned} I &= \frac{1}{2}\ln|\sec\theta+\tan\theta| + C = \frac{1}{2}\ln\left|\frac{1}{3}\sqrt{4x^2+9}+\frac{2x}{3}\right| + C \\ &= \frac{1}{2}\ln\left|\frac{\sqrt{4x^2+9}+2x}{3}\right| + C = \frac{1}{2}\ln|\sqrt{4x^2+9}+2x| - \frac{1}{2}\ln 3 + C = \frac{1}{2}\ln|\sqrt{4x^2+9}+2x| + C \end{aligned}$$

4. $I = \int \frac{dx}{(x^2+4)^2}$

(a) Show that the substitution $x = 2\tan\theta$ transforms the integral I into $\frac{1}{8}\int \cos^2\theta\,d\theta$.

(b) Use the formula $\int \cos^2\theta\,d\theta = \frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta$ to evaluate I in terms of θ.

(c) Show that $\sin\theta = \frac{x}{\sqrt{x^2+4}}$ and $\cos\theta = \frac{2}{\sqrt{x^2+4}}$.

(d) Express I in terms of x.

SOLUTION

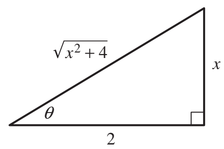
(a) If $x = 2\tan\theta$, then $dx = 2\sec^2\theta\,d\theta$, and

$$\begin{aligned} I &= \int \frac{dx}{(x^2+4)^2} = \int \frac{2\sec^2\theta\,d\theta}{(4\tan^2\theta+4)^2} = \frac{2}{16}\int \frac{\sec^2\theta\,d\theta}{(\tan^2\theta+1)^2} \\ &= \frac{1}{8}\int \frac{\sec^2\theta\,d\theta}{(\sec^2\theta)^2} = \frac{1}{8}\int \frac{d\theta}{\sec^2\theta} = \frac{1}{8}\int \cos^2\theta\,d\theta. \end{aligned}$$

(b) Using the formula $\int \cos^2\, d\theta = \frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta$, we get

$$I = \frac{1}{8}\int \cos^2\theta\, d\theta = \frac{1}{16}\theta + \frac{1}{16}\sin\theta\cos\theta + C.$$

(c) Since $x = 2\tan\theta$, we construct a right triangle with $\tan\theta = \frac{x}{2}$:



From this triangle we see that

$$\sin\theta = \frac{x}{\sqrt{x^2+4}} \quad \text{and} \quad \cos\theta = \frac{2}{\sqrt{x^2+4}}.$$

(d) Since $x = 2\tan\theta$, then $\theta = \tan^{-1}(\frac{x}{2})$, and

$$I = \frac{1}{16}\tan^{-1}\left(\frac{x}{2}\right) + \frac{1}{16}\left(\frac{x}{\sqrt{x^2+4}}\right)\left(\frac{2}{\sqrt{x^2+4}}\right) + C = \frac{1}{16}\tan^{-1}\left(\frac{x}{2}\right) + \frac{x}{8(x^2+4)} + C.$$

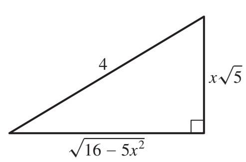
In Exercises 5–10, use the indicated substitution to evaluate the integral.

5. $\int \sqrt{16-5x^2}\, dx, \quad x = \frac{4}{\sqrt{5}}\sin\theta$

SOLUTION Let $x = \frac{4}{\sqrt{5}}\sin\theta$. Then $dx = \frac{4}{\sqrt{5}}\cos\theta\, d\theta$, and

$$\begin{aligned} I &= \int \sqrt{16-5x^2}\, dx = \int \sqrt{16 - 5\left(\frac{4}{\sqrt{5}}\sin\theta\right)^2} \cdot \frac{4}{\sqrt{5}}\cos\theta\, d\theta = \frac{4}{\sqrt{5}}\int \sqrt{16-16\sin^2\theta} \cdot \cos\theta\, d\theta \\ &= \frac{4}{\sqrt{5}} \cdot 4\int \cos\theta \cdot \cos\theta\, d\theta = \frac{16}{\sqrt{5}}\int \cos^2\theta\, d\theta \\ &= \frac{16}{\sqrt{5}}\left(\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right) + C = \frac{8}{\sqrt{5}}(\theta + \sin\theta\cos\theta) + C \end{aligned}$$

Since $x = \frac{4}{\sqrt{5}}\sin\theta$, we construct a right triangle with $\sin\theta = \frac{x\sqrt{5}}{4}$:



From this triangle we see that $\cos\theta = \frac{1}{4}\sqrt{16-5x^2}$, so we have

$$\begin{aligned} I &= \frac{8}{\sqrt{5}}(\theta + \sin\theta\cos\theta) + C \\ &= \frac{8}{\sqrt{5}}\left(\sin^{-1}\left(\frac{x\sqrt{5}}{4}\right) + \frac{x\sqrt{5}}{4} \cdot \frac{1}{4}\sqrt{16-5x^2}\right) + C \\ &= \frac{8}{\sqrt{5}}\sin^{-1}\left(\frac{x\sqrt{5}}{4}\right) + \frac{1}{2}x\sqrt{16-5x^2} + C \end{aligned}$$

6. $\int_0^{1/2} \frac{x^2}{\sqrt{1-x^2}}\, dx, \quad x = \sin\theta$

SOLUTION Let $x = \sin\theta$. Then $dx = \cos\theta\, d\theta$, and

$$\sqrt{1-x^2} = \sqrt{1-\sin^2\theta} = \sqrt{\cos^2\theta} = \cos\theta.$$

Converting the limits of integration to θ, we find

$$x = \frac{1}{2} \Rightarrow \theta = \sin^{-1}\left(\frac{1}{2}\right) = \frac{\pi}{6}$$
$$x = 0 \Rightarrow \theta = \sin^{-1}(0) = 0$$

Therefore

$$I = \int_0^{1/2} \frac{x^2}{\sqrt{1-x^2}}\,dx = \int_0^{\pi/6} \frac{\sin^2\theta}{\cos\theta}(\cos\theta\,d\theta) = \int_0^{\pi/6} \sin^2\theta\,d\theta = \left(\frac{1}{2}\theta - \frac{1}{2}\sin\theta\cos\theta\right)\Bigg|_0^{\pi/6}$$
$$= \left[\frac{\pi}{12} - \frac{1}{2}\left(\frac{1}{2}\right)\left(\frac{\sqrt{3}}{2}\right)\right] - [0-0] = \frac{\pi}{12} - \frac{\sqrt{3}}{8} = \frac{2\pi - 3\sqrt{3}}{24}.$$

7. $\displaystyle\int \frac{dx}{x\sqrt{x^2-9}}, \quad x = 3\sec\theta$

SOLUTION Let $x = 3\sec\theta$. Then $dx = 3\sec\theta\tan\theta\,d\theta$, and

$$\sqrt{x^2-9} = \sqrt{9\sec^2\theta - 9} = 3\sqrt{\sec^2\theta - 1} = 3\sqrt{\tan^2\theta} = 3\tan\theta.$$

Thus,

$$\int \frac{dx}{x\sqrt{x^2-9}} = \int \frac{(3\sec\theta\tan\theta\,d\theta)}{(3\sec\theta)(3\tan\theta)} = \frac{1}{3}\int d\theta = \frac{1}{3}\theta + C.$$

Since $x = 3\sec\theta$, $\theta = \sec^{-1}(\frac{x}{3})$, and

$$\int \frac{dx}{x\sqrt{x^2-9}} = \frac{1}{3}\sec^{-1}\left(\frac{x}{3}\right) + C.$$

8. $\displaystyle\int_{1/2}^{1} \frac{dx}{x^2\sqrt{x^2+4}}, \quad x = 2\tan\theta$

SOLUTION Let $x = 2\tan\theta$. Then $dx = 2\sec^2\theta\,d\theta$, and

$$\sqrt{x^2+4} = \sqrt{4\tan^2\theta + 4} = 2\sqrt{\tan^2\theta + 1} = 2\sqrt{\sec^2\theta} = 2\sec\theta.$$

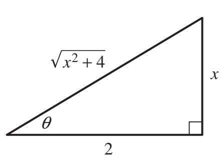
This gives us

$$\int \frac{dx}{x^2\sqrt{x^2+4}} = \int \frac{2\sec^2\theta\,d\theta}{4\tan^2\theta(2\sec\theta)} = \frac{1}{4}\int \frac{\sec\theta\,d\theta}{\tan^2\theta} = \frac{1}{4}\int \frac{\cos\theta}{\sin^2\theta}\,d\theta.$$

Now use substitution, with $u = \sin\theta$ and $du = \cos\theta\,d\theta$. Then

$$\frac{1}{4}\int \frac{\cos\theta}{\sin^2\theta}\,d\theta = \frac{1}{4}\int u^{-2}\,du = \frac{1}{4}\left(-u^{-1}\right) + C = -\frac{1}{4\sin\theta} + C.$$

Since $x = 2\tan\theta$, we construct a right triangle with $\tan\theta = \frac{x}{2}$:



From this triangle we see that $\sin\theta = \frac{x}{\sqrt{x^2+4}}$. Thus

$$\int_{1/2}^{1} \frac{dx}{x^2\sqrt{x^2+4}} = -\frac{\sqrt{x^2+4}}{4x}\Bigg|_{1/2}^{1} = -\frac{1}{4}\left[\sqrt{5} - \frac{\sqrt{\frac{1}{4}+4}}{\frac{1}{2}}\right] = \frac{1}{4}\left[\sqrt{17} - \sqrt{5}\right].$$

9. $\displaystyle\int \frac{dx}{(x^2-4)^{3/2}}, \quad x = 2\sec\theta$

SOLUTION Let $x = 2\sec\theta$. Then $dx = 2\sec\theta\tan\theta\,d\theta$, and

$$x^2 - 4 = 4\sec^2\theta - 4 = 4(\sec^2\theta - 1) = 4\tan^2\theta.$$

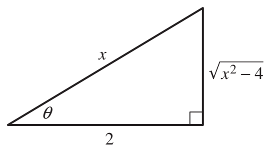
This gives

$$I = \int \frac{dx}{(x^2-4)^{3/2}} = \int \frac{2\sec\theta\tan\theta\,d\theta}{(4\tan^2\theta)^{3/2}} = \int \frac{2\sec\theta\tan\theta\,d\theta}{8\tan^3\theta} = \frac{1}{4}\int \frac{\sec\theta\,d\theta}{\tan^2\theta} = \frac{1}{4}\int \frac{\cos\theta}{\sin^2\theta}\,d\theta.$$

Now use substitution with $u = \sin\theta$ and $du = \cos\theta\,d\theta$. Then

$$I = \frac{1}{4}\int u^{-2}\,du = -\frac{1}{4}u^{-1} + C = \frac{-1}{4\sin\theta} + C.$$

Since $x = 2\sec\theta$, we construct a right triangle with $\sec\theta = \frac{x}{2}$:



From this triangle we see that $\sin\theta = \sqrt{x^2-4}/x$, so therefore

$$I = \frac{-1}{4(\sqrt{x^2-4}/x)} + C = \frac{-x}{4\sqrt{x^2-4}} + C.$$

10. $\displaystyle\int_0^1 \frac{dx}{(4+9x^2)^2}, \quad x = \frac{2}{3}\tan\theta$

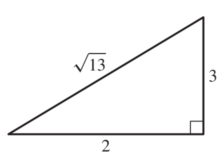
SOLUTION Let $x = \frac{2}{3}\tan\theta$. Then $dx = \frac{2}{3}\sec^2\theta\,d\theta$, and

$$4 + 9x^2 = 4 + 9\left(\frac{2}{3}\tan\theta\right)^2 = 4 + 4\tan^2\theta = 4(1+\tan^2\theta) = 4\sec^2\theta$$

This gives

$$\begin{aligned}\int \frac{dx}{(4+9x^2)^2} &= \int \frac{\frac{2}{3}\sec^2\theta\,d\theta}{16\sec^4\theta} = \frac{1}{24}\int \frac{d\theta}{\sec^2\theta}\\ &= \frac{1}{24}\int \cos^2\theta\,d\theta = \frac{1}{24}\left(\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right) + C\\ &= \frac{1}{48}(\theta + \sin\theta\cos\theta) + C\end{aligned}$$

The limits of integration are from $x = 0$ to $x = 1$. $x = 0$ corresponds to $\theta = 0$, while $x = 1$ corresponds to the angle θ with $\tan\theta = \frac{3}{2}$. So we construct a right triangle with $\tan\theta = \frac{3}{2}$:



From this triangle we see that $\sin\theta = \frac{3}{\sqrt{13}}$ and $\cos\theta = \frac{2}{\sqrt{13}}$, so that

$$\begin{aligned}\int_0^1 \frac{dx}{(4+9x^2)^2} &= \frac{1}{48}(\theta + \sin\theta\cos\theta)\Big|_0^{\tan^{-1}(3/2)}\\ &= \frac{1}{48}\left(\tan^{-1}\left(\frac{3}{2}\right) + \frac{3}{\sqrt{13}}\cdot\frac{2}{\sqrt{13}} - 0 - 0\right) = \frac{1}{48}\tan^{-1}\left(\frac{3}{2}\right) + \frac{1}{104}\end{aligned}$$

11. Evaluate $\int \frac{x\,dx}{\sqrt{x^2-4}}$ in two ways: using the direct substitution $u = x^2 - 4$ and by trigonometric substitution.

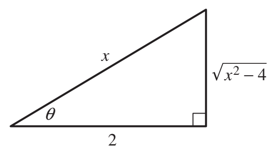
SOLUTION Let $u = x^2 - 4$. Then $du = 2x\,dx$, and

$$I_1 = \int \frac{x\,dx}{\sqrt{x^2-4}} = \frac{1}{2}\int \frac{du}{\sqrt{u}} = \frac{1}{2}\left(2u^{1/2}\right) + C = \sqrt{u} + C = \sqrt{x^2-4} + C.$$

To use trigonometric substitution, let $x = 2\sec\theta$. Then $dx = 2\sec\theta\tan\theta\,d\theta$, $x^2 - 4 = 4\sec^2\theta - 4 = 4\tan^2\theta$, and

$$I_1 = \int \frac{x\,dx}{\sqrt{x^2-4}} = \int \frac{2\sec\theta(2\sec\theta\tan\theta\,d\theta)}{2\tan\theta} = 2\int \sec^2\theta\,d\theta = 2\tan\theta + C.$$

Since $x = 2\sec\theta$, we construct a right triangle with $\sec\theta = \frac{x}{2}$:



From this triangle we see that

$$I_1 = 2\left(\frac{\sqrt{x^2-4}}{2}\right) + C = \sqrt{x^2-4} + C.$$

12. Is the substitution $u = x^2 - 4$ effective for evaluating the integral $\int \frac{x^2\,dx}{\sqrt{x^2-4}}$? If not, evaluate using trigonometric substitution.

SOLUTION If $u = x^2 - 4$, then $du = 2x\,dx$, $x^2 = u + 4$, $dx = du/2x = du/2\sqrt{u+4}$, and

$$I = \int \frac{x^2\,dx}{\sqrt{x^2-4}} = \int \frac{(u+4)}{\sqrt{u}}\left(\frac{du}{2\sqrt{u+4}}\right) = \frac{1}{2}\int \frac{u+4}{\sqrt{u^2+4u}}\,du$$

This substitution is clearly not effective for evaluating this integral.

Instead, use the trigonometric substitution $x = 2\sec\theta$. Then $dx = 2\sec\theta\tan\theta$,

$$\sqrt{x^2-4} = \sqrt{4\sec^2\theta - 4} = 2\tan\theta,$$

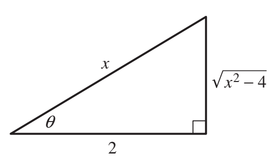
and we have

$$I = \int \frac{x^2\,dx}{\sqrt{x^2-4}} = \int \frac{4\sec^2\theta(2\sec\theta\tan\theta\,d\theta)}{2\tan\theta} = 4\int \sec^3\theta\,d\theta.$$

Now use the reduction formula for $\int \sec^m x\,dx$ from Section 8.7.2:

$$4\int \sec^3\theta\,d\theta = 4\left[\frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\int \sec\theta\,d\theta\right] = 2\tan\theta\sec\theta + 2\big[\ln|\sec\theta + \tan\theta|\big] + C.$$

Since $x = 2\sec\theta$, we construct a right triangle with $\sec\theta = \frac{x}{2}$:



From this triangle we see that $\tan\theta = \frac{1}{2}\sqrt{x^2-4}$. Therefore

$$I = 2\left(\frac{1}{2}\sqrt{x^2-4}\right)\left(\frac{x}{2}\right) + 2\ln\left|\frac{x}{2} + \frac{1}{2}\sqrt{x^2-4}\right| + C = \frac{1}{2}x\sqrt{x^2-4} + 2\ln\left|\frac{1}{2}\left(x + \sqrt{x^2-4}\right)\right| + C.$$

Finally, since

$$\ln\left|\frac{1}{2}(x + \sqrt{x^2-4})\right| = \ln\left(\frac{1}{2}\right) + \ln|x + \sqrt{x^2-4}|,$$

and $\ln(\frac{1}{2})$ is a constant, we can "absorb" this constant into the constant of integration, so that

$$I = \frac{1}{2}x\sqrt{x^2-4} + 2\ln|x + \sqrt{x^2-4}| + C.$$

13. Evaluate using the substitution $u = 1 - x^2$ or trigonometric substitution.

(a) $\displaystyle\int \frac{x}{\sqrt{1-x^2}}\,dx$ **(b)** $\displaystyle\int x^2\sqrt{1-x^2}\,dx$

(c) $\displaystyle\int x^3\sqrt{1-x^2}\,dx$ **(d)** $\displaystyle\int \frac{x^4}{\sqrt{1-x^2}}\,dx$

SOLUTION

(a) Let $u = 1 - x^2$. Then $du = -2x\,dx$, and we have

$$\int \frac{x}{\sqrt{1-x^2}}\,dx = -\frac{1}{2}\int \frac{-2x\,dx}{\sqrt{1-x^2}} = -\frac{1}{2}\int \frac{du}{u^{1/2}}.$$

(b) Let $x = \sin\theta$. Then $dx = \cos\theta\,d\theta$, $1 - x^2 = \cos^2\theta$, and so

$$\int x^2\sqrt{1-x^2}\,dx = \int \sin^2\theta(\cos\theta)\cos\theta\,d\theta = \int \sin^2\theta\cos^2\theta\,d\theta.$$

(c) Use the substitution $u = 1 - x^2$. Then $du = -2x\,dx$, $x^2 = 1 - u$, and so

$$\int x^3\sqrt{1-x^2}\,dx = -\frac{1}{2}\int x^2\sqrt{1-x^2}(-2x\,dx) = -\frac{1}{2}\int (1-u)u^{1/2}\,du.$$

(d) Let $x = \sin\theta$. Then $dx = \cos\theta\,d\theta$, $1 - x^2 = \cos^2\theta$, and so

$$\int \frac{x^4}{\sqrt{1-x^2}}\,dx = \int \frac{\sin^4\theta}{\cos\theta}\cos\theta\,d\theta = \int \sin^4\theta\,d\theta.$$

14. Evaluate:

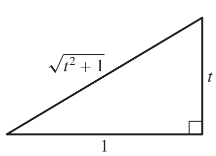
(a) $\displaystyle\int \frac{dt}{(t^2+1)^{3/2}}$ **(b)** $\displaystyle\int \frac{t\,dt}{(t^2+1)^{3/2}}$

SOLUTION

(a) Use the substitution $t = \tan\theta$, so that $dt = \sec^2\theta\,d\theta$. Then

$$\int \frac{dt}{(t^2+1)^{3/2}} = \int \frac{\sec^2\theta}{(\tan^2\theta+1)^{3/2}}\,d\theta = \int \frac{\sec^2\theta}{(\sec^2\theta)^{3/2}}\,d\theta = \int \cos\theta\,d\theta = \sin\theta + C$$

Since $t = \tan\theta$, we construct a right triangle with $\tan\theta = t$:



From this we see that $\sin\theta = \frac{t}{\sqrt{t^2+1}}$, so that the integral is

$$\int \frac{dt}{(t^2+1)^{3/2}} = \sin\theta + C = \frac{t}{\sqrt{t^2+1}} + C$$

(b) Use the substitution $u = t^2 + 1$, $du = 2t\,dt$; then

$$\int \frac{t\,dt}{(t^2+1)^{3/2}} = \frac{1}{2}\int u^{-3/2}\,du = -u^{-1/2} + C = -\frac{1}{\sqrt{t^2+1}} + C$$

In Exercises 15–32, evaluate using trigonometric substitution. Refer to the table of trigonometric integrals as necessary.

15. $\displaystyle\int \frac{x^2\,dx}{\sqrt{9-x^2}}$

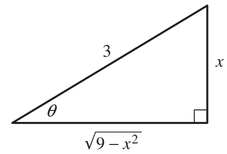
SOLUTION Let $x = 3\sin\theta$. Then $dx = 3\cos\theta\,d\theta$,

$$9 - x^2 = 9 - 9\sin^2\theta = 9(1 - \sin^2\theta) = 9\cos^2\theta,$$

and

$$I = \int \frac{x^2\,dx}{\sqrt{9-x^2}} = \int \frac{9\sin^2\theta(3\cos\theta\,d\theta)}{3\cos\theta} = 9\int \sin^2\theta\,d\theta = 9\left[\frac{1}{2}\theta - \frac{1}{2}\sin\theta\cos\theta\right] + C.$$

Since $x = 3\sin\theta$, we construct a right triangle with $\sin\theta = \frac{x}{3}$:



From this we see that $\cos\theta = \sqrt{9-x^2}/3$, and so

$$I = \frac{9}{2}\sin^{-1}\left(\frac{x}{3}\right) - \frac{9}{2}\left(\frac{x}{3}\right)\left(\frac{\sqrt{9-x^2}}{3}\right) + C = \frac{9}{2}\sin^{-1}\left(\frac{x}{3}\right) - \frac{1}{2}x\sqrt{9-x^2} + C.$$

16. $\displaystyle\int \frac{dt}{(16-t^2)^{3/2}}$

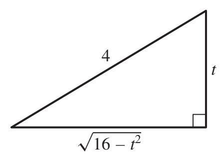
SOLUTION Let $t = 4\sin\theta$. Then $dt = 4\cos\theta\,d\theta$, and

$$(16-t^2)^{3/2} = (16-16\sin^2\theta)^{3/2} = (16\cos^2\theta)^{3/2} = (4\cos\theta)^3 = 64\cos^3\theta$$

so that

$$I = \int \frac{dt}{(16-t^2)^{3/2}} = \int \frac{4\cos\theta}{64\cos^3\theta}\,d\theta = \frac{1}{16}\int \sec^2\theta\,d\theta + C = \frac{1}{16}\tan\theta + C$$

Since $t = 4\sin\theta$, we construct a right triangle with $\sin\theta = \frac{t}{4}$:



From this, we see that $\tan\theta = \frac{t}{\sqrt{16-t^2}}$, so that

$$I = \frac{1}{16}\tan\theta + C = \frac{t}{16\sqrt{16-t^2}} + C$$

17. $\displaystyle\int \frac{dx}{x\sqrt{x^2+16}}$

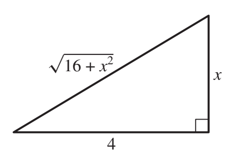
SOLUTION Use the substitution $x = 4\tan\theta$, so that $dx = 4\sec^2\theta\,d\theta$. Then

$$x\sqrt{x^2+16} = 4\tan\theta\sqrt{(4\tan\theta)^2+16} = 4\tan\theta\sqrt{16(\tan^2\theta+1)} = 16\tan\theta\sec\theta$$

so that

$$I = \int \frac{dx}{x\sqrt{x^2+16}} = \int \frac{4\sec^2\theta}{16\tan\theta\sec\theta}\,d\theta = \frac{1}{4}\int \frac{\sec\theta}{\tan\theta}\,d\theta = \frac{1}{4}\int \csc\theta\,d\theta = -\frac{1}{4}\ln|\csc x + \cot x| + C$$

Since $x = 4\tan\theta$, we construct a right triangle with $\tan\theta = \frac{x}{4}$:



From this, we see that $\csc x = \frac{\sqrt{x^2+16}}{x}$ and $\cot x = \frac{4}{x}$, so that

$$I = -\frac{1}{4}\ln|\csc x + \cot x| + C = -\frac{1}{4}\ln\left|\frac{\sqrt{x^2+16}}{x} + \frac{4}{x}\right| + C = -\frac{1}{4}\ln\left|\frac{4+\sqrt{x^2+16}}{x}\right| + C$$

18. $\int \sqrt{12+4t^2}\,dt$

SOLUTION First simplify the integral:

$$I = \int \sqrt{12+4t^2}\,dt = 2\int \sqrt{3+t^2}\,dt$$

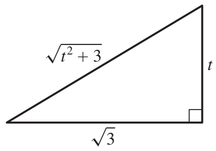
Now let $t = \sqrt{3}\tan\theta$. Then $dt = \sqrt{3}\sec^2\theta\,d\theta$,

$$3+t^2 = 3+3\tan^2\theta = 3(1+\tan^2\theta) = 3\sec^2\theta,$$

and

$$I = 2\int \sqrt{3\sec^2\theta}\left(\sqrt{3}\sec^2\theta\,d\theta\right) = 6\int \sec^3\theta\,d\theta = 6\left[\frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\int \sec\theta\,d\theta\right]$$
$$= 3\tan\theta\sec\theta + 3\ln|\sec\theta+\tan\theta| + C.$$

Since $t = \sqrt{3}\tan\theta$, we construct a right triangle with $\tan\theta = \frac{t}{\sqrt{3}}$:



From this we see that $\sec\theta = \sqrt{t^2+3}/\sqrt{3}$. Therefore,

$$I = 3\left(\frac{t}{\sqrt{3}}\right)\left(\frac{\sqrt{t^2+3}}{\sqrt{3}}\right) + 3\ln\left|\frac{\sqrt{t^2+3}}{\sqrt{3}} + \frac{t}{\sqrt{3}}\right| + C_1 = t\sqrt{t^2+3} + 3\ln\left|\sqrt{t^2+3}+t\right| + 3\ln\left(\frac{1}{\sqrt{3}}\right) + C_1$$
$$= t\sqrt{t^2+3} + 3\ln\left|\sqrt{t^2+3}+t\right| + C,$$

where $C = 3\ln(\frac{1}{\sqrt{3}}) + C_1$.

19. $\int \frac{dx}{\sqrt{x^2-9}}$

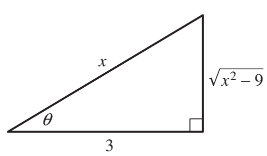
SOLUTION Let $x = 3\sec\theta$. Then $dx = 3\sec\theta\tan\theta\,d\theta$,

$$x^2-9 = 9\sec^2\theta - 9 = 9(\sec^2\theta - 1) = 9\tan^2\theta,$$

and

$$I = \int \frac{dx}{\sqrt{x^2-9}} = \int \frac{3\sec\theta\tan\theta\,d\theta}{3\tan\theta} = \int \sec\theta\,d\theta = \ln|\sec\theta+\tan\theta| + C.$$

Since $x = 3\sec\theta$, we construct a right triangle with $\sec\theta = \frac{x}{3}$:



From this we see that $\tan\theta = \sqrt{x^2-9}/3$, and so

$$I = \ln\left|\frac{x}{3} + \frac{\sqrt{x^2-9}}{3}\right| + C_1 = \ln\left|x+\sqrt{x^2-9}\right| + \ln\left(\frac{1}{3}\right) + C_1 = \ln\left|x+\sqrt{x^2-9}\right| + C,$$

where $C = \ln\left(\frac{1}{3}\right) + C_1$.

20. $\displaystyle\int \frac{dt}{t^2\sqrt{t^2-25}}$

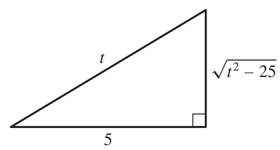
SOLUTION Let $t = 5\sec\theta$. Then $dt = 5\sec\theta\tan\theta\,d\theta$,

$$t^2 - 25 = 25\sec^2\theta - 25 = 25(\sec^2\theta - 1) = 25\tan^2\theta,$$

and

$$I = \int \frac{dt}{t^2\sqrt{t^2-25}} = \int \frac{5\sec\theta\tan\theta\,d\theta}{(25\sec^2\theta)(5\tan\theta)} = \frac{1}{25}\int \frac{d\theta}{\sec\theta} = \frac{1}{25}\int \cos\theta\,d\theta = \frac{1}{25}\sin\theta + C.$$

Since $t = 5\sec\theta$, we construct a right triangle with $\sec\theta = \frac{t}{5}$:



From this we see that $\sin\theta = \sqrt{t^2-25}/t$, and so

$$I = \frac{1}{25}\left(\frac{\sqrt{t^2-25}}{t}\right) + C = \frac{\sqrt{t^2-25}}{25t} + C.$$

21. $\displaystyle\int \frac{dy}{y^2\sqrt{5-y^2}}$

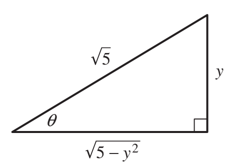
SOLUTION Let $y = \sqrt{5}\sin\theta$. Then $dy = \sqrt{5}\cos\theta\,d\theta$,

$$5 - y^2 = 5 - 5\sin^2\theta = 5(1-\sin^2\theta) = 5\cos^2\theta,$$

and

$$I = \int \frac{dy}{y^2\sqrt{5-y^2}} = \int \frac{\sqrt{5}\cos\theta\,d\theta}{(5\sin^2\theta)(\sqrt{5}\cos\theta)} = \frac{1}{5}\int \frac{d\theta}{\sin^2\theta} = \frac{1}{5}\int \csc^2\theta\,d\theta = \frac{1}{5}(-\cot\theta) + C.$$

Since $y = \sqrt{5}\sin\theta$, we construct a right triangle with $\sin\theta = \frac{y}{\sqrt{5}}$:



From this we see that $\cot\theta = \sqrt{5-y^2}/y$, which gives us

$$I = \frac{1}{5}\left(\frac{-\sqrt{5-y^2}}{y}\right) + C = -\frac{\sqrt{5-y^2}}{5y} + C.$$

22. $\displaystyle\int x^3\sqrt{9-x^2}\,dx$

SOLUTION Let $x = 3\sin\theta$. Then $dx = 3\cos\theta\,d\theta$,

$$9 - x^2 = 9 - 9\sin^2\theta = 9(1-\sin^2\theta) = 9\cos^2\theta,$$

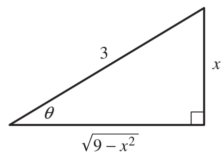
and

$$\begin{aligned} I &= \int x^3\sqrt{9-x^2}\,dx = \int (27\sin^3\theta)(3\cos\theta)(3\cos\theta\,d\theta) \\ &= 243\int \sin^3\theta\cos^2\theta\,d\theta = 243\int (1-\cos^2\theta)\cos^2\theta\sin\theta\,d\theta \\ &= 243\left[\int \cos^2\theta\sin\theta\,d\theta - \int \cos^4\theta\sin\theta\,d\theta\right]. \end{aligned}$$

Now use substitution, with $u = \cos\theta$ and $du = -\sin\theta\,d\theta$ for both integrals:

$$I = 243\left[-\frac{1}{3}\cos^3\theta + \frac{1}{5}\cos^5\theta\right] + C.$$

Since $x = 3\sin\theta$, we construct a right triangle with $\sin\theta = \frac{x}{3}$:



From this we see that $\cos\theta = \sqrt{9-x^2}/3$. Thus

$$I = 243\left[-\frac{1}{3}\left(\frac{\sqrt{9-x^2}}{3}\right)^3 + \frac{1}{5}\left(\frac{\sqrt{9-x^2}}{3}\right)^5\right] + C = -3(9-x^2)^{3/2} + \frac{1}{5}(9-x^2)^{5/2} + C.$$

Alternately, let $u = 9 - x^2$. Then

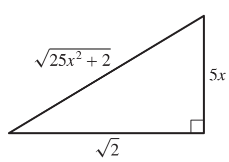
$$I = \int x^3\sqrt{9-x^2}\,dx = -\frac{1}{2}\int (9-u)\sqrt{u}\,du = -\frac{1}{2}\left(6u^{3/2} - \frac{2}{5}u^{5/2}\right) + C$$
$$= \frac{1}{5}u^{5/2} - 3u^{3/2} + C = \frac{1}{5}(9-x^2)^{5/2} - 3(9-x^2)^{3/2} + C.$$

23. $\displaystyle\int \frac{dx}{\sqrt{25x^2+2}}$

SOLUTION Let $x = \frac{\sqrt{2}}{5}\tan\theta$. Then $dx = \frac{\sqrt{2}}{5}\sec^2\theta\,d\theta$, $25x^2 + 2 = 2\tan^2\theta + 2 = 2\sec^2\theta$, and

$$I = \int \frac{dx}{\sqrt{25x^2+2}} = \int \frac{\frac{\sqrt{2}}{5}\sec^2\theta\,d\theta}{\sqrt{2}\sec\theta} = \frac{1}{5}\int \sec\theta\,d\theta = \frac{1}{5}\ln|\sec\theta + \tan\theta| + C.$$

Since $x = \frac{\sqrt{2}}{5}\tan\theta$, we construct a right triangle with $\tan\theta = \frac{5x}{\sqrt{2}}$:



From this we see that $\sec\theta = \frac{1}{\sqrt{2}}\sqrt{25x^2+2}$, so that

$$I = \frac{1}{5}\ln|\sec\theta + \tan\theta| + C = \frac{1}{5}\ln\left|\frac{\sqrt{25x^2+2}}{\sqrt{2}} + \frac{5x}{\sqrt{2}}\right| + C$$
$$= \frac{1}{5}\ln\left|\frac{5x + \sqrt{25x^2+2}}{\sqrt{2}}\right| + C = \frac{1}{5}\ln\left|5x + \sqrt{25x^2+2}\right| - \frac{1}{5}\ln\sqrt{2} + C$$
$$= \frac{1}{5}\ln\left|5x + \sqrt{25x^2+2}\right| + C$$

24. $\displaystyle\int \frac{dt}{(9t^2+4)^2}$

SOLUTION First factor out the t^2-coefficient:

$$I = \int \frac{dt}{(9t^2+4)^2} = \int \frac{dt}{\left[9\left(t^2+\frac{4}{9}\right)\right]^2} = \frac{1}{81}\int \frac{dt}{\left(t^2+\frac{4}{9}\right)^2}.$$

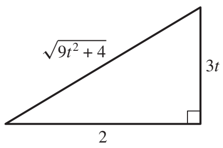
Now let $t = \frac{2}{3}\tan\theta$. Then $dt = \frac{2}{3}\sec^2\theta\,d\theta$,

$$t^2 + \frac{4}{9} = \frac{4}{9}\tan^2\theta + \frac{4}{9} = \frac{4}{9}(\tan^2\theta + 1) = \frac{4}{9}\sec^2\theta,$$

and

$$I = \frac{1}{81}\int \frac{\frac{2}{3}\sec^2 d\theta}{\frac{16}{81}\sec^4\theta\, d\theta} = \frac{1}{24}\int \cos^2\theta\, d\theta = \frac{1}{24}\left[\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right] + C.$$

Since $t = \frac{2}{3}\tan\theta$, we construct a right triangle with $\tan\theta = \frac{3t}{2}$:



From this we see that $\sin\theta = 3t/\sqrt{9t^2+4}$ and $\cos\theta = 2/\sqrt{9t^2+4}$. Thus

$$I = \frac{1}{48}\tan^{-1}\left(\frac{3t}{2}\right) + \frac{1}{48}\left(\frac{3t}{\sqrt{9t^2+4}}\right)\left(\frac{2}{\sqrt{9t^2+4}}\right) + C = \frac{1}{48}\tan^{-1}\left(\frac{3t}{2}\right) + \frac{t}{8(9t^2+4)} + C.$$

25. $\displaystyle\int \frac{dz}{z^3\sqrt{z^2-4}}$

SOLUTION Let $z = 2\sec\theta$. Then $dz = 2\sec\theta\tan\theta\, d\theta$,

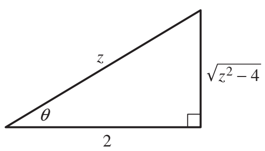
$$z^2 - 4 = 4\sec^2\theta - 4 = 4(\sec^2\theta - 1) = 4\tan^2\theta,$$

and

$$I = \int \frac{dz}{z^3\sqrt{z^2-4}} = \int \frac{2\sec\theta\tan\theta\, d\theta}{(8\sec^3\theta)(2\tan\theta)} = \frac{1}{8}\int \frac{d\theta}{\sec^2\theta} = \frac{1}{8}\int \cos^2\theta\, d\theta$$

$$= \frac{1}{8}\left[\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right] + C = \frac{1}{16}\theta + \frac{1}{16}\sin\theta\cos\theta + C.$$

Since $z = 2\sec\theta$, we construct a right triangle with $\sec\theta = \frac{z}{2}$:



From this we see that $\sin\theta = \sqrt{z^2-4}/z$ and $\cos\theta = 2/z$. Then

$$I = \frac{1}{16}\sec^{-1}\left(\frac{z}{2}\right) + \frac{1}{16}\left(\frac{\sqrt{z^2-4}}{z}\right)\left(\frac{2}{z}\right) + C = \frac{1}{16}\sec^{-1}\left(\frac{z}{2}\right) + \frac{\sqrt{z^2-4}}{8z^2} + C.$$

26. $\displaystyle\int \frac{dy}{\sqrt{y^2-9}}$

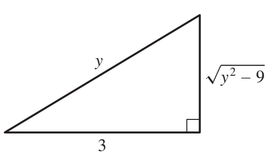
SOLUTION Let $y = 3\sec\theta$, so that $dy = 3\sec\theta\tan\theta\, d\theta$ and

$$y^2 - 9 = (3\sec\theta)^2 - 9 = 9(\sec^2\theta - 1) = 9\tan^2\theta$$

so that

$$I = \int \frac{dy}{\sqrt{y^2-9}} = \int \frac{3\sec\theta\tan\theta}{3\tan\theta}\, d\theta = \int \sec\theta\, d\theta = \ln|\sec\theta + \tan\theta| + C$$

Since $y = 3\sec\theta$, we construct a right triangle with $\sec\theta = \frac{y}{3}$:



From this, we see that $\tan\theta = \frac{1}{3}\sqrt{y^2-9}$, so that

$$I = \ln|\sec\theta + \tan\theta| + C = \ln\left|\frac{y}{3} + \frac{\sqrt{y^2-9}}{3}\right| + C$$
$$= \ln\left|\frac{y+\sqrt{y^2-9}}{3}\right| + C = \ln\left|y+\sqrt{y^2-9}\right| - \ln 3 + C = \ln\left|y+\sqrt{y^2-9}\right| + C$$

27. $\displaystyle\int \frac{x^2\,dx}{(6x^2-49)^{1/2}}$

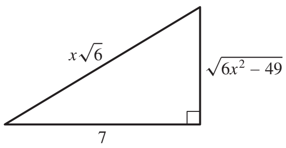
SOLUTION Let $x = \frac{7}{\sqrt{6}}\sec\theta$; then $dx = \frac{7}{\sqrt{6}}\sec\theta\tan\theta\,d\theta$, and

$$6x^2 - 49 = 6\left(\frac{7}{\sqrt{6}}\sec\theta\right)^2 - 49 = 49(\sec^2\theta - 1) = 49\tan^2\theta$$

so that

$$I = \int \frac{x^2\,dx}{(6x^2-49)^{1/2}} = \int \frac{\frac{49}{6}\sec^2\theta(\frac{7}{\sqrt{6}}\sec\theta\tan\theta)}{7\tan\theta}\,d\theta$$
$$= \frac{49}{6\sqrt{6}}\int \sec^3\theta\,d\theta = \frac{49}{6\sqrt{6}}\left(\frac{1}{2}\tan\theta\sec\theta + \frac{1}{2}\int\sec\theta\,d\theta\right)$$
$$= \frac{49}{12\sqrt{6}}(\tan\theta\sec\theta + \ln|\sec\theta+\tan\theta|) + C$$

Since $x = \frac{7}{\sqrt{6}}\sec\theta$, we construct a right triangle with $\sec\theta = \frac{x\sqrt{6}}{7}$:



From this we see that $\tan\theta = \frac{1}{7}\sqrt{6x^2-49}$, so that

$$I = \frac{49}{12\sqrt{6}}\left(\frac{x\sqrt{6}\sqrt{6x^2-49}}{49} + \ln\left|\frac{x\sqrt{6}+\sqrt{6x^2-49}}{7}\right|\right) + C$$
$$= \frac{49}{12\sqrt{6}}\left(\frac{x\sqrt{6}\sqrt{6x^2-49}}{49} + \ln\left|x\sqrt{6}+\sqrt{6x^2-49}\right| - \ln 7\right) + C$$
$$= \frac{1}{12\sqrt{6}}\left(x\sqrt{6}\sqrt{6x^2-49} + 49\ln\left|x\sqrt{6}+\sqrt{6x^2-49}\right|\right) + C$$

28. $\displaystyle\int \frac{dx}{(x^2-4)^2}$

SOLUTION Let $x = 2\sec\theta$. Then $dx = 2\sec\theta\tan\theta\,d\theta$,

$$x^2 - 4 = 4\sec^2\theta - 4 = 4(\sec^2\theta - 1) = 4\tan^2\theta,$$

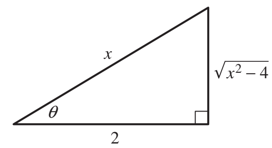
and

$$I = \int \frac{dx}{(x^2-4)^2} = \int \frac{2\sec\theta\tan\theta\,d\theta}{16\tan^4\theta} = \frac{1}{8}\int\frac{\sec\theta\,d\theta}{\tan^3\theta}$$
$$= \frac{1}{8}\int\frac{\cos^2\theta}{\sin^3\theta}\,d\theta = \frac{1}{8}\int\frac{1-\sin^2\theta}{\sin^3\theta}\,d\theta = \frac{1}{8}\int\csc^3\theta\,d\theta - \frac{1}{8}\int\csc\theta\,d\theta.$$

Now use the reduction formula for $\displaystyle\int\csc^3\theta\,d\theta$:

$$I = \frac{1}{8}\left[-\frac{\cot\theta\csc\theta}{2} + \frac{1}{2}\int\csc\theta\,d\theta\right] - \frac{1}{8}\int\csc\theta\,d\theta = -\frac{1}{16}\cot\theta\csc\theta - \frac{1}{16}\int\csc\theta\,d\theta$$
$$= -\frac{1}{16}\cot\theta\csc\theta - \frac{1}{16}\ln|\csc\theta - \cot\theta| + C.$$

Since $x = 2\sec\theta$, we construct a right triangle with $\sec\theta = \frac{x}{2}$:



From this we see that $\cot\theta = 2/\sqrt{x^2-4}$ and $\csc\theta = x/\sqrt{x^2-4}$. Thus

$$I = -\frac{1}{16}\left(\frac{2}{\sqrt{x^2-4}}\right)\left(\frac{x}{\sqrt{x^2-4}}\right) - \frac{1}{16}\ln\left|\frac{x}{\sqrt{x^2-4}} - \frac{2}{\sqrt{x^2-4}}\right| + C$$
$$= \frac{-x}{8(x^2-4)} - \frac{1}{16}\ln\left|\frac{x-2}{\sqrt{x^2-4}}\right| + C.$$

29. $\displaystyle\int \frac{dt}{(t^2+9)^2}$

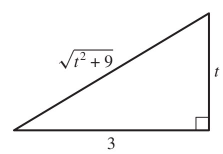
SOLUTION Let $t = 3\tan\theta$. Then $dt = 3\sec^2\theta\, d\theta$,

$$t^2 + 9 = 9\tan^2\theta + 9 = 9(\tan^2\theta + 1) = 9\sec^2\theta,$$

and

$$I = \int \frac{dt}{(t^2+9)^2} = \int \frac{3\sec^2\theta\, d\theta}{81\sec^4\theta} = \frac{1}{27}\int \cos^2\theta\, d\theta = \frac{1}{27}\left[\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right] + C.$$

Since $t = 3\tan\theta$, we construct a right triangle with $\tan\theta = \frac{t}{3}$:



From this we see that $\sin\theta = t/\sqrt{t^2+9}$ and $\cos\theta = 3/\sqrt{t^2+9}$. Thus

$$I = \frac{1}{54}\tan^{-1}\left(\frac{t}{3}\right) + \frac{1}{54}\left(\frac{t}{\sqrt{t^2+9}}\right)\left(\frac{3}{\sqrt{t^2+9}}\right) + C = \frac{1}{54}\tan^{-1}\left(\frac{t}{3}\right) + \frac{t}{18(t^2+9)} + C.$$

30. $\displaystyle\int \frac{dx}{(x^2+1)^3}$

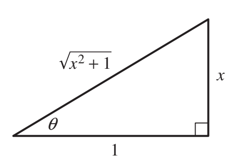
SOLUTION Let $x = \tan\theta$. Then $dx = \sec^2\theta\, d\theta$, $x^2 + 1 = \tan^2\theta + 1 = \sec^2\theta$, and

$$I = \int \frac{dx}{(x^2+1)^3} = \int \frac{\sec^2\theta\, d\theta}{\sec^6\theta} = \int \cos^4\theta\, d\theta.$$

Using the reduction formula for $\displaystyle\int \cos^4\theta\, d\theta$, we get

$$I = \frac{\cos^3\theta\sin\theta}{4} + \frac{3}{4}\int \cos^2\theta\, d\theta = \frac{1}{4}\cos^3\theta\sin\theta + \frac{3}{4}\left(\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right) + C.$$

Since $x = \tan\theta$, we construct the following right triangle:



From this we see that $\sin\theta = x/\sqrt{x^2+1}$ and $\cos\theta = 1/\sqrt{x^2+1}$. Thus

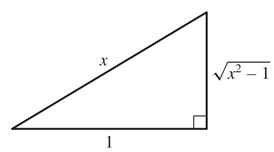
$$I = \frac{1}{4}\left(\frac{1}{\sqrt{x^2+1}}\right)^3\left(\frac{x}{\sqrt{x^2+1}}\right) + \frac{3}{8}\tan^{-1}x + \frac{3}{8}\left(\frac{x}{\sqrt{x^2+1}}\right)\left(\frac{1}{\sqrt{x^2+1}}\right) + C$$
$$= \frac{x}{4(x^2+1)^2} + \frac{3x}{8(x^2+1)} + \frac{3}{8}\tan^{-1}x + C.$$

31. $\displaystyle\int \frac{x^2\,dx}{(x^2-1)^{3/2}}$

SOLUTION Let $x = \sec\theta$. Then $dx = \sec\theta\tan\theta\,d\theta$, and $x^2 - 1 = \sec^2\theta - 1 = \tan^2\theta$. Thus

$$\begin{aligned} I &= \int \frac{x^2}{(x^2-1)^{3/2}}\,dx = \int \frac{\sec^2\theta}{(\tan^2\theta)^{3/2}}\sec\theta\tan\theta\,d\theta \\ &= \int \frac{\sec^2\theta\sec\theta\tan\theta}{\tan^3\theta}\,d\theta = \int \frac{\sec^3\theta}{\tan^2\theta}\,d\theta \\ &= \int \frac{\sec^2\theta}{\tan^2\theta}\sec\theta\,d\theta = \int \csc^2\theta\sec\theta\,d\theta = \int (1+\cot^2\theta)\sec\theta\,d\theta \\ &= \int \sec\theta + \cot\theta\csc\theta\,d\theta = \ln|\sec\theta + \tan\theta| - \csc\theta + C \end{aligned}$$

Since $x = \sec\theta$, we construct the following right triangle:



From this we see that $\tan\theta = \sqrt{x^2-1}$ and that $\csc\theta = \frac{x}{\sqrt{x^2-1}}$, so that

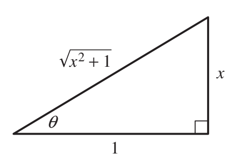
$$I = \ln\left|x + \sqrt{x^2-1}\right| - \frac{x}{\sqrt{x^2-1}} + C$$

32. $\displaystyle\int \frac{x^2\,dx}{(x^2+1)^{3/2}}$

SOLUTION Let $x = \tan\theta$. Then $dx = \sec^2\theta\,d\theta$, $x^2 + 1 = \tan^2\theta + 1 = \sec^2\theta$, and

$$\begin{aligned} I &= \int \frac{x^2\,dx}{(x^2+1)^{3/2}} = \int \frac{\tan^2\theta(\sec^2\theta\,d\theta)}{(\sec^2\theta)^{3/2}} = \int \frac{\tan^2\theta}{\sec\theta}\,d\theta = \int \frac{\sin^2\theta}{\cos\theta}\,d\theta = \int \frac{1-\cos^2\theta}{\cos\theta}\,d\theta \\ &= \int \frac{1}{\cos\theta}\,d\theta - \int \frac{\cos^2\theta}{\cos\theta}\,d\theta = \int \sec\theta\,d\theta - \int \cos\theta\,d\theta = \ln|\sec\theta + \tan\theta| - \sin\theta + C. \end{aligned}$$

Since $x = \tan\theta$, we construct the following right triangle:



From this we see that $\sec\theta = \sqrt{x^2+1}$ and $\sin\theta = x/\sqrt{x^2+1}$. Thus

$$I = \ln\left|\sqrt{x^2+1} + x\right| - \frac{x}{\sqrt{x^2+1}} + C.$$

33. Prove for $a > 0$:

$$\int \frac{dx}{x^2+a} = \frac{1}{\sqrt{a}}\tan^{-1}\frac{x}{\sqrt{a}} + C$$

SOLUTION Let $x = \sqrt{a}\,u$. Then, $x^2 = au^2$, $dx = \sqrt{a}\,du$, and

$$\int \frac{dx}{x^2+a} = \frac{1}{\sqrt{a}}\int \frac{du}{u^2+1} = \frac{1}{\sqrt{a}}\tan^{-1}u + C = \frac{1}{\sqrt{a}}\tan^{-1}\left(\frac{x}{\sqrt{a}}\right) + C.$$

34. Prove for $a > 0$:

$$\int \frac{dx}{(x^2+a)^2} = \frac{1}{2a}\left(\frac{x}{x^2+a} + \frac{1}{\sqrt{a}}\tan^{-1}\frac{x}{\sqrt{a}}\right) + C$$

SOLUTION Let $x = \sqrt{a}\,u$. Then, $x^2 = au^2$, $dx = \sqrt{a}\,du$, and

$$\int \frac{dx}{(x^2+a)^2} = \frac{1}{a^{3/2}} \int \frac{du}{(u^2+1)^2}.$$

Now, let $u = \tan\theta$. Then $du = \sec^2\theta\,d\theta$, and

$$\begin{aligned}\int \frac{dx}{(x^2+a)^2} &= \frac{1}{a^{3/2}} \int \frac{\sec^2\theta}{(\sec^2\theta)^2}\,d\theta = \frac{1}{a^{3/2}} \int \cos^2\theta\,d\theta = \frac{1}{a^{3/2}}\left(\frac{1}{2}\sin\theta\cos\theta + \frac{1}{2}\theta\right) + C\\ &= \frac{1}{2a^{3/2}}\left(\frac{u}{1+u^2} + \tan^{-1} u\right) + C = \frac{1}{2a^{3/2}}\left(\frac{x/\sqrt{a}}{1+(x/\sqrt{a})^2} + \tan^{-1}\left(\frac{x}{\sqrt{a}}\right)\right) + C\\ &= \frac{1}{2a}\left(\frac{x}{x^2+a} + \frac{1}{\sqrt{a}}\tan^{-1}\left(\frac{x}{\sqrt{a}}\right)\right) + C.\end{aligned}$$

35. Let $I = \int \frac{dx}{\sqrt{x^2-4x+8}}$.

(a) Complete the square to show that $x^2 - 4x + 8 = (x-2)^2 + 4$.

(b) Use the substitution $u = x - 2$ to show that $I = \int \frac{du}{\sqrt{u^2+2^2}}$. Evaluate the u-integral.

(c) Show that $I = \ln\left|\sqrt{(x-2)^2+4} + x - 2\right| + C$.

SOLUTION

(a) Completing the square, we get

$$x^2 - 4x + 8 = x^2 - 4x + 4 + 4 = (x-2)^2 + 4.$$

(b) Let $u = x - 2$. Then $du = dx$, and

$$I = \int \frac{dx}{\sqrt{x^2-4x+8}} = \int \frac{dx}{\sqrt{(x-2)^2+4}} = \int \frac{du}{\sqrt{u^2+4}}.$$

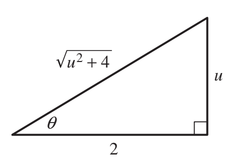
Now let $u = 2\tan\theta$. Then $du = 2\sec^2\theta\,d\theta$,

$$u^2 + 4 = 4\tan^2\theta + 4 = 4(\tan^2\theta + 1) = 4\sec^2\theta,$$

and

$$I = \int \frac{2\sec^2\theta\,d\theta}{2\sec\theta} = \int \sec\theta\,d\theta = \ln|\sec\theta + \tan\theta| + C.$$

Since $u = 2\tan\theta$, we construct a right triangle with $\tan\theta = \frac{u}{2}$:



From this we see that $\sec\theta = \sqrt{u^2+4}/2$. Thus

$$I = \ln\left|\frac{\sqrt{u^2+4}}{2} + \frac{u}{2}\right| + C_1 = \ln\left|\sqrt{u^2+4} + u\right| + \left(\ln\frac{1}{2} + C_1\right) = \ln\left|\sqrt{u^2+4} + u\right| + C.$$

(c) Substitute back for x in the result of part (b):

$$I = \ln\left|\sqrt{(x-2)^2+4} + x - 2\right| + C.$$

36. Evaluate $\int \frac{dx}{\sqrt{12x - x^2}}$. First complete the square to write $12x - x^2 = 36 - (x-6)^2$.

SOLUTION First complete the square:

$$12x - x^2 = -\left(x^2 - 12x + 36 - 36\right) = -\left(x^2 - 12x + 36\right) + 36 = 36 - (x-6)^2.$$

Now let $u = x - 6$, and $du = dx$. This gives us

$$I = \int \frac{dx}{\sqrt{12x - x^2}} = \int \frac{dx}{\sqrt{36 - (x-6)^2}} = \int \frac{du}{\sqrt{36 - u^2}}.$$

Next, let $u = 6\sin\theta$. Then $du = 6\cos\theta\, d\theta$,

$$36 - u^2 = 36 - 36\sin^2\theta = 36(1 - \sin^2\theta) = 36\cos^2\theta,$$

and

$$I = \int \frac{6\cos\theta\, d\theta}{6\cos\theta} = \int d\theta = \theta + C.$$

Substituting back, we find

$$I = \sin^{-1}\left(\frac{u}{6}\right) + C = \sin^{-1}\left(\frac{x-6}{6}\right) + C.$$

In Exercises 37–42, evaluate the integral by completing the square and using trigonometric substitution.

37. $\displaystyle\int \frac{dx}{\sqrt{x^2 + 4x + 13}}$

SOLUTION First complete the square:

$$x^2 + 4x + 13 = x^2 + 4x + 4 + 9 = (x+2)^2 + 9.$$

Let $u = x + 2$. Then $du = dx$, and

$$I = \int \frac{dx}{\sqrt{x^2 + 4x + 13}} = \int \frac{dx}{\sqrt{(x+2)^2 + 9}} = \int \frac{du}{\sqrt{u^2 + 9}}.$$

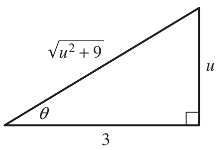
Now let $u = 3\tan\theta$. Then $du = 3\sec^2\theta\, d\theta$,

$$u^2 + 9 = 9\tan^2\theta + 9 = 9(\tan^2\theta + 1) = 9\sec^2\theta,$$

and

$$I = \int \frac{3\sec^2\theta\, d\theta}{3\sec\theta} = \int \sec\theta\, d\theta = \ln|\sec\theta + \tan\theta| + C.$$

Since $u = 3\tan\theta$, we construct the following right triangle:



From this we see that $\sec\theta = \sqrt{u^2 + 9}/3$. Thus

$$\begin{aligned} I &= \ln\left|\frac{\sqrt{u^2+9}}{3} + \frac{u}{3}\right| + C_1 = \ln\left|\sqrt{u^2+9} + u\right| + \left(\ln\frac{1}{3} + C_1\right) \\ &= \ln\left|\sqrt{(x+2)^2 + 9} + x + 2\right| + C = \ln\left|\sqrt{x^2 + 4x + 13} + x + 2\right| + C. \end{aligned}$$

38. $\displaystyle\int \frac{dx}{\sqrt{2 + x - x^2}}$

SOLUTION First complete the square:

$$2 + x - x^2 = -\left(x^2 - x\right) + 2 = -\left(x^2 - x + \frac{1}{4}\right) + 2 + \frac{1}{4} = \frac{9}{4} - \left(x - \frac{1}{2}\right)^2.$$

Let $u = x - \frac{1}{2}$ and $du = dx$. This gives us

$$I = \int \frac{dx}{\sqrt{2 + x - x^2}} = \int \frac{dx}{\sqrt{\frac{9}{4} - (x - \frac{1}{2})^2}} = \int \frac{du}{\sqrt{\frac{9}{4} - u^2}}.$$

Now let $u = \frac{3}{2}\sin\theta$. Then $du = \frac{3}{2}\cos\theta\, d\theta$,

$$\frac{9}{4} - u^2 = \frac{9}{4} - \frac{9}{4}\sin^2\theta = \frac{9}{4}(1 - \sin^2\theta) = \frac{9}{4}\cos^2\theta,$$

and

$$I = \int \frac{\frac{3}{2}\cos\theta\, d\theta}{\frac{3}{2}\cos\theta} = \int d\theta = \theta + C = \sin^{-1}\left(\frac{2u}{3}\right) + C = \sin^{-1}\left(\frac{2(x - \frac{1}{2})}{3}\right) + C = \sin^{-1}\left(\frac{2x - 1}{3}\right) + C.$$

39. $\displaystyle\int \frac{dx}{\sqrt{x + 6x^2}}$

SOLUTION First complete the square:

$$6x^2 + x = \left(6x^2 + x + \frac{1}{24}\right) - \frac{1}{24} = \left(\sqrt{6}x + \frac{1}{2\sqrt{6}}\right)^2 - \frac{1}{24}$$

Let $u = \sqrt{6}x + \frac{1}{2\sqrt{6}}$ so that $du = \sqrt{6}\, dx$. Then

$$I = \int \frac{1}{\sqrt{x + 6x^2}}\, dx = \int \frac{1}{\sqrt{\left(\sqrt{6}x + \frac{1}{2\sqrt{6}}\right)^2 - \frac{1}{24}}}\, dx = \frac{1}{\sqrt{6}}\int \frac{1}{\sqrt{u^2 - \frac{1}{24}}}\, du$$

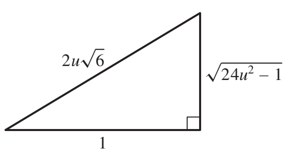
Now let $u = \frac{1}{2\sqrt{6}}\sec\theta$. Then $du = \frac{1}{2\sqrt{6}}\sec\theta\tan\theta$, and

$$u^2 - \frac{1}{24} = \frac{1}{24}(\sec^2\theta - 1) = \frac{1}{24}\tan^2\theta$$

so that

$$I = \frac{1}{\sqrt{6}}\int \frac{1}{\frac{1}{2\sqrt{6}}\tan\theta}\frac{1}{2\sqrt{6}}\sec\theta\tan\theta\, d\theta = \frac{1}{\sqrt{6}}\int \sec\theta\, d\theta = \frac{1}{\sqrt{6}}\ln|\sec\theta + \tan\theta| + C$$

Since $u = \frac{1}{2\sqrt{6}}\sec\theta$, we construct the following right triangle:



from which we see that $\tan\theta = \sqrt{24u^2 - 1}$ and $\sec\theta = 2u\sqrt{6}$. Thus

$$I = \frac{1}{\sqrt{6}}\ln\left|2u\sqrt{6} + \sqrt{24u^2 - 1}\right| + C = \frac{1}{\sqrt{6}}\ln\left|2\sqrt{6}\left(\sqrt{6}x + \frac{1}{2\sqrt{6}}\right) + \sqrt{24\left(6x^2 + x + \frac{1}{24}\right) - 1}\right| + C$$

$$= \frac{1}{\sqrt{6}}\ln\left|12x + 1 + \sqrt{144x^2 + 24x}\right| + C$$

40. $\displaystyle\int \sqrt{x^2 - 4x + 7}\, dx$

SOLUTION First complete the square:

$$x^2 - 4x + 7 = x^2 - 4x + 4 + 3 = (x - 2)^2 + 3.$$

Let $u = x - 2$. Then $du = dx$, and

$$I = \int \sqrt{x^2 - 4x + 7}\, dx = \int \sqrt{(x - 2)^2 + 3}\, dx = \int \sqrt{u^2 + 3}\, du.$$

Now let $u = \sqrt{3}\tan\theta$. Then $du = \sqrt{3}\sec^2\theta\, d\theta$,

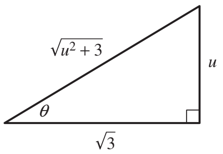
$$u^2 + 3 = 3\tan^2\theta + 3 = 3(\tan^2\theta + 1) = 3\sec^2\theta,$$

and

$$I = \int \sqrt{3\sec^2\theta}\sqrt{3}\sec^2\theta\, d\theta = 3\int \sec^3\theta\, d\theta = 3\left[\frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\int \sec\theta\, d\theta\right]$$

$$= \frac{3}{2}\tan\theta\sec\theta + \frac{3}{2}\ln|\sec\theta + \tan\theta| + C.$$

Since $u = \sqrt{3}\tan\theta$, we construct a right triangle with $\tan\theta = \frac{u}{\sqrt{3}}$:



From this we see that $\sec\theta = \sqrt{u^2+3}/3$. Thus

$$\begin{aligned} I &= \frac{3}{2}\left(\frac{u}{\sqrt{3}}\right)\left(\frac{\sqrt{u^2+3}}{\sqrt{3}}\right) + \frac{3}{2}\ln\left|\frac{\sqrt{u^2+3}}{\sqrt{3}} + \frac{u}{\sqrt{3}}\right| + C_1 \\ &= \frac{1}{2}u\sqrt{u^2+3} + \frac{3}{2}\ln\left|\sqrt{u^2+3}+u\right| + \left(\frac{3}{2}\ln\frac{1}{\sqrt{3}} + C_1\right) \\ &= \frac{1}{2}(x-2)\sqrt{(x-2)^2+3} + \frac{3}{2}\ln\left|\sqrt{(x-2)^2+3}+x-2\right| + C \\ &= \frac{1}{2}(x-2)\sqrt{x^2-4x+7} + \frac{3}{2}\ln\left|\sqrt{x^2-4x+7}+x-2\right| + C. \end{aligned}$$

41. $\int \sqrt{x^2-4x+3}\,dx$

SOLUTION First complete the square:

$$x^2-4x+3 = x^2-4x+4-1 = (x-2)^2-1.$$

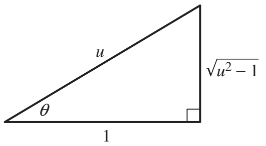
Let $u = x-2$. Then $du = dx$, and

$$I = \int \sqrt{x^2-4x+3}\,dx = \int \sqrt{(x-2)^2-1}\,dx = \int \sqrt{u^2-1}\,du.$$

Now let $u = \sec\theta$. Then $du = \sec\theta\tan\theta\,d\theta$, $u^2-1 = \sec^2\theta - 1 = \tan^2\theta$, and

$$\begin{aligned} I &= \int \sqrt{\tan^2\theta}(\sec\theta\tan\theta\,d\theta) = \int \tan^2\theta\sec\theta\,d\theta = \int \left(\sec^2\theta - 1\right)\sec\theta\,d\theta \\ &= \int \sec^3\theta\,d\theta - \int \sec\theta\,d\theta = \left(\frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\int \sec\theta\,d\theta\right) - \int \sec\theta\,d\theta \\ &= \frac{1}{2}\tan\theta\sec\theta - \frac{1}{2}\int \sec\theta\,d\theta = \frac{1}{2}\tan\theta\sec\theta - \frac{1}{2}\ln|\sec\theta+\tan\theta| + C. \end{aligned}$$

Since $u = \sec\theta$, we construct the following right triangle:



From this we see that $\tan\theta = \sqrt{u^2-1}$. Thus

$$\begin{aligned} I &= \frac{1}{2}u\sqrt{u^2-1} - \frac{1}{2}\ln\left|u+\sqrt{u^2-1}\right| + C = \frac{1}{2}(x-2)\sqrt{(x-2)^2-1} - \frac{1}{2}\ln\left|x-2+\sqrt{(x-2)^2-1}\right| + C \\ &= \frac{1}{2}(x-2)\sqrt{x^2-4x+3} - \frac{1}{2}\ln\left|x-2+\sqrt{x^2-4x+3}\right| + C. \end{aligned}$$

42. $\int \frac{dx}{(x^2+6x+6)^2}$

SOLUTION First complete the square:

$$x^2+6x+6 = x^2+6x+9-3 = (x+3)^2-3.$$

Let $u = x+3$. Then $du = dx$, and

$$I = \int \frac{dx}{(x^2+6x+6)^2} = \int \frac{dx}{((x+3)^2-3)^2} = \int \frac{du}{(u^2-3)^2}.$$

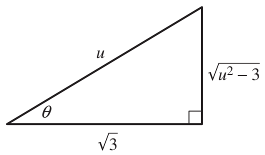
Now let $u = \sqrt{3}\sec\theta$. Then $du = \sqrt{3}\sec\theta\tan\theta$,

$$u^2 - 3 = 3\sec^2\theta - 3 = 3(\sec^2\theta - 1) = 3\tan^2\theta,$$

and

$$\begin{aligned} I &= \int \frac{\sqrt{3}\sec\theta\tan\theta\,d\theta}{9\tan^4\theta} = \frac{\sqrt{3}}{9}\int \frac{\sec\theta\,d\theta}{\tan^3\theta} = \frac{\sqrt{3}}{9}\int \frac{\cos^2\theta}{\sin^3\theta}\,d\theta = \frac{\sqrt{3}}{9}\int \frac{(1-\sin^2\theta)\,d\theta}{\sin^3\theta} \\ &= \frac{\sqrt{3}}{9}\left[\int \csc^3\theta\,d\theta - \int \csc\theta\,d\theta\right] = \frac{\sqrt{3}}{9}\left[\left(-\frac{\cot\theta\csc\theta}{2} + \frac{1}{2}\int \csc\theta\,d\theta\right) - \int \csc\theta\,d\theta\right] \\ &= \frac{\sqrt{3}}{9}\left[-\frac{1}{2}\cot\theta\csc\theta - \frac{1}{2}\int \csc\theta\,d\theta\right] = -\frac{\sqrt{3}}{18}\cot\theta\csc\theta - \frac{\sqrt{3}}{18}\ln|\csc\theta - \cot\theta| + C. \end{aligned}$$

Since $u = \sqrt{3}\sec\theta$, we construct a right triangle with $\sec\theta = \frac{u}{\sqrt{3}}$:



From this we see that $\cot\theta = \sqrt{3}/\sqrt{u^2-3}$ and $\csc\theta = u/\sqrt{u^2-3}$. Thus

$$\begin{aligned} I &= -\frac{\sqrt{3}}{18}\left(\frac{\sqrt{3}}{\sqrt{u^2-3}}\right)\left(\frac{u}{\sqrt{u^2-3}}\right) - \frac{\sqrt{3}}{18}\ln\left|\frac{u}{\sqrt{u^2-3}} - \frac{\sqrt{3}}{\sqrt{u^2-3}}\right| + C \\ &= \frac{-u}{6(u^2-3)} - \frac{\sqrt{3}}{18}\ln\left|\frac{u-\sqrt{3}}{\sqrt{u^2-3}}\right| + C = \frac{-(x+3)}{6((x+3)^2-3)} - \frac{\sqrt{3}}{18}\ln\left|\frac{x+3-\sqrt{3}}{\sqrt{(x+3)^2-3}}\right| + C \\ &= \frac{-(x+3)}{6(x^2+6x+6)} - \frac{\sqrt{3}}{18}\ln\left|\frac{x+3-\sqrt{3}}{\sqrt{x^2+6x+6}}\right| + C. \end{aligned}$$

In Exercises 43–52, indicate a good method for evaluating the integral (but do not evaluate). Your choices are: substitution (specify u and du), Integration by Parts (specify u and v′), a trigonometric method, or trigonometric substitution (specify). If it appears that these techniques are not sufficient, state this.

43. $\displaystyle\int \frac{x\,dx}{\sqrt{12-6x-x^2}}$

SOLUTION Complete the square so the the denominator is $\sqrt{15-(x+3)^2}$ and then use trigonometric substitution with $x + 3 = \sin\theta$.

44. $\displaystyle\int \sqrt{4x^2-1}\,dx$

SOLUTION Use trigonometric substitution, with $x = \frac{1}{2}\sec\theta$.

45. $\displaystyle\int \sin^3 x\cos^3 x\,dx$

SOLUTION Use one of the following trigonometric methods: rewrite $\sin^3 x = (1-\cos^2 x)\sin x$ and let $u = \cos x$, or rewrite $\cos^3 x = (1-\sin^2 x)\cos x$ and let $u = \sin x$.

46. $\displaystyle\int x\sec^2 x\,dx$

SOLUTION Use Integration by Parts, with $u = x$ and $v' = \sec^2 x$.

47. $\displaystyle\int \frac{dx}{\sqrt{9-x^2}}$

SOLUTION Either use the substitution $x = 3u$ and then recognize the formula for the inverse sine:

$$\int \frac{du}{\sqrt{1-u^2}} = \sin^{-1} u + C,$$

or use trigonometric substitution, with $x = 3\sin\theta$.

48. $\int \sqrt{1-x^3}\,dx$

SOLUTION Not solvable by any method yet considered. (In fact, this has no antiderivative using elementary functions).

49. $\int \sin^{3/2} x\,dx$

SOLUTION Not solvable by any method yet considered.

50. $\int x^2\sqrt{x+1}\,dx$

SOLUTION Use integration by parts twice, first with $u = x^2$ and then with $u = x$.

51. $\int \frac{dx}{(x+1)(x+2)^3}$

SOLUTION The techniques we have covered thus far are not sufficient to treat this integral. This integral requires a technique known as partial fractions.

52. $\int \frac{dx}{(x+12)^4}$

SOLUTION Use the substitution $u = x + 12$, and then recognize the formula

$$\int u^{-4}\,du = -\frac{1}{3u^3} + C.$$

In Exercises 53–56, evaluate using Integration by Parts as a first step.

53. $\int \sec^{-1} x\,dx$

SOLUTION Let $u = \sec^{-1} x$ and $v' = 1$. Then $v = x$, $u' = 1/x\sqrt{x^2-1}$, and

$$I = \int \sec^{-1} x\,dx = x\sec^{-1} x - \int \frac{x}{x\sqrt{x^2-1}}\,dx = x\sec^{-1} x - \int \frac{dx}{\sqrt{x^2-1}}.$$

To evaluate the integral on the right, let $x = \sec\theta$. Then $dx = \sec\theta\tan\theta\,d\theta$, $x^2 - 1 = \sec^2\theta - 1 = \tan^2\theta$, and

$$\int \frac{dx}{\sqrt{x^2-1}} = \int \frac{\sec\theta\tan\theta\,d\theta}{\tan\theta} = \int \sec\theta\,d\theta = \ln|\sec\theta + \tan\theta| + C = \ln\left|x + \sqrt{x^2-1}\right| + C.$$

Thus, the final answer is

$$I = x\sec^{-1} x - \ln\left|x + \sqrt{x^2-1}\right| + C.$$

54. $\int \frac{\sin^{-1} x}{x^2}\,dx$

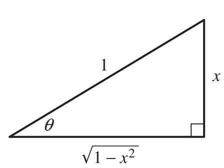
SOLUTION Let $u = \sin^{-1} x$ and $v' = x^{-2}$. Then $u' = 1/\sqrt{1-x^2}$, $v = -x^{-1}$, and

$$I = \int \frac{\sin^{-1} x}{x^2}\,dx = -\frac{\sin^{-1} x}{x} + \int \frac{dx}{x\sqrt{1-x^2}}.$$

To evaluate the integral on the right, let $x = \sin\theta$. Then $dx = \cos\theta\,d\theta$, $1 - x^2 = 1 - \sin^2\theta = \cos^2\theta$, and

$$\int \frac{dx}{x\sqrt{1-x^2}} = \int \frac{\cos\theta\,d\theta}{(\sin\theta)(\cos\theta)} = \int \csc\theta\,d\theta = \ln|\csc\theta - \cot\theta| + C.$$

Since $x = \sin\theta$, we construct the following right triangle:



From this we see that $\csc\theta = 1/x$ and $\cot\theta = \sqrt{1-x^2}/x$. Thus

$$\int \frac{dx}{x\sqrt{1-x^2}} = \ln\left|\frac{1}{x} - \frac{\sqrt{1-x^2}}{x}\right| + C = \ln\left|\frac{1-\sqrt{1-x^2}}{x}\right| + C.$$

The final answer is

$$I = -\frac{\sin^{-1} x}{x} + \ln\left|\frac{1-\sqrt{1-x^2}}{x}\right| + C.$$

55. $\int \ln(x^2+1)\,dx$

SOLUTION Start by using integration by parts, with $u = \ln(x^2+1)$ and $v' = 1$; then $u' = \frac{2x}{x^2+1}$ and $v = x$, so that

$$\begin{aligned} I = \int \ln(x^2+1)\,dx &= x\ln(x^2+1) - 2\int \frac{x^2}{x^2+1}\,dx = x\ln(x^2+1) - 2\int\left(1 - \frac{1}{x^2+1}\right)dx \\ &= x\ln(x^2+1) - 2x + 2\int \frac{1}{x^2+1}\,dx \end{aligned}$$

To deal with the remaining integral, use the substitution $x = \tan\theta$, so that $dx = \sec^2\theta\,d\theta$ and

$$\int \frac{1}{x^2+1}\,dx = \int \frac{\sec^2\theta}{\tan^2\theta+1}\,d\theta = \int \frac{\sec^2\theta}{\sec^2\theta}\,d\theta = \int 1\,d\theta = \theta = \tan^{-1} x + C$$

so that finally

$$I = x\ln(x^2+1) - 2x + 2\tan^{-1} x + C$$

56. $\int x^2\ln(x^2+1)\,dx$

SOLUTION Start by using integration by parts with $u = \ln(x^2+1)$, $v' = x^2$; then $u' = \frac{2x}{x^2+1}$ and $v = \frac{1}{3}x^3$, so that

$$I = \int x^2\ln(x^2+1)\,dx = \frac{1}{3}x^3\ln(x^2+1) - \frac{2}{3}\int \frac{x^4}{x^2+1}\,dx$$

To deal with the remaining integral, use the substitution $x = \tan\theta$; then $dx = \sec^2\theta\,d\theta$ and

$$\int \frac{x^4}{x^2+1}\,dx = \int \frac{\tan^4\theta}{\tan^2\theta+1}\sec^2\theta\,d\theta = \int \frac{\tan^4\theta}{\sec^2\theta}\sec^2\theta\,d\theta = \int \tan^4\theta\,d\theta$$

Using the reduction formula for $\tan^n$ gives

$$\int \tan^4\theta\,d\theta = \frac{1}{3}\tan^3\theta - \int \tan^2\theta\,d\theta = \frac{1}{3}\tan^3\theta - \tan\theta + \theta + C$$

so that, substituting back for $x = \tan\theta$, we get

$$I = \frac{1}{3}x^3\ln(x^2+1) - \frac{2}{3}\left(\frac{1}{3}x^3 - x + \tan^{-1} x\right) + C = \frac{1}{3}x^3\ln(x^2+1) - \frac{2}{9}x^3 + \frac{2}{3}x - \frac{2}{3}\tan^{-1} x + C$$

57. Find the average height of a point on the semicircle $y = \sqrt{1-x^2}$ for $-1 \le x \le 1$.

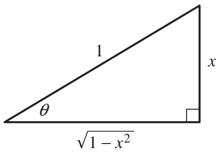
SOLUTION The average height is given by the formula

$$y_{\text{ave}} = \frac{1}{1-(-1)}\int_{-1}^{1}\sqrt{1-x^2}\,dx = \frac{1}{2}\int_{-1}^{1}\sqrt{1-x^2}\,dx$$

Let $x = \sin\theta$. Then $dx = \cos\theta\,d\theta$, $1 - x^2 = \cos^2\theta$, and

$$\int \sqrt{1-x^2}\,dx = \int (\cos\theta)(\cos\theta\,d\theta) = \int \cos^2\theta\,d\theta = \frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta + C.$$

Since $x = \sin\theta$, we construct the following right triangle:



From this we see that $\cos\theta = \sqrt{1-x^2}$. Therefore,

$$y_{\text{ave}} = \frac{1}{2}\left(\frac{1}{2}\sin^{-1}x + \frac{1}{2}x\sqrt{1-x^2}\right)\Big|_{-1}^{1} = \frac{1}{2}\left[\left(\frac{1}{2}\pi + 0\right) - \left(-\frac{1}{2}\pi + 0\right)\right] = \frac{\pi}{4}.$$

58. Find the volume of the solid obtained by revolving the graph of $y = x\sqrt{1-x^2}$ over [0, 1] about the y-axis.

SOLUTION Using the method of cylindrical shells, the volume is given by

$$V = 2\pi\int_0^1 x\left(x\sqrt{1-x^2}\right)dx = 2\pi\int_0^1 x^2\sqrt{1-x^2}\,dx.$$

To evaluate this integral, let $x = \sin\theta$. Then $dx = \cos\theta\,d\theta$,

$$1 - x^2 = 1 - \sin^2\theta = \cos^2\theta,$$

and

$$I = \int x^2\sqrt{1-x^2}\,dx = \int \sin^2\theta\cos^2\theta\,d\theta = \int\left(1-\cos^2\theta\right)\cos^2\theta\,d\theta = \int\cos^2\theta\,d\theta - \int\cos^4\theta\,d\theta.$$

Now use the reduction formula for $\int\cos^4\theta\,d\theta$:

$$I = \int\cos^2\theta\,d\theta - \left[\frac{\cos^3\theta\sin\theta}{4} + \frac{3}{4}\int\cos^2\theta\,d\theta\right] = -\frac{1}{4}\cos^3\theta\sin\theta + \frac{1}{4}\int\cos^2\theta\,d\theta$$

$$= -\frac{1}{4}\cos^3\theta\sin\theta + \frac{1}{4}\left[\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right] + C = -\frac{1}{4}\cos^3\theta\sin\theta + \frac{1}{8}\theta + \frac{1}{8}\sin\theta\cos\theta + C.$$

Since $\sin\theta = x$, we know that $\cos\theta = \sqrt{1-x^2}$. Then we have

$$I = -\frac{1}{4}(1-x^2)^{3/2}x + \frac{1}{8}\sin^{-1}x + \frac{1}{8}x\sqrt{1-x^2} + C.$$

Now we can complete the volume:

$$V = 2\pi\left(-\frac{1}{4}x(1-x^2)^{3/2} + \frac{1}{8}\sin^{-1}x + \frac{1}{8}x\sqrt{1-x^2}\right)\Big|_0^1 = 2\pi\left[\left(0 + \frac{\pi}{16} + 0\right) - (0)\right] = \frac{\pi^2}{8}.$$

59. Find the volume of the solid obtained by revolving the region between the graph of $y^2 - x^2 = 1$ and the line $y = 2$ about the line $y = 2$.

SOLUTION First solve the equation $y^2 - x^2 = 1$ for y:

$$y = \pm\sqrt{x^2+1}.$$

The region in question is bounded in part by the top half of this hyperbola, which is the equation

$$y = \sqrt{x^2+1}.$$

The limits of integration are obtained by finding the points of intersection of this equation with $y = 2$:

$$2 = \sqrt{x^2+1} \Rightarrow x = \pm\sqrt{3}.$$

The radius of each disk is given by $2 - \sqrt{x^2+1}$; the volume is therefore given by

$$V = \int_{-\sqrt{3}}^{\sqrt{3}}\pi r^2\,dx = 2\pi\int_0^{\sqrt{3}}\left(2-\sqrt{x^2+1}\right)^2dx = 2\pi\int_0^{\sqrt{3}}\left[4 - 4\sqrt{x^2+1} + (x^2+1)\right]dx$$

$$= 8\pi\int_0^{\sqrt{3}}dx - 8\pi\int_0^{\sqrt{3}}\sqrt{x^2+1}\,dx + 2\pi\int_0^{\sqrt{3}}(x^2+1)\,dx.$$

To evaluate the integral $\int \sqrt{x^2+1}\,dx$, let $x = \tan\theta$. Then $dx = \sec^2\theta\,d\theta$, $x^2+1 = \sec^2\theta$, and

$$\int \sqrt{x^2+1}\,dx = \int \sec^3\theta\,d\theta = \frac{1}{2}\tan\theta\sec\theta + \frac{1}{2}\int \sec\theta\,d\theta$$
$$= \frac{1}{2}\tan\theta\sec\theta + \frac{1}{2}\ln|\sec\theta+\tan\theta| + C = \frac{1}{2}x\sqrt{x^2+1} + \frac{1}{2}\ln\left|\sqrt{x^2+1}+x\right| + C.$$

Now we can compute the volume:

$$V = \left[8\pi x - 8\pi\left(\frac{1}{2}x\sqrt{x^2+1} + \frac{1}{2}\ln\left|\sqrt{x^2+1}+x\right|\right) + \frac{2}{3}\pi x^3 + 2\pi x\right]\Bigg|_0^{\sqrt{3}}$$
$$= \left(10\pi x + \frac{2}{3}\pi x^3 - 4\pi x\sqrt{x^2+1} - 4\pi\ln\left|\sqrt{x^2+1}+x\right|\right)\Bigg|_0^{\sqrt{3}}$$
$$= \left(10\pi\sqrt{3} + 2\pi\sqrt{3} - 8\pi\sqrt{3} - 4\pi\ln\left|2+\sqrt{3}\right|\right) - (0) = 4\pi\left[\sqrt{3} - \ln\left|2+\sqrt{3}\right|\right].$$

60. Find the volume of revolution for the region in Exercise 59, but revolve around $y = 3$.

SOLUTION Using the washer method, the volume is given by

$$V = \int_{-\sqrt{3}}^{\sqrt{3}} \pi\left(R^2 - r^2\right)dx = 2\pi\int_0^{\sqrt{3}}\left[\left(3-\sqrt{x^2+1}\right)^2 - 1^2\right]dx$$
$$= 2\pi\int_0^{\sqrt{3}}\left(9 - 6\sqrt{x^2+1} + \left(x^2+1\right) - 1\right)dx = 2\pi\int_0^{\sqrt{3}}\left(9 - 6\sqrt{x^2+1} + x^2\right)dx$$
$$= 2\pi\left[9x - 6\left(\frac{1}{2}x\sqrt{x^2+1} + \frac{1}{2}\ln\left|\sqrt{x^2+1}+x\right|\right) + \frac{1}{3}x^3\right]\Bigg|_0^{\sqrt{3}}$$
$$= 2\pi\left[\left(9\sqrt{3} - 3\sqrt{3}(2) - 3\ln\left|2+\sqrt{3}\right| + \sqrt{3}\right) - (0)\right] = 8\pi\sqrt{3} - 6\pi\ln\left|2+\sqrt{3}\right|.$$

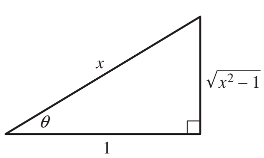
61. Compute $\int \frac{dx}{x^2-1}$ in two ways and verify that the answers agree: first via trigonometric substitution and then using the identity

$$\frac{1}{x^2-1} = \frac{1}{2}\left(\frac{1}{x-1} - \frac{1}{x+1}\right)$$

SOLUTION Using trigonometric substitution, let $x = \sec\theta$. Then $dx = \sec\theta\tan\theta d\theta$, $x^2-1 = \sec^2\theta - 1 = \tan^2\theta$, and

$$I = \int \frac{dx}{x^2-1} = \int \frac{\sec\theta\tan\theta\,d\theta}{\tan^2\theta} = \int \frac{\sec\theta}{\tan\theta}\,d\theta = \int \frac{d\theta}{\sin\theta} = \int \csc\theta\,d\theta = \ln|\csc\theta - \cot\theta| + C.$$

Since $x = \sec\theta$, we construct the following right triangle:



From this we see that $\csc\theta = x/\sqrt{x^2-1}$ and $\cot\theta = 1/\sqrt{x^2-1}$. This gives us

$$I = \ln\left|\frac{x}{\sqrt{x^2-1}} - \frac{1}{\sqrt{x^2-1}}\right| + C = \ln\left|\frac{x-1}{\sqrt{x^2-1}}\right| + C.$$

Using the given identity, we get

$$I = \int \frac{dx}{x^2-1} = \frac{1}{2}\int\left(\frac{1}{x-1} - \frac{1}{x+1}\right)dx = \frac{1}{2}\int\frac{dx}{x-1} - \frac{1}{2}\int\frac{dx}{x+1} = \frac{1}{2}\ln|x-1| - \frac{1}{2}\ln|x+1| + C.$$

To confirm that these answers agree, note that

$$\frac{1}{2}\ln|x-1| - \frac{1}{2}\ln|x+1| = \frac{1}{2}\ln\left|\frac{x-1}{x+1}\right| = \ln\sqrt{\left|\frac{x-1}{x+1}\right|} = \ln\left|\frac{\sqrt{x-1}}{\sqrt{x+1}}\cdot\frac{\sqrt{x-1}}{\sqrt{x-1}}\right| = \ln\left|\frac{x-1}{\sqrt{x^2-1}}\right|.$$

62. CAS You want to divide an 18-inch pizza equally among three friends using vertical slices at $\pm x$ as in Figure 6. Find an equation satisfied by x and find the approximate value of x using a computer algebra system.

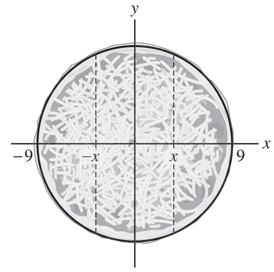


FIGURE 6 Dividing a pizza into three equal parts.

SOLUTION First find the value of x which divides evenly a pizza with a 1-inch radius. By proportionality, we can then take this answer and multiply by 9 to get the answer for the 18-inch pizza. The total area of a 1-inch radius pizza is $\pi \cdot 1^2 = \pi$ (in square inches). The three equal pieces will have an area of $\pi/3$. The center piece is further divided into 4 equal pieces, each of area $\pi/12$. From Example 1, we know that

$$\int_0^x \sqrt{1-x^2}\,dx = \frac{1}{2}\sin^{-1} x + \frac{1}{2}x\sqrt{1-x^2}.$$

Setting this expression equal to $\pi/12$ and solving for x using a computer algebra system, we find $x = 0.265$. For the 18-inch pizza, the value of x should be

$$x = 9(0.265) = 2.385 \text{ inches.}$$

63. A charged wire creates an electric field at a point P located at a distance D from the wire (Figure 7). The component $E_\perp$ of the field perpendicular to the wire (in N/C) is

$$E_\perp = \int_{x_1}^{x_2} \frac{k\lambda D}{(x^2+D^2)^{3/2}}\,dx$$

where λ is the charge density (coulombs per meter), $k = 8.99 \times 10^9$ N·m^2/C^2 (Coulomb constant), and x_1, x_2 are as in the figure. Suppose that $\lambda = 6 \times 10^{-4}$ C/m, and $D = 3$ m. Find $E_\perp$ if (a) $x_1 = 0$ and $x_2 = 30$ m, and (b) $x_1 = -15$ m and $x_2 = 15$ m.

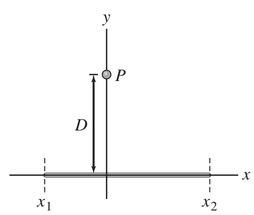

FIGURE 7

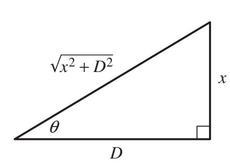
SOLUTION Let $x = D\tan\theta$. Then $dx = D\sec^2\theta\,d\theta$,

$$x^2 + D^2 = D^2\tan^2\theta + D^2 = D^2(\tan^2\theta + 1) = D^2\sec^2\theta,$$

and

$$\begin{aligned} E_\perp &= \int_{x_1}^{x_2} \frac{k\lambda D}{(x^2+D^2)^{3/2}}\,dx = k\lambda D\int_{x_1}^{x_2} \frac{D\sec^2\theta\,d\theta}{(D^2\sec^2\theta)^{3/2}} \\ &= \frac{k\lambda D^2}{D^3}\int_{x_1}^{x_2} \frac{\sec^2\theta\,d\theta}{\sec^3\theta} = \frac{k\lambda}{D}\int_{x_1}^{x_2} \cos\theta\,d\theta = \frac{k\lambda}{D}\sin\theta\Big|_{x_1}^{x_2} \end{aligned}$$

Since $x = D\tan\theta$, we construct a right triangle with $\tan\theta = x/D$:



From this we see that $\sin\theta = x/\sqrt{x^2+D^2}$. Then

$$E_\perp = \frac{k\lambda}{D}\left(\frac{x}{\sqrt{x^2+D^2}}\right)\Bigg|_{x_1}^{x_2}$$

(a) Plugging in the values for the constants k, λ, D, and evaluating the antiderivative for $x_1 = 0$ and $x_2 = 30$, we get

$$E_\perp = \frac{(8.99\times 10^9)(6\times 10^{-4})}{3}\left[\frac{30}{\sqrt{30^2+3^2}} - 0\right] \approx 1.789\times 10^6\ \frac{V}{\text{m}}$$

(b) If $x_1 = -15$ m and $x_2 = 15$ m, we get

$$E_\perp = \frac{(8.99\times 10^9)(6\times 10^{-4})}{3}\left[\frac{15}{\sqrt{15^2+3^2}} - \frac{-15}{\sqrt{(-15)^2+3^2}}\right] \approx 3.526\times 10^6\ \frac{V}{\text{m}}$$

Further Insights and Challenges

64. Let $J_n = \int \frac{dx}{(x^2+1)^n}$. Use Integration by Parts to prove

$$J_{n+1} = \left(1-\frac{1}{2n}\right)J_n + \left(\frac{1}{2n}\right)\frac{x}{(x^2+1)^n}$$

Then use this recursion relation to calculate J_2 and J_3.

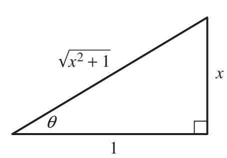
SOLUTION Let $x = \tan\theta$. Then $dx = \sec^2\theta\,d\theta$, $x^2+1 = \tan^2\theta+1 = \sec^2\theta$, and

$$J_{n+1} = \int \frac{dx}{(x^2+1)^{n+1}} = \int \frac{\sec^2\theta\,d\theta}{\sec^{2n+2}\theta} = \int \sec^{-2n}\theta\,d\theta = \int \cos^{2n}\theta\,d\theta.$$

Using the reduction formula for $\int \cos^m\theta\,d\theta$, we get

$$J_{n+1} = \frac{\cos^{2n-1}\theta\sin\theta}{2n} + \frac{2n-1}{2n}\int \cos^{2n-2}\theta\,d\theta.$$

Since $x = \tan\theta$, we construct the following right triangle:



From this we see that $\cos\theta = 1/\sqrt{x^2+1}$, and $\sin\theta = x/\sqrt{x^2+1}$. This gives us

$$J_{n+1} = \frac{1}{2n}\left(\frac{1}{\sqrt{x^2+1}}\right)^{2n-1}\left(\frac{x}{\sqrt{x^2+1}}\right) + \frac{2n-1}{2n}\int\left(\frac{1}{\sqrt{x^2+1}}\right)^{2n-2}\left(\frac{1}{\sqrt{x^2+1}}\right)^2 dx.$$

Here we've used the fact that

$$d\theta = \frac{dx}{\sec^2\theta} = \cos^2\theta\,dx = \left(\frac{1}{\sqrt{x^2+1}}\right)^2 dx.$$

Simplifying, we get

$$\begin{aligned} J_{n+1} &= \left(\frac{1}{2n}\right)\frac{x}{(\sqrt{x^2+1})^{2n}} + \frac{2n-1}{2n}\int\frac{dx}{(\sqrt{x^2+1})^{2n}} = \frac{1}{2n}\frac{x}{(x^2+1)^n} + \frac{2n-1}{2n}\int\frac{dx}{(x^2+1)^n} \\ &= \frac{1}{2n}\frac{x}{(x^2+1)^n} + \left(1-\frac{1}{2n}\right)J_n. \end{aligned}$$

To use this formula, we first compute J_1:

$$J_1 = \int\frac{dx}{x^2+1} = \tan^{-1}x + C.$$

Now use the formula to compute J_2 and J_3:

$$J_2 = \frac{1}{2}\frac{x}{x^2+1} + \left(1 - \frac{1}{2}\right) J_1 = \frac{x}{2(x^2+1)} + \frac{1}{2}\tan^{-1} x + C;$$

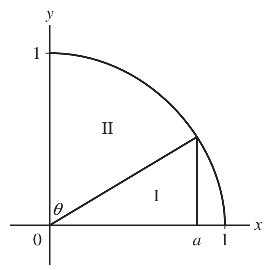
$$J_3 = \frac{1}{4}\frac{x}{(x^2+1)^2} + \left(1 - \frac{1}{4}\right) J_2 = \frac{1}{4}\left[\frac{x}{(x^2+1)^2} + \frac{3x}{8(x^2+1)} + \frac{3}{8}\tan^{-1} x\right] + C.$$

65. Prove the formula

$$\int \sqrt{1-x^2}\,dx = \frac{1}{2}\sin^{-1} x + \frac{1}{2}x\sqrt{1-x^2} + C$$

using geometry by interpreting the integral as the area of part of the unit circle.

SOLUTION The integral $\int_0^a \sqrt{1-x^2}\,dx$ is the area bounded by the unit circle, the x-axis, the y-axis, and the line $x = a$. This area can be divided into two regions as follows:



Region I is a triangle with base a and height $\sqrt{1-a^2}$. Region II is a sector of the unit circle with central angle $\theta = \frac{\pi}{2} - \cos^{-1} a = \sin^{-1} a$. Thus,

$$\int_0^a \sqrt{1-x^2}\,dx = \frac{1}{2}a\sqrt{1-a^2} + \frac{1}{2}\sin^{-1} a = \left(\frac{1}{2}x\sqrt{1-x^2} + \frac{1}{2}\sin^{-1} x\right)\Big|_0^a.$$

7.4 Integrals Involving Hyperbolic and Inverse Hyperbolic Functions

Preliminary Questions

1. Which hyperbolic substitution can be used to evaluate the following integrals?

(a) $\displaystyle\int \frac{dx}{\sqrt{x^2+1}}$ **(b)** $\displaystyle\int \frac{dx}{\sqrt{x^2+9}}$ **(c)** $\displaystyle\int \frac{dx}{\sqrt{9x^2+1}}$

SOLUTION The appropriate hyperbolic substitutions are

(a) $x = \sinh t$
(b) $x = 3\sinh t$
(c) $3x = \sinh t$

2. Which two of the hyperbolic integration formulas differ from their trigonometric counterparts by a minus sign?

SOLUTION The integration formulas for $\sinh x$ and $\tanh x$ differ from their trigonometric counterparts by a minus sign.

3. Which antiderivative of $y = (1-x^2)^{-1}$ should we use to evaluate the integral $\int_3^5 (1-x^2)^{-1}\,dx$?

SOLUTION Because the integration interval lies outside $-1 < x < 1$, the appropriate antiderivative of $y = (1-x^2)^{-1}$ is $\frac{1}{2}\ln\left|\frac{1+x}{1-x}\right|$.

Exercises

In Exercises 1–16, calculate the integral.

1. $\displaystyle\int \cosh(3x)\,dx$

SOLUTION $\displaystyle\int \cosh(3x)\,dx = \frac{1}{3}\sinh 3x + C.$

2. $\displaystyle\int \sinh(x+1)\,dx$

SOLUTION $\displaystyle\int \sinh(x+1)\,dx = \cosh(x+1) + C.$

3. $\int x \sinh(x^2+1)\,dx$

SOLUTION $\int x \sinh(x^2+1)\,dx = \frac{1}{2}\cosh(x^2+1) + C.$

4. $\int \sinh^2 x \cosh x\,dx$

SOLUTION Let $u = \sinh x$. Then $du = \cosh x\,dx$ and

$$\int \sinh^2 x \cosh x\,dx = \int u^2\,du = \frac{1}{3}u^3 + C = \frac{1}{3}(\sinh x)^3 + C.$$

5. $\int \operatorname{sech}^2(1-2x)\,dx$

SOLUTION $\int \operatorname{sech}^2(1-2x)\,dx = -\frac{1}{2}\tanh(1-2x) + C.$

6. $\int \tanh(3x)\operatorname{sech}(3x)\,dx$

SOLUTION $\int \tanh(3x)\operatorname{sech}(3x)\,dx = -\frac{1}{3}\operatorname{sech} 3x + C.$

7. $\int \tanh x \operatorname{sech}^2 x\,dx$

SOLUTION Let $u = \tanh x$. Then $du = \operatorname{sech}^2 x\,dx$ nd

$$\int \tanh x \operatorname{sech}^2 x\,dx = \int u\,du = \frac{1}{2}u^2 + C = \frac{\tanh^2 x}{2} + C.$$

8. $\int \frac{\cosh x}{3\sinh x + 4}\,dx$

SOLUTION Let $u = 3\sinh x + 4$. Then $du = 3\cosh x\,dx$ and

$$\int \frac{\cosh x}{3\sinh x + 4}\,dx = \int \frac{du}{3u} = \frac{1}{3}\ln|u| + C = \frac{1}{3}\ln|3\sinh x + 4| + C.$$

9. $\int \tanh x\,dx$

SOLUTION $\int \tanh x\,dx = \ln\cosh x + C.$

10. $\int x \operatorname{csch}(x^2)\coth(x^2)\,dx$

SOLUTION Let $u = x^2$. Then $du = 2x\,dx$ and

$$\int x \operatorname{csch}(x^2)\coth(x^2)\,dx = \frac{1}{2}\int \operatorname{csch} u \coth u\,du = -\frac{1}{2}\operatorname{csch} u + C = -\frac{1}{2}\operatorname{csch}(x^2) + C.$$

11. $\int \frac{\cosh x}{\sinh x}\,dx$

SOLUTION $\int \frac{\cosh x}{\sinh x}\,dx = \ln|\sinh x| + C.$

12. $\int \frac{\cosh x}{\sinh^2 x}\,dx$

SOLUTION $\int \frac{\cosh x}{\sinh^2 x}\,dx = \int \operatorname{csch} x \coth x\,dx = -\operatorname{csch} x + C.$

13. $\int \sinh^2(4x-9)\,dx$

SOLUTION $\int \sinh^2(4x-9)\,dx = \frac{1}{2}\int (\cosh(8x-18) - 1)\,dx = \frac{1}{16}\sinh(8x-18) - \frac{1}{2}x + C.$

14. $\int \sinh^3 x \cosh^6 x\, dx$

SOLUTION Let $u = \cosh x$. Then $du = \sinh x\, dx$ and

$$\int \sinh^3 x \cosh^6 x\, dx = \int (\cosh^2 x - 1)\cosh^6 x \sinh x\, dx = \int (u^2 - 1)u^6\, du = \int (u^8 - u^6)\, du$$
$$= \frac{1}{9}u^9 - \frac{1}{7}u^7 + C = \frac{1}{9}\cosh^9 x - \frac{1}{7}\cosh^7 x + C.$$

15. $\int \sinh^2 x \cosh^2 x\, dx$

SOLUTION

$$\int \sinh^2 x \cosh^2 x\, dx = \frac{1}{4}\int \sinh^2 2x\, dx = \frac{1}{8}\int (\cosh 4x - 1)\, dx = \frac{1}{32}\sinh 4x - \frac{1}{8}x + C.$$

16. $\int \tanh^3 x\, dx$

SOLUTION

$$\int \tanh^3 x\, dx = \int (1 - \operatorname{sech}^2 x)\tanh x\, dx = \ln \cosh x - \int \tanh x \operatorname{sech}^2 x\, dx.$$

To evaluate the remaining integral, let $u = \tanh x$. Then $du = \operatorname{sech}^2 x\, dx$ and

$$\int \tanh x \operatorname{sech}^2 x\, dx = \int u\, du = \frac{1}{2}u^2 + C = \frac{1}{2}\tanh^2 x + C.$$

Therefore,

$$\int \tanh^3 x\, dx = \ln \cosh x - \frac{1}{2}\tanh^2 x + C.$$

In Exercises 17–30, calculate the integral in terms of the inverse hyperbolic functions.

17. $\int \frac{dx}{\sqrt{x^2 - 1}}$

SOLUTION $\int \frac{dx}{\sqrt{x^2 - 1}} = \cosh^{-1} x + C.$

18. $\int \frac{dx}{\sqrt{9x^2 - 4}}$

SOLUTION $\int \frac{dx}{\sqrt{9x^2 - 4}} = \frac{1}{3}\cosh^{-1}\left(\frac{3x}{2}\right) + C.$

19. $\int \frac{dx}{\sqrt{16 + 25x^2}}$

SOLUTION $\int \frac{dx}{\sqrt{16 + 25x^2}} = \frac{1}{5}\sinh^{-1}\left(\frac{5x}{4}\right) + C.$

20. $\int \frac{dx}{\sqrt{1 + 3x^2}}$

SOLUTION $\int \frac{dx}{\sqrt{1 + 3x^2}} = \frac{1}{\sqrt{3}}\sinh^{-1}(\sqrt{3}x) + C.$

21. $\int \sqrt{x^2 - 1}\, dx$

SOLUTION Let $x = \cosh t$. Then $dx = \sinh t\, dt$ and

$$\int \sqrt{x^2 - 1}\, dx = \int \sinh^2 t\, dt = \frac{1}{2}\int (\cosh 2t - 1)\, dt = \frac{1}{4}\sinh 2t - \frac{1}{2}t + C$$
$$= \frac{1}{2}\sinh t \cosh t - \frac{1}{2}t + C = \frac{1}{2}x\sqrt{x^2 - 1} - \frac{1}{2}\cosh^{-1} x + C.$$

22. $\displaystyle\int \frac{x^2\,dx}{\sqrt{x^2+1}}$

SOLUTION Let $x = \sinh t$. Then $dx = \cosh t\,dt$ and

$$\int \frac{x^2}{\sqrt{x^2+1}}\,dx = \int \sinh^2 t\,dt = \frac{1}{2}\int (\cosh 2t - 1)\,dt = \frac{1}{4}\sinh 2t - \frac{1}{2}t + C = \frac{1}{2}\sinh t\cosh t - \frac{1}{2}t + C$$
$$= \frac{1}{2}x\sqrt{x^2+1} - \frac{1}{2}\sinh^{-1} x + C.$$

23. $\displaystyle\int_{-1/2}^{1/2} \frac{dx}{1-x^2}$

SOLUTION

$$\int_{-1/2}^{1/2} \frac{dx}{1-x^2} = \tanh^{-1} x\Big|_{-1/2}^{1/2} = \tanh^{-1}\left(\frac{1}{2}\right) - \tanh^{-1}\left(-\frac{1}{2}\right) = 2\tanh^{-1}\left(\frac{1}{2}\right).$$

24. $\displaystyle\int_4^5 \frac{dx}{1-x^2}$

SOLUTION

$$\int_4^5 \frac{dx}{1-x^2} = \frac{1}{2}\ln\left|\frac{1+x}{1-x}\right|\Big|_4^5 = \frac{1}{2}\left(\ln\frac{3}{2} - \ln\frac{5}{3}\right) = \frac{1}{2}\ln\frac{9}{10}.$$

25. $\displaystyle\int_0^1 \frac{dx}{\sqrt{1+x^2}}$

SOLUTION $\displaystyle\int_0^1 \frac{dx}{\sqrt{1+x^2}} = \sinh^{-1}\Big|_0^1 = \sinh^{-1}(1) - \sinh^{-1}(0) = \sinh^{-1} 1.$

26. $\displaystyle\int_2^{10} \frac{dx}{4x^2-1}$

SOLUTION $\displaystyle\int_2^{10} \frac{dx}{4x^2-1} = -\frac{1}{2}\coth^{-1}(2x)\Big|_2^{10} = \frac{1}{2}(\coth^{-1} 4 - \coth^{-1} 20).$

27. $\displaystyle\int_{-3}^{-1} \frac{dx}{x\sqrt{x^2+16}}$

SOLUTION $\displaystyle\int_{-3}^{-1} \frac{dx}{x\sqrt{x^2+16}} = \frac{1}{4}\operatorname{csch}^{-1}\left(\frac{x}{4}\right)\Big|_{-3}^{-1} = \frac{1}{4}\left(\operatorname{csch}^{-1}\left(-\frac{1}{4}\right) - \operatorname{csch}^{-1}\left(-\frac{3}{4}\right)\right).$

28. $\displaystyle\int_{0.2}^{0.8} \frac{dx}{x\sqrt{1-x^2}}$

SOLUTION $\displaystyle\int_{0.2}^{0.8} \frac{dx}{x\sqrt{1-x^2}} = -\operatorname{sech}^{-1} x\Big|_{0.2}^{0.8} = \operatorname{sech}^{-1}(0.2) - \operatorname{sech}^{-1}(0.8)$

29. $\displaystyle\int \frac{\sqrt{x^2-1}\,dx}{x^2}$

SOLUTION Let $x = \cosh t$. Then $dx = \sinh t\,dt$ and

$$\int \frac{\sqrt{x^2-1}\,dx}{x^2} = \int \frac{\sinh^2 t}{\cosh^2 t}\,dt = \int \tanh^2 t\,dt = \int (1 - \operatorname{sech}^2 t)\,dt$$
$$= t - \tanh t + C = \cosh^{-1} x - \frac{\sqrt{x^2-1}}{x} + C.$$

30. $\displaystyle\int_1^9 \frac{dx}{x\sqrt{x^4+1}}$

SOLUTION Let $u = x^2$. Then $du = 2x\,dx$ or $\frac{dx}{x} = \frac{1}{2}\frac{du}{x^2} = \frac{1}{2}\frac{du}{u}$. Hence,

$$\int_1^9 \frac{dx}{x\sqrt{x^4+1}} = \frac{1}{2}\int_1^{81} \frac{du}{u\sqrt{u^2+1}} = -\operatorname{csch}^{-1} u\Big|_1^{81} = \operatorname{csch}^{-1} 1 - \operatorname{csch}^{-1} 81.$$

31. Verify the formulas

$$\sinh^{-1} x = \ln |x + \sqrt{x^2+1}|$$
$$\cosh^{-1} x = \ln |x + \sqrt{x^2-1}| \qquad (\text{for } x \geq 1)$$

SOLUTION Let $x = \sinh t$. Then

$$\cosh t = \sqrt{1+\sinh^2 t} = \sqrt{1+x^2}.$$

Moreover, because

$$\sinh t + \cosh t = \frac{e^t - e^{-t}}{2} + \frac{e^t + e^{-t}}{2} = e^t,$$

it follows that

$$\sinh^{-1} x = t = \ln(\sinh t + \cosh t) = \ln(x + \sqrt{x^2+1}).$$

Now, Let $x = \cosh t$. Then

$$\sinh t = \sqrt{\cosh^2 t - 1} = \sqrt{x^2-1}.$$

and

$$\cosh^{-1} x = t = \ln(\sinh t + \cosh t) = \ln(x + \sqrt{x^2-1}).$$

Because $\cosh t \geq 1$ for all t, this last expression is only valid for $x = \cosh t \geq 1$.

32. Verify that $\tanh^{-1} x = \frac{1}{2}\ln\left|\frac{1+x}{1-x}\right|$ for $|x| < 1$.

SOLUTION Let $A = \tanh^{-1} x$. Then

$$x = \tanh A = \frac{\sinh A}{\cosh A} = \frac{e^A - e^{-A}}{e^A + e^{-A}}.$$

Solving for A yields

$$A = \frac{1}{2}\ln\frac{x+1}{1-x};$$

hence,

$$\tanh^{-1} x = \frac{1}{2}\ln\frac{x+1}{1-x} = \frac{1}{2}\ln\left|\frac{1+x}{1-x}\right|.$$

for $|x| < 1$ (so that both $1+x$ and $1-x$ are positive).

33. Evaluate $\int \sqrt{x^2+16}\,dx$ using trigonometric substitution. Then use Exercise 31 to verify that your answer agrees with the answer in Example 3.

SOLUTION Let $x = 4\tan\theta$. Then $dx = 4\sec^2\theta\,d\theta$ and

$$\int \sqrt{x^2+16}\,dx = 16\int \sec^3\theta\,d\theta = 8\tan\theta\sec\theta + 8\int \sec\theta\,d\theta = 8\tan\theta\sec\theta + 8\ln|\sec\theta + \tan\theta| + C$$
$$= 8\cdot\frac{x}{4}\cdot\frac{\sqrt{x^2+16}}{4} + 8\ln\left|\frac{\sqrt{x^2+16}}{4} + \frac{x}{4}\right| + C$$
$$= \frac{1}{2}x\sqrt{x^2+16} + 8\ln\left|\frac{x}{4} + \sqrt{\left(\frac{x}{4}\right)^2+1}\right| + C.$$

Using Exercise 31,

$$\ln\left|\frac{x}{4} + \sqrt{\left(\frac{x}{4}\right)^2+1}\right| = \sinh^{-1}\left(\frac{x}{4}\right),$$

so we can write the antiderivative as

$$\frac{1}{2}x\sqrt{x^2+16} + 8\sinh^{-1}\left(\frac{x}{4}\right) + C,$$

which agrees with the answer in Example 3.

34. Evaluate $\int \sqrt{x^2-9}\,dx$ in two ways: using trigonometric substitution and using hyperbolic substitution. Then use Exercise 31 to verify that the two answers agree.

SOLUTION First, let $x = 3\sec\theta$. Then $dx = 3\sec\theta\tan\theta\,d\theta$ and

$$\begin{aligned}\int \sqrt{x^2-9}\,dx &= 9\int \tan^2\theta\sec\theta\,d\theta = 9\int \sec^3\theta\,d\theta - 9\int \sec\theta\,d\theta\\ &= \frac{9}{2}\sec\theta\tan\theta + \frac{9}{2}\int \sec\theta\,d\theta - 9\int \sec\theta\,d\theta\\ &= \frac{9}{2}\sec\theta\tan\theta - \frac{9}{2}\ln|\sec\theta+\tan\theta| + C\\ &= \frac{9}{2}\cdot\frac{x}{3}\cdot\frac{\sqrt{x^2-9}}{3} - \frac{9}{2}\ln\left|\frac{x}{3}+\frac{\sqrt{x^2-9}}{3}\right| + C\\ &= \frac{1}{2}x\sqrt{x^2-9} - \frac{9}{2}\ln\left|\frac{x}{3}+\sqrt{\left(\frac{x}{3}\right)^2-1}\right| + C.\end{aligned}$$

Alternately, let $x = 3\cosh t$. Then $dx = 3\sinh t\,dt$ and

$$\begin{aligned}\int \sqrt{x^2-9}\,dx = 9\int \sinh^2 t\,dt &= \frac{9}{2}\int (\cosh 2t - 1)\,dt = \frac{9}{2}\sinh t\cosh t - \frac{9}{2}t + C\\ &= \frac{1}{2}x\sqrt{x^2-9} - \frac{9}{2}\cosh^{-1}\left(\frac{x}{3}\right) + C.\end{aligned}$$

Using Exercise 31,

$$\cosh^{-1}\left(\frac{x}{3}\right) = \ln\left|\frac{x}{3}+\sqrt{\left(\frac{x}{3}\right)^2-1}\right|,$$

so our two answers agree.

35. Prove the reduction formula for $n \ge 2$:

$$\int \cosh^n x\,dx = \frac{1}{n}\cosh^{n-1}x\sinh x + \frac{n-1}{n}\int \cosh^{n-2}x\,dx \qquad \boxed{5}$$

SOLUTION Using Integration by Parts with $u = \cosh^{n-1}x$ and $v' = \cosh x$, we have

$$\begin{aligned}\int \cosh^n x\,dx &= \cosh^{n-1}x\sinh x - (n-1)\int \cosh^{n-2}x\sinh^2 x\,dx\\ &= \cosh^{n-1}x\sinh x - (n-1)\int \cosh^n x\,dx + (n-1)\int \cosh^{n-2}x\,dx.\end{aligned}$$

Adding $(n-1)\int \cosh^n x\,dx$ to both sides then yields

$$n\int \cosh^n x\,dx = \cosh^{n-1}x\sinh x + (n-1)\int \cosh^{n-2}x\,dx.$$

Finally,

$$\int \cosh^n x\,dx = \frac{1}{n}\cosh^{n-1}x\sinh x + \frac{n-1}{n}\int \cosh^{n-2}x\,dx.$$

36. Use Eq. (5) to evaluate $\int \cosh^4 x\,dx$.

SOLUTION Using Eq. (5) twice,

$$\begin{aligned}\int \cosh^4 x\,dx &= \frac{1}{4}\cosh^3 x\sinh x + \frac{3}{4}\int \cosh^2 x\,dx\\ &= \frac{1}{4}\cosh^3 x\sinh x + \frac{3}{4}\left(\frac{1}{2}\cosh x\sinh x + \frac{1}{2}\int dx\right)\\ &= \frac{1}{4}\cosh^3 x\sinh x + \frac{3}{8}\cosh x\sinh x + \frac{3}{8}x + C.\end{aligned}$$

In Exercises 37–40, evaluate the integral.

37. $\int \frac{\tanh^{-1} x\, dx}{x^2 - 1}$

SOLUTION Let $u = \tanh^{-1} x$. Then $du = \frac{1}{1-x^2}\, dx = -\frac{1}{x^2-1}\, dx$ and

$$\int \frac{\tanh^{-1} x}{x^2 - 1}\, dx = -\int u\, du = -\frac{1}{2}u^2 + C = -\frac{1}{2}\left(\tanh^{-1} x\right)^2 + C.$$

38. $\int \sinh^{-1} x\, dx$

SOLUTION Using Integration by Parts with $u = \sinh^{-1} x$ and $v' = 1$,

$$\int \sinh^{-1} x\, dx = x \sinh^{-1} x - \int \frac{x}{\sqrt{x^2+1}}\, dx = x \sinh^{-1} x - \sqrt{x^2+1} + C.$$

39. $\int \tanh^{-1} x\, dx$

SOLUTION Using Integration by Parts with $u = \tanh^{-1} x$ and $v' = 1$,

$$\int \tanh^{-1} x\, dx = x \tanh^{-1} x - \int \frac{x}{1-x^2}\, dx = x \tanh^{-1} x + \frac{1}{2} \ln |1 - x^2| + C.$$

40. $\int x \tanh^{-1} x\, dx$

SOLUTION Using Integration by Parts with $u = \tanh^{-1} x$ and $v' = x$,

$$\int x \tanh^{-1} x\, dx = \frac{1}{2}x^2 \tanh^{-1} x - \frac{1}{2}\int \frac{x^2}{1-x^2}\, dx = \frac{1}{2}x^2 \tanh^{-1} x - \frac{1}{2}\int \left(\frac{1}{1-x^2} - 1\right) dx$$
$$= \frac{1}{2}x^2 \tanh^{-1} x - \frac{1}{2}\tanh^{-1} x + \frac{1}{2}x + C.$$

Further Insights and Challenges

41. Show that if $u = \tanh(x/2)$, then

$$\cosh x = \frac{1+u^2}{1-u^2}, \qquad \sinh x = \frac{2u}{1-u^2}, \qquad dx = \frac{2du}{1-u^2}$$

Hint: For the first relation, use the identities

$$\sinh^2\left(\frac{x}{2}\right) = \frac{1}{2}(\cosh x - 1), \qquad \cosh^2\left(\frac{x}{2}\right) = \frac{1}{2}(\cosh x + 1)$$

SOLUTION Let $u = \tanh(x/2)$. Then

$$u = \frac{\sinh(x/2)}{\cosh(x/2)} = \sqrt{\frac{\cosh x - 1}{\cosh x + 1}}.$$

Solving for $\cosh x$ yields

$$\cosh x = \frac{1+u^2}{1-u^2}.$$

Next,

$$\sinh x = \sqrt{\cosh^2 x - 1} = \sqrt{\frac{(1+u^2)^2 - (1-u^2)^2}{(1-u^2)^2}} = \frac{2u}{1-u^2}.$$

Finally, if $u = \tanh(x/2)$, then $x = 2\tanh^{-1} u$ and

$$dx = \frac{2\,du}{1-u^2}.$$

Exercises 42 and 43: evaluate using the substitution of Exercise 41.

42. $\int \operatorname{sech} x\, dx$

SOLUTION Let $u = \tanh(x/2)$. Then, by Exercise 41,

$$\operatorname{sech} x = \frac{1}{\cosh x} = \frac{1-u^2}{1+u^2} \quad \text{and} \quad dx = \frac{2\,du}{1-u^2},$$

so

$$\int \operatorname{sech} x\, dx = 2\int \frac{du}{1+u^2} = 2\tan^{-1} u + C = 2\tan^{-1}\left(\tanh\frac{x}{2}\right) + C.$$

43. $\int \frac{dx}{1+\cosh x}$

SOLUTION Let $u = \tanh(x/2)$. Then, by Exercise 41,

$$1+\cosh x = 1 + \frac{1+u^2}{1-u^2} = \frac{2}{1-u^2} \quad \text{and} \quad dx = \frac{2\,du}{1-u^2},$$

so

$$\int \frac{dx}{1+\cosh x} = \int du = u + C = \tanh\frac{x}{2} + C.$$

44. Suppose that $y = f(x)$ satisfies $y'' = y$. Prove:
(a) $f(x)^2 - (f'(x))^2$ is constant.
(b) If $f(0) = f'(0) = 0$, then $f(x)$ is the zero function.
(c) $f(x) = f(0)\cosh x + f'(0)\sinh x$.

SOLUTION
(a)

$$\frac{d}{dx}\left[f(x)^2 - (f'(x))^2\right] = 2f(x)f'(x) - 2f'(x)f''(x) = 2f(x)f'(x) - 2f'(x)f(x) = 0$$

so that $f(x)^2 - (f'(x))^2$ must be constant, since it has zero derivative everywhere.
(b) If $f(0) = f'(0) = 0$, then part (a) implies that $f(x)^2 - (f'(x))^2$ is the zero function, since it is constant and vanishes at 0. Thus $f(x) = \pm f'(x)$. But Theorem 1 in Section 5.8 states that the only function $y = f(x)$ with $y' = ky$ is $y = Ce^{kx}$; thus either $f(x) = Ce^x$ or $f(x) = Ce^{-x}$. But in either case, $f(0) = C = 0$, so we must have $C = 0$ and $f(x)$ is the zero function.
(c) Let $g(x) = f(x) - f(0)\cosh x - f'(0)\sinh x$. Then

$$\begin{aligned} g'(x) &= f'(x) - f(0)(\cosh x)' - f'(0)(\sinh x)' = f'(x) - f(0)\sinh x - f'(0)\cosh x \\ g''(x) &= f''(x) - f(0)(\sinh x)' - f'(0)(\cosh x)' = f''(x) - f(0)\cosh x - f'(0)\sinh x \\ &= f(x) - f(0)\cosh x - f'(0)\sinh x = g(x) \end{aligned}$$

since $f''(x) = f(x)$. But also

$$\begin{aligned} g(0) &= f(0) - f(0)\cosh 0 - f'(0)\sinh 0 = f(0) - f(0) = 0 \\ g'(0) &= f'(0) - f(0)\sinh 0 - f'(0)\cosh 0 = f'(0) - f'(0) = 0 \end{aligned}$$

Thus $g(x)$ satisfies the conditions the problem, and in particular of part (b) [replace f by g], so that $g(x)$ must be the zero function. But this means that $f(x) - f(0)\cosh x - f'(0)\sinh x = 0$ so that

$$f(x) = f(0)\cosh x + f'(0)\sinh x$$

*Exercises 45–48 refer to the function $gd(y) = \tan^{-1}(\sinh y)$, called the **gudermannian**. In a map of the earth constructed by Mercator projection, points located y radial units from the equator correspond to points on the globe of latitude $gd(y)$.*

45. Prove that $\frac{d}{dy} gd(y) = \operatorname{sech} y$.

SOLUTION Let $gd(y) = \tan^{-1}(\sinh y)$. Then

$$\frac{d}{dy} gd(y) = \frac{1}{1+\sinh^2 y}\cosh y = \frac{1}{\cosh y} = \operatorname{sech} y,$$

where we have used the identity $1 + \sinh^2 y = \cosh^2 y$.

46. Let $f(y) = 2\tan^{-1}(e^y) - \pi/2$. Prove that $gd(y) = f(y)$. *Hint:* Show that $gd'(y) = f'(y)$ and $f(0) = g(0)$.

SOLUTION Let $f(y) = 2\tan^{-1}\left(e^y\right) - \frac{\pi}{2}$. Then

$$f'(y) = \frac{2e^y}{1+e^{2y}} = \frac{2}{e^{-y}+e^y} = \frac{1}{\frac{e^y+e^{-y}}{2}} = \frac{1}{\cosh y} = \operatorname{sech} y.$$

In the previous exercise we found that $\frac{d}{dy}gd(y) = \operatorname{sech} y$; therefore, $gd'(y) = f'(y)$. Now, since the two functions have equal derivatives, they differ by a constant; that is,

$$gd(y) = f(y) + C.$$

To find C we substitute $y = 0$:

$$\begin{aligned}\tan^{-1}(\sinh 0) &= 2\tan^{-1}(e^0) - \frac{\pi}{2} + C\\ \tan^{-1}0 &= 2\tan^{-1}(1) - \frac{\pi}{2} + C\\ 0 &= 2\cdot\frac{\pi}{4} - \frac{\pi}{2} + C\\ C &= 0.\end{aligned}$$

Therefore,

$$gd(y) = f(y).$$

47. Let $t(y) = \sinh^{-1}(\tan y)$. Show that $t(y)$ is the inverse of $gd(y)$ for $0 \le y < \pi/2$.

SOLUTION Let $x = gd(y) = \tan^{-1}(\sinh y)$. Solving for y yields $y = \sinh^{-1}(\tan x)$. Therefore,

$$gd^{-1}(y) = \sinh^{-1}(\tan y).$$

48. Verify that $t(y)$ in Exercise 47 satisfies $t'(y) = \sec y$, and find a value of a such that

$$t(y) = \int_a^y \frac{dt}{\cos t}$$

SOLUTION Let $t(y) = \sinh^{-1}(\tan y)$. Then

$$t'(y) = \frac{1}{\cos^2 y\sqrt{\tan^2 y + 1}} = \frac{1}{\cos^2 y\sqrt{\frac{1}{\cos^2 y}}} = \frac{1}{\cos^2 y\cdot\frac{1}{|\cos y|}} = \frac{1}{|\cos y|} = |\sec y|.$$

For $0 \le y < \frac{\pi}{2}$, $\sec y > 0$; therefore $t'(y) = \sec y$. Integrating this last relation yields

$$t(y) - t(a) = \int_a^y \frac{1}{\cos t}\,dt.$$

For this to be of the desired form, we must have $t(a) = \sinh^{-1}(\tan a) = 0$. The only value for a that satisfies this equation is $a = 0$.

49. The relations $\cosh(it) = \cos t$ and $\sinh(it) = i\sin t$ were discussed in the Excursion. Use these relations to show that the identity $\cos^2 t + \sin^2 t = 1$ results from setting $x = it$ in the identity $\cosh^2 x - \sinh^2 x = 1$.

SOLUTION Let $x = it$. Then

$$\cosh^2 x = (\cosh(it))^2 = \cos^2 t$$

and

$$\sinh^2 x = (\sinh(it))^2 = i^2\sin^2 t = -\sin^2 t.$$

Thus,

$$1 = \cosh^2(it) - \sinh^2(it) = \cos^2 t - (-\sin^2 t) = \cos^2 t + \sin^2 t,$$

as desired.

7.5 The Method of Partial Fractions

Preliminary Questions

1. Suppose that $\int f(x)\,dx = \ln x + \sqrt{x+1} + C$. Can $f(x)$ be a rational function? Explain.

SOLUTION No, $f(x)$ cannot be a rational function because the integral of a rational function cannot contain a term with a non-integer exponent such as $\sqrt{x+1}$.

2. Which of the following are *proper* rational functions?

(a) $\dfrac{x}{x-3}$

(b) $\dfrac{4}{9-x}$

(c) $\dfrac{x^2+12}{(x+2)(x+1)(x-3)}$

(d) $\dfrac{4x^3-7x}{(x-3)(2x+5)(9-x)}$

SOLUTION

(a) No, this is not a proper rational function because the degree of the numerator is not less than the degree of the denominator.

(b) Yes, this is a proper rational function.

(c) Yes, this is a proper rational function.

(d) No, this is not a proper rational function because the degree of the numerator is not less than the degree of the denominator.

3. Which of the following quadratic polynomials are irreducible? To check, complete the square if necessary.

(a) x^2+5

(b) x^2-5

(c) x^2+4x+6

(d) x^2+4x+2

SOLUTION

(a) Square is already completed; irreducible.

(b) Square is already completed; factors as $(x-\sqrt{5})(x+\sqrt{5})$.

(c) $x^2+4x+6=(x+2)^2+2$; irreducible.

(d) $x^2+4x+2=(x+2)^2-2$; factors as $(x+2-\sqrt{2})(x+2+\sqrt{2})$.

4. Let $P(x)/Q(x)$ be a proper rational function where $Q(x)$ factors as a product of distinct linear factors $(x-a_i)$. Then

$$\int \frac{P(x)\,dx}{Q(x)}$$

(choose the correct answer):

(a) is a sum of logarithmic terms $A_i\ln(x-a_i)$ for some constants A_i.

(b) may contain a term involving the arctangent.

SOLUTION The correct answer is **(a)**: the integral is a sum of logarithmic terms $A_i\ln(x-a_i)$ for some constants A_i.

Exercises

1. Match the rational functions (a)–(d) with the corresponding partial fraction decompositions (i)–(iv).

(a) $\dfrac{x^2+4x+12}{(x+2)(x^2+4)}$

(b) $\dfrac{2x^2+8x+24}{(x+2)^2(x^2+4)}$

(c) $\dfrac{x^2-4x+8}{(x-1)^2(x-2)^2}$

(d) $\dfrac{x^4-4x+8}{(x+2)(x^2+4)}$

(i) $x-2+\dfrac{4}{x+2}-\dfrac{4x-4}{x^2+4}$

(ii) $\dfrac{-8}{x-2}+\dfrac{4}{(x-2)^2}+\dfrac{8}{x-1}+\dfrac{5}{(x-1)^2}$

(iii) $\dfrac{1}{x+2}+\dfrac{2}{(x+2)^2}+\dfrac{-x+2}{x^2+4}$

(iv) $\dfrac{1}{x+2}+\dfrac{4}{x^2+4}$

SOLUTION

(a) $\dfrac{x^2+4x+12}{(x+2)(x^2+4)} = \dfrac{1}{x+2} + \dfrac{4}{x^2+4}$.

(b) $\dfrac{2x^2+8x+24}{(x+2)^2(x^2+4)} = \dfrac{1}{x+2} + \dfrac{2}{(x+2)^2} + \dfrac{-x+2}{x^2+4}$.

(c) $\dfrac{x^2-4x+8}{(x-1)^2(x-2)^2} = \dfrac{-8}{x-2} + \dfrac{4}{(x-2)^2} + \dfrac{8}{x-1} + \dfrac{5}{(x-1)^2}$.

(d) $\dfrac{x^4-4x+8}{(x+2)(x^2+4)} = x-2+\dfrac{4}{x+2} - \dfrac{4x-4}{x^2+4}$.

2. Determine the constants A, B:

$$\frac{2x-3}{(x-3)(x-4)} = \frac{A}{x-3} + \frac{B}{x-4}$$

SOLUTION Clearing denominators gives

$$2x-3 = A(x-4) + B(x-3).$$

Setting $x = 4$ then yields

$$8-3 = A(0) + B(1) \qquad \text{or} \qquad B = 5,$$

while setting $x = 3$ yields

$$6-3 = A(-1) + 0 \qquad \text{or} \qquad A = -3.$$

3. Clear denominators in the following partial fraction decomposition and determine the constant B (substitute a value of x or use the method of undetermined coefficients).

$$\frac{3x^2+11x+12}{(x+1)(x+3)^2} = \frac{1}{x+1} - \frac{B}{x+3} - \frac{3}{(x+3)^2}$$

SOLUTION Clearing denominators gives

$$3x^2+11x+12 = (x+3)^2 - B(x+1)(x+3) - 3(x+1).$$

Setting $x = 0$ then yields

$$12 = 9 - B(1)(3) - 3(1) \qquad \text{or} \qquad B = -2.$$

To use the method of undetermined coefficients, expand the right-hand side and gather like terms:

$$3x^2+11x+12 = (1-B)x^2 + (3-4B)x + (6-3B).$$

Equating x^2-coefficients on both sides, we find

$$3 = 1 - B \qquad \text{or} \qquad B = -2.$$

4. Find the constants in the partial fraction decomposition

$$\frac{2x+4}{(x-2)(x^2+4)} = \frac{A}{x-2} + \frac{Bx+C}{x^2+4}$$

SOLUTION Clearing denominators gives

$$2x+4 = A(x^2+4) + (Bx+C)(x-2).$$

Setting $x = 2$ then yields

$$4+4 = A(4+4) + 0 \qquad \text{or} \qquad A = 1.$$

To find B and C, expand the right side, gather like terms, and use the method of undetermined coefficients:

$$2x+4 = (B+1)x^2 + (-2B+C)x + (4-2C).$$

Equating x^2-coefficients, we find

$$0 = B+1 \qquad \text{or} \qquad B = -1,$$

while equating constants yields

$$4 = 4 - 2C \qquad \text{or} \qquad C = 0.$$

Thus, $A = 1$, $B = -1$, $C = 0$.

In Exercises 5–8, evaluate using long division first to write $f(x)$ as the sum of a polynomial and a proper rational function.

5. $\displaystyle\int \frac{x\,dx}{3x-4}$

SOLUTION Long division gives us

$$\frac{x}{3x-4} = \frac{1}{3} + \frac{4/3}{3x-4}$$

Therefore the integral is

$$\int \frac{x}{3x-4}\,dx = \int \frac{1}{3} - \frac{4}{9x-12}\,dx = \frac{1}{3}x - \frac{4}{9}\ln|9x-12| + C$$

6. $\displaystyle\int \frac{(x^2+2)\,dx}{x+3}$

SOLUTION Long division gives us

$$\frac{x^2+2}{x+3} = x - 3 + \frac{11}{x+3}.$$

Therefore the integral is

$$\int \frac{x^2+2}{x+3}\,dx = \int (x-3)\,dx + 11\int \frac{dx}{x+3} = \frac{x^2}{2} - 3x + 11\ln|x+3| + C.$$

7. $\displaystyle\int \frac{(x^3+2x^2+1)\,dx}{x+2}$

SOLUTION Long division gives us

$$\frac{x^3+2x^2+1}{x+2} = x^2 + \frac{1}{x+2}$$

Therefore the integral is

$$\int \frac{x^3+2x^2+1}{x+2}\,dx = \int x^2 + \frac{1}{x+2}\,dx = \frac{1}{3}x^3 + \ln|x+2| + C$$

8. $\displaystyle\int \frac{(x^3+1)\,dx}{x^2+1}$

SOLUTION Long division gives

$$\frac{x^3+1}{x^2+1} = x - \frac{x-1}{x^2+1}$$

Therefore the integral is

$$\begin{aligned}\int \frac{x^3+1}{x^2+1}\,dx &= \int x - \frac{x-1}{x^2+1}\,dx = \frac{1}{2}x^2 - \int \frac{x}{x^2+1}\,dx + \frac{1}{x^2+1}\,dx\\ &= \frac{1}{2}x^2 - \frac{1}{2}\int \frac{2x\,dx}{x^2+1} + \frac{1}{x^2+1}\,dx = \frac{1}{2}x^2 - \frac{1}{2}\ln(x^2+1) + \tan^{-1}x + C\end{aligned}$$

In Exercises 9–44, evaluate the integral.

9. $\displaystyle\int \frac{dx}{(x-2)(x-4)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{(x-2)(x-4)} = \frac{A}{x-2} + \frac{B}{x-4}.$$

Clearing denominators gives us

$$1 = A(x-4) + B(x-2).$$

Setting $x = 2$ then yields

$$1 = A(2-4) + 0 \qquad \text{or} \qquad A = -\frac{1}{2},$$

while setting $x = 4$ yields

$$1 = 0 + B(4-2) \qquad \text{or} \qquad B = \frac{1}{2}.$$

The result is:

$$\frac{1}{(x-2)(x-4)} = \frac{-\frac{1}{2}}{x-2} + \frac{\frac{1}{2}}{x-4}.$$

Thus,

$$\int \frac{dx}{(x-2)(x-4)} = -\frac{1}{2}\int \frac{dx}{x-2} + \frac{1}{2}\int \frac{dx}{x-4} = -\frac{1}{2}\ln|x-2| + \frac{1}{2}\ln|x-4| + C.$$

10. $\displaystyle\int \frac{(x+3)\,dx}{x+4}$

SOLUTION Start with long division:

$$\frac{x+3}{x+4} = 1 - \frac{1}{x+4}$$

so that

$$\int \frac{x+3}{x+4}\,dx = \int 1 - \frac{1}{x+4}\,dx = x - \ln|x+4| + C$$

11. $\displaystyle\int \frac{dx}{x(2x+1)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{x(2x+1)} = \frac{A}{x} + \frac{B}{2x+1}.$$

Clearing denominators gives us

$$1 = A(2x+1) + Bx.$$

Setting $x = 0$ then yields

$$1 = A(1) + 0 \qquad \text{or} \qquad A = 1,$$

while setting $x = -\frac{1}{2}$ yields

$$1 = 0 + B\left(-\frac{1}{2}\right) \qquad \text{or} \qquad B = -2.$$

The result is:

$$\frac{1}{x(2x+1)} = \frac{1}{x} + \frac{-2}{2x+1}.$$

Thus,

$$\int \frac{dx}{x(2x+1)} = \int \frac{dx}{x} - \int \frac{2\,dx}{2x+1} = \ln|x| - \ln|2x+1| + C.$$

For the integral on the right, we have used the substitution $u = 2x+1$, $du = 2\,dx$.

12. $\int \frac{(2x-1)\,dx}{x^2-5x+6}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{2x-1}{x^2-5x+6} = \frac{2x-1}{(x-2)(x-3)} = \frac{A}{x-2} + \frac{B}{x-3}.$$

Clearing denominators gives us

$$2x-1 = A(x-3) + B(x-2).$$

Setting $x = 2$ then yields

$$3 = A(-1) + 0 \qquad \text{or} \qquad A = -3,$$

while setting $x = 3$ yields

$$5 = 0 + B(1) \qquad \text{or} \qquad B = 5.$$

The result is:

$$\frac{2x-1}{x^2-5x+6} = \frac{-3}{x-2} + \frac{5}{x-3}.$$

Thus,

$$\int \frac{(2x-1)\,dx}{x^2-5x+6} = -3\int \frac{dx}{x-2} + 5\int \frac{dx}{x-3} = -3\ln|x-2| + 5\ln|x-3| + C.$$

13. $\int \frac{x^2\,dx}{x^2+9}$

SOLUTION

$$\int \frac{x^2}{x^2+9}\,dx = \int 1 - \frac{9}{x^2+9}\,dx = x - 3\tan^{-1}\left(\frac{x}{3}\right) + C$$

14. $\int \frac{dx}{(x-2)(x-3)(x+2)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{(x-2)(x-3)(x+2)} = \frac{A}{x-2} + \frac{B}{x-3} + \frac{C}{x+2}.$$

Clearing denominators gives us

$$1 = A(x-3)(x+2) + B(x-2)(x+2) + C(x-2)(x-3).$$

Setting $x = 2$ then yields

$$1 = A(-1)(4) + 0 + 0 \qquad \text{or} \qquad A = -\frac{1}{4},$$

while setting $x = 3$ yields

$$1 = 0 + B(1)(5) + 0 \qquad \text{or} \qquad B = \frac{1}{5},$$

and setting $x = -2$ yields

$$1 = 0 + 0 + C(-4)(-5) \qquad \text{or} \qquad C = \frac{1}{20}.$$

The result is:

$$\frac{1}{(x-2)(x-3)(x+2)} = \frac{-\frac{1}{4}}{x-2} + \frac{\frac{1}{5}}{x-3} + \frac{\frac{1}{20}}{x+2}.$$

Thus,

$$\begin{aligned}\int \frac{dx}{(x-2)(x-3)(x+2)} &= -\frac{1}{4}\int \frac{dx}{x-2} + \frac{1}{5}\int \frac{dx}{x-3} + \frac{1}{20}\int \frac{dx}{x+2} \\ &= -\frac{1}{4}\ln|x-2| + \frac{1}{5}\ln|x-3| + \frac{1}{20}\ln|x+2| + C.\end{aligned}$$

15. $\displaystyle\int \frac{(x^2+3x-44)\,dx}{(x+3)(x+5)(3x-2)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{x^2+3x-44}{(x+3)(x+5)(3x-2)} = \frac{A}{x+3} + \frac{B}{x+5} + \frac{C}{3x-2}.$$

Clearing denominators gives us

$$x^2+3x-44 = A(x+5)(3x-2) + B(x+3)(3x-2) + C(x+3)(x+5).$$

Setting $x=-3$ then yields

$$9-9-44 = A(2)(-11)+0+0 \qquad \text{or} \qquad A=2,$$

while setting $x=-5$ yields

$$25-15-44 = 0+B(-2)(-17)+0 \qquad \text{or} \qquad B=-1,$$

and setting $x=\frac{2}{3}$ yields

$$\frac{4}{9}+2-44 = 0+0+C\left(\frac{11}{3}\right)\left(\frac{17}{3}\right) \qquad \text{or} \qquad C=-2.$$

The result is:

$$\frac{x^2+3x-44}{(x+3)(x+5)(3x-2)} = \frac{2}{x+3} + \frac{-1}{x+5} + \frac{-2}{3x-2}.$$

Thus,

$$\begin{aligned}\int \frac{(x^2+3x-44)\,dx}{(x+3)(x+5)(3x-2)} &= 2\int\frac{dx}{x+3} - \int\frac{dx}{x+5} - 2\int\frac{dx}{3x-2}\\ &= 2\ln|x+3| - \ln|x+5| - \frac{2}{3}\ln|3x-2| + C.\end{aligned}$$

To evaluate the last integral, we have made the substitution $u=3x-2$, $du=3\,dx$.

16. $\displaystyle\int \frac{3\,dx}{(x+1)(x^2+x)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{3}{(x+1)(x^2+x)} = \frac{3}{(x+1)(x)(x+1)} = \frac{3}{x(x+1)^2} = \frac{A}{x} + \frac{B}{x+1} + \frac{C}{(x+1)^2}.$$

Clearing denominators gives us

$$3 = A(x+1)^2 + Bx(x+1) + Cx.$$

Setting $x=0$ then yields

$$3 = A(1)+0+0 \qquad \text{or} \qquad A=3,$$

while setting $x=-1$ yields

$$3 = 0+0+C(-1) \qquad \text{or} \qquad C=-3.$$

Now plug in $A=3$ and $C=-3$:

$$3 = 3(x+1)^2 + Bx(x+1) - 3x.$$

The constant B can be determined by plugging in for x any value other than 0 or -1. Plugging in $x=1$ gives us

$$3 = 3(4) + B(1)(2) - 3 \qquad \text{or} \qquad B=-3.$$

The result is

$$\frac{3}{(x+1)(x^2+x)} = \frac{3}{x} + \frac{-3}{x+1} + \frac{-3}{(x+1)^2}.$$

Thus,

$$\int \frac{3\,dx}{(x+1)(x^2+x)} = 3\int\frac{dx}{x} - 3\int\frac{dx}{x+1} - 3\int\frac{dx}{(x+1)^2} = 3\ln|x| - 3\ln|x+1| + \frac{3}{x+1} + C.$$

17. $\displaystyle\int \frac{(x^2+11x)\,dx}{(x-1)(x+1)^2}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{x^2+11x}{(x-1)(x+1)^2} = \frac{A}{x-1} + \frac{B}{x+1} + \frac{C}{(x+1)^2}.$$

Clearing denominators gives us

$$x^2+11x = A(x+1)^2 + B(x-1)(x+1) + C(x-1).$$

Setting $x=1$ then yields

$$12 = A(4)+0+0 \qquad \text{or} \qquad A=3,$$

while setting $x=-1$ yields

$$-10 = 0+0+C(-2) \qquad \text{or} \qquad C=5.$$

Plugging in these values results in

$$x^2+11x = 3(x+1)^2 + B(x-1)(x+1) + 5(x-1).$$

The constant B can be determined by plugging in for x any value other than 1 or -1. If we plug in $x=0$, we get

$$0 = 3 + B(-1)(1) + 5(-1) \qquad \text{or} \qquad B=-2.$$

The result is

$$\frac{x^2+11x}{(x-1)(x+1)^2} = \frac{3}{x-1} + \frac{-2}{x+1} + \frac{5}{(x+1)^2}.$$

Thus,

$$\int \frac{(x^2+11x)\,dx}{(x-1)(x+1)^2} = 3\int \frac{dx}{x-1} - 2\int \frac{dx}{x+1} + 5\int \frac{dx}{(x+1)^2} = 3\ln|x-1| - 2\ln|x+1| - \frac{5}{x+1} + C.$$

18. $\displaystyle\int \frac{(4x^2-21x)\,dx}{(x-3)^2(2x+3)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{4x^2-21x}{(x-3)^2(2x+3)} = \frac{A}{x-3} + \frac{B}{(x-3)^2} + \frac{C}{2x+3}.$$

Clearing denominators gives us

$$4x^2-21x = A(x-3)(2x+3) + B(2x+3) + C(x-3)^2.$$

Setting $x=3$ then yields

$$-27 = 0 + B(9) + 0 \qquad \text{or} \qquad B=-3,$$

while setting $x=-\frac{3}{2}$ yields

$$9 + \frac{63}{2} = 0+0+C\left(\frac{81}{4}\right) \qquad \text{or} \qquad C=2.$$

Plugging in these values results in

$$4x^2-21x = A(x-3)(2x+3) - 3(2x+3) + 2(x-3)^2.$$

Setting $x=0$ gives us

$$0 = A(-3)(3) - 9 + 18 \qquad \text{or} \qquad A=1.$$

The result is

$$\frac{4x^2-21x}{(x-3)^2(2x+3)} = \frac{1}{x-3} + \frac{-3}{(x-3)^2} + \frac{2}{2x+3}.$$

Thus,

$$\int \frac{(4x^2-21x)\,dx}{(x-3)^2(2x+3)} = \int \frac{dx}{x-3} - 3\int \frac{dx}{(x-3)^2} + \int \frac{2\,dx}{2x+3} = \ln|x-3| + \frac{3}{x-3} + \ln|2x+3| + C.$$

19. $\displaystyle\int \frac{dx}{(x-1)^2(x-2)^2}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{(x-1)^2(x-2)^2} = \frac{A}{x-1} + \frac{B}{(x-1)^2} + \frac{C}{x-2} + \frac{D}{(x-2)^2}.$$

Clearing denominators gives us

$$1 = A(x-1)(x-2)^2 + B(x-2)^2 + C(x-2)(x-1)^2 + D(x-1)^2.$$

Setting $x = 1$ then yields

$$1 = B(1) \qquad \text{or} \qquad B = 1,$$

while setting $x = 2$ yields

$$1 = D(1) \qquad \text{or} \qquad D = 1.$$

Plugging in these values gives us

$$1 = A(x-1)(x-2)^2 + (x-2)^2 + C(x-2)(x-1)^2 + (x-1)^2.$$

Setting $x = 0$ now yields

$$1 = A(-1)(4) + 4 + C(-2)(1) + 1 \qquad \text{or} \qquad -4 = -4A - 2C,$$

while setting $x = 3$ yields

$$1 = A(2)(1) + 1 + C(1)(4) + 4 \qquad \text{or} \qquad -4 = 2A + 4C.$$

Solving this system of two equations in two unknowns gives $A = 2$ and $C = -2$. The result is

$$\frac{1}{(x-1)^2(x-2)^2} = \frac{2}{x-1} + \frac{1}{(x-1)^2} + \frac{-2}{x-2} + \frac{1}{(x-2)^2}.$$

Thus,

$$\begin{aligned}\int \frac{dx}{(x-1)^2(x-2)^2} &= 2\int \frac{dx}{x-1} + \int \frac{dx}{(x-1)^2} - 2\int \frac{dx}{x-2} + \int \frac{dx}{(x-2)^2} \\ &= 2\ln|x-1| - \frac{1}{x-1} - 2\ln|x-2| - \frac{1}{x-2} + C.\end{aligned}$$

20. $\displaystyle\int \frac{(x^2-8x)\,dx}{(x+1)(x+4)^3}$

SOLUTION The partial fraction decomposition is

$$\frac{x^2-8x}{(x+1)(x+4)^3} = \frac{A}{x+1} + \frac{B}{x+4} + \frac{C}{(x+4)^2} + \frac{D}{(x+4)^3}$$

Clearing fractions gives

$$x^2 - 8x = A(x+4)^3 + B(x+4)^2(x+1) + C(x+4)(x+1) + D(x+1)$$

Setting $x = -4$ gives $48 = -3D$ so that $D = -16$. Setting $x = -1$ gives $9 = 27A$ so that $A = \frac{1}{3}$. Thus

$$x^2 - 8x = \frac{1}{3}(x+4)^3 + B(x+4)^2(x+1) + C(x+4)(x+1) - 16(x+1)$$

The coefficient of x^3 on the right hand side must be zero; it is $\frac{1}{3} + B$, so that $B = -\frac{1}{3}$. Finally, the constant term on the right must be zero as well; substituting the known values of A, B, and D gives for the constant term

$$\frac{1}{3}\cdot 64 - \frac{1}{3}\cdot 16 + 4C - 16 = 4C$$

so that $C = 0$, and the partial fraction decomposition is

$$\frac{x^2-8x}{(x+1)(x+4)^3} = \frac{1}{3(x+1)} - \frac{1}{3(x+4)} - \frac{16}{(x+4)^3}$$

Thus

$$\int \frac{x^2-8x}{(x+1)(x+4)^3}\,dx = \frac{1}{3}\int \frac{1}{x+1}\,dx - \frac{1}{3}\int \frac{1}{x+4}\,dx - 16\int \frac{1}{(x+4)^3}\,dx$$
$$= \frac{1}{3}\ln|x+1| - \frac{1}{3}\ln|x+4| + 8(x+4)^{-2} + C = \frac{1}{3}\ln\left|\frac{x+1}{x+4}\right| + 8(x+4)^{-2} + C$$

21. $\int \frac{8\,dx}{x(x+2)^3}$

SOLUTION The partial fraction decomposition is

$$\frac{8}{x(x+2)^3} = \frac{A}{x} + \frac{B}{x+2} + \frac{C}{(x+2)^2} + \frac{D}{(x+2)^3}$$

Clearing fractions gives

$$8 = A(x+2)^3 + Bx(x+2)^2 + Cx(x+2) + Dx$$

Setting $x=0$ gives $8=8A$ so $A=1$; setting $x=-2$ gives $8=-2D$ so that $D=-4$; the result is

$$8 = (x+2)^3 + Bx(x+2)^2 + Cx(x+2) - 4x$$

The coefficient of x^3 on the right-hand side must be zero, since it is zero on the left. We compute it to be $1+B$, so that $B=-1$. Finally, we look at the coefficient of x^2 on the right-hand side; it must be zero as well. We compute it to be

$$3\cdot 2 - 4 + C = C + 2$$

so that $C=-2$ and the partial fraction decomposition is

$$\frac{8}{x(x+2)^3} = \frac{1}{x} - \frac{1}{x+2} - \frac{2}{(x+2)^2} - \frac{4}{(x+2)^3}$$

and

$$\int \frac{8}{x(x+2)^3}\,dx = \int \frac{1}{x}\,dx - \frac{1}{x+2}\,dx - 2\int (x+2)^{-2}\,dx - 4\int (x+2)^{-3}\,dx$$
$$= \ln|x| - \ln|x+2| + 2(x+2)^{-1} + 2(x+2)^{-2} + C = \ln\left|\frac{x}{x+2}\right| + \frac{2}{x+2} + \frac{2}{(x+2)^2} + C$$

22. $\int \frac{x^2\,dx}{x^2+3}$

SOLUTION

$$\int \frac{x^2}{x^2+3}\,dx = \int 1 - \frac{3}{x^2+3}\,dx = \int 1\,dx - 3\int \frac{1}{x^2+3}\,dx = x - \sqrt{3}\tan^{-1}\left(\frac{x}{\sqrt{3}}\right) + C$$

23. $\int \frac{dx}{2x^2-3}$

SOLUTION The partial fraction decomposition has the form

$$\frac{1}{2x^2-3} = \frac{1}{(\sqrt{2}x-\sqrt{3})(\sqrt{2}x+\sqrt{3})} = \frac{A}{\sqrt{2}x-\sqrt{3}} + \frac{B}{\sqrt{2}x+\sqrt{3}}.$$

Clearing denominators, we get

$$1 = A\left(\sqrt{2}x+\sqrt{3}\right) + B\left(\sqrt{2}x-\sqrt{3}\right).$$

Setting $x=\sqrt{3}/\sqrt{2}$ then yields

$$1 = A\left(\sqrt{3}+\sqrt{3}\right) + 0 \qquad \text{or} \qquad A = \frac{1}{2\sqrt{3}},$$

while setting $x=-\sqrt{3}/\sqrt{2}$ yields

$$1 = 0 + B\left(-\sqrt{3}-\sqrt{3}\right) \qquad \text{or} \qquad B = \frac{-1}{2\sqrt{3}}.$$

The result is

$$\frac{1}{2x^2-3} = \frac{1/2\sqrt{3}}{\sqrt{2}x-\sqrt{3}} - \frac{1/2\sqrt{3}}{\sqrt{2}x+\sqrt{3}}.$$

Thus,

$$\int \frac{dx}{2x^2-3} = \frac{1}{2\sqrt{3}}\int \frac{dx}{\sqrt{2}x-\sqrt{3}} - \frac{1}{2\sqrt{3}}\int \frac{dx}{\sqrt{2}x+\sqrt{3}}.$$

For the first integral, let $u = \sqrt{2}x - \sqrt{3}$, $du = \sqrt{2}\,dx$, and for the second, let $w = \sqrt{2}x + \sqrt{3}$, $dw = \sqrt{2}\,dx$. Then we have

$$\int \frac{dx}{2x^2-3} = \frac{1}{2\sqrt{3}(\sqrt{2})}\int \frac{du}{u} - \frac{1}{2\sqrt{3}(\sqrt{2})}\int \frac{dw}{w} = \frac{1}{2\sqrt{6}}\ln\left|\sqrt{2}x-\sqrt{3}\right| - \frac{1}{2\sqrt{6}}\ln\left|\sqrt{2}x+\sqrt{3}\right| + C.$$

24. $\displaystyle\int \frac{dx}{(x-4)^2(x-1)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{(x-4)^2(x-1)} = \frac{A}{x-4} + \frac{B}{(x-4)^2} + \frac{C}{(x-1)}.$$

Clearing denominators, we get

$$1 = A(x-4)(x-1) + B(x-1) + C(x-4)^2.$$

Setting $x = 1$ then yields

$$1 = 0 + 0 + C(9) \qquad \text{or} \qquad C = \frac{1}{9},$$

while setting $x = 4$ yields

$$1 = 0 + B(3) + 0 \qquad \text{or} \qquad B = \frac{1}{3}.$$

Plugging in $B = \frac{1}{3}$ and $C = \frac{1}{9}$, and setting $x = 5$, we find

$$1 = A(1)(4) + \frac{1}{3}(4) + \frac{1}{9}(1) \qquad \text{or} \qquad A = -\frac{1}{9}.$$

The result is

$$\frac{1}{(x-4)^2(x-1)} = \frac{-\frac{1}{9}}{x-4} + \frac{\frac{1}{3}}{(x-4)^2} + \frac{\frac{1}{9}}{x-1}.$$

Thus,

$$\begin{aligned}\int \frac{dx}{(x-4)^2(x-1)} &= -\frac{1}{9}\int \frac{dx}{x-4} + \frac{1}{3}\int \frac{dx}{(x-4)^2} + \frac{1}{9}\int \frac{dx}{x-1}\\ &= -\frac{1}{9}\ln|x-4| - \frac{1}{3(x-4)} + \frac{1}{9}\ln|x-1| + C.\end{aligned}$$

25. $\displaystyle\int \frac{4x^2-20}{(2x+5)^3}\,dx$

SOLUTION The partial fraction decomposition is

$$\frac{4x^2-20}{(2x+5)^3} = \frac{A}{2x+5} + \frac{B}{(2x+5)^2} + \frac{C}{(2x+5)^3}$$

Clearing fractions gives

$$4x^2 - 20 = A(2x+5)^2 + B(2x+5) + C$$

Setting $x = -5/2$ gives $5 = C$ so that $C = 5$. The coefficient of x^2 on the left-hand side is 4, and on the right-hand side is $4A$, so that $A = 1$ and we have

$$4x^2 - 20 = (2x+5)^2 + B(2x+5) + 5$$

Considering the constant terms now gives $-20 = 25 + 5B + 5$ so that $B = -10$. Thus

$$\int \frac{4x^2 - 20}{(2x+5)^3} = \int \frac{1}{2x+5}\,dx - 10\int \frac{1}{(2x+5)^2}\,dx + 5\int \frac{1}{(2x+5)^3}\,dx$$
$$= \frac{1}{2}\ln|2x+5| + \frac{5}{2x+5} - \frac{5}{4(2x+5)^2} + C$$

26. $\displaystyle\int \frac{3x+6}{x^2(x-1)(x-3)}\,dx$

SOLUTION The partial fraction decomposition has the form:

$$\frac{3x+6}{x^2(x-1)(x-3)} = \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x-1} + \frac{D}{x-3}.$$

Clearing denominators gives us

$$3x + 6 = Ax(x-1)(x-3) + B(x-1)(x-3) + Cx^2(x-3) + Dx^2(x-1).$$

Setting $x = 0$, then yields

$$6 = 0 + B(-1)(-3) + 0 + 0 \qquad \text{or} \qquad B = 2,$$

while setting $x = 1$ yields

$$9 = 0 + 0 + C(1)(-2) + 0 \qquad \text{or} \qquad C = -\frac{9}{2},$$

and setting $x = 3$ yields

$$15 = 0 + 0 + 0 + D(9)(2) \qquad \text{or} \qquad D = \frac{5}{6}.$$

In order to find A, let's look at the x^3-coefficient on the right-hand side (which must equal 0, since there's no x^3 term on the left):

$$0 = A + C + D = A - \frac{9}{2} + \frac{5}{6}, \qquad \text{so} \qquad A = \frac{11}{3}.$$

The result is

$$\frac{3x+6}{x^2(x-1)(x-3)} = \frac{\frac{11}{3}}{x} + \frac{2}{x^2} + \frac{-\frac{9}{2}}{x-1} + \frac{\frac{5}{6}}{x-3}.$$

Thus,

$$\int \frac{(3x+6)\,dx}{x^2(x-1)(x-3)} = \frac{11}{3}\int \frac{dx}{x} + 2\int \frac{dx}{x^2} - \frac{9}{2}\int \frac{dx}{x-1} + \frac{5}{6}\int \frac{dx}{x-3}$$
$$= \frac{11}{3}\ln|x| - \frac{2}{x} - \frac{9}{2}\ln|x-1| + \frac{5}{6}\ln|x-3| + C.$$

27. $\displaystyle\int \frac{dx}{x(x-1)^3}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{x(x-1)^3} = \frac{A}{x} + \frac{B}{x-1} + \frac{C}{(x-1)^2} + \frac{D}{(x-1)^3}.$$

Clearing denominators, we get

$$1 = A(x-1)^3 + Bx(x-1)^2 + Cx(x-1) + Dx.$$

Setting $x = 0$ then yields

$$1 = A(-1) + 0 + 0 + 0 \qquad \text{or} \qquad A = -1,$$

while setting $x = 1$ yields

$$1 = 0 + 0 + 0 + D(1) \qquad \text{or} \qquad D = 1.$$

Plugging in $A = -1$ and $D = 1$ gives us

$$1 = -(x-1)^3 + Bx(x-1)^2 + Cx(x-1) + x.$$

Now, setting $x = 2$ yields

$$1 = -1 + 2B + 2C + 2 \qquad \text{or} \qquad 2B + 2C = 0,$$

and setting $x = 3$ yields

$$1 = -8 + 12B + 6C + 3 \qquad \text{or} \qquad 2B + C = 1.$$

Solving these two equations in two unknowns, we find $B = 1$ and $C = -1$. The result is

$$\frac{1}{x(x-1)^3} = \frac{-1}{x} + \frac{1}{x-1} + \frac{-1}{(x-1)^2} + \frac{1}{(x-1)^3}.$$

Thus,

$$\int \frac{dx}{x(x-1)^3} = -\int \frac{dx}{x} + \int \frac{dx}{x-1} - \int \frac{dx}{(x-1)^2} + \int \frac{dx}{(x-1)^3}$$
$$= -\ln|x| + \ln|x-1| + \frac{1}{x-1} - \frac{1}{2(x-1)^2} + C.$$

28. $\displaystyle\int \frac{(3x^2-2)\,dx}{x-4}$

SOLUTION First we use long division to write

$$\frac{3x^2-2}{x-4} = 3x + 12 + \frac{46}{x-4}.$$

Then the integral becomes

$$\int \frac{(3x^2-2)\,dx}{x-4} = \int (3x+12)\,dx + 46\int \frac{dx}{x-4} = \frac{3}{2}x^2 + 12x + 46\ln|x-4| + C.$$

29. $\displaystyle\int \frac{(x^2-x+1)\,dx}{x^2+x}$

SOLUTION First use long division to write

$$\frac{x^2-x+1}{x^2+x} = 1 + \frac{-2x+1}{x^2+x} = 1 + \frac{-2x+1}{x(x+1)}.$$

The partial fraction decomposition of the term on the right has the form:

$$\frac{-2x+1}{x(x+1)} = \frac{A}{x} + \frac{B}{x+1}.$$

Clearing denominators gives us

$$-2x + 1 = A(x+1) + Bx.$$

Setting $x = 0$ then yields

$$1 = A(1) + 0 \qquad \text{or} \qquad A = 1,$$

while setting $x = -1$ yields

$$3 = 0 + B(-1) \qquad \text{or} \qquad B = -3.$$

The result is

$$\frac{-2x+1}{x(x+1)} = \frac{1}{x} + \frac{-3}{x+1}.$$

Thus,

$$\int \frac{(x^2-x+1)\,dx}{x^2+x} = \int dx + \int \frac{dx}{x} - 3\int \frac{dx}{x+1} = x + \ln|x| - 3\ln|x+1| + C.$$

30. $\displaystyle\int \frac{dx}{x(x^2+1)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{x(x^2+1)} = \frac{A}{x} + \frac{Bx+C}{x^2+1}.$$

Clearing denominators, we get

$$1 = A(x^2+1) + (Bx+C)x.$$

Setting $x = 0$ then yields

$$1 = A(1) + 0 \qquad \text{or} \qquad A = 1.$$

This gives us

$$1 = x^2 + 1 + Bx^2 + Cx = (B+1)x^2 + Cx + 1.$$

Equating x^2-coefficients, we find

$$B + 1 = 0 \qquad \text{or} \qquad B = -1;$$

while equating x-coefficients yields $C = 0$. The result is

$$\frac{1}{x(x^2+1)} = \frac{1}{x} + \frac{-x}{x^2+1}.$$

Thus,

$$\int \frac{dx}{x(x^2+1)} = \int \frac{dx}{x} - \int \frac{x\,dx}{x^2+1}.$$

For the integral on the right, use the substitution $u = x^2+1$, $du = 2x\,dx$. Then we have

$$\int \frac{dx}{x(x^2+1)} = \int \frac{dx}{x} - \frac{1}{2}\int \frac{du}{u} = \ln|x| - \frac{1}{2}\ln|x^2+1| + C.$$

31. $\displaystyle\int \frac{(3x^2-4x+5)\,dx}{(x-1)(x^2+1)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{3x^2-4x+5}{(x-1)(x^2+1)} = \frac{A}{x-1} + \frac{Bx+C}{x^2+1}.$$

Clearing denominators, we get

$$3x^2 - 4x + 5 = A(x^2+1) + (Bx+C)(x-1).$$

Setting $x = 1$ then yields

$$3 - 4 + 5 = A(2) + 0 \qquad \text{or} \qquad A = 2.$$

This gives us

$$3x^2 - 4x + 5 = 2(x^2+1) + (Bx+C)(x-1) = (B+2)x^2 + (C-B)x + (2-C).$$

Equating x^2-coefficients, we find

$$3 = B + 2 \qquad \text{or} \qquad B = 1;$$

while equating constant coefficients yields

$$5 = 2 - C \qquad \text{or} \qquad C = -3.$$

The result is

$$\frac{3x^2-4x+5}{(x-1)(x^2+1)} = \frac{2}{x-1} + \frac{x-3}{x^2+1}.$$

Thus,

$$\int \frac{(3x^2-4x+5)\,dx}{(x-1)(x^2+1)} = 2\int \frac{dx}{x-1} + \int \frac{(x-3)\,dx}{x^2+1} = 2\int \frac{dx}{x-1} + \int \frac{x\,dx}{x^2+1} - 3\int \frac{dx}{x^2+1}.$$

For the second integral, use the substitution $u = x^2+1$, $du = 2x\,dx$. The final answer is

$$\int \frac{(3x^2-4x+5)\,dx}{(x-1)(x^2+1)} = 2\ln|x-1| + \frac{1}{2}\ln|x^2+1| - 3\tan^{-1}x + C.$$

32. $\displaystyle\int \frac{x^2}{(x+1)(x^2+1)}\,dx$

SOLUTION The partial fraction decomposition has the form

$$\frac{x^2}{(x+1)(x^2+1)} = \frac{A}{x+1} + \frac{Bx+C}{x^2+1}.$$

Clearing denominators, we get

$$x^2 = A(x^2+1) + (Bx+C)(x+1).$$

Setting $x = -1$ then yields

$$1 = A(2) + 0 \qquad \text{or} \qquad A = \frac{1}{2}.$$

This gives us

$$x^2 = \frac{1}{2}x^2 + \frac{1}{2} + Bx^2 + Bx + Cx + C = \left(B + \frac{1}{2}\right)x^2 + (B+C)x + \left(C + \frac{1}{2}\right).$$

Equating x^2-coefficients, we find

$$1 = B + \frac{1}{2} \qquad \text{or} \qquad B = \frac{1}{2},$$

while equating constant coefficients yields

$$0 = C + \frac{1}{2} \qquad \text{or} \qquad C = -\frac{1}{2}.$$

The result is

$$\frac{x^2}{(x+1)(x^2+1)} = \frac{\frac{1}{2}}{x+1} + \frac{\frac{1}{2}x - \frac{1}{2}}{x^2+1}.$$

Thus,

$$\int \frac{x^2\,dx}{(x+1)(x^2+1)} = \frac{1}{2}\int \frac{dx}{x+1} + \frac{1}{2}\int \frac{(x-1)\,dx}{x^2+1} = \frac{1}{2}\int \frac{dx}{x+1} + \frac{1}{2}\int \frac{x\,dx}{x^2+1} - \frac{1}{2}\int \frac{dx}{x^2+1}$$
$$= \frac{1}{2}\ln|x+1| + \frac{1}{4}\ln|x^2+1| - \frac{1}{2}\tan^{-1}x + C.$$

Here we used $u = x^2+1$, $du = 2x\,dx$ for the second integral.

33. $\displaystyle\int \frac{dx}{x(x^2+25)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{x(x^2+25)} = \frac{A}{x} + \frac{Bx+C}{x^2+25}.$$

Clearing denominators, we get

$$1 = A(x^2+25) + (Bx+C)x.$$

Setting $x = 0$ then yields

$$1 = A(25) + 0 \qquad \text{or} \qquad A = \frac{1}{25}.$$

This gives us

$$1 = \frac{1}{25}x^2 + 1 + Bx^2 + Cx = \left(B + \frac{1}{25}\right)x^2 + Cx + 1.$$

Equating x^2-coefficients, we find

$$0 = B + \frac{1}{25} \qquad \text{or} \qquad B = -\frac{1}{25},$$

while equating x-coefficients yields $C = 0$. The result is

$$\frac{1}{x(x^2+25)} = \frac{\frac{1}{25}}{x} + \frac{-\frac{1}{25}x}{x^2+25}.$$

Thus,

$$\int \frac{dx}{x(x^2+25)} = \frac{1}{25}\int \frac{dx}{x} - \frac{1}{25}\int \frac{x\,dx}{x^2+25}.$$

For the integral on the right, use $u = x^2 + 25$, $du = 2x\,dx$. Then we have

$$\int \frac{dx}{x(x^2+25)} = \frac{1}{25}\ln|x| - \frac{1}{50}\ln|x^2+25| + C.$$

34. $\displaystyle\int \frac{dx}{x^2(x^2+25)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{x^2(x^2+25)} = \frac{A}{x} + \frac{B}{x^2} + \frac{Cx+D}{x^2+25}.$$

Clearing denominators, we get

$$1 = Ax(x^2+25) + B(x^2+25) + (Cx+D)x^2.$$

Setting $x = 0$ then yields

$$1 = 0 + B(25) + 0 \qquad \text{or} \qquad B = \frac{1}{25}.$$

This gives us

$$1 = Ax^3 + 25Ax + \frac{1}{25}x^2 + 1 + Cx^3 + Dx^2 = (A+C)x^3 + \left(D + \frac{1}{25}\right)x^2 + 25Ax + 1.$$

Equating x-coefficients yields

$$0 = 25A \qquad \text{or} \qquad A = 0,$$

while equating x^3-coefficients yields

$$0 = A + C = 0 + C \qquad \text{or} \qquad C = 0,$$

and equating x^2-coefficients yields

$$0 = D + \frac{1}{25} \qquad \text{or} \qquad D = \frac{-1}{25}.$$

The result is

$$\frac{1}{x^2(x^2+25)} = \frac{\frac{1}{25}}{x^2} + \frac{\frac{-1}{25}}{x^2+25}.$$

Thus,

$$\int \frac{dx}{x^2(x^2+25)} = \frac{1}{25}\int \frac{dx}{x^2} - \frac{1}{25}\int \frac{dx}{x^2+25} = -\frac{1}{25x} - \frac{1}{125}\tan^{-1}\left(\frac{x}{5}\right) + C.$$

35. $\displaystyle\int \frac{(6x^2+2)\,dx}{x^2+2x-3}$

SOLUTION Long division gives

$$\frac{6x^2+2}{x^2+2x-3} = 6 - \frac{12x-20}{x^2+2x-3} = 6 - \frac{12x-20}{(x+3)(x-1)}$$

The partial fraction decomposition of the second term is

$$\frac{12x-20}{(x+3)(x-1)} = \frac{A}{x+3} + \frac{B}{x-1}$$

Clear fractions to get

$$12x - 20 = A(x-1) + B(x+3)$$

Set $x = 1$ to get $-8 = 4B$ so that $B = -2$. Set $x = -3$ to get $-56 = -4A$ so that $A = 14$, and we have

$$\int \frac{6x^2+2}{x^2+2x-3} = \int 6 - \frac{14}{x+3} + \frac{2}{x-1}\,dx = \int 6\,dx - 14\int \frac{1}{x+3}\,dx + 2\int \frac{1}{x-1}\,dx$$
$$= 6x - 14\ln|x+3| + 2\ln|x-1| + C$$

36. $\displaystyle\int \frac{6x^2+7x-6}{(x^2-4)(x+2)}\,dx$

SOLUTION The partial fraction decomposition has the form:

$$\frac{6x^2+7x-6}{(x^2-4)(x+2)} = \frac{6x^2+7x-6}{(x-2)(x+2)(x+2)} = \frac{A}{x-2} + \frac{B}{x+2} + \frac{C}{(x+2)^2}.$$

Clearing denominators, we get

$$6x^2+7x-6 = A(x+2)^2 + B(x-2)(x+2) + C(x-2).$$

Setting $x = 2$ then yields

$$24 + 14 - 6 = A(16) + 0 + 0 \qquad \text{or} \qquad A = 2,$$

while setting $x = -2$ yields

$$24 - 14 - 6 = 0 + 0 + C(-4) \qquad \text{or} \qquad C = -1.$$

This gives us

$$6x^2 + 7x - 6 = 2(x+2)^2 + B(x-2)(x+2) - (x-2).$$

Now, setting $x = 1$ yields

$$6 + 7 - 6 = 2(9) + B(-1)(3) - (-1) \qquad \text{or} \qquad B = 4.$$

The result is

$$\frac{6x^2+7x-6}{(x^2-4)(x+2)} = \frac{2}{x-2} + \frac{4}{x+2} + \frac{-1}{(x+2)^2}.$$

Thus,

$$\int \frac{(6x^2+7x-6)\,dx}{(x^2-4)(x+2)} = 2\int \frac{dx}{x-2} + 4\int \frac{dx}{x+2} - \int \frac{dx}{(x+2)^2} = 2\ln|x-2| + 4\ln|x+2| + \frac{1}{x+2} + C.$$

37. $\displaystyle\int \frac{10\,dx}{(x-1)^2(x^2+9)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{10}{(x-1)^2(x^2+9)} = \frac{A}{x-1} + \frac{B}{(x-1)^2} + \frac{Cx+D}{x^2+9}.$$

Clearing denominators, we get

$$10 = A(x-1)(x^2+9) + B(x^2+9) + (Cx+D)(x-1)^2.$$

Setting $x = 1$ then yields

$$10 = 0 + B(10) + 0 \qquad \text{or} \qquad B = 1.$$

Expanding the right-hand side, we have

$$10 = (A+C)x^3 + (1 - A - 2C + D)x^2 + (9A + C - 2D)x + (9 - 9A + D).$$

Equating coefficients of like powers of x then yields

$$\begin{aligned} A + C &= 0 \\ 1 - A - 2C + D &= 0 \\ 9A + C - 2D &= 0 \\ 9 - 9A + D &= 10 \end{aligned}$$

From the first equation, we have $C = -A$, and from the fourth equation we have $D = 1 + 9A$. Substituting these into the second equation, we get

$$1 - A - 2(-A) + (1 + 9A) = 0 \qquad \text{or} \qquad A = -\frac{1}{5}.$$

Finally, $C = \frac{1}{5}$ and $D = -\frac{4}{5}$. The result is

$$\frac{10}{(x-1)^2(x^2+9)} = \frac{-\frac{1}{5}}{x-1} + \frac{1}{(x-1)^2} + \frac{\frac{1}{5}x - \frac{4}{5}}{x^2+9}.$$

Thus,

$$\begin{aligned} \int \frac{10\,dx}{(x-1)^2(x^2+9)} &= -\frac{1}{5}\int \frac{dx}{x-1} + \int \frac{dx}{(x-1)^2} + \frac{1}{5}\int \frac{x\,dx}{x^2+9} - \frac{4}{5}\int \frac{dx}{x^2+9} \\ &= -\frac{1}{5}\ln|x-1| - \frac{1}{x-1} + \frac{1}{10}\ln|x^2+9| - \frac{4}{15}\tan^{-1}\left(\frac{x}{3}\right) + C. \end{aligned}$$

38. $\displaystyle\int \frac{10\,dx}{(x+1)(x^2+9)^2}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{10}{(x+1)(x^2+9)^2} = \frac{A}{x+1} + \frac{Bx+C}{x^2+9} + \frac{Dx+E}{(x^2+9)^2}.$$

Clearing denominators gives us

$$10 = A(x^2+9)^2 + (Bx+C)(x+1)(x^2+9) + (Dx+E)(x+1).$$

Setting $x = -1$ then yields

$$10 = A(100) + 0 + 0 \qquad \text{or} \qquad A = \frac{1}{10}.$$

Expanding the right-hand side, we find

$$10 = \left(B + \frac{1}{10}\right)x^4 + (B+C)x^3 + \left(9B + C + D + \frac{18}{10}\right)x^2(9B + 9C + D + E)x + \left(9C + E + \frac{81}{10}\right).$$

Equating x^4-coefficients yields

$$B + \frac{1}{10} = 0 \qquad \text{or} \qquad B = -\frac{1}{10},$$

while equating x^3-coefficients yields

$$-\frac{1}{10} + C = 0 \qquad \text{or} \qquad C = \frac{1}{10},$$

and equating x^2-coefficients yields

$$-\frac{9}{10} + \frac{1}{10} + D + \frac{18}{10} = 0 \qquad \text{or} \qquad D = -1.$$

Finally, equating constant coefficients, we find

$$10 = \frac{9}{10} + E + \frac{81}{10} \qquad \text{or} \qquad E = 1.$$

The result is

$$\frac{10}{(x+1)(x^2+9)^2} = \frac{\frac{1}{10}}{x+1} + \frac{-\frac{1}{10}x + \frac{1}{10}}{x^2+9} + \frac{-x+1}{(x^2+9)^2}.$$

Thus,

$$\int \frac{10\,dx}{(x+1)(x^2+9)^2} = \frac{1}{10}\int \frac{dx}{x+1} - \frac{1}{10}\int \frac{x\,dx}{x^2+9} + \frac{1}{10}\int \frac{dx}{x^2+9} - \int \frac{x\,dx}{(x^2+9)^2} + \int \frac{dx}{(x^2+9)^2}.$$

For the second and fourth integrals, use the substitution $u = x^2 + 9$, $du = 2x\,dx$. Then we have

$$\int \frac{10\,dx}{(x+1)(x^2+9)^2} = \frac{1}{10}\ln|x+1| - \frac{1}{20}\ln|x^2+9| + \frac{1}{30}\tan^{-1}\left(\frac{x}{3}\right) + \frac{1}{2(x^2+9)} + \int \frac{dx}{(x^2+9)^2}.$$

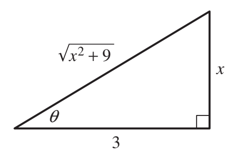
For the last integral, use the trigonometric substitution

$$x = 3\tan\theta, \qquad dx = 3\sec^2\theta\,d\theta, \qquad x^2+9 = 9\tan^2\theta + 9 = 9\sec^2\theta.$$

Then,

$$\int \frac{dx}{(x^2+9)^2} = \int \frac{3\sec^2\theta\,d\theta}{(9\sec^2\theta)^2} = \frac{1}{27}\int \frac{d\theta}{\sec^2\theta} = \frac{1}{27}\int \cos^2\theta\,d\theta = \frac{1}{27}\left[\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right] + C.$$

Now we construct a right triangle with $\tan\theta = \frac{x}{3}$:



From this we see that $\sin\theta = x/\sqrt{x^2+9}$ and $\cos\theta = 3/\sqrt{x^2+9}$. Thus

$$\int \frac{dx}{(x^2+9)^2} = \frac{1}{54}\tan^{-1}\left(\frac{x}{3}\right) + \frac{1}{54}\left(\frac{x}{\sqrt{x^2+9}}\right)\left(\frac{3}{\sqrt{x^2+9}}\right) + C = \frac{1}{54}\tan^{-1}\left(\frac{x}{3}\right) + \frac{x}{18(x^2+9)} + C.$$

Collecting all the terms, we obtain

$$\begin{aligned}\int \frac{10\,dx}{(x+1)(x^2+9)^2} &= \frac{1}{10}\ln|x+1| - \frac{1}{20}\ln|x^2+9| + \frac{1}{30}\tan^{-1}\left(\frac{x}{3}\right) + \frac{1}{2(x^2+9)} \\ &\quad + \frac{1}{54}\tan^{-1}\left(\frac{x}{3}\right) + \frac{x}{18(x^2+9)} + C \\ &= \frac{1}{10}\ln|x+1| - \frac{1}{20}\ln|x^2+9| + \frac{7}{135}\tan^{-1}\left(\frac{x}{3}\right) + \frac{x+9}{18(x^2+9)} + C.\end{aligned}$$

39. $\displaystyle\int \frac{dx}{x(x^2+8)^2}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{x(x^2+8)^2} = \frac{A}{x} + \frac{Bx+C}{x^2+8} + \frac{Dx+E}{(x^2+8)^2}.$$

Clearing denominators, we get

$$1 = A(x^2+8)^2 + (Bx+C)x(x^2+8) + (Dx+E)x.$$

Expanding the right-hand side gives us

$$1 = (A+B)x^4 + Cx^3 + (16A+8B+D)x^2 + (8C+E)x + 64A.$$

Equating coefficients of like powers of x yields

$$\begin{aligned} A + B &= 0 \\ C &= 0 \\ 16A + 8B + D &= 0 \\ 8C + E &= 0 \\ 64A &= 1 \end{aligned}$$

The solution to this system of equations is

$$A = \frac{1}{64}, \qquad B = -\frac{1}{64}, \qquad C = 0, \qquad D = -\frac{1}{8}, \qquad E = 0.$$

Therefore

$$\frac{1}{x(x^2+8)^2} = \frac{\frac{1}{64}}{x} + \frac{-\frac{1}{64}x}{x^2+8} + \frac{-\frac{1}{8}x}{(x^2+8)^2},$$

and

$$\int \frac{dx}{x(x^2+8)^2} = \frac{1}{64}\int \frac{dx}{x} - \frac{1}{64}\int \frac{x\,dx}{x^2+8} - \frac{1}{8}\int \frac{x\,dx}{(x^2+8)^2}.$$

For the second and third integrals, use the substitution $u = x^2+8$, $du = 2x\,dx$. Then we have

$$\int \frac{dx}{x(x^2+8)^2} = \frac{1}{64}\ln|x| - \frac{1}{128}\ln|x^2+8| + \frac{1}{16(x^2+8)} + C.$$

40. $\displaystyle\int \frac{100x\,dx}{(x-3)(x^2+1)^2}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{100x}{(x-3)(x^2+1)^2} = \frac{A}{x-3} + \frac{Bx+C}{x^2+1} + \frac{Dx+E}{(x^2+1)^2}.$$

Clearing denominators, we get

$$100x = A(x^2+1)^2 + (Bx+C)(x-3)(x^2+1) + (Dx+E)(x-3).$$

Setting $x = 3$ then yields

$$300 = A(100) + 0 + 0 \qquad \text{or} \qquad A = 3.$$

Expanding the right-hand side, we find

$$100x = (B+3)x^4 + (C-3B)x^3 + (B-3C+D+6)x^2 + (C-3B-3D+E)x + (3-3C-3E).$$

Equating coefficients of like powers of x then yields

$$\begin{aligned} B+3 &= 0 \\ C-3B &= 0 \\ B-3C+D+6 &= 0 \\ C-3B-3D+E &= 100 \\ 3-3C-3E &= 0 \end{aligned}$$

The solution to this system of equations is

$$B = -3, \qquad C = -9, \qquad D = -30, \qquad E = 10.$$

Therefore

$$\frac{100x}{(x-3)(x^2+1)^2} = \frac{3}{x-3} + \frac{-3x-9}{x^2+1} + \frac{-30x+10}{(x^2+1)^2},$$

and

$$\begin{aligned} \int \frac{100x\,dx}{(x-3)(x^2+1)^2} &= 3\int \frac{dx}{x-3} + \int \frac{(-3x-9)\,dx}{x^2+1} + \int \frac{(-30x+10)\,dx}{(x^2+1)^2} \\ &= 3\int \frac{dx}{x-3} - 3\int \frac{x\,dx}{x^2+1} - 9\int \frac{dx}{x^2+1} - 30\int \frac{x\,dx}{(x^2+1)^2} + 10\int \frac{dx}{(x^2+1)^2}. \end{aligned}$$

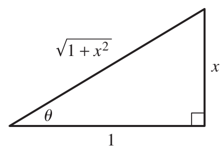
For the second and fourth integrals, use the substitution $u = x^2+1$, $du = 2x\,dx$. Then we have

$$\int \frac{100x\,dx}{(x-3)(x^2+1)^2} = 3\ln|x-3| - \frac{3}{2}\ln|x^2+1| - 9\tan^{-1}x + \frac{15}{x^2+1} + 10\int \frac{dx}{(x^2+1)^2}.$$

For the last integral, use the trigonometric substitution $x = \tan\theta$, $dx = \sec^2\theta\, d\theta$. Then $x^2 + 1 = \tan^2\theta + 1 = \sec^2\theta$, and

$$\int \frac{dx}{(x^2+1)^2} = \int \frac{\sec^2\theta\, d\theta}{\sec^4\theta} = \int \cos^2\theta = \frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta + C.$$

We construct the following right triangle with $\tan\theta = x$:



From this we see that $\sin\theta = x/\sqrt{1+x^2}$ and $\cos\theta = 1/\sqrt{1+x^2}$. Thus

$$\int \frac{dx}{(x^2+1)^2} = \frac{1}{2}\tan^{-1}x + \frac{1}{2}\left(\frac{x}{\sqrt{1+x^2}}\right)\left(\frac{1}{\sqrt{1+x^2}}\right) + C = \frac{1}{2}\tan^{-1}x + \frac{x}{2(x^2+1)} + C.$$

Collecting all the terms, we obtain

$$\begin{aligned}\int \frac{100x\, dx}{(x-3)(x^2+1)^2} &= 3\ln|x-3| - \frac{3}{2}\ln|x^2+1| - 9\tan^{-1}x + \frac{15}{x^2+1} + 10\left(\frac{1}{2}\tan^{-1}x + \frac{x}{2(x^2+1)}\right) + C \\ &= 3\ln|x-3| - \frac{3}{2}\ln|x^2+1| - 4\tan^{-1}x + \frac{5x+15}{x^2+1} + C.\end{aligned}$$

41. $\displaystyle\int \frac{dx}{(x+2)(x^2+4x+10)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{(x+2)(x^2+4x+10)} = \frac{A}{x+2} + \frac{Bx+C}{x^2+4x+10}.$$

Clearing denominators, we get

$$1 = A(x^2+4x+10) + (Bx+C)(x+2).$$

Setting $x = -2$ then yields

$$1 = A(6) + 0 \qquad \text{or} \qquad A = \frac{1}{6}.$$

Expanding the right-hand side gives us

$$1 = \left(\frac{1}{6} + B\right)x^2 + \left(\frac{2}{3} + 2B + C\right)x + \left(\frac{5}{3} + 2C\right).$$

Equating x^2-coefficients yields

$$0 = \frac{1}{6} + B \qquad \text{or} \qquad B = -\frac{1}{6},$$

while equating constant coefficients yields

$$1 = \frac{5}{3} + 2C \qquad \text{or} \qquad C = -\frac{1}{3}.$$

The result is

$$\frac{1}{(x+2)(x^2+4x+10)} = \frac{\frac{1}{6}}{x+2} + \frac{-\frac{1}{6}x - \frac{1}{3}}{x^2+4x+10}.$$

Thus,

$$\int \frac{dx}{(x+2)(x^2+4x+10)} = \frac{1}{6}\int \frac{dx}{x+2} - \frac{1}{6}\int \frac{(x+2)\,dx}{x^2+4x+10}.$$

For the second integral, let $u = x^2 + 4x + 10$. Then $du = (2x+4)\,dx$, and

$$\begin{aligned}\int \frac{dx}{(x+2)(x^2+4x+10)} &= \frac{1}{6}\ln|x+2| - \frac{1}{12}\int \frac{(2x+4)\,dx}{x^2+4x+10} \\ &= \frac{1}{6}\ln|x+2| - \frac{1}{12}\ln|x^2+4x+10| + C.\end{aligned}$$

42. $\displaystyle\int \frac{9\,dx}{(x+1)(x^2-2x+6)}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{9}{(x+1)(x^2-2x+6)} = \frac{A}{x+1} + \frac{Bx+C}{x^2-2x+6}.$$

Clearing denominators gives us

$$9 = A(x^2-2x+6) + (Bx+C)(x+1).$$

Setting $x=-1$ then yields

$$9 = A(9) + 0 \qquad \text{or} \qquad A = 1.$$

Expanding the right-hand side gives us

$$9 = (1+B)x^2 + (-2+B+C)x + (6+C).$$

Equating x^2-coefficients yields

$$0 = 1 + B \qquad \text{or} \qquad B = -1,$$

while equating constant coefficients yields

$$9 = 6 + C \qquad \text{or} \qquad C = 3.$$

The result is

$$\frac{9}{(x+1)(x^2-2x+6)} = \frac{1}{x+1} + \frac{-x+3}{x^2-2x+6}.$$

Thus,

$$\int \frac{9\,dx}{(x+1)(x^2-2x+6)} = \int \frac{dx}{x+1} + \int \frac{(-x+3)\,dx}{x^2-2x+6}.$$

To evaluate the integral on the right, we first write

$$\int \frac{(-x+3)\,dx}{x^2-2x+6} = -\int \frac{(x-1-2)\,dx}{x^2-2x+6} = -\int \frac{(x-1)\,dx}{x^2-2x+6} + 2\int \frac{dx}{x^2-2x+6}.$$

For the first integral, use the substitution $u = x^2-2x+6$, $du = (2x-2)\,dx$. Then

$$-\int \frac{(x-1)\,dx}{x^2-2x+6} = -\frac{1}{2}\int \frac{(2x-2)\,dx}{x^2-2x+6} = -\frac{1}{2}\ln|x^2-2x+6| + C.$$

For the second integral, we first complete the square:

$$2\int \frac{dx}{x^2-2x+6} = 2\int \frac{dx}{(x^2-2x+1)+5} = 2\int \frac{dx}{(x-1)^2+5}.$$

Now let $u = x-1$, $du = dx$. Then

$$2\int \frac{dx}{(x-1)^2+5} = 2\int \frac{du}{u^2+5} = 2\left(\frac{1}{\sqrt{5}}\right)\tan^{-1}\left(\frac{u}{\sqrt{5}}\right) + C = \frac{2}{\sqrt{5}}\tan^{-1}\left(\frac{x-1}{\sqrt{5}}\right) + C.$$

Collecting all the terms, we have

$$\int \frac{9\,dx}{(x+1)(x^2-2x+6)} = \ln|x+1| - \frac{1}{2}\ln|x^2-2x+6| + \frac{2}{\sqrt{5}}\tan^{-1}\left(\frac{x-1}{\sqrt{5}}\right) + C.$$

43. $\displaystyle\int \frac{25\,dx}{x(x^2+2x+5)^2}$

SOLUTION The partial fraction decomposition has the form

$$\frac{25}{x(x^2+2x+5)^2} = \frac{A}{x} + \frac{Bx+C}{x^2+2x+5} + \frac{Dx+E}{(x^2+2x+5)^2}.$$

Clearing denominators yields:

$$\begin{aligned} 25 &= A(x^2+2x+5)^2 + x(Bx+C)(x^2+2x+5) + x(Dx+E) \\ &= (Ax^4+4Ax^3+14Ax^2+20Ax+25A) + (Bx^4+Cx^3+2Bx^3+2Cx^2+5Bx^2+5Cx) + Dx^2 + Ex. \end{aligned}$$

Equating constant terms yields

$$25A = 25 \qquad \text{or} \qquad A = 1,$$

while equating x^4-coefficients yields

$$A + B = 0 \qquad \text{or} \qquad B = -A = -1.$$

Equating x^3-coefficients yields

$$4A + C + 2B = 0 \qquad \text{or} \qquad C = -2,$$

and equating x^2-coefficients yields

$$14A + 2C + 5B + D = 0 \qquad \text{or} \qquad D = -5.$$

Finally, equating x-coefficients yields

$$20A + 5C + E = 0 \qquad \text{or} \qquad E = -10.$$

Thus,

$$\begin{aligned}\int \frac{25\,dx}{x(x^2+2x+5)^2} &= \int \left(\frac{1}{x} - \frac{x+2}{x^2+2x+5} - 5\frac{x+2}{(x^2+2x+5)^2}\right) dx \\ &= \ln|x| - \int \frac{x+2}{x^2+2x+5}\,dx - 5\int \frac{x+2}{(x^2+2x+5)^2}\,dx.\end{aligned}$$

The two integrals on the right both require the substitution $u = x + 1$, so that $x^2 + 2x + 5 = (x+1)^2 + 4 = u^2 + 4$ and $du = dx$. This means:

$$\begin{aligned}\int \frac{25\,dx}{x(x^2+2x+5)^2} &= \ln|x| - \int \frac{u+1}{u^2+4}\,du - 5\int \frac{u+1}{(u^2+4)^2}\,du \\ &= \ln|x| - \int \frac{u}{u^2+4}\,du - \int \frac{1}{u^2+4}\,du - 5\int \frac{u}{(u^2+4)^2}\,du - 5\int \frac{1}{(u^2+4)^2}\,du.\end{aligned}$$

For the first and third integrals, we make the substitution $w = u^2 + 4$, $dw = 2u\,du$. Then we have

$$\begin{aligned}\int \frac{25\,dx}{x(x^2+2x+5)^2} &= \ln|x| - \frac{1}{2}\ln|u^2+4| - \frac{1}{2}\tan^{-1}\left(\frac{u}{2}\right) + \frac{5}{2(u^2+4)} - 5\int \frac{du}{(u^2+4)^2} \\ &= \ln|x| - \frac{1}{2}\ln|x^2+2x+5| - \frac{1}{2}\tan^{-1}\left(\frac{x+1}{2}\right) + \frac{5}{2(x^2+2x+5)} - 5\int \frac{du}{(u^2+4)^2}.\end{aligned}$$

For the remaining integral, we use the trigonometric substitution $2\tan w = u$, so that $u^2 + 4 = 4\tan^2 w + 4 = 4\sec^2 w$ and $du = 2\sec^2 w\,dw$. This means

$$\begin{aligned}\int \frac{1}{(u^2+4)^2}\,du &= \frac{1}{8}\int \frac{1}{\sec^4 w}\sec^2 w\,dw = \frac{1}{8}\int \cos^2 w\,dw \\ &= \frac{1}{8}\left(\frac{1}{4}\sin 2w + \frac{w}{2}\right) + C = \left(\frac{1}{16}\sin w\cos w + \frac{w}{16}\right) + C \\ &= \frac{1}{16}\frac{u}{\sqrt{u^2+4}}\frac{2}{\sqrt{u^2+4}} + \frac{1}{16}\tan^{-1}\left(\frac{u}{2}\right) + C = \frac{1}{8}\frac{u}{u^2+4} + \frac{1}{16}\tan^{-1}\left(\frac{u}{2}\right) + C \\ &= \frac{1}{8}\frac{x+1}{x^2+2x+5} + \frac{1}{16}\tan^{-1}\left(\frac{x+1}{2}\right).\end{aligned}$$

Hence, the integral is

$$\begin{aligned}\int \frac{25\,dx}{x(x^2+2x+5)^2} &= \ln|x| - \frac{1}{2}\ln|x^2+2x+5| - \frac{1}{2}\tan^{-1}\left(\frac{x+1}{2}\right) \\ &\quad + \frac{5}{2(x^2+2x+5)} - \frac{5}{8}\frac{x+1}{x^2+2x+5} - \frac{5}{16}\tan^{-1}\left(\frac{x+1}{2}\right) \\ &= \ln|x| + \frac{15-5x}{8(x^2+2x+5)} - \frac{13}{16}\tan^{-1}\left(\frac{x+1}{2}\right) - \frac{1}{2}\ln|x^2+2x+5| + C.\end{aligned}$$

44. $\displaystyle\int \frac{(x^2+3)\,dx}{(x^2+2x+3)^2}$

SOLUTION The partial fraction decomposition has the form:

$$\frac{x^2+3}{(x^2+2x+3)^2} = \frac{Ax+B}{x^2+2x+3} + \frac{Cx+D}{(x^2+2x+3)^2}.$$

Clearing denominators gives us

$$x^2+3 = (Ax+B)(x^2+2x+3) + Cx + D.$$

Expanding the right-hand side, we get

$$x^2+3 = Ax^3 + (2A+B)x^2 + (3A+2B+C)x + (3B+D).$$

Equating coefficients of like powers of x then yields

$$\begin{aligned} A &= 0 \\ 2A + B &= 1 \\ 3A + 2B + C &= 0 \\ 3B + D &= 3 \end{aligned}$$

The solution to this system of equations is

$$A = 0, \qquad B = 1, \qquad C = -2, \qquad D = 0.$$

Therefore

$$\frac{x^2+3}{(x^2+2x+3)^2} = \frac{1}{x^2+2x+3} + \frac{-2x}{(x^2+2x+3)^2},$$

and

$$\int \frac{(x^2+3)\,dx}{(x^2+2x+3)^2} = \int \frac{dx}{x^2+2x+3} - \int \frac{2x\,dx}{(x^2+2x+3)^2}.$$

The first integral can be evaluated by completing the square:

$$\int \frac{dx}{x^2+2x+3} = \int \frac{dx}{x^2+2x+1+2} = \int \frac{dx}{(x+1)^2+2}.$$

Now use the substitution $u = x+1$, $du = dx$. Then

$$\int \frac{dx}{x^2+2x+3} = \int \frac{du}{u^2+2} = \frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{x+1}{\sqrt{2}}\right) + C.$$

For the second integral, let $u = x^2+2x+3$. We want $du = (2x+2)\,dx$ to appear in the numerator, so we write

$$\begin{aligned} \int \frac{2x\,dx}{(x^2+2x+3)^2} &= \int \frac{(2x+2-2)\,dx}{(x^2+2x+3)^2} = \int \frac{(2x+2)\,dx}{(x^2+2x+3)^2} - 2\int \frac{dx}{(x^2+2x+3)^2} \\ &= \int \frac{du}{u^2} - 2\int \frac{dx}{(x^2+2x+3)^2} = -\frac{1}{u} - 2\int \frac{dx}{(x^2+2x+3)^2} \\ &= \frac{-1}{x^2+2x+3} - 2\int \frac{dx}{(x^2+3x+3)^2}. \end{aligned}$$

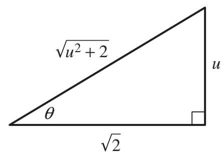
Finally, for this last integral, complete the square, then substitute $u = x+1$, $du = dx$:

$$\int \frac{dx}{(x^2+2x+3)^2} = \int \frac{dx}{((x+1)^2+2)^2} = \int \frac{du}{(u^2+2)^2}.$$

Now use the trigonometric substitution $u = \sqrt{2}\tan\theta$. Then $du = \sqrt{2}\sec^2\theta\,d\theta$, and $u^2+2 = 2\tan^2\theta + 2 = 2\sec^2\theta$. Thus

$$\int \frac{du}{(u^2+2)^2} = \int \frac{\sqrt{2}\sec^2\theta\,d\theta}{4\sec^4\theta} = \frac{\sqrt{2}}{4}\int \cos^2\theta\,d\theta = \frac{\sqrt{2}}{4}\left[\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right] = \frac{\sqrt{2}}{8}\theta + \frac{\sqrt{2}}{8}\sin\theta\cos\theta + C.$$

We construct a right triangle with $\tan\theta = u/\sqrt{2}$:



From this we see that $\sin\theta = u/\sqrt{u^2+2}$ and $\cos\theta = \sqrt{2}/\sqrt{u^2+2}$. Therefore

$$\int \frac{du}{(u^2+2)^2} = \frac{\sqrt{2}}{8}\tan^{-1}\left(\frac{u}{\sqrt{2}}\right) + \frac{\sqrt{2}}{8}\left(\frac{u}{\sqrt{u^2+2}}\right)\left(\frac{\sqrt{2}}{\sqrt{u^2+2}}\right) + C$$

$$= \frac{\sqrt{2}}{8}\tan^{-1}\left(\frac{u}{\sqrt{2}}\right) + \frac{u}{4(u^2+2)} + C = \frac{\sqrt{2}}{8}\tan^{-1}\left(\frac{x+1}{\sqrt{2}}\right) + \frac{x+1}{4(x^2+2x+3)} + C.$$

Collecting all the terms, we have

$$\int \frac{(x^2+3)\,dx}{(x^2+2x+3)^2} = \frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{x+1}{\sqrt{2}}\right) - \left[\frac{-1}{x^2+2x+3} - 2\left(\frac{\sqrt{2}}{8}\tan^{-1}\left(\frac{x+1}{\sqrt{2}}\right) + \frac{x+1}{4(x^2+2x+3)}\right)\right] + C$$

$$= \left(\frac{1}{\sqrt{2}} + \frac{\sqrt{2}}{4}\right)\tan^{-1}\left(\frac{x+1}{\sqrt{2}}\right) + \frac{2+(x+1)}{2(x^2+2x+3)} + C$$

$$= \frac{3\sqrt{2}}{4}\tan^{-1}\left(\frac{x+1}{\sqrt{2}}\right) + \frac{x+3}{2(x^2+2x+3)} + C.$$

In Exercises 45–48, evaluate by using first substitution and then partial fractions if necessary.

45. $\displaystyle\int \frac{x\,dx}{x^4+1}$

SOLUTION Use the substitution $u = x^2$ so that $du = 2x\,dx$, and

$$\int \frac{x}{x^4+1}\,dx = \frac{1}{2}\int \frac{1}{u^2+1}\,du = \frac{1}{2}\tan^{-1} u = \frac{1}{2}\tan^{-1}(x^2)$$

46. $\displaystyle\int \frac{x\,dx}{(x+2)^4}$

SOLUTION Use the substitution $u = x+2$ and $du = dx$; then

$$\int \frac{x}{(x+2)^4}\,dx = \int \frac{u-2}{u^4}\,du = \int \frac{1}{u^3}\,du - 2\int \frac{1}{u^4}\,du$$

$$= -\frac{1}{2u^2} + \frac{2}{3u^3} + C = \frac{2}{3(x+2)^3} - \frac{1}{2(x+2)^2} + C$$

47. $\displaystyle\int \frac{e^x\,dx}{e^{2x}-e^x}$

SOLUTION Use the substitution $u = e^x$. Then $du = e^x\,dx = u\,dx$ so that $dx = \frac{1}{u}\,du$. Then

$$\int \frac{e^x\,dx}{e^{2x}-e^x} = \int \frac{u\cdot\frac{1}{u}\,du}{u^2-u} = \int \frac{1}{u(u-1)}\,du$$

Using partial fractions, we have

$$\frac{1}{u(u-1)} = \frac{A}{u} + \frac{B}{u-1} = \frac{(A+B)u - A}{u(u-1)}$$

Upon equating coefficients in the numerators, we have $A+B=0$, $A=-1$ so that $B=1$. Then

$$\int \frac{e^x\,dx}{e^{2x}-e^x} = -\int \frac{1}{u}\,du + \int \frac{1}{u-1}\,du = \ln|u-1| - \ln|u| + C = \ln|e^x-1| - \ln e^x + C$$

48. $\displaystyle\int \frac{\sec^2\theta\,d\theta}{\tan^2\theta - 1}$

SOLUTION Let $u = \tan\theta$; then $du = \sec^2\theta\,d\theta$ and

$$\int \frac{\sec^2\theta\,d\theta}{\tan^2\theta-1} = \int \frac{1}{u^2-1}\,du = -\int \frac{1}{1-u^2}\,du = -\tanh^{-1}(u) + C = -\tanh^{-1}(\tan\theta) + C$$

49. Evaluate $\int \frac{\sqrt{x}\,dx}{x-1}$. *Hint:* Use the substitution $u = \sqrt{x}$ (sometimes called a **rationalizing substitution**).

SOLUTION Let $u = \sqrt{x}$. Then $du = (1/2\sqrt{x})\,dx = (1/2u)\,dx$. Thus

$$\int \frac{\sqrt{x}\,dx}{x-1} = \int \frac{u(2u\,du)}{u^2-1} = 2\int \frac{u^2\,du}{u^2-1} = 2\int \frac{(u^2-1+1)\,du}{u^2-1}$$
$$= 2\int \left(\frac{u^2-1}{u^2-1} + \frac{1}{u^2-1}\right) du = 2\int du + \int \frac{2\,du}{u^2-1} = 2u + \int \frac{2\,du}{u^2-1}.$$

The partial fraction decomposition of the remaining integral has the form:

$$\frac{2}{u^2-1} = \frac{2}{(u-1)(u+1)} = \frac{A}{u-1} + \frac{B}{u+1}.$$

Clearing denominators gives us

$$2 = A(u+1) + B(u-1).$$

Setting $u = 1$ yields $2 = A(2) + 0$ or $A = 1$, while setting $u = -1$ yields $2 = 0 + B(-2)$ or $B = -1$. The result is

$$\frac{2}{u^2-1} = \frac{1}{u-1} + \frac{-1}{u+1}.$$

Thus,

$$\int \frac{2\,du}{u^2-1} = \int \frac{du}{u-1} - \int \frac{du}{u+1} = \ln|u-1| - \ln|u+1| + C.$$

The final answer is

$$\int \frac{\sqrt{x}\,dx}{x-1} = 2u + \ln|u-1| - \ln|u+1| + C = 2\sqrt{x} + \ln|\sqrt{x}-1| - \ln|\sqrt{x}+1| + C.$$

50. Evaluate $\int \frac{dx}{x^{1/2} - x^{1/3}}$.

SOLUTION First use the substitution $u = x^{1/6}$. Then

$$du = \frac{1}{6}x^{-5/6}\,dx \quad \Rightarrow \quad 6x^{5/6}\,du = dx \quad \Rightarrow \quad 6u^5\,du = dx$$

and we have (using long division)

$$\int \frac{dx}{x^{1/2}-x^{1/3}} = \int \frac{6u^5}{u^3-u^2}\,du = 6\int \frac{u^3}{u-1}\,du = 6\int u^2 + u + 1 + \frac{1}{u-1}\,du$$
$$= 6\left(\frac{1}{3}u^3 + \frac{1}{2}u^2 + u + \ln|u-1|\right) + C = 2u^3 + 3u^2 + 6u + 6\ln|u-1| + C$$
$$= 2x^{1/2} + 3x^{1/3} + 6x^{1/6} + 6\ln\left|x^{1/6}-1\right| + C$$

51. Evaluate $\int \frac{dx}{x^2-1}$ in two ways: using partial fractions and using trigonometric substitution. Verify that the two answers agree.

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{x^2-1} = \frac{1}{(x-1)(x+1)} = \frac{A}{x-1} + \frac{B}{x+1}.$$

Clearing denominators gives us

$$1 = A(x+1) + B(x-1).$$

Setting $x = 1$, we get $1 = A(2)$ or $A = \frac{1}{2}$; while setting $x = -1$, we get $1 = B(-2)$ or $B = -\frac{1}{2}$. The result is

$$\frac{1}{x^2-1} = \frac{\frac{1}{2}}{x-1} + \frac{-\frac{1}{2}}{x+1}.$$

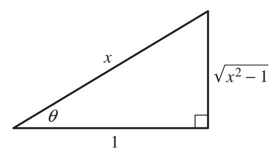
Thus,

$$\int \frac{dx}{x^2-1} = \frac{1}{2}\int \frac{dx}{x-1} - \frac{1}{2}\int \frac{dx}{x+1} = \frac{1}{2}\ln|x-1| - \frac{1}{2}\ln|x+1| + C.$$

Using trigonometric substitution, let $x = \sec\theta$. Then $dx = \tan\theta\sec\theta\,d\theta$, and $x^2 - 1 = \sec^2\theta - 1 = \tan^2\theta$. Thus

$$\int \frac{dx}{x^2-1} = \int \frac{\tan\theta\sec\theta\,d\theta}{\tan^2\theta} = \int \frac{\sec\theta\,d\theta}{\tan\theta} = \int \frac{\cos\theta\,d\theta}{\sin\theta\cos\theta}$$
$$= \int \csc\theta\,d\theta = \ln|\csc\theta - \cot\theta| + C.$$

Now we construct a right triangle with $\sec\theta = x$:



From this we see that $\csc\theta = x/\sqrt{x^2-1}$ and $\cot\theta = 1/\sqrt{x^2-1}$. Thus

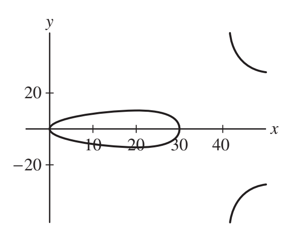
$$\int \frac{dx}{x^2-1} = \ln\left|\frac{x}{\sqrt{x^2-1}} - \frac{1}{\sqrt{x^2-1}}\right| + C = \ln\left|\frac{x-1}{\sqrt{x^2-1}}\right| + C.$$

To check that these two answers agree, we write

$$\frac{1}{2}\ln|x-1| - \frac{1}{2}\ln|x+1| = \frac{1}{2}\left|\frac{x-1}{x+1}\right| = \ln\left|\sqrt{\frac{x-1}{x+1}}\right| = \ln\left|\frac{\sqrt{x-1}}{\sqrt{x+1}}\cdot\frac{\sqrt{x-1}}{\sqrt{x-1}}\right| = \ln\left|\frac{x-1}{\sqrt{x^2-1}}\right|.$$

52. GU Graph the equation $(x-40)y^2 = 10x(x-30)$ and find the volume of the solid obtained by revolving the region between the graph and the x-axis for $0 \le x \le 30$ around the x-axis.

SOLUTION The graph of $(x-40)y^2 = 10x(x-30)$ is shown below



Using the disk method, the volume is given by

$$V = \int_0^{30} \pi r^2\,dx = \pi\int_0^{30}\left(\sqrt{\frac{10x(x-30)}{x-40}}\right)^2 dx = \pi\int_0^{30}\frac{10x(x-30)\,dx}{x-40}.$$

To find the anti-derivative, expand the numerator and then use long division:

$$\frac{10x(x-30)}{x-40} = \frac{10x^2-300x}{x-40} = 10x + 100 + \frac{4000}{x-40}.$$

Thus,

$$\pi\int_0^{30}\frac{10x(x-30)\,dx}{x-40} = \pi\left[10\int_0^{30} x\,dx + 100\int_0^{30} dx + 4000\int_0^{30}\frac{dx}{x-40}\right]$$
$$= \pi\left(5x^2 + 100x + 4000\ln|x-40|\right)\Big|_0^{30}$$
$$= \pi\left[\left(4500 + 3000 + 4000\ln(10)\right) - \left(0 + 4000\ln(40)\right)\right]$$
$$= (7500 - 4000\ln 4)\pi.$$

In Exercises 53–66, evaluate the integral using the appropriate method or combination of methods covered thus far in the text.

53. $\displaystyle\int \frac{dx}{x^2\sqrt{4-x^2}}$

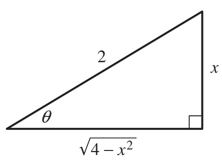
SOLUTION Use the trigonometric substitution $x = 2\sin\theta$. Then $dx = 2\cos\theta\,d\theta$,

$$4 - x^2 = 4 - 4\sin^2\theta = 4(1-\sin^2\theta) = 4\cos^2\theta,$$

and

$$\int \frac{dx}{x^2\sqrt{4-x^2}} = \int \frac{2\cos\theta\,d\theta}{(4\sin^2\theta)(2\cos\theta)} = \frac{1}{4}\int \csc^2\theta\,d\theta = -\frac{1}{4}\cot\theta + C.$$

Now construct a right triangle with $\sin\theta = x/2$:



From this we see that $\cot\theta = \sqrt{4-x^2}/x$. Thus

$$\int \frac{dx}{x^2\sqrt{4-x^2}} = -\frac{1}{4}\left(\frac{\sqrt{4-x^2}}{x}\right) + C = -\frac{\sqrt{4-x^2}}{4x} + C.$$

54. $\displaystyle\int \frac{dx}{x(x-1)^2}$

SOLUTION Using partial fractions, we first write

$$\frac{1}{x(x-1)^2} = \frac{A}{x} + \frac{B}{x-1} + \frac{C}{(x-1)^2}.$$

Clearing denominators gives us

$$1 = A(x-1)^2 + Bx(x-1) + Cx.$$

Setting $x = 0$ yields

$$1 = A(1) + 0 + 0 \qquad \text{or} \qquad A = 1,$$

while setting $x = 1$ yields

$$1 = 0 + 0 + C \qquad \text{or} \qquad C = 1,$$

and setting $x = 2$ yields

$$1 = 1 + 2B + 2 \qquad \text{or} \qquad B = -1.$$

The result is

$$\frac{1}{x(x-1)^2} = \frac{1}{x} + \frac{-1}{x-1} + \frac{1}{(x-1)^2}.$$

Thus,

$$\int \frac{dx}{x(x-1)^2} = \int \frac{dx}{x} - \int \frac{dx}{x-1} + \int \frac{dx}{(x-1)^2} = \ln|x| - \ln|x-1| - \frac{1}{x-1} + C.$$

55. $\displaystyle\int \cos^2 4x\,dx$

SOLUTION Use the substitution $u = 4x$, $du = 4\,dx$. Then we have

$$\int \cos^2(4x)\,dx = \frac{1}{4}\int \cos^2(4x)4\,dx = \frac{1}{4}\int \cos^2 u\,du = \frac{1}{4}\left[\frac{1}{2}u + \frac{1}{2}\sin u\cos u\right] + C$$
$$= \frac{1}{8}u + \frac{1}{8}\sin u\cos u + C = \frac{1}{2}x + \frac{1}{8}\sin 4x\cos 4x + C.$$

56. $\int x \sec^2 x \, dx$

SOLUTION Use integration by parts, with $u = x$ and $v' = \sec^2 x$. Then $u' = 1$, $v = \tan x$, and

$$\int x \sec^2 x \, dx = x \tan x - \int \tan x \, dx = x \tan x - \big(-\ln|\cos x| \big) + C = x \tan x + \ln|\cos x| + C.$$

57. $\int \frac{dx}{(x^2+9)^2}$

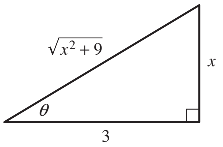
SOLUTION Use the trigonometric substitution $x = 3\tan\theta$. Then $dx = 3\sec^2\theta \, d\theta$,

$$x^2 + 9 = 9\tan^2\theta + 9 = 9(\tan^2\theta + 1) = 9\sec^2\theta,$$

and

$$\int \frac{dx}{(x^2+9)^2} = \int \frac{3\sec^2\theta \, d\theta}{(9\sec^2\theta)^2} = \frac{3}{81}\int \frac{\sec^2\theta \, d\theta}{\sec^4\theta} = \frac{1}{27}\int \cos^2\theta \, d\theta = \frac{1}{27}\left(\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right) + C.$$

Now construct a right triangle with $\tan\theta = x/3$:



From this we see that $\sin\theta = x/\sqrt{x^2+9}$ and $\cos\theta = 3/\sqrt{x^2+9}$. Thus

$$\int \frac{dx}{\sqrt{x^2+9}^2} = \frac{1}{54}\tan^{-1}\left(\frac{x}{3}\right) + \frac{1}{54}\left(\frac{x}{\sqrt{x^2+9}}\right)\left(\frac{3}{\sqrt{x^2+9}}\right) + C = \frac{1}{54}\tan^{-1}\left(\frac{x}{3}\right) + \frac{x}{18(x^2+9)} + C.$$

58. $\int \theta \sec^{-1}\theta \, d\theta$

SOLUTION Use Integration by Parts, with $u = \sec^{-1}\theta$ and $v' = \theta$. Then $u' = 1/\theta\sqrt{\theta^2-1}$, $v = \theta^2/2$, and

$$\int \theta\sec^{-1}\theta \, d\theta = \frac{\theta^2}{2}\sec^{-1}\theta - \int \frac{\theta^2 \, d\theta}{2\theta\sqrt{\theta^2-1}} = \frac{\theta^2}{2}\sec^{-1}\theta - \frac{1}{2}\int \frac{\theta \, d\theta}{\sqrt{\theta^2-1}}.$$

To evaluate the remaining integral, use the substitution $w = \theta^2 - 1$, $dw = 2\theta \, d\theta$. Then

$$\int \frac{\theta \, d\theta}{\sqrt{\theta^2-1}} = \frac{1}{2}\int \frac{2\theta \, d\theta}{\sqrt{\theta^2-1}} = \frac{1}{2}\int \frac{dw}{\sqrt{w}} = \frac{1}{2}\left(2\sqrt{w}\right) + C = \sqrt{\theta^2-1} + C.$$

The final answer is

$$\int \theta\sec^{-1}\theta \, d\theta = \frac{\theta^2}{2}\sec^{-1}\theta - \frac{1}{2}\sqrt{\theta^2-1} + C.$$

59. $\int \tan^5 x \sec x \, dx$

SOLUTION Use the trigonometric identity $\tan^2 x = \sec^2 x - 1$ to write

$$\int \tan^5 x \sec x \, dx = \int \left(\sec^2 x - 1\right)^2 \tan x \sec x \, dx.$$

Now use the substitution $u = \sec x$, $du = \sec x \tan x \, dx$:

$$\int \tan^5 x \sec x \, dx = \int (u^2-1)^2 \, du = \int \left(u^4 - 2u^2 + 1\right) du$$
$$= \frac{1}{5}u^5 - \frac{2}{3}u^3 + u + C = \frac{1}{5}\sec^5 x - \frac{2}{3}\sec^3 x + \sec x + C.$$

60. $\int \frac{(3x^2-1)\, dx}{x(x^2-1)}$

SOLUTION The denominator expands to $x^3 - x$, so if we let $u = x^3 - x$, then $du = (3x^2-1)\, dx$, which is the numerator. Thus

$$\int \frac{(3x^2-1)\, dx}{x(x^2-1)} = \int \frac{du}{u} = \ln|u| + C = \ln(x(x^2-1)) + C$$

61. $\int \ln(x^4 - 1)\,dx$

SOLUTION Apply integration by parts with $u = \ln(x^4-1)$, $v' = 1$; then $u' = \frac{4x^3}{x^4-1}$ and $v = x$, so after simplification,

$$\begin{aligned}\int \ln(x^4-1)\,dx &= x\ln(x^4-1) - 4\int \frac{x^4}{x^4-1}\,dx = x\ln(x^4-1) - 4\int 1 + \frac{1}{x^4-1}\,dx\\ &= x\ln(x^4-1) - 4\int 1\,dx - 4\int \frac{1}{x^4-1}\,dx\\ &= x\ln(x^4-1) - 4x - 4\int \frac{1}{2}\left(\frac{1}{x^2-1} - \frac{1}{x^2+1}\right)dx\\ &= x\ln(x^4-1) - 4x - 2\int \frac{1}{x^2-1}\,dx + 2\int \frac{1}{x^2+1}\,dx\\ &= x\ln(x^4-1) - 4x + 2\tanh^{-1} x + 2\tan^{-1} x + C\end{aligned}$$

62. $\int \frac{x\,dx}{(x^2-1)^{3/2}}$

SOLUTION Use the substitution $u = x^2 - 1$, $du = 2x\,dx$. Then we have

$$\int \frac{x\,dx}{(x^2-1)^{3/2}} = \frac{1}{2}\int \frac{2x\,dx}{(x^2-1)^{3/2}} = \frac{1}{2}\int \frac{du}{u^{3/2}} = \frac{1}{2}(-2)u^{-1/2} + C = \frac{-1}{\sqrt{u}} + C = \frac{-1}{\sqrt{x^2-1}} + C.$$

63. $\int \frac{x^2\,dx}{(x^2-1)^{3/2}}$

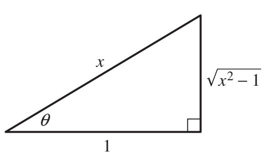
SOLUTION Use the trigonometric substitution $x = \sec\theta$. Then $dx = \sec\theta\tan\theta\,d\theta$,

$$x^2 - 1 = \sec^2\theta - 1 = \tan^2\theta,$$

and

$$\begin{aligned}\int \frac{x^2\,dx}{(x^2-1)^{3/2}} &= \int \frac{(\sec^2\theta)\sec\theta\tan\theta\,d\theta}{(\tan^2\theta)^{3/2}} = \int \frac{\sec^3\theta\,d\theta}{\tan^2\theta} = \int \frac{(\tan^2\theta+1)\sec\theta\,d\theta}{\tan^2\theta}\\ &= \int \frac{\tan^2\theta\sec\theta\,d\theta}{\tan^2\theta} + \int \frac{\sec\theta\,d\theta}{\tan^2\theta} = \int \sec\theta\,d\theta + \int \csc\theta\cot\theta\,d\theta\\ &= \ln|\sec\theta + \tan\theta| - \csc\theta + C.\end{aligned}$$

Now construct a right triangle with $\sec\theta = x$:



From this we see that $\tan\theta = \sqrt{x^2-1}$ and $\csc\theta = x/\sqrt{x^2-1}$. So the final answer is

$$\int \frac{x^2\,dx}{(x^2-1)^{3/2}} = \ln\left|x + \sqrt{x^2-1}\right| - \frac{x}{\sqrt{x^2-1}} + C.$$

64. $\int \frac{(x+1)\,dx}{(x^2+4x+8)^2}$

SOLUTION At first it might appear that one would use partial fractions to simplify this problem, but in fact it's already in simplified form. Instead, use the substitution $u = x^2 + 4x + 8$, $du = (2x+4)\,dx$. Then we have

$$\begin{aligned}\int \frac{(x+1)\,dx}{(x^2+4x+8)^2} &= \frac{1}{2}\int \frac{(2x+2)\,dx}{(x^2+4x+8)^2} = \frac{1}{2}\int \frac{(2x+2+2-2)\,dx}{(x^2+4x+8)^2}\\ &= \frac{1}{2}\int \frac{(2x+4)\,dx}{(x^2+4x+8)^2} - \int \frac{dx}{(x^2+4x+8)^2}\\ &= \frac{1}{2}\int \frac{du}{u^2} - \int \frac{dx}{(x^2+4x+8)^2} = \frac{-1}{2u} - \int \frac{dx}{(x^2+4x+8)^2}.\end{aligned}$$

To evaluate the remaining integral, complete the square, then let $w = x + 2$, $dw = dx$:

$$\int \frac{dx}{(x^2+4x+8)^2} = \int \frac{dx}{(x^2+4x+4+4)^2} = \int \frac{dx}{((x+2)^2+4)^2} = \int \frac{dw}{(w^2+4)^2}.$$

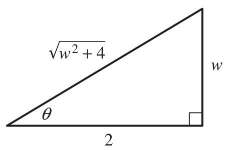
Next, let $w = 2\tan\theta$, $dw = 2\sec^2\theta\, d\theta$. Then

$$w^2 + 4 = 4\tan^2\theta + 4 = 4(\tan^2\theta + 1) = 4\sec^2\theta,$$

and we have

$$\int \frac{dw}{(w^2+4)^2} = \int \frac{2\sec^2\theta\, d\theta}{16\sec^4\theta} = \frac{1}{8}\cos^2\theta\, d\theta = \frac{1}{8}\left(\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta\right) + C = \frac{1}{16}\theta + \frac{1}{16}\sin\theta\cos\theta + C.$$

Now construct a right triangle with $\tan\theta = w/2$:



From this we see that $\sin\theta = w/\sqrt{w^2+4}$ and $\cos\theta = 2/\sqrt{w^2+4}$. Thus

$$\int \frac{dw}{(w^2+4)^2} = \frac{1}{16}\tan^{-1}\left(\frac{w}{2}\right) + \frac{1}{16}\left(\frac{w}{\sqrt{w^2+4}}\right)\left(\frac{2}{\sqrt{w^2+4}}\right) + C = \frac{1}{16}\tan^{-1}\left(\frac{w}{2}\right) + \frac{w}{8(w^2+4)} + C.$$

In terms of x, we have

$$\int \frac{dx}{(x^2+4x+8)^2} = \int \frac{dw}{(w^2+4)^2} = \frac{1}{16}\tan^{-1}\left(\frac{x+2}{2}\right) + \frac{x+2}{8((x+2)^2+4)} + C.$$

Collecting all the terms, we have

$$\begin{aligned}\int \frac{(x+1)\,dx}{(x^2+4x+8)^2} &= \frac{-1}{2(x^2+4x+8)} - \frac{1}{16}\tan^{-1}\left(\frac{x+2}{2}\right) - \frac{x+2}{8(x^2+4x+8)} + C \\ &= -\frac{1}{16}\tan^{-1}\left(\frac{x+2}{2}\right) - \frac{x+6}{8(x^2+4x+8)} + C.\end{aligned}$$

65. $\displaystyle\int \frac{\sqrt{x}\,dx}{x^3+1}$

SOLUTION Use the substitution $u = x^{3/2}$, $du = \frac{3}{2}x^{1/2}\,dx$. Then $x^3 = (x^{3/2})^2 = u^2$, so we have

$$\int \frac{\sqrt{x}\,dx}{x^3+1} = \frac{2}{3}\int \frac{du}{u^2+1} = \frac{2}{3}\tan^{-1}u + C = \frac{2}{3}\tan^{-1}(x^{3/2}) + C.$$

66. $\displaystyle\int \frac{x^{1/2}\,dx}{x^{1/3}+1}$

SOLUTION Use the substitution $u = x^{1/6}$, $du = \frac{1}{6}x^{-5/6}\,dx$. Then $dx = 6x^{5/6}\,du = 6u^5\,du$, and we get

$$\int \frac{x^{1/2}\,dx}{x^{1/3}+1} = \int \frac{u^3(6u^5\,du)}{u^2+1} = 6\int \frac{u^8\,du}{u^2+1}.$$

By long division

$$\frac{u^8}{u^2+1} = u^6 - u^4 + u^2 - 1 + \frac{1}{u^2+1},$$

thus

$$\int \frac{u^8}{u^2+1}\,du = \int \left(u^6 - u^4 + u^2 - 1 + \frac{1}{u^2+1}\right)du = \frac{1}{7}u^7 - \frac{1}{5}u^5 + \frac{1}{3}u^3 - u + \tan^{-1}u + C.$$

The final answer is

$$\int \frac{x^{1/2}}{x^{1/3}+1} = \frac{6}{7}x^{7/6} - \frac{6}{5}x^{5/6} + 2x^{1/2} - 6x^{1/6} + 6\tan^{-1}(x^{1/6}) + C.$$

67. Show that the substitution $\theta = 2\tan^{-1} t$ (Figure 2) yields the formulas

$$\cos\theta = \frac{1-t^2}{1+t^2}, \qquad \sin\theta = \frac{2t}{1+t^2}, \qquad d\theta = \frac{2\,dt}{1+t^2} \qquad \boxed{10}$$

This substitution transforms the integral of any rational function of $\cos\theta$ and $\sin\theta$ into an integral of a rational function of t (which can then be evaluated using partial fractions). Use it to evaluate $\int \frac{d\theta}{\cos\theta + \frac{3}{4}\sin\theta}$.

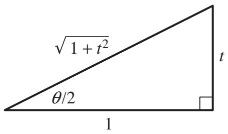


FIGURE 2

SOLUTION If $\theta = 2\tan^{-1} t$, then $d\theta = 2\,dt/(1+t^2)$. We also have that $\cos(\frac{\theta}{2}) = 1/\sqrt{1+t^2}$ and $\sin(\frac{\theta}{2}) = t/\sqrt{1+t^2}$. To find $\cos\theta$, we use the double angle identity $\cos\theta = 1 - 2\sin^2(\frac{\theta}{2})$. This gives us

$$\cos\theta = 1 - 2\left(\frac{t}{\sqrt{1+t^2}}\right)^2 = 1 - \frac{2t^2}{1+t^2} = \frac{1+t^2-2t^2}{1+t^2} = \frac{1-t^2}{1+t^2}.$$

To find $\sin\theta$, we use the double angle identity $\sin\theta = 2\sin(\frac{\theta}{2})\cos(\frac{\theta}{2})$. This gives us

$$\sin\theta = 2\left(\frac{t}{\sqrt{1+t^2}}\right)\left(\frac{1}{\sqrt{1+t^2}}\right) = \frac{2t}{1+t^2}.$$

With these formulas, we have

$$\int \frac{d\theta}{\cos\theta + (3/4)\sin\theta} = \int \frac{\frac{2\,dt}{1+t^2}}{\left(\frac{1-t^2}{1+t^2}\right) + \frac{3}{4}\left(\frac{2t}{1+t^2}\right)} = \int \frac{8\,dt}{4(1-t^2)+3(2t)} = \int \frac{8\,dt}{4+6t-4t^2} = \int \frac{4\,dt}{2+3t-2t^2}.$$

The partial fraction decomposition has the form

$$\frac{4}{2+3t-2t^2} = \frac{A}{2-t} + \frac{B}{1+2t}.$$

Clearing denominators gives us

$$4 = A(1+2t) + B(2-t).$$

Setting $t = 2$ then yields

$$4 = A(5) + 0 \qquad \text{or} \qquad A = \frac{4}{5},$$

while setting $t = -\frac{1}{2}$ yields

$$4 = 0 + B\left(\frac{5}{2}\right) \qquad \text{or} \qquad B = \frac{8}{5}.$$

The result is

$$\frac{4}{2+3t-2t^2} = \frac{\frac{4}{5}}{2-t} + \frac{\frac{8}{5}}{1+2t}.$$

Thus,

$$\int \frac{4}{2+3t-2t^2}\,dt = \frac{4}{5}\int \frac{dt}{2-t} + \frac{8}{5}\int \frac{dt}{1+2t} = -\frac{4}{5}\ln|2-t| + \frac{4}{5}\ln|1+2t| + C.$$

The original substitution was $\theta = 2\tan^{-1} t$, which means that $t = \tan(\frac{\theta}{2})$. The final answer is then

$$\int \frac{d\theta}{\cos\theta + \frac{3}{4}\sin\theta} = -\frac{4}{5}\ln\left|2 - \tan\left(\frac{\theta}{2}\right)\right| + \frac{4}{5}\ln\left|1 + 2\tan\left(\frac{\theta}{2}\right)\right| + C.$$

68. Use the substitution of Exercise 67 to evaluate $\int \frac{d\theta}{\cos\theta + \sin\theta}$.

SOLUTION Using the substitution $\theta = 2\tan^{-1} t$, we get

$$\int \frac{d\theta}{\cos\theta + \sin\theta} = \int \frac{2\,dt/(1+t^2)}{(1-t^2)/(1+t^2) + 2t/(1+t^2)} = \int \frac{2\,dt}{1-t^2+2t} = -2\int \frac{dt}{t^2-2t-1}.$$

The partial fraction decomposition has the form

$$\frac{-2}{t^2-2t-1} = \frac{A}{t-1-\sqrt{2}} + \frac{B}{t-1+\sqrt{2}}.$$

Clearing denominators gives us

$$-2 = A(t-1+\sqrt{2}) + B(t-1-\sqrt{2}).$$

Setting $t = 1+\sqrt{2}$ then yields $A = -\frac{1}{\sqrt{2}}$, while setting $t = 1-\sqrt{2}$ yields $B = \frac{1}{\sqrt{2}}$. Thus,

$$\int \frac{d\theta}{\cos\theta + \sin\theta} = \frac{1}{\sqrt{2}}\int \frac{dt}{t-1+\sqrt{2}} - \frac{1}{\sqrt{2}}\int \frac{dt}{t-1-\sqrt{2}} = \frac{1}{\sqrt{2}}\ln|t-1+\sqrt{2}| - \frac{1}{\sqrt{2}}\ln|t-1-\sqrt{2}| + C$$

$$= \frac{1}{\sqrt{2}}\ln\left|\frac{\tan\left(\frac{\theta}{2}\right) - 1 + \sqrt{2}}{\tan\left(\frac{\theta}{2}\right) - 1 - \sqrt{2}}\right| + C.$$

Further Insights and Challenges

69. Prove the general formula

$$\int \frac{dx}{(x-a)(x-b)} = \frac{1}{a-b}\ln\frac{x-a}{x-b} + C$$

where a, b are constants such that $a \neq b$.

SOLUTION The partial fraction decomposition has the form:

$$\frac{1}{(x-a)(x-b)} = \frac{A}{x-a} + \frac{B}{x-b}.$$

Clearing denominators, we get

$$1 = A(x-b) + B(x-a).$$

Setting $x = a$ then yields

$$1 = A(a-b) + 0 \qquad \text{or} \qquad A = \frac{1}{a-b},$$

while setting $x = b$ yields

$$1 = 0 + B(b-a) \qquad \text{or} \qquad B = \frac{1}{b-a}.$$

The result is

$$\frac{1}{(x-a)(x-b)} = \frac{\frac{1}{a-b}}{x-a} + \frac{\frac{1}{b-a}}{x-b}.$$

Thus,

$$\int \frac{dx}{(x-a)(x-b)} = \frac{1}{a-b}\int \frac{dx}{x-a} + \frac{1}{b-a}\int \frac{dx}{x-b} = \frac{1}{a-b}\ln|x-a| + \frac{1}{b-a}\ln|x-b| + C$$

$$= \frac{1}{a-b}\ln|x-a| - \frac{1}{a-b}\ln|x-b| + C = \frac{1}{a-b}\ln\left|\frac{x-a}{x-b}\right| + C.$$

70. The method of partial fractions shows that

$$\int \frac{dx}{x^2-1} = \frac{1}{2}\ln|x-1| - \frac{1}{2}\ln|x+1| + C$$

The computer algebra system Mathematica evaluates this integral as $-\tanh^{-1} x$, where $\tanh^{-1} x$ is the inverse hyperbolic tangent function. Can you reconcile the two answers?

SOLUTION Let

$$y = \tanh x = \frac{e^x - e^{-x}}{e^x + e^{-x}}.$$

Solving for x in terms of y, we find

$$(e^x + e^{-x})y = e^x - e^{-x}$$
$$e^{-x}(1 + y) = e^x(1 - y)$$
$$e^{2x} = \frac{1+y}{1-y}$$
$$x = \frac{1}{2}\ln\left|\frac{1+y}{1-y}\right|$$

Thus,

$$\tanh^{-1} x = \frac{1}{2}\ln\left|\frac{1+x}{1-x}\right|,$$

so

$$-\tanh^{-1} x = \frac{1}{2}\ln\left|\frac{1-x}{1+x}\right| = \frac{1}{2}\ln|1-x| - \frac{1}{2}\ln|1+x|,$$

as desired.

71. Suppose that $Q(x) = (x-a)(x-b)$, where $a \neq b$, and let $P(x)/Q(x)$ be a proper rational function so that

$$\frac{P(x)}{Q(x)} = \frac{A}{(x-a)} + \frac{B}{(x-b)}$$

(a) Show that $A = \dfrac{P(a)}{Q'(a)}$ and $B = \dfrac{P(b)}{Q'(b)}$.

(b) Use this result to find the partial fraction decomposition for $P(x) = 3x - 2$ and $Q(x) = x^2 - 4x - 12$.

SOLUTION

(a) Clearing denominators gives us

$$P(x) = A(x-b) + B(x-a).$$

Setting $x = a$ then yields

$$P(a) = A(a-b) + 0 \qquad \text{or} \qquad A = \frac{P(a)}{a-b},$$

while setting $x = b$ yields

$$P(b) = 0 + B(b-a) \qquad \text{or} \qquad B = \frac{P(b)}{b-a}.$$

Now use the product rule to differentiate $Q(x)$:

$$Q'(x) = (x-a)(1) + (1)(x-b) = x - a + x - b = 2x - a - b;$$

therefore,

$$Q'(a) = 2a - a - b = a - b$$
$$Q'(b) = 2b - a - b = b - a$$

Substituting these into the above results, we find

$$A = \frac{P(a)}{Q'(a)} \quad \text{and} \quad B = \frac{P(b)}{Q'(b)}.$$

(b) The partial fraction decomposition has the form:

$$\frac{P(x)}{Q(x)} = \frac{3x-2}{x^2-4x-12} = \frac{3x-2}{(x-6)(x+2)} = \frac{A}{x-6} + \frac{B}{x+2};$$
$$A = \frac{P(6)}{Q'(6)} = \frac{3(6)-2}{2(6)-4} = \frac{16}{8} = 2;$$

$$B = \frac{P(-2)}{Q'(-2)} = \frac{3(-2) - 2}{2(-2) - 4} = \frac{-8}{-8} = 1.$$

The result is

$$\frac{3x - 2}{x^2 - 4x - 12} = \frac{2}{x - 6} + \frac{1}{x + 2}.$$

72. Suppose that $Q(x) = (x - a_1)(x - a_2) \cdots (x - a_n)$, where the roots a_j are all distinct. Let $P(x)/Q(x)$ be a proper rational function so that

$$\frac{P(x)}{Q(x)} = \frac{A_1}{(x - a_1)} + \frac{A_2}{(x - a_2)} + \cdots + \frac{A_n}{(x - a_n)}$$

(a) Show that $A_j = \dfrac{P(a_j)}{Q'(a_j)}$ for $j = 1, \ldots, n$.

(b) Use this result to find the partial fraction decomposition for $P(x) = 2x^2 - 1$, $Q(x) = x^3 - 4x^2 + x + 6 = (x + 1)(x - 2)(x - 3)$.

SOLUTION

(a) To differentiate $Q(x)$, first take the logarithm of both sides, and then differentiate:

$$\ln\big(Q(x)\big) = \ln\big[(x - a_1)(x - a_2) \cdots (x - a_n)\big] = \ln(x - a_1) + \ln(x - a_2) + \cdots + \ln(x - a_n)$$
$$\frac{d}{dx} \ln\big(Q(x)\big) = \frac{Q'(x)}{Q(x)} = \frac{1}{x - a_1} + \frac{1}{x - a_2} + \cdots + \frac{1}{x - a_n}$$

Multiplying both sides by $Q(x)$ gives us

$$\begin{aligned} Q'(x) &= Q(x)\left[\frac{1}{x - a_1} + \cdots + \frac{1}{x - a_n}\right] \\ &= (x - a_2)(x - a_3) \cdots (x - a_n) + (x - a_1)(x - a_3) \cdots (x - a_n) + \cdots + (x - a_1)(x - a_2) \cdots (x - a_{n-1}). \end{aligned}$$

In other words, the ith product in the formula for $Q'(x)$ has the $(x - a_i)$ factor removed. This means that

$$Q'(a_j) = (a_j - a_1) \cdots (a_j - a_{j-1})(a_j - a_{j+1}) \cdots (a_j - a_n).$$

Now clear denominators in the expression for $P(x)/Q(x)$:

$$\begin{aligned} P(x) &= \frac{A_1 Q(x)}{x - a_1} + \frac{A_2 Q(x)}{x - a_2} + \cdots + \frac{A_n Q(x)}{x - a_n} \\ &= A_1(x - a_2) \cdots (x - a_n) + (x - a_1)A_2(x - a_3) \cdots (x - a_n) + \cdots + (x - a_1)(x - a_2) \cdots (x - a_{n-1})A_n. \end{aligned}$$

Setting $x = a_j$, we get

$$P(a_j) = (a_j - a_1)(a_j - a_2) \cdots (a_j - a_{j-1})A_j(a_j - a_{j+1}) \cdots (a_j - a_n),$$

so that

$$A_j = \frac{P(a_j)}{(a_j - a_1) \cdots (a_j - a_{j-1})(a_j - a_{j+1}) \cdots (a_j - a_n)} = \frac{P(a_j)}{Q'(a_j)}.$$

(b) Let $P(x) = 2x^2 - 1$ and $Q(x) = (x + 1)(x - 2)(x - 3)$, so that $Q'(x) = 3x^2 - 8x + 1$. Then $a_1 = -1$, $a_2 = 2$, and $a_3 = 3$, so that

$$A_1 = P(-1)/Q'(-1) = \frac{1}{12};$$
$$A_2 = P(2)/Q'(2) = -\frac{7}{3};$$
$$A_3 = P(3)/Q'(3) = \frac{17}{4}.$$

Thus

$$\frac{P(x)}{Q(x)} = \frac{1}{12(x + 1)} - \frac{7}{1 = 3(x - 2)} + \frac{17}{4(x - 3)}.$$

7.6 Improper Integrals

Preliminary Questions

1. State whether the integral converges or diverges:

(a) $\int_1^{\infty} x^{-3}\,dx$

(b) $\int_0^1 x^{-3}\,dx$

(c) $\int_1^{\infty} x^{-2/3}\,dx$

(d) $\int_0^1 x^{-2/3}\,dx$

SOLUTION

(a) The integral is improper because one of the limits of integration is infinite. Because the power of x in the integrand is less than -1, this integral converges.
(b) The integral is improper because the integrand is undefined at $x = 0$. Because the power of x in the integrand is less than -1, this integral diverges.
(c) The integral is improper because one of the limits of integration is infinite. Because the power of x in the integrand is greater than -1, this integral diverges.
(d) The integral is improper because the integrand is undefined at $x = 0$. Because the power of x in the integrand is greater than -1, this integral converges.

2. Is $\int_0^{\pi/2} \cot x\,dx$ an improper integral? Explain.

SOLUTION Because the integrand $\cot x$ is undefined at $x = 0$, this is an improper integral.

3. Find a value of $b > 0$ that makes $\int_0^b \frac{1}{x^2 - 4}\,dx$ an improper integral.

SOLUTION Any value of b satisfying $|b| \geq 2$ will make this an improper integral.

4. Which comparison would show that $\int_0^{\infty} \frac{dx}{x + e^x}$ converges?

SOLUTION Note that, for $x > 0$,

$$\frac{1}{x + e^x} < \frac{1}{e^x} = e^{-x}.$$

Moreover

$$\int_0^{\infty} e^{-x}\,dx$$

converges. Therefore,

$$\int_0^{\infty} \frac{1}{x + e^x}\,dx$$

converges by the comparison test.

5. Explain why it is not possible to draw any conclusions about the convergence of $\int_1^{\infty} \frac{e^{-x}}{x}\,dx$ by comparing with the integral $\int_1^{\infty} \frac{dx}{x}$.

SOLUTION For $1 \leq x < \infty$,

$$\frac{e^{-x}}{x} < \frac{1}{x},$$

but

$$\int_1^{\infty} \frac{dx}{x}$$

diverges. Knowing that an integral is smaller than a divergent integral does not allow us to draw any conclusions using the comparison test.

Exercises

1. Which of the following integrals is improper? Explain your answer, but do not evaluate the integral.

(a) $\int_0^2 \frac{dx}{x^{1/3}}$

(b) $\int_1^{\infty} \frac{dx}{x^{0.2}}$

(c) $\int_{-1}^{\infty} e^{-x}\,dx$

(d) $\int_0^1 e^{-x}\,dx$

(e) $\int_0^{\pi/2} \sec x\,dx$

(f) $\int_0^{\infty} \sin x\,dx$

(g) $\int_0^1 \sin x\,dx$ **(h)** $\int_0^1 \frac{dx}{\sqrt{3-x^2}}$ **(i)** $\int_1^\infty \ln x\,dx$

(j) $\int_0^3 \ln x\,dx$

SOLUTION

(a) Improper. The function $x^{-1/3}$ is infinite at 0.
(b) Improper. Infinite interval of integration.
(c) Improper. Infinite interval of integration.
(d) Proper. The function e^{-x} is continuous on the finite interval [0, 1].
(e) Improper. The function $\sec x$ is infinite at $\frac{\pi}{2}$.
(f) Improper. Infinite interval of integration.
(g) Proper. The function $\sin x$ is continuous on the finite interval [0, 1].
(h) Proper. The function $1/\sqrt{3-x^2}$ is continuous on the finite interval [0, 1].
(i) Improper. Infinite interval of integration.
(j) Improper. The function $\ln x$ is infinite at 0.

2. Let $f(x) = x^{-4/3}$.

(a) Evaluate $\int_1^R f(x)\,dx$.

(b) Evaluate $\int_1^\infty f(x)\,dx$ by computing the limit

$$\lim_{R\to\infty} \int_1^R f(x)\,dx$$

SOLUTION

(a) $\int_1^R x^{-4/3}\,dx = -3x^{-1/3}\Big|_1^R = -3R^{-1/3} - \big(-3(1)\big) = 3\left(1 - \frac{1}{R^{1/3}}\right)$.

(b) $\int_1^\infty x^{-4/3}\,dx = \lim_{R\to\infty} \int_1^R x^{-4/3}\,dx = \lim_{R\to\infty} 3\left(1 - \frac{1}{R^{1/3}}\right) = 3(1-0) = 3.$

3. Prove that $\int_1^\infty x^{-2/3}\,dx$ diverges by showing that

$$\lim_{R\to\infty} \int_1^R x^{-2/3}\,dx = \infty$$

SOLUTION First compute the proper integral:

$$\int_1^R x^{-2/3}\,dx = 3x^{1/3}\Big|_1^R = 3R^{1/3} - 3 = 3\left(R^{1/3} - 1\right).$$

Then show divergence:

$$\int_1^\infty x^{-2/3}\,dx = \lim_{R\to\infty} \int_1^R x^{-2/3}\,dx = \lim_{R\to\infty} 3\left(R^{1/3} - 1\right) = \infty.$$

4. Determine whether $\int_0^3 \frac{dx}{(3-x)^{3/2}}$ converges by computing

$$\lim_{R\to 3-} \int_0^R \frac{dx}{(3-x)^{3/2}}$$

SOLUTION First evaluate the integral on the interval $[0, R]$ for $0 < R < 3$:

$$\int_0^R \frac{dx}{(3-x)^{3/2}} = 2(3-x)^{-1/2}\Big|_0^R = \frac{2}{\sqrt{3-R}} - \frac{2}{\sqrt{3}}.$$

Now compute the limit as $R \to 3^-$:

$$\int_0^3 \frac{dx}{(3-x)^{3/2}} = \lim_{R\to 3^-} \int_0^R \frac{dx}{(3-x)^{3/2}} = \lim_{R\to 3^-} \left(\frac{2}{\sqrt{3-R}} - \frac{2}{\sqrt{3}}\right) = \infty;$$

thus, the integral diverges.

In Exercises 5–40, determine whether the improper integral converges and, if so, evaluate it.

5. $\displaystyle\int_1^\infty \frac{dx}{x^{19/20}}$

SOLUTION First evaluate the integral over the finite interval $[1, R]$ for $R > 1$:

$$\int_1^R \frac{dx}{x^{19/20}} = 20x^{1/20}\Big|_1^R = 20R^{1/20} - 20.$$

Now compute the limit as $R \to \infty$:

$$\int_1^\infty \frac{dx}{x^{19/20}} = \lim_{R\to\infty}\int_1^R \frac{dx}{x^{19/20}} = \lim_{R\to\infty}\left(20R^{1/20} - 20\right) = \infty.$$

The integral does not converge.

6. $\displaystyle\int_1^\infty \frac{dx}{x^{20/19}}$

SOLUTION First evaluate the integral over the finite interval $[1, R]$ for $R > 1$:

$$\int_1^R \frac{dx}{x^{20/19}} = -19x^{-1/19}\Big|_1^R = \frac{-19}{R^{1/19}} - (-19) = 19 - \frac{19}{R^{1/19}}.$$

Now compute the limit as $R \to \infty$:

$$\int_1^\infty \frac{dx}{x^{20/19}} = \lim_{R\to\infty}\int_1^R \frac{dx}{x^{20/19}} = \lim_{R\to\infty}\left(19 - \frac{19}{R^{1/19}}\right) = 19 - 0 = 19.$$

7. $\displaystyle\int_{-\infty}^4 e^{0.0001t}\,dt$

SOLUTION First evaluate the integral over the finite interval $[R, 4]$ for $R < 4$:

$$\int_R^4 e^{(0.0001)t}\,dt = \frac{e^{(0.0001)t}}{0.0001}\Bigg|_R^4 = 10{,}000\left(e^{0.0004} - e^{(0.0001)R}\right).$$

Now compute the limit as $R \to -\infty$:

$$\begin{aligned}\int_{-\infty}^4 e^{(0.0001)t}\,dt &= \lim_{R\to-\infty}\int_R^4 e^{(0.0001)t}\,dt = \lim_{R\to-\infty} 10{,}000\left(e^{0.0004} - e^{(0.0001)R}\right)\\ &= 10{,}000\left(e^{0.0004} - 0\right) = 10{,}000e^{0.0004}.\end{aligned}$$

8. $\displaystyle\int_{20}^\infty \frac{dt}{t}$

SOLUTION First evaluate the integral over the finite interval $[20, R]$ for $20 < R$:

$$\int_{20}^R \frac{dt}{t} = \ln|t|\big|_{20}^R = \ln R - \ln 20.$$

Now compute the limit as $R \to \infty$:

$$\int_{20}^\infty \frac{dt}{t} = \lim_{R\to\infty}\int_{20}^R \frac{dt}{t} = \lim_{R\to\infty}(\ln R - \ln 20) = \infty;$$

thus, the integral does not converge.

9. $\displaystyle\int_0^5 \frac{dx}{x^{20/19}}$

SOLUTION The function $x^{-20/19}$ is infinite at the endpoint 0, so we'll first evaluate the integral on the finite interval $[R, 5]$ for $0 < R < 5$:

$$\int_R^5 \frac{dx}{x^{20/19}} = -19x^{-1/19}\Big|_R^5 = -19\left(5^{-1/19} - R^{-1/19}\right) = 19\left(\frac{1}{R^{1/19}} - \frac{1}{5^{1/19}}\right).$$

Now compute the limit as $R \to 0^+$:

$$\int_0^5 \frac{dx}{x^{20/19}} = \lim_{R\to 0^+} \int_R^5 \frac{dx}{x^{20/19}} = \lim_{R\to 0^+} 19\left(\frac{1}{R^{1/19}} - \frac{1}{5^{1/19}}\right) = \infty;$$

thus, the integral does not converge.

10. $\displaystyle\int_0^5 \frac{dx}{x^{19/20}}$

SOLUTION The function $x^{-19/20}$ is infinite at the endpoint 0, so we'll first evaluate the integral on the finite interval $[R, 5]$ for $0 < R < 5$:

$$\int_R^5 \frac{dx}{x^{19/20}} = 20x^{1/20}\Big|_R^5 = 20\left(5^{1/20} - R^{1/20}\right).$$

Now compute the limit as $R \to 0^+$:

$$\int_0^5 \frac{dx}{x^{19/20}} = \lim_{R\to 0^+} \int_R^5 \frac{dx}{x^{19/20}} = \lim_{R\to 0^+} 20\left(5^{1/20} - R^{1/20}\right) = 20\left(5^{1/20} - 0\right) = 20 \cdot 5^{1/20}.$$

11. $\displaystyle\int_0^4 \frac{dx}{\sqrt{4-x}}$

SOLUTION The function $1/\sqrt{4-x}$ is infinite at $x = 4$, but is left-continuous at $x = 4$, so we'll first evaluate the integral on the interval $[0, R]$ for $0 < R < 4$:

$$\int_0^R \frac{dx}{\sqrt{4-x}} = -2\sqrt{4-x}\Big|_0^R = -2\sqrt{4-R} - (-2)\sqrt{4} = 4 - 2\sqrt{4-R}.$$

Now compute the limit as $R \to 4^-$:

$$\int_0^4 \frac{dx}{\sqrt{4-x}} = \lim_{R\to 4^-} \int_0^R \frac{dx}{\sqrt{4-x}} = \lim_{R\to 4^-} \left(4 - 2\sqrt{4-R}\right) = 4 - 0 = 4.$$

12. $\displaystyle\int_5^6 \frac{dx}{(x-5)^{3/2}}$

SOLUTION The function $(x-5)^{-3/2}$ is infinite at $x = 5$, but is right-continuous at $x = 5$, so we'll first evaluate the integral on the interval $[R, 6]$ for $5 < R < 6$:

$$\int_R^6 \frac{dx}{(x-5)^{3/2}} = 2(x-5)^{-1/2}\Big|_R^6 = \frac{-2}{\sqrt{1}} - \frac{-2}{\sqrt{R-5}} = \frac{2}{\sqrt{R-5}} - 2.$$

Now compute the limit as $R \to 5^+$:

$$\int_5^6 \frac{dx}{(x-5)^{-3/2}} = \lim_{R\to 5^+} \int_R^6 \frac{dx}{(x-5)^{3/2}} = \lim_{R\to 5^+} \left(\frac{2}{\sqrt{R-5}} - 2\right) = \infty;$$

thus, the integral does not converge.

13. $\displaystyle\int_2^\infty x^{-3}\,dx$

SOLUTION First evaluate the integral on the finite interval $[2, R]$ for $2 < R$:

$$\int_2^R x^{-3}\,dx = \frac{x^{-2}}{-2}\Big|_2^R = \frac{-1}{2R^2} - \frac{-1}{2(2^2)} = \frac{1}{8} - \frac{1}{2R^2}.$$

Now compute the limit as $R \to \infty$:

$$\int_2^\infty x^{-3}\,dx = \lim_{R\to\infty} \int_2^R x^{-3}\,dx = \lim_{R\to\infty} \left(\frac{1}{8} - \frac{1}{2R^2}\right) = \frac{1}{8}.$$

14. $\displaystyle\int_0^\infty \frac{dx}{(x+1)^3}$

SOLUTION First evaluate the integral on the finite interval $[0, R]$ for $R > 0$:

$$\int_0^R \frac{dx}{(x+1)^3} = \frac{(x+1)^{-2}}{-2}\Big|_0^R = \frac{-1}{2(R+1)^2} - \frac{-1}{2(1)^2} = \frac{1}{2} - \frac{1}{2(R+1)^2}.$$

Now compute the limit as $R \to \infty$:

$$\int_0^\infty \frac{dx}{(x+1)^3} = \lim_{R\to\infty} \int_0^R \frac{dx}{(x+1)^3} = \lim_{R\to\infty} \left(\frac{1}{2} - \frac{1}{2(R+1)^2}\right) = \frac{1}{2}.$$

15. $\displaystyle\int_{-3}^\infty \frac{dx}{(x+4)^{3/2}}$

SOLUTION First evaluate the integral on the finite interval $[-3, R]$ for $R > -3$:

$$\int_{-3}^R \frac{dx}{(x+4)^{3/2}} = -2(x+4)^{-1/2}\Big|_{-3}^R = \frac{-2}{\sqrt{R+4}} - \frac{-2}{\sqrt{1}} = 2 - \frac{2}{\sqrt{R+4}}.$$

Now compute the limit as $R \to \infty$:

$$\int_{-3}^\infty \frac{dx}{(x+4)^{3/2}} = \lim_{R\to\infty} \int_{-3}^R \frac{dx}{(x+4)^{3/2}} = \lim_{R\to\infty} \left(2 - \frac{2}{\sqrt{R+4}}\right) = 2 - 0 = 2.$$

16. $\displaystyle\int_2^\infty e^{-2x}\,dx$

SOLUTION First evaluate the integral on the finite interval $[2, R]$ for $R > 2$:

$$\int_2^R e^{-2x}\,dx = \frac{e^{-2x}}{-2}\Big|_2^R = -\frac{1}{2}\left(e^{-2R} - e^{-4}\right) = \frac{1}{2}\left(e^{-4} - e^{-2R}\right).$$

Now compute the limit as $R \to \infty$:

$$\int_2^\infty e^{-2x}\,dx = \lim_{R\to\infty} \int_2^R e^{-2x}\,dx = \lim_{R\to\infty} \left(e^{-4} - e^{-2R}\right) = \frac{1}{2}\left(e^{-4} - 0\right) = \frac{1}{2e^4}.$$

17. $\displaystyle\int_0^1 \frac{dx}{x^{0.2}}$

SOLUTION The function $x^{-0.2}$ is infinite at $x = 0$ and right-continuous at $x = 0$, so we'll first evaluate the integral on the interval $[R, 1]$ for $0 < R < 1$:

$$\int_R^1 \frac{dx}{x^{0.2}} = \frac{x^{0.8}}{0.8}\Big|_R^1 = 1.25\left(1 - R^{0.8}\right).$$

Now compute the limit as $R \to 0^+$:

$$\int_0^1 \frac{dx}{x^{0.2}} = \lim_{R\to 0^+} \int_R^1 \frac{dx}{x^{0.2}} = \lim_{R\to 0^+} 1.25\left(1 - R^{0.8}\right) = 1.25(1-0) = 1.25.$$

18. $\displaystyle\int_2^\infty x^{-1/3}\,dx$

SOLUTION First evaluate the integral on the finite interval $[2, R]$ for $R > 2$:

$$\int_2^R x^{-1/3}\,dx = \frac{3}{2}x^{2/3}\Big|_2^R = \frac{3}{2}\left(R^{2/3} - 2^{2/3}\right).$$

Now compute the limit as $R \to \infty$:

$$\int_2^\infty x^{-1/3}\,dx = \lim_{R\to\infty} \int_2^R x^{-1/3}\,dx = \lim_{R\to\infty} \frac{3}{2}\left(R^{2/3} - 2^{2/3}\right) = \infty;$$

thus, the integral does not converge.

19. $\displaystyle\int_4^\infty e^{-3x}\,dx$

SOLUTION First evaluate the integral on the finite interval $[4, R]$ for $R > 4$:

$$\int_4^R e^{-3x}\,dx = \frac{e^{-3x}}{-3}\Big|_4^R = -\frac{1}{3}\left(e^{-3R} - e^{-12}\right) = \frac{1}{3}\left(e^{-12} - e^{-3R}\right).$$

Now compute the limit as $R \to \infty$:

$$\int_4^\infty e^{-3x}\,dx = \lim_{R\to\infty}\int_4^R e^{-3x}\,dx = \lim_{R\to\infty}\frac{1}{3}\left(e^{-12} - e^{-3R}\right) = \frac{1}{3}\left(e^{-12} - 0\right) = \frac{1}{3e^{12}}.$$

20. $\displaystyle\int_4^\infty e^{3x}\,dx$

SOLUTION First evaluate the integral on the finite interval $[4, R]$ for $R > 4$:

$$\int_4^R e^{3x}\,dx = \left.\frac{e^{3x}}{3}\right|_4^R = \frac{1}{3}\left(e^{3R} - e^{12}\right).$$

Now compute the limit as $R \to \infty$:

$$\int_4^\infty e^{3x}\,dx = \lim_{R\to\infty}\int_4^R e^{3x}\,dx = \lim_{R\to\infty}\frac{1}{3}\left(e^{3R} - e^{12}\right) = \infty;$$

thus, the integral does not converge.

21. $\displaystyle\int_{-\infty}^0 e^{3x}\,dx$

SOLUTION First evaluate the integral on the finite interval $[R, 0]$ for $R < 0$:

$$\int_R^0 e^{3x}\,dx = \left.\frac{e^{3x}}{3}\right|_R^0 = \frac{1}{3} - \frac{e^{3R}}{3}.$$

Now compute the limit as $R \to -\infty$:

$$\int_{-\infty}^0 e^{3x}\,dx = \lim_{R\to-\infty}\int_R^0 e^{3x}\,dx = \lim_{R\to-\infty}\left(\frac{1}{3} - \frac{e^{3R}}{3}\right) = \frac{1}{3} - 0 = \frac{1}{3}.$$

22. $\displaystyle\int_1^2 \frac{dx}{(x-1)^2}$

SOLUTION The function $(x-1)^{-2}$ is infinite at $x = 1$ and is right-continuous at $x = 1$, so we first evaluate the integral on the interval $[R, 2]$ for $1 < R < 2$:

$$\int_R^2 \frac{dx}{(x-1)^2} = \left.\frac{(x-1)^{-1}}{-1}\right|_R^2 = \frac{-1}{1} - \frac{-1}{R-1} = \frac{1}{R-1} - 1.$$

Now compute the limit as $R \to 1^+$:

$$\int_1^2 \frac{dx}{(x-1)^2} = \lim_{R\to1^+}\int_R^2 \frac{dx}{(x-1)^2} = \lim_{R\to1^+}\left(\frac{1}{R-1} - 1\right) = \infty;$$

thus, the integral does not converge.

23. $\displaystyle\int_1^3 \frac{dx}{\sqrt{3-x}}$

SOLUTION The function $f(x) = 1/\sqrt{3-x}$ is infinite at $x = 3$ and is left continuous at $x = 3$, so we first evaluate the integral on the interval $[1, R]$ for $1 < R < 3$:

$$\int_1^R \frac{dx}{\sqrt{3-x}} = \left.-2\sqrt{3-x}\right|_1^R = -2\sqrt{3-R} + 2\sqrt{2}.$$

Now compute the limit as $R \to 3^-$:

$$\int_1^3 \frac{dx}{\sqrt{3-x}} = \lim_{R\to3-}\int_1^R \frac{dx}{\sqrt{3-x}} = 0 + 2\sqrt{2} = 2\sqrt{2}.$$

24. $\displaystyle\int_{-2}^4 \frac{dx}{(x+2)^{1/3}}$

SOLUTION The function $(x+2)^{-1/3}$ is infinite at $x = -2$ and right-continuous at $x = -2$, so we'll first evaluate the integral on the interval $[R, 4]$ for $-2 < R < 4$:

$$\int_R^4 \frac{dx}{(x+2)^{1/3}} = \left.\frac{3}{2}(x+2)^{2/3}\right|_R^4 = \frac{3}{2}\left(6^{2/3} - (R+2)^{2/3}\right).$$

Now compute the limit as $R \to -2^+$:

$$\int_{-2}^{4} \frac{dx}{(x+2)^{1/3}} = \lim_{R\to -2^+} \int_{R}^{4} \frac{dx}{(x+2)^{1/3}} = \lim_{R\to 2^+} \frac{3}{2}\left(6^{2/3} - (R+2)^{2/3}\right) = \frac{3}{2}\left(6^{2/3} - 0\right) = \frac{3\cdot 6^{2/3}}{2}.$$

25. $\displaystyle\int_0^\infty \frac{dx}{1+x}$

SOLUTION First evaluate the integral on the finite interval $[0, R]$ for $R > 0$:

$$\int_0^R \frac{dx}{1+x} = \ln|1+x|\Big|_0^R = \ln|1+R| - \ln 1 = \ln|1+R|.$$

Now compute the limit as $R \to \infty$:

$$\int_0^\infty \frac{dx}{1+x} = \lim_{R\to\infty} \int_0^R \frac{dx}{1+x} = \lim_{R\to\infty} \ln|1+R| = \infty;$$

thus, the integral does not converge.

26. $\displaystyle\int_{-\infty}^{0} xe^{-x^2}\,dx$

SOLUTION First evaluate the indefinite integral using substitution, with $u = -x^2$, $du = -2x\,dx$. This gives us

$$\int xe^{-x^2}\,dx = -\frac{1}{2}\int e^{-x^2}(-2x\,dx) = -\frac{1}{2}\int e^u\,du = -\frac{1}{2}e^u + C = -\frac{1}{2}e^{-x^2} + C.$$

Next, evaluate the integral on the finite interval $[R, 0]$ for $R < 0$:

$$\int_R^0 xe^{-x^2}\,dx = -\frac{1}{2}e^{-x^2}\Big|_R^0 = -\frac{1}{2}\left(1 - e^{-R^2}\right).$$

Finally, compute the limit as $R \to -\infty$:

$$\int_{-\infty}^0 xe^{-x^2}\,dx = \lim_{R\to-\infty} \int_R^0 xe^{-x^2}\,dx = \lim_{R\to-\infty} \frac{1}{2}\left(e^{-R^2} - 1\right) = \frac{1}{2}(0-1) = -\frac{1}{2}.$$

27. $\displaystyle\int_0^\infty \frac{x\,dx}{(1+x^2)^2}$

SOLUTION First evaluate the indefinite integral, using the substitution $u = x^2$, $du = 2x\,dx$; then

$$\int \frac{x\,dx}{(1+x^2)^2} = \frac{1}{2}\int \frac{1}{(1+u)^2}\,du = -\frac{1}{2(u+1)} + C = -\frac{1}{2(x^2+1)} + C$$

Thus, for $R > 0$,

$$\int_0^R \frac{x\,dx}{(x^2+1)^2} = \left(-\frac{1}{2(x^2+1)}\right)\Bigg|_0^R = -\frac{1}{2(R^2+1)} + \frac{1}{2}$$

and thus in the limit

$$\int_0^\infty \frac{x\,dx}{(x^2+1)^2} = \lim_{R\to\infty} \int_0^R \frac{x\,dx}{(x^2+1)^2} = \frac{1}{2} - \lim_{R\to\infty} \frac{1}{2(R^2+1)} = \frac{1}{2}$$

28. $\displaystyle\int_3^6 \frac{x\,dx}{\sqrt{x-3}}$

SOLUTION First, evaluate the indefinite integral using the substitution $u = x - 3$, $du = dx$:

$$\int \frac{x}{\sqrt{x-3}}\,dx = \int \frac{u+3}{\sqrt{u}}\,du = \frac{2}{3}u^{3/2} + 6u^{1/2} + C = \frac{2}{3}(x-3)^{3/2} + 6(x-3)^{1/2} + C.$$

Next, evaluate the definite integral over the interval $[R, 6]$ for $R > 3$:

$$\int_R^6 \frac{x}{\sqrt{x-3}}\,dx = \left(\frac{2}{3}(x-3)^{3/2} + 6(x-3)^{1/2}\right)\Big|_R^6 = \frac{2}{3}3^{3/2} + 6\sqrt{3} - \frac{2}{3}(R-3)^{3/2} - 6(R-3)^{1/2}$$
$$= 8\sqrt{3} - \frac{2}{3}(R-3)^{3/2} - 6(R-3)^{1/2}.$$

Finally, we compute the limit as $R \to 3^+$:

$$\int_3^6 \frac{x}{\sqrt{x-3}}\,dx = \lim_{R\to 3^+}\int_R^6 \frac{x}{\sqrt{x-3}}\,dx = \lim_{R\to 3^+}\left(8\sqrt{3} - \frac{2}{3}(R-3)^{3/2} - 6(R-3)^{1/2}\right) = 8\sqrt{3}.$$

29. $\displaystyle\int_0^\infty e^{-x}\cos x\,dx$

SOLUTION First evaluate the indefinite integral using Integration by Parts, with $u = e^{-x}$, $v' = \cos x$. Then $u' = -e^{-x}$, $v = \sin x$, and

$$\int e^{-x}\cos x\,dx = e^{-x}\sin x - \int \sin x(-e^{-x})\,dx = e^{-x}\sin x + \int e^{-x}\sin x\,dx.$$

Now use Integration by Parts again, with $u = e^{-x}$, $v' = \sin x$. Then $u' = -e^{-x}$, $v = -\cos x$, and

$$\int e^{-x}\cos x\,dx = e^{-x}\sin x + \left[-e^{-x}\cos x - \int e^{-x}\cos x\,dx\right].$$

Solving this equation for $\int e^{-x}\cos x\,dx$, we find

$$\int e^{-x}\cos x\,dx = \frac{1}{2}e^{-x}(\sin x - \cos x) + C.$$

Thus,

$$\int_0^R e^{-x}\cos x\,dx = \frac{1}{2}e^{-x}(\sin x - \cos x)\Big|_0^R = \frac{\sin R - \cos R}{2e^R} - \frac{\sin 0 - \cos 0}{2} = \frac{\sin R - \cos R}{2e^R} + \frac{1}{2},$$

and

$$\int_0^\infty e^{-x}\cos x\,dx = \lim_{R\to\infty}\left(\frac{\sin R - \cos R}{2e^R} + \frac{1}{2}\right) = 0 + \frac{1}{2} = \frac{1}{2}.$$

30. $\displaystyle\int_1^\infty xe^{-2x}\,dx$

SOLUTION First evaluate the indefinite integral using Integration by Parts, with $u = x$ and $v' = e^{-2x}$. Then $u' = 1$, $v = -\frac{1}{2}e^{-2x}$, and

$$\int xe^{-2x}\,dx = -\frac{1}{2}xe^{-2x} - \int\left(-\frac{1}{2}\right)e^{-2x}\,dx = -\frac{1}{2}e^{-2x} + \frac{1}{2}\int e^{-2x}\,dx$$
$$= -\frac{1}{2}xe^{-2x} - \frac{1}{4}e^{-2x} + C = -\frac{1}{4}e^{-2x}(2x+1) + C = \frac{-(2x+1)}{4e^{2x}} + C.$$

Therefore,

$$\int_1^\infty xe^{-2x}\,dx = \lim_{R\to-\infty}\int_1^R xe^{-2x}\,dx = \lim_{R\to\infty}\left(\frac{-(2x+1)}{4e^{2x}}\Big|_1^R\right) = \lim_{R\to\infty}\left[\frac{-(2R+1)}{4e^{2R}} + \frac{3}{4e^2}\right].$$

Use L'Hôpital's Rule to evaluate the limit:

$$\int_1^\infty xe^{-2x}\,dx = \frac{3}{4e^2} - \lim_{R\to\infty}\frac{2}{8e^{2R}} = \frac{3}{4e^2} - 0 = \frac{3}{4e^2}.$$

31. $\displaystyle\int_0^3 \frac{dx}{\sqrt{9-x^2}}$

SOLUTION The function $(9-x^2)^{-1/2}$ is infinite at $x = 3$, and is left-continuous at $x = 3$, so we'll first evaluate the integral on the interval $[0, R]$ for $0 < R < 3$:

$$\int_0^R \frac{dx}{\sqrt{9-x^2}} = \sin^{-1}\frac{x}{3}\Big|_0^R = \sin^{-1}\frac{R}{3} - \sin^{-1}0 = \sin^{-1}\frac{R}{3}.$$

Thus,

$$\int_0^3 \frac{dx}{\sqrt{9-x^2}} = \lim_{R\to 3^-} \sin^{-1}\frac{R}{3} = \sin^{-1} 1 = \frac{\pi}{2}.$$

32. $\displaystyle\int_0^1 \frac{e^{\sqrt{x}}\,dx}{\sqrt{x}}$

SOLUTION Let $u = \sqrt{x}$, $du = \frac{1}{2}x^{-1/2}\,dx$. Then

$$\int \frac{e^{\sqrt{x}}\,dx}{\sqrt{x}} = 2\int e^{\sqrt{x}}\left(\frac{dx}{2\sqrt{x}}\right) = 2\int e^u\,du = 2e^u + C = 2e^{\sqrt{x}} + C.$$

The function $e^{\sqrt{x}}/\sqrt{x}$ is infinite and right-continuous at $x = 0$, so we first evaluate the integral on $[R, 1]$ for $0 < R < 1$:

$$\int_R^1 \frac{e^{\sqrt{x}}\,dx}{\sqrt{x}} = 2e^{\sqrt{x}}\Big|_R^1 = 2e - 2e^{\sqrt{R}}.$$

Now we compute the limit as $R \to 0+$:

$$\int_0^1 \frac{e^{\sqrt{x}}\,dx}{\sqrt{x}} = \lim_{R\to 0^+}\left(2e - 2e^{\sqrt{x}}\right) = 2e - 2(1) = 2(e-1).$$

33. $\displaystyle\int_1^\infty \frac{e^{\sqrt{x}}\,dx}{\sqrt{x}}$

SOLUTION Let $u = \sqrt{x}$, $du = \frac{1}{2}x^{-1/2}\,dx$. Then

$$\int \frac{e^{\sqrt{x}}\,dx}{\sqrt{x}} = 2\int e^{\sqrt{x}}\left(\frac{dx}{2\sqrt{x}}\right) = 2\int e^u\,du = 2e^u + C = 2e^{\sqrt{x}} + C,$$

and

$$\int_1^\infty \frac{e^{\sqrt{x}}\,dx}{\sqrt{x}} = \lim_{R\to\infty}\int_1^R \frac{e^{\sqrt{x}}\,dx}{\sqrt{x}} = \lim_{R\to\infty} 2e^{\sqrt{x}}\Big|_1^R = \lim_{R\to\infty}\left(2e^{\sqrt{R}} - 2e\right) = \infty.$$

The integral does not converge.

34. $\displaystyle\int_0^{\pi/2} \sec\theta\,d\theta$

SOLUTION First, evaluate the integral on the interval $[0, R]$ for $0 < R < \frac{\pi}{2}$:

$$\int_0^R \sec\theta\,d\theta = \ln|\sec\theta + \tan\theta|\Big|_0^R = \ln|\sec R + \tan R|.$$

Now we compute the limit as $R \to \frac{\pi}{2}^-$:

$$\int_0^{\pi/2} \sec\theta\,d\theta = \lim_{R\to\pi/2^-}\int_0^R \sec\theta\,d\theta = \lim_{R\to\pi/2^-} \ln|\sec R + \tan R| = \infty.$$

The integral does not converge.

35. $\displaystyle\int_0^\infty \sin x\,dx$

SOLUTION First evaluate the integral on the finite interval $[0, R]$ for $R > 0$:

$$\int_0^R \sin x\,dx = -\cos x\Big|_0^R = -\cos R + \cos 0 = 1 - \cos R.$$

Thus,

$$\int_0^R \sin x\,dx = \lim_{R\to\infty}(1 - \cos R) = 1 - \lim_{R\to\infty}\cos R.$$

This limit does not exist, since the value of $\cos R$ oscillates between 1 and -1 as R approaches infinity. Hence the integral does not converge.

36. $\displaystyle\int_0^{\pi/2} \tan x\, dx$

SOLUTION The function $\tan x$ is infinite and left-continuous at $x = \frac{\pi}{2}$, so we'll first evaluate the integral on $[0, R]$ for $0 < R < \frac{\pi}{2}$:

$$\int_0^R \tan x\, dx = \ln|\sec x|\Big|_0^R = \ln|\sec R|.$$

Thus,

$$\int_0^{\pi/2} \tan x\, dx = \lim_{R\to\frac{\pi}{2}^-} \int_0^R \tan x\, dx = \lim_{R\to\frac{\pi}{2}^-} \big(\ln|\sec R|\big) = \infty.$$

The integral does not converge.

37. $\displaystyle\int_0^1 \ln x\, dx$

SOLUTION The function $\ln x$ is infinite and right-continuous at $x = 0$, so we'll first evaluate the integral on $[R, 1]$ for $0 < R < 1$. Use Integration by Parts with $u = \ln x$ and $v' = 1$. Then $u' = 1/x$, $v = x$, and we have

$$\int_R^1 \ln x\, dx = x\ln x\Big|_R^1 - \int_R^1 dx = (x\ln x - x)\Big|_R^1 = (\ln 1 - 1) - (R\ln R - R) = R - 1 - R\ln R.$$

Thus,

$$\int_0^1 \ln x\, dx = \lim_{R\to 0^+}(R - 1 - R\ln R) = -1 - \lim_{R\to 0^+} R\ln R.$$

To compute the limit, rewrite the function as a quotient and apply L'Hôpital's Rule:

$$\int_0^1 \ln x\, dx = -1 - \lim_{R\to 0^+} \frac{\ln R}{\frac{1}{R}} = -1 - \lim_{R\to 0^+} \frac{\frac{1}{R}}{\frac{-1}{R^2}} = -1 - \lim_{R\to 0^+}(-R) = -1 - 0 = -1.$$

38. $\displaystyle\int_1^2 \frac{dx}{x\ln x}$

SOLUTION Evaluate the indefinite integral using substitution, with $u = \ln x$, $du = (1/x)\,dx$. Then

$$\int \frac{dx}{x\ln x} = \int \frac{du}{u} = \ln|u| + C = \ln|\ln x| + C.$$

Thus,

$$\int_R^2 \frac{dx}{x\ln x} = \ln|\ln x|\Big|_R^2 = \ln(\ln 2) - \ln(\ln R),$$

and

$$\int_1^2 \frac{dx}{x\ln x} = \lim_{R\to 1^+}\big[\ln(\ln 2) - \ln(\ln R)\big] = \ln(\ln 2) - \lim_{R\to 1^+} \ln(\ln R) = \infty.$$

The integral does not converge.

39. $\displaystyle\int_0^1 \frac{\ln x}{x^2}\, dx$

SOLUTION Use Integration by Parts, with $u = \ln x$ and $v' = x^{-2}$. Then $u' = 1/x$, $v = -x^{-1}$, and

$$\int \frac{\ln x}{x^2}\, dx = -\frac{1}{x}\ln x + \int \frac{dx}{x^2} = -\frac{1}{x}\ln x - \frac{1}{x} + C.$$

The function is infinite and right-continuous at $x = 0$, so we'll first evaluate the integral on $[R, 1]$ for $0 < R < 1$:

$$\int_a^1 \frac{\ln x}{x^2}\, dx = \left(-\frac{1}{x}\ln x - \frac{1}{x}\right)\Bigg|_R^1 = \left(-\frac{1}{1}\ln 1 - \frac{1}{1}\right) - \left(-\frac{1}{R}\ln R - \frac{1}{R}\right) = \frac{1}{R}\ln R + \frac{1}{R} - 1.$$

Thus,

$$\int_0^1 \frac{\ln x}{x^2}\, dx = \lim_{R\to 0^+} \frac{1}{R}\ln R + \frac{1}{R} - 1 = -1 + \lim_{R\to 0^+} \frac{\ln R + 1}{R} = -\infty.$$

The integral does not converge.

40. $\int_1^\infty \frac{\ln x}{x^2}\,dx$

SOLUTION Use Integration by Parts, with $u = \ln x$ and $v' = x^{-2}$. Then $u' = x^{-1}$, $v = -x^{-1}$, and

$$\int \frac{\ln x}{x^2}\,dx = -\frac{1}{x}\ln x + \int x^{-2}\,dx = -\frac{1}{x}\ln x - \frac{1}{x} + C.$$

Thus,

$$\int_1^R \frac{\ln x}{x^2}\,dx = \left(-\frac{1}{x}\ln x - \frac{1}{x}\right)\Bigg|_1^R = \left(-\frac{1}{R}\ln R - \frac{1}{R}\right) - \left(-\frac{1}{1}\ln 1 - \frac{1}{1}\right) = 1 - \frac{1}{R}\ln R - \frac{1}{R}.$$

Use L'Hôpital's Rule to compute the limit:

$$\int_1^\infty \frac{\ln x}{x^2}\,dx = \lim_{R\to\infty}\left(1 - \frac{1}{R}\ln R - \frac{1}{R}\right) = 1 - \lim_{R\to\infty}\left(\frac{\ln R}{R}\right) - 0 = 1 - \lim_{R\to\infty}\frac{\frac{1}{R}}{1} = 1 - \frac{0}{1} = 1.$$

41. Let $I = \int_4^\infty \frac{dx}{(x-2)(x-3)}$.

(a) Show that for $R > 4$,

$$\int_4^R \frac{dx}{(x-2)(x-3)} = \ln\left|\frac{R-3}{R-2}\right| - \ln\frac{1}{2}$$

(b) Then show that $I = \ln 2$.

SOLUTION

(a) The partial fraction decomposition takes the form

$$\frac{1}{(x-2)(x-3)} = \frac{A}{x-2} + \frac{B}{x-3}.$$

Clearing denominators gives us

$$1 = A(x-3) + B(x-2).$$

Setting $x = 2$ then yields $A = -1$, while setting $x = 3$ yields $B = 1$. Thus,

$$\int \frac{dx}{(x-2)(x-3)} = \int \frac{dx}{x-3} - \int \frac{dx}{x-2} = \ln|x-3| - \ln|x-2| + C = \ln\left|\frac{x-3}{x-2}\right| + C,$$

and, for $R > 4$,

$$\int_4^R \frac{dx}{(x-2)(x-3)} = \ln\left|\frac{x-3}{x-2}\right|\Bigg|_4^R = \ln\left|\frac{R-3}{R-2}\right| - \ln\frac{1}{2}.$$

(b) Using the result from part (a),

$$I = \lim_{R\to\infty}\left(\ln\left|\frac{R-3}{R-2}\right| - \ln\frac{1}{2}\right) = \ln 1 - \ln\frac{1}{2} = \ln 2.$$

42. Evaluate the integral $I = \int_1^\infty \frac{dx}{x(2x+5)}$.

SOLUTION The partial fraction decomposition takes the form

$$\frac{1}{x(2x+5)} = \frac{A}{x} + \frac{B}{2x+5}.$$

Clearing denominators gives us

$$1 = A(2x+5) + Bx.$$

Setting $x = 0$ then yields $A = \frac{1}{5}$, while setting $x = -\frac{5}{2}$ yields $B = -\frac{2}{5}$. Thus,

$$\int \frac{dx}{x(2x+5)} = \frac{1}{5}\int \frac{dx}{x} - \frac{2}{5}\int \frac{dx}{2x+5} = \frac{1}{5}\ln|x| - \frac{1}{5}\ln|2x+5| + C = \frac{1}{5}\ln\left|\frac{x}{2x+5}\right| + C,$$

and, for $R > 1$,

$$\int_1^R \frac{dx}{x(2x+5)} = \frac{1}{5}\ln\left|\frac{x}{2x+5}\right|\Bigg|_1^R = \frac{1}{5}\ln\left|\frac{R}{2R+5}\right| - \frac{1}{5}\ln\frac{1}{7}.$$

Thus,

$$I = \lim_{R\to\infty}\left(\frac{1}{5}\ln\left|\frac{R}{2R+5}\right| - \frac{1}{5}\ln\frac{1}{7}\right) = \frac{1}{5}\ln\frac{1}{2} - \frac{1}{5}\ln\frac{1}{7} = \frac{1}{5}\ln\frac{7}{2}.$$

43. Evaluate $I = \int_0^1 \frac{dx}{x(2x+5)}$ or state that it diverges.

SOLUTION The partial fraction decomposition takes the form

$$\frac{1}{x(2x+5)} = \frac{A}{x} + \frac{B}{2x+5}.$$

Clearing denominators gives us

$$1 = A(2x+5) + Bx.$$

Setting $x = 0$ then yields $A = \frac{1}{5}$, while setting $x = -\frac{5}{2}$ yields $B = -\frac{2}{5}$. Thus,

$$\int \frac{dx}{x(2x+5)} = \frac{1}{5}\int\frac{dx}{x} - \frac{2}{5}\int\frac{dx}{2x+5} = \frac{1}{5}\ln|x| - \frac{1}{5}\ln|2x+5| + C = \frac{1}{5}\ln\left|\frac{x}{2x+5}\right| + C,$$

and, for $0 < R < 1$,

$$\int_R^1 \frac{dx}{x(2x+5)} = \frac{1}{5}\ln\left|\frac{x}{2x+5}\right|\Bigg|_R^1 = \frac{1}{5}\ln\frac{1}{7} - \frac{1}{5}\ln\left|\frac{R}{2R+5}\right|.$$

Thus,

$$I = \lim_{R\to 0+}\left(\frac{1}{5}\ln\frac{1}{7} - \frac{1}{5}\ln\left|\frac{R}{2R+5}\right|\right) = \infty.$$

The integral does not converge.

44. Evaluate $I = \int_2^\infty \frac{dx}{(x+3)(x+1)^2}$ or state that it diverges.

SOLUTION The partial fraction decomposition takes the form

$$\frac{1}{(x+3)(x+1)^2} = \frac{A}{x+3} + \frac{B}{x+1} + \frac{C}{(x+1)^2}.$$

Clearing denominators gives us

$$1 = A(x+1)^2 + B(x+1)(x+3) + C(x+3).$$

Setting $x = -3$ then yields $A = \frac{1}{4}$, while setting $x = -1$ yields $C = \frac{1}{2}$. Setting $x = 0$ gives $1 = \frac{1}{4} + 3B + \frac{3}{2}$ or $B = -\frac{1}{4}$. Thus,

$$\int \frac{dx}{(x+3)(x+1)^2} = \frac{1}{4}\int\frac{dx}{x+3} - \frac{1}{4}\int\frac{dx}{x+1} + \frac{1}{2}\int\frac{dx}{(x+1)^2}$$
$$= \frac{1}{4}\ln|x+3| - \frac{1}{4}\ln|x+1| - \frac{1}{2(x+1)} + C = \frac{1}{4}\ln\left|\frac{x+3}{x+1}\right| - \frac{1}{2(x+1)} + C,$$

and, for $R > 2$,

$$\int_2^R \frac{dx}{(x+3)(x+1)^2} = \left(\frac{1}{4}\ln\left|\frac{x+3}{x+1}\right| - \frac{1}{2(x+1)}\right)\Bigg|_2^R = \frac{1}{4}\ln\left|\frac{R+3}{R+1}\right| - \frac{1}{2(R+1)} - \frac{1}{4}\ln\frac{5}{3} + \frac{1}{6}.$$

Thus

$$I = \lim_{R\to\infty}\left(\frac{1}{4}\ln\left|\frac{R+3}{R+1}\right| - \frac{1}{2(R+1)} - \frac{1}{4}\ln\frac{5}{3} + \frac{1}{6}\right) = \frac{1}{6} - \frac{1}{4}\ln\frac{5}{3}.$$

In Exercises 45–48, determine whether the doubly infinite improper integral converges and, if so, evaluate it. Use definition (2).

45. $\displaystyle\int_{-\infty}^{\infty} \frac{x\,dx}{1+x^2}$

SOLUTION Using the substitution $u = x^2 + 1$, $du = 2x\,dx$, we obtain

$$\int \frac{x\,dx}{1+x^2} = \frac{1}{2}\ln(x^2+1) + C.$$

Thus,

$$\int_0^{\infty} \frac{x\,dx}{1+x^2} = \lim_{R\to\infty}\int_0^R \frac{x\,dx}{1+x^2} = \lim_{R\to\infty}\frac{1}{2}\ln(R^2+1) = \infty;$$

$$\int_{-\infty}^{0} \frac{x\,dx}{1+x^2} = \lim_{R\to-\infty}\int_R^0 \frac{x\,dx}{1+x^2} = \lim_{R\to-\infty}\frac{1}{2}\ln(R^2+1) = \infty;$$

It follows that

$$\int_{-\infty}^{\infty} \frac{x\,dx}{1+x^2}$$

diverges.

46. $\displaystyle\int_{-\infty}^{\infty} e^{-|x|}\,dx$

SOLUTION First, we find

$$\int_0^{\infty} e^{-|x|}\,dx = \int_0^{\infty} e^{-x}\,dx = \lim_{R\to\infty}\int_0^R e^{-x}\,dx = \lim_{R\to\infty}\left(1 - e^{-R}\right) = 1;$$

$$\int_{-\infty}^{0} e^{-|x|}\,dx = \int_{\infty}^{0} e^{x}\,dx = \lim_{R\to-\infty}\int_R^0 e^{x}\,dx = \lim_{R\to-\infty}\left(1 - e^{R}\right) = 1;$$

and

$$\int_{\infty}^{\infty} e^{-|x|}\,dx = 1 + 1 = 2.$$

47. $\displaystyle\int_{-\infty}^{\infty} xe^{-x^2}\,dx$

SOLUTION First note that

$$\int xe^{-x^2}\,dx = -\frac{1}{2}e^{-x^2} + C.$$

Thus,

$$\int_0^{\infty} xe^{-x^2}\,dx = \lim_{R\to\infty}\int_0^R xe^{-x^2}\,dx = \lim_{R\to\infty}\left(\frac{1}{2} - \frac{1}{2}e^{-R^2}\right) = \frac{1}{2};$$

$$\int_{-\infty}^{0} xe^{-x^2}\,dx = \lim_{R\to-\infty}\int_R^0 xe^{-x^2}\,dx = \lim_{R\to-\infty}\left(-\frac{1}{2} + \frac{1}{2}e^{-R^2}\right) = -\frac{1}{2};$$

and

$$\int_{-\infty}^{\infty} xe^{-x^2}\,dx = \frac{1}{2} - \frac{1}{2} = 0.$$

48. $\displaystyle\int_{-\infty}^{\infty} \frac{dx}{(x^2+1)^{3/2}}$

SOLUTION First, we evaluate the indefinite integral using the trigonometric substitution $x = \tan\theta$, $dx = \sec^2\theta\,d\theta$. Then

$$\int \frac{dx}{(1+x^2)^{3/2}} = \int \frac{\sec^2\theta}{\sec^3\theta}\,d\theta = \int \cos\theta\,d\theta = \sin\theta + C = \frac{x}{\sqrt{1+x^2}} + C.$$

Thus,

$$\int_0^\infty \frac{dx}{(1+x^2)^{3/2}} = \lim_{R\to\infty}\int_0^R \frac{dx}{(1+x^2)^{3/2}} = \lim_{R\to\infty}\frac{R}{\sqrt{1+R^2}} = 1;$$

$$\int_{-\infty}^0 \frac{dx}{(1+x^2)^{3/2}} = \lim_{R\to-\infty}\int_R^0 \frac{dx}{(1+x^2)^{3/2}} = \lim_{R\to-\infty} -\frac{R}{\sqrt{1+R^2}} = 1;$$

and

$$\int_\infty^\infty \frac{dx}{(1+x^2)^{(3/2)}} = 1+1 = 2.$$

49. Define $J = \int_{-1}^1 \frac{dx}{x^{1/3}}$ as the sum of the two improper integrals $\int_{-1}^0 \frac{dx}{x^{1/3}} + \int_0^1 \frac{dx}{x^{1/3}}$. Show that J converges and that $J = 0$.

SOLUTION Note that since $x^{-1/3}$ is an odd function, one might expect this integral over a symmetric interval to be zero. To prove this, we start by evaluating the indefinite integral:

$$\int \frac{dx}{x^{1/3}} = \frac{3}{2}x^{2/3} + C$$

Then

$$\int_{-1}^0 \frac{dx}{x^{1/3}} = \lim_{R\to0^-}\int_{-1}^R \frac{dx}{x^{1/3}} = \lim_{R\to0^-}\frac{3}{2}x^{2/3}\Big|_{-1}^R = \lim_{R\to0^-}\frac{3}{2}R^{2/3} - \frac{3}{2} = -\frac{3}{2}$$

$$\int_0^1 \frac{dx}{x^{1/3}} = \lim_{R\to0^+}\int_R^1 \frac{dx}{x^{1/3}} = \lim_{R\to0^+}\frac{3}{2}x^{2/3}\Big|_R^1 = \frac{3}{2} - \lim_{R\to0^+}\frac{3}{2}R^{2/3} = \frac{3}{2}$$

so that

$$J = \int_{-1}^1 \frac{dx}{x^{1/3}} = \int_{-1}^0 \frac{dx}{x^{1/3}} + \int_0^1 \frac{dx}{x^{1/3}} = -\frac{3}{2} + \frac{3}{2} = 0$$

50. Determine whether $J = \int_{-1}^1 \frac{dx}{x^2}$ (defined as in Exercise 49) converges.

SOLUTION We have

$$\int \frac{dx}{x^2} = -\frac{1}{x} + C$$

so that

$$\int_{-1}^0 \frac{dx}{x^2} = \lim_{R\to0^-}\int_{-1}^R \frac{dx}{x^2} = \lim_{R\to0^-}\left(-\frac{1}{x}\Big|_{-1}^R\right) = \lim_{R\to0^-}\left(-\frac{1}{R}+1\right) = 1 - \lim_{R\to0^-}\frac{1}{R} = \infty$$

$$\int_0^1 \frac{dx}{x^2} = \lim_{R\to0^+}\int_R^1 \frac{dx}{x^2} = \lim_{R\to0^+}\left(-\frac{1}{x}\Big|_R^1\right) = \lim_{R\to0^+}\left(-1+\frac{1}{R}\right) = -1 + \lim_{R\to0^+}\frac{1}{R} = \infty$$

so that the integral diverges.

51. For which values of a does $\int_0^\infty e^{ax}\,dx$ converge?

SOLUTION First evaluate the integral on the finite interval $[0, R]$ for $R > 0$:

$$\int_0^R e^{ax}\,dx = \frac{1}{a}e^{ax}\Big|_0^R = \frac{1}{a}\left(e^{aR}-1\right).$$

Thus,

$$\int_0^\infty e^{ax}\,dx = \lim_{R\to\infty}\frac{1}{a}\left(e^{aR}-1\right).$$

If $a > 0$, then $e^{aR} \to \infty$ as $R \to \infty$. If $a < 0$, then $e^{aR} \to 0$ as $R \to \infty$, and

$$\int_0^\infty e^{ax}\,dx = \lim_{R\to\infty}\frac{1}{a}\left(e^{aR}-1\right) = -\frac{1}{a}.$$

The integral converges for $a < 0$.

52. Show that $\int_0^1 \frac{dx}{x^p}$ converges if $p < 1$ and diverges if $p \geq 1$.

SOLUTION The function x^{-p} is infinite and right-continuous at $x = 0$, so we'll first evaluate the integral on $[R, 1]$ for $0 < R < 1$:

$$\int_R^1 \frac{dx}{x^p} = \left.\frac{x^{-p+1}}{-p+1}\right|_R^1 = \frac{1}{-p+1}\left(1 - R^{-p+1}\right).$$

If $p < 1$, then $-p + 1 = 1 - p > 0$, and

$$\int_0^1 \frac{dx}{x^p} = \lim_{R\to 0^+} \frac{1}{1-p}\left(1 - R^{1-p}\right) = \frac{1}{1-p}(1-0) = \frac{1}{1-p}.$$

If $p > 1$, then $-p + 1 < 0$, and

$$\int_0^1 \frac{dx}{x^p} = \lim_{R\to 0^+} \frac{1}{1-p}\left(1 - R^{1-p}\right) = \lim_{R\to 0^+} \frac{1}{1-p}\left(1 - \frac{1}{a^{p-1}}\right) = \infty.$$

If $p = 1$, then

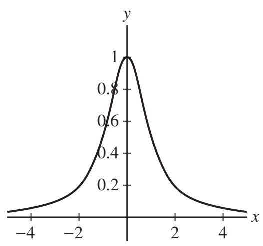
$$\int_R^1 \frac{dx}{x^p} = \int_R^1 \frac{dx}{x} = \ln x\Big|_R^1 = \ln 1 - \ln R = -\ln R; \text{ and}$$

$$\int_0^1 \frac{dx}{x} = \lim_{R\to 0^+}(-\ln R) = \infty.$$

Thus, the integral converges for $p < 1$ and diverges for $p \geq 1$.

53. Sketch the region under the graph of $f(x) = \frac{1}{1+x^2}$ for $-\infty < x < \infty$, and show that its area is π.

SOLUTION The graph is shown below.



Since $(1 + x^2)^{-1}$ is an even function, we can first compute the area under the graph for $x > 0$:

$$\int_0^R \frac{dx}{1+x^2} = \tan^{-1} x\Big|_0^R = \tan^{-1} R - \tan^{-1} 0 = \tan^{-1} R.$$

Thus,

$$\int_0^\infty \frac{dx}{1+x^2} = \lim_{R\to\infty} \tan^{-1} R = \frac{\pi}{2}.$$

By symmetry, we have

$$\int_{-\infty}^\infty \frac{dx}{1+x^2} = \int_{-\infty}^0 \frac{dx}{1+x^2} + \int_0^\infty \frac{dx}{1+x^2} = \frac{\pi}{2} + \frac{\pi}{2} = \pi.$$

54. Show that $\frac{1}{\sqrt{x^4+1}} \leq \frac{1}{x^2}$ for all x, and use this to prove that $\int_1^\infty \frac{dx}{\sqrt{x^4+1}}$ converges.

SOLUTION Since $\sqrt{x^4+1} \geq \sqrt{x^4} = x^2$, it follows that

$$\frac{1}{\sqrt{x^4+1}} \leq \frac{1}{x^2}.$$

The integral

$$\int_1^\infty \frac{dx}{x^2}$$

converges by Theorem 2, since $2 > 1$. Therefore, by the comparison test,

$$\int_1^\infty \frac{dx}{\sqrt{x^4+1}} \text{ converges.}$$

55. Show that $\int_1^\infty \frac{dx}{x^3+4}$ converges by comparing with $\int_1^\infty x^{-3}\,dx$.

SOLUTION The integral $\int_1^\infty x^{-3}\,dx$ converges because $3 > 1$. Since $x^3+4 \ge x^3$, it follows that

$$\frac{1}{x^3+4} \le \frac{1}{x^3}.$$

Therefore, by the comparison test,

$$\int_1^\infty \frac{dx}{x^3+4} \text{ converges.}$$

56. Show that $\int_2^\infty \frac{dx}{x^3-4}$ converges by comparing with $\int_2^\infty 2x^{-3}\,dx$.

SOLUTION The integral $\int_1^\infty x^{-3}\,dx$ converges because $3 > 1$. If $\int_1^\infty x^{-3}\,dx = M < \infty$, then

$$\int_1^\infty 2x^{-3}\,dx = 2\int_1^\infty x^{-3}\,dx = 2M$$

also converges. If $x \ge 2$, then $x^3 \ge 8$ so $2x^3 - 8 \ge x^3$ and $x^3 - 4 \ge \frac{1}{2}x^3$. Then we have, for $x \ge 2$,

$$\frac{1}{x^3-4} \le \frac{2}{x^3}.$$

Therefore, by the comparison test:

$$\int_2^\infty \frac{2}{x^3-4} \text{ converges.}$$

57. Show that $0 \le e^{-x^2} \le e^{-x}$ for $x \ge 1$ (Figure 10). Use the Comparison Test to show that $\int_0^\infty e^{-x^2}\,dx$ converges. *Hint:* It suffices (why?) to make the comparison for $x \ge 1$ because

$$\int_0^\infty e^{-x^2}\,dx = \int_0^1 e^{-x^2}\,dx + \int_1^\infty e^{-x^2}\,dx$$

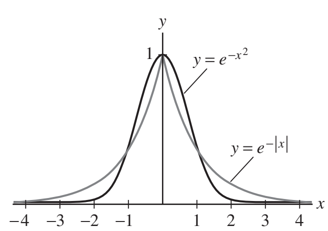


FIGURE 10 Comparison of $y = e^{-|x|}$ and $y = e^{-x^2}$.

SOLUTION For $x \ge 1$, $x^2 \ge x$, so $-x^2 \le -x$ and $e^{-x^2} \le e^{-x}$. Now

$$\int_1^\infty e^{-x}\,dx \text{ converges,} \quad \text{so} \quad \int_1^\infty e^{-x^2}\,dx \text{ converges}$$

by the comparison test. Finally, because e^{-x^2} is continuous on $[0, 1]$,

$$\int_0^\infty e^{-x^2}\,dx \text{ converges.}$$

We conclude that our integral converges by writing it as a sum:

$$\int_0^\infty e^{-x^2}\,dx = \int_0^1 e^{-x^2}\,dx + \int_1^\infty e^{-x^2}\,dx$$

58. Prove that $\int_{-\infty}^{\infty} e^{-x^2}\,dx$ converges by comparing with $\int_{-\infty}^{\infty} e^{-|x|}\,dx$ (Figure 10).

SOLUTION From Figure 10, we see that for $|x| \ge 1$, $e^{-x^2} \le e^{-|x|}$. Now

$$\int_{-\infty}^{-1} e^{-|x|}\,dx \quad \text{and} \quad \int_{1}^{\infty} e^{-|x|}\,dx$$

both converge, so

$$\int_{-\infty}^{-1} e^{-x^2}\,dx \quad \text{and} \quad \int_{1}^{\infty} e^{-x^2}\,dx$$

must also converge by the comparison test. Because e^{-x^2} is continuous on $[-1, 1]$, it follows that

$$\int_{-\infty}^{\infty} e^{-x^2}\,dx = \int_{-\infty}^{-1} e^{-x^2}\,dx + \int_{-1}^{1} e^{-x^2}\,dx + \int_{1}^{\infty} e^{-x^2}\,dx$$

converges.

59. Show that $\int_{1}^{\infty} \frac{1-\sin x}{x^2}\,dx$ converges.

SOLUTION Let $f(x) = \frac{1-\sin x}{x^2}$. Since $f(x) \le \frac{2}{x^2}$ and $\int_{1}^{\infty} 2x^{-2}\,dx = 2$, it follows that

$$\int_{1}^{\infty} \frac{1-\sin x}{x^2}\,dx \text{ converges}$$

by the comparison test.

60. Let $a > 0$. Recall that $\lim_{x\to\infty} \frac{x^a}{\ln x} = \infty$ (by Exercise 64 in Section 4.5).

(a) Show that $x^a > 2\ln x$ for all x sufficiently large.

(b) Show that $e^{-x^a} < x^{-2}$ for all x sufficiently large.

(c) Show that $\int_{1}^{\infty} e^{-x^a}\,dx$ converges.

SOLUTION

(a) Since $\lim_{x\to\infty} x^a/\ln x = \infty$, there must be some number $M > 0$ such that, for all $x > M$,

$$\frac{x^a}{\ln x} > 2.$$

But this means that, for all $x > M$,

$$x^a > 2\ln x.$$

(b) For all $x > M$, we have $x^a > 2\ln x$. Then

$$-x^a < -2\ln x = \ln x^{-2}$$

so that

$$e^{-x^a} < e^{\ln x^{-2}} = x^{-2}.$$

(c) By the above calculations, we can use the comparison test on the interval $[M, \infty)$:

$$\int_{M}^{\infty} \frac{dx}{x^2} \text{ converges} \Rightarrow \int_{M}^{\infty} e^{-x^a}\,dx \text{ also converges.}$$

Since e^{-x^a} is continuous on $[1, M]$, we have that

$$\int_{M}^{\infty} e^{-x^a}\,dx \text{ converges} \Rightarrow \int_{1}^{\infty} e^{-x^a}\,dx \text{ also converges.}$$

In Exercises 61–74, use the Comparison Test to determine whether or not the integral converges.

61. $\int_{1}^{\infty} \frac{1}{\sqrt{x^5+2}}\,dx$

SOLUTION Since $\sqrt{x^5+2} \ge \sqrt{x^5} = x^{5/2}$, it follows that

$$\frac{1}{\sqrt{x^5+2}} \le \frac{1}{x^{5/2}}.$$

The integral $\int_1^{\infty} dx/x^{5/2}$ converges because $\frac{5}{2} > 1$. Therefore, by the comparison test:

$$\int_1^{\infty} \frac{dx}{\sqrt{x^5+2}} \text{ also converges.}$$

62. $\displaystyle\int_1^{\infty} \frac{dx}{(x^3+2x+4)^{1/2}}$

SOLUTION For all $x \geq 1$, $\sqrt{x^3+2x+4} \geq \sqrt{x^3} = x^{3/2}$. Thus

$$\frac{1}{\sqrt{x^3+2x+4}} \leq \frac{1}{x^{3/2}}.$$

The integral $\int_1^{\infty} dx/x^{3/2}$ converges because $\frac{3}{2} > 1$. Therefore, by the comparison test,

$$\int_1^{\infty} \frac{dx}{\sqrt{x^3+2x+4}} \text{ also converges.}$$

63. $\displaystyle\int_3^{\infty} \frac{dx}{\sqrt{x}-1}$

SOLUTION Since $\sqrt{x} \geq \sqrt{x}-1$, we have (for $x > 1$)

$$\frac{1}{\sqrt{x}} \leq \frac{1}{\sqrt{x}-1}.$$

The integral $\int_1^{\infty} dx/\sqrt{x} = \int_1^{\infty} dx/x^{1/2}$ diverges because $\frac{1}{2} < 1$. Since the function $x^{-1/2}$ is continuous (and therefore finite) on [1, 3], we also know that $\int_3^{\infty} dx/x^{1/2}$ diverges. Therefore, by the comparison test,

$$\int_3^{\infty} \frac{dx}{\sqrt{x}-1} \text{ also diverges.}$$

64. $\displaystyle\int_0^{5} \frac{dx}{x^{1/3}+x^3}$

SOLUTION For $0 \leq x \leq 5$, $x^{1/3}+x^3 \geq x^{1/3}$, so that

$$\frac{1}{x^{1/3}+x^3} \leq \frac{1}{x^{1/3}}.$$

The integral $\int_0^{5} x^{-1/3}\,dx$ converges; therefore, by the comparison test

$$\int_0^{5} \frac{dx}{x^{1/3}+x^3} \text{ also converges.}$$

65. $\displaystyle\int_1^{\infty} e^{-(x+x^{-1})}\,dx$

SOLUTION For all $x \geq 1$, $\frac{1}{x} > 0$ so $x + \frac{1}{x} \geq x$. Then

$$-\left(x+x^{-1}\right) \leq -x \qquad \text{and} \qquad e^{-(x+x^{-1})} \leq e^{-x}.$$

The integral $\int_1^{\infty} e^{-x}\,dx$ converges by direct computation:

$$\int_1^{\infty} e^{-x}\,dx = \lim_{R\to\infty}\int_1^{R} e^{-x}\,dx = \lim_{R\to\infty} -e^{-x}\Big|_1^{R} = \lim_{R\to\infty} -e^{-R}+e^{-1} = 0+e^{-1} = e^{-1}.$$

Therefore, by the comparison test,

$$\int_1^{\infty} e^{-(x+x^{-1})} \text{ also converges.}$$

66. $\displaystyle\int_0^1 \frac{|\sin x|}{\sqrt{x}}\,dx$

SOLUTION For all x, $|\sin x| \le 1$. Therefore, for $x \ne 0$,

$$\frac{|\sin x|}{\sqrt{x}} \le \frac{1}{\sqrt{x}}.$$

The integral

$$\int_0^1 \frac{dx}{\sqrt{x}} = \int_0^1 \frac{dx}{x^{1/2}}$$

converges, since $\frac{1}{2} < 1$. Therefore, by the comparison test,

$$\int_0^1 \frac{|\sin x|}{\sqrt{x}}\,dx \text{ also converges.}$$

67. $\displaystyle\int_0^1 \frac{e^x}{x^2}\,dx$

SOLUTION For $0 < x < 1$, $e^x > 1$, and therefore

$$\frac{1}{x^2} < \frac{e^x}{x^2}.$$

The integral $\displaystyle\int_0^1 dx/x^2$ diverges since $2 > 1$. Therefore, by the comparison test,

$$\int_0^1 \frac{e^x}{x^2} \text{ also diverges.}$$

68. $\displaystyle\int_1^\infty \frac{1}{x^4 + e^x}\,dx$

SOLUTION For $x > 1$, $x^4 + e^x \ge x^4$, and

$$\frac{1}{x^4 + e^x} \le \frac{1}{x^4}.$$

The integral $\displaystyle\int_0^1 dx/x^4$ converges, since $4 > 1$. Therefore, by the comparison test,

$$\int_1^\infty \frac{dx}{x^4 + e^x} \text{ also converges.}$$

69. $\displaystyle\int_0^1 \frac{1}{x^4 + \sqrt{x}}\,dx$

SOLUTION For $0 < x < 1$, $x^4 + \sqrt{x} \ge \sqrt{x}$, and

$$\frac{1}{x^4 + \sqrt{x}} \le \frac{1}{\sqrt{x}}.$$

The integral $\displaystyle\int_0^1 (1/\sqrt{x})\,dx$ converges, since $p = \frac{1}{2} < 1$. Therefore, by the comparison test,

$$\int_0^1 \frac{dx}{x^4 + \sqrt{x}} \text{ also converges.}$$

70. $\displaystyle\int_1^\infty \frac{\ln x}{\sinh x}\,dx$

SOLUTION For $x > 1$, $e^{-x} < \frac{1}{2}e^x$, so

$$\sinh x = \frac{e^x - e^{-x}}{2} \ge \frac{1}{4}e^x.$$

Similarly, $\ln x < x$ for all $x > 1$, so

$$\frac{\ln x}{\sinh x} \le \frac{4x}{e^x} \quad \text{for all } x \ge 1.$$

Because

$$\int_1^\infty 4xe^{-x}\,dx = -4xe^{-x}\Big|_1^\infty + \int_1^\infty 4e^{-x}\,dx = \frac{8}{e},$$

it follows by the comparison test that

$$\int_1^\infty \frac{\ln x}{\sinh x}\,dx \text{ converges.}$$

71. $\displaystyle\int_1^\infty \frac{dx}{\sqrt{x^{1/3}+x^3}}$

SOLUTION For $x \ge 0$, $\sqrt{x^{1/3}+x^3} \ge \sqrt{x^3} = x^{3/2}$, so that

$$\frac{1}{\sqrt{x^{1/3}+x^3}} \le \frac{1}{x^{3/2}}$$

The integral $\displaystyle\int_1^\infty x^{-3/2}\,dx$ converges since $p = 3/2 > 1$. Therefore, by the comparison test,

$$\int \frac{1}{\sqrt{x^{1/3}+x^3}}\,dx \quad \text{also converges.}$$

72. $\displaystyle\int_0^1 \frac{dx}{(8x^2+x^4)^{1/3}}$

SOLUTION Clearly $8x^2 + x^4 \ge 8x^2$, so that

$$\frac{1}{(8x^2+x^4)^{1/3}} \le \frac{1}{(8x^2)^{1/3}}$$

Thus

$$\int_0^1 \frac{1}{(8x^2+x^4)}\,dx \le \int_0^1 \frac{1}{(8x^2)^{1/3}}\,dx = \frac{1}{2}\int_0^1 \frac{1}{x^{2/3}}\,dx$$

But $\displaystyle\int_0^1 x^{-2/3}\,dx$ converges since $p = 2/3 < 1$. Therefore, by the comparison test,

$$\int_0^1 \frac{1}{(8x^2+x^4)^{1/3}}\,dx \quad \text{also converges.}$$

73. $\displaystyle\int_1^\infty \frac{dx}{(x+x^2)^{1/3}}$

SOLUTION For $x > 1$, $x < x^2$ so that $x + x^2 < 2x^2$; then

$$\int_1^\infty \frac{1}{(x+x^2)^{1/3}}\,dx \ge \int_1^\infty \frac{1}{(2x^2)^{1/3}}\,dx = \frac{1}{2^{1/3}}\int_1^\infty \frac{1}{x^{2/3}}\,dx$$

But $\displaystyle\int_1^\infty \frac{1}{x^{2/3}}\,dx$ diverges since $p = 2/3 < 1$. Therefore, by the comparison test,

$$\int_1^\infty \frac{1}{(x+x^2)^{1/3}}\,dx \quad \text{diverges as well.}$$

74. $\displaystyle\int_0^1 \frac{dx}{xe^x+x^2}$

SOLUTION $xe^x + x^2 = x(e^x + x)$; for $0 \le x \le 1$, $e^x \le e^1 = e$ and $x \le 1$, so that $x(e^x + x) \le x(e + 1)$. It follows that

$$\int_0^1 \frac{1}{xe^x+x^2}\,dx \ge \int_0^1 \frac{1}{x(e+1)}\,dx = \frac{1}{e+1}\int_0^1 \frac{1}{x}\,dx$$

But $\displaystyle\int_0^1 \frac{1}{x}\,dx$ diverges since $p = 1$. Therefore, by the comparison test,

$$\int_0^1 \frac{1}{xe^x+x^2}\,dx \quad \text{diverges as well.}$$

Hint for Exercise 73: Show that for $x \geq 1$,

$$\frac{1}{(x+x^2)^{1/3}} \geq \frac{1}{2^{1/3}x^{2/3}}$$

Hint for Exercise 74: Show that for $0 \leq x \leq 1$,

$$\frac{1}{xe^x + x^2} \geq \frac{1}{(e+1)x}$$

75. Define $J = \int_0^\infty \frac{dx}{x^{1/2}(x+1)}$ as the sum of the two improper integrals

$$\int_0^1 \frac{dx}{x^{1/2}(x+1)} + \int_1^\infty \frac{dx}{x^{1/2}(x+1)}$$

Use the Comparison Test to show that J converges.

SOLUTION For the first integral, note that for $0 \leq x \leq 1$, we have $1 \leq 1 + x$, so that $x^{1/2}(x+1) \geq x^{1/2}$. It follows that

$$\int_0^1 \frac{1}{x^{1/2}(x+1)}\,dx \leq \int_0^1 \frac{1}{x^{1/2}}\,dx$$

which converges since $p = 1/2 < 1$. Thus the first integral converges by the comparison test. For the second integral, for $1 \leq x$, we have $x^{1/2}(x+1) = x^{3/2} + x^{1/2} \geq x^{3/2}$, so that

$$\int_1^\infty \frac{1}{x^{1/2}(x+1)}\,dx = \int_1^\infty \frac{1}{x^{3/2} + x^{1/2}}\,dx \leq \int_1^\infty \frac{1}{x^{3/2}}\,dx$$

which converges since $p = 3/2 > 1$. Thus the second integral converges as well by the comparison test, and therefore J, which is the sum of the two, converges.

76. Determine whether $J = \int_0^\infty \frac{dx}{x^{3/2}(x+1)}$ (defined as in Exercise 75) converges.

SOLUTION We have $x^{3/2}(x+1) = x^{5/2} + x^{3/2}$. For $0 \leq x \leq 1$, $x^{5/2} \leq x^{3/2}$, so that $x^{5/2} + x^{3/2} \leq 2x^{3/2}$. Then

$$\int_0^1 \frac{1}{x^{3/2}(x+1)}\,dx = \int_0^1 \frac{1}{x^{5/2} + x^{3/2}}\,dx \geq \int_0^1 \frac{1}{2x^{3/2}}\,dx = \frac{1}{2}\int_0^1 \frac{1}{x^{3/2}}\,dx$$

But this integral diverges since $p = 3/2 > 1$. By the comparison test, $\int_0^1 \frac{1}{x^{3/2}(x+1)}\,dx$ diverges as well, so that J diverges.

77. An investment pays a dividend of \$250/year continuously forever. If the interest rate is 7%, what is the present value of the entire income stream generated by the investment?

SOLUTION The present value of the income stream after T years is

$$\int_0^T 250e^{-0.07t}\,dt = \left.\frac{250e^{-0.07t}}{-0.07}\right|_0^T = \frac{-250}{0.07}\left(e^{-0.07T} - 1\right) = \frac{250}{0.07}\left(1 - e^{-0.07T}\right).$$

Therefore the present value of the entire income stream is

$$\int_0^\infty 250e^{-0.07t} = \lim_{T\to\infty}\int_0^T 250e^{-0.07t} = \lim_{T\to\infty}\frac{250}{0.07}\left(1 - e^{-0.07T}\right) = \frac{250}{0.07}(1-0) = \frac{250}{0.07} = \$3571.43.$$

78. An investment is expected to earn profits at a rate of $10{,}000e^{0.01t}$ dollars per year forever. Find the present value of the income stream if the interest rate is 4%.

SOLUTION The present value of the income stream after T years is

$$\int_0^T \left(10{,}000e^{0.01t}\right)e^{-0.04t}\,dt = 10{,}000\int_0^T e^{-0.03t}\,dt = \left.\frac{10{,}000}{-0.03}e^{-0.03t}\right|_0^T = -333{,}333.33\left(e^{-0.03t} - 1\right).$$

Therefore the present value of the entire income stream is

$$\int_0^\infty 10{,}000e^{-0.03t} = \lim_{T\to\infty} 333{,}333.33\left(1 - e^{-0.03t}\right) = \$333{,}333.33.$$

79. Compute the present value of an investment that generates income at a rate of $5000te^{0.01t}$ dollars per year forever, assuming an interest rate of 6%.

SOLUTION The present value of the income stream after T years is

$$\int_0^T \left(5000te^{0.01t}\right) e^{-0.06t}\,dt = 5000\int_0^T te^{-0.05t}\,dt$$

Compute the indefinite integral using Integration by Parts, with $u = t$ and $v' = e^{-0.05t}$. Then $u' = 1$, $v = (-1/0.05)e^{-0.05t}$, and

$$\int te^{-0.05t}\,dt = \frac{-t}{0.05}e^{-0.05t} + \frac{1}{0.05}\int e^{-0.05t}\,dt = -20te^{-0.05t} + \frac{20}{-0.05}e^{-0.05t} + C$$
$$= e^{-0.05t}(-20t - 400) + C.$$

Thus,

$$5000\int_0^T te^{-0.05t}\,dt = 5000e^{-0.05t}(-20t-400)\Big|_0^T = 5000e^{-0.05T}(-20T-400) - 5000(-400)$$
$$= 2{,}000{,}000 - 5000e^{-0.05T}(20T+400).$$

Use L'Hôpital's Rule to compute the limit:

$$\lim_{T\to\infty}\left(2{,}000{,}000 - \frac{5000(20T+400)}{e^{0.05T}}\right) = 2{,}000{,}000 - \lim_{T\to\infty}\frac{5000(20)}{0.05e^{0.05T}} = 2{,}000{,}000 - 0 = \$2{,}000{,}000.$$

80. Find the volume of the solid obtained by rotating the region below the graph of $y = e^{-x}$ about the x-axis for $0 \le x < \infty$.

SOLUTION Using the disk method, the volume is given by

$$V = \int_0^\infty \pi\left(e^{-x}\right)^2\,dx = \pi\int_0^\infty e^{-2x}\,dx.$$

First compute the volume over a finite interval:

$$\pi\int_0^R e^{-2x}\,dx = \frac{-\pi}{2}e^{-2x}\Big|_0^R = \frac{-\pi}{2}\left(e^{-2R}-1\right) = \frac{\pi}{2}\left(1-e^{-2R}\right).$$

Thus,

$$V = \lim_{R\to\infty}\pi\int_0^R e^{-2x}\,dx = \lim_{R\to\infty}\frac{\pi}{2}\left(1-e^{-2R}\right) = \frac{\pi}{2}(1-0) = \frac{\pi}{2}.$$

81. The solid S obtained by rotating the region below the graph of $y = x^{-1}$ about the x-axis for $1 \le x < \infty$ is called **Gabriel's Horn** (Figure 11).

(a) Use the Disk Method (Section 6.3) to compute the volume of S. Note that the volume is finite even though S is an infinite region.

(b) It can be shown that the surface area of S is

$$A = 2\pi\int_1^\infty x^{-1}\sqrt{1+x^{-4}}\,dx$$

Show that A is infinite. If S were a container, you could fill its interior with a finite amount of paint, but you could not paint its surface with a finite amount of paint.

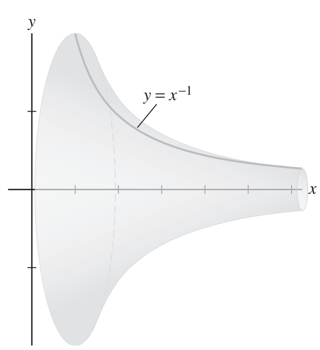

FIGURE 11

SOLUTION

(a) The volume is given by

$$V = \int_1^\infty \pi \left(\frac{1}{x}\right)^2 dx.$$

First compute the volume over a finite interval:

$$\int_1^R \pi \left(\frac{1}{x}\right)^2 dx = \pi \int_1^R x^{-2}\, dx = \pi \left.\frac{x^{-1}}{-1}\right|_1^R = \pi \left(\frac{-1}{R} - \frac{-1}{1}\right) = \pi \left(1 - \frac{1}{R}\right).$$

Thus,

$$V = \lim_{R\to\infty} \int_1^\infty \pi x^{-2}\, dx = \lim_{R\to\infty} \pi \left(1 - \frac{1}{R}\right) = \pi.$$

(b) For $x > 1$, we have

$$\frac{1}{x}\sqrt{1 + \frac{1}{x^4}} = \frac{1}{x}\sqrt{\frac{x^4+1}{x^4}} = \frac{\sqrt{x^4+1}}{x^3} \geq \frac{\sqrt{x^4}}{x^3} = \frac{x^2}{x^3} = \frac{1}{x}.$$

The integral $\int_1^\infty \frac{1}{x}\, dx$ diverges, since $p = 1 \geq 1$. Therefore, by the comparison test,

$$\int_1^\infty \frac{1}{x}\sqrt{1 + \frac{1}{x^4}}\, dx \text{ also diverges.}$$

Finally,

$$A = 2\pi \int_1^\infty \frac{1}{x}\sqrt{1 + \frac{1}{x^4}}\, dx$$

diverges.

82. Compute the volume of the solid obtained by rotating the region below the graph of $y = e^{-|x|/2}$ about the x-axis for $-\infty < x < \infty$.

SOLUTION The graph of y is symmetric around the y-axis, so it suffices to compute the volume for $0 \leq x \leq \infty$, where we have $y = e^{-x/2}$. Using the disk method,

$$\begin{aligned} V &= 2\int_0^\infty \pi \left(e^{-x/2}\right)^2 dx = 2\pi \int_0^\infty e^{-x}\, dx = 2\pi \lim_{R\to\infty} \int_0^R e^{-x}\, dx \\ &= -\lim_{R\to\infty} 2\pi e^{-x}\Big|_0^R = -2\pi \lim_{R\to\infty} (e^{-R} - 1) = 2\pi \end{aligned}$$

Therefore $V = 2\pi$.

83. When a capacitor of capacitance C is charged by a source of voltage V, the power expended at time t is

$$P(t) = \frac{V^2}{R}(e^{-t/RC} - e^{-2t/RC})$$

where R is the resistance in the circuit. The total energy stored in the capacitor is

$$W = \int_0^\infty P(t)\, dt$$

Show that $W = \frac{1}{2}CV^2$.

SOLUTION The total energy contained after the capacitor is fully charged is

$$W = \frac{V^2}{R}\int_0^\infty \left(e^{-t/RC} - e^{-2t/RC}\right) dt.$$

The energy after a finite amount of time ($t = T$) is

$$\frac{V^2}{R}\int_0^T \left(e^{-t/RC} - e^{-2t/RC}\right) dt = \frac{V^2}{R}\left(-RCe^{-t/RC} + \frac{RC}{2}e^{-2t/RC}\right)\Bigg|_0^T$$
$$= V^2 C\left[\left(-e^{-T/RC} + \frac{1}{2}e^{-2T/RC}\right) - \left(-1 + \frac{1}{2}\right)\right]$$
$$= CV^2\left(\frac{1}{2} - e^{-T/RC} + \frac{1}{2}e^{-2T/RC}\right).$$

Thus,

$$W = \lim_{T\to\infty} CV^2\left(\frac{1}{2} - e^{-T/RC} + \frac{1}{2}e^{-2T/RC}\right) = CV^2\left(\frac{1}{2} - 0 + 0\right) = \frac{1}{2}CV^2.$$

84. For which integers p does $\displaystyle\int_0^{1/2} \frac{dx}{x(\ln x)^p}$ converge?

SOLUTION If $p = 1$, the integral diverges. By substituting $u = \ln x$ and $du = dx/x$, we get

$$\int \frac{dx}{x(\ln x)} = \int \frac{du}{u} = \ln|u| + C = \ln|\ln x| + C,$$

so

$$\int_0^{1/2} \frac{dx}{x(\ln x)} = \lim_{R\to 0+} (\ln|\ln x|)\Bigg|_R^{1/2} = \lim_{R\to 0+} (\ln|\ln(1/2)| - \ln|\ln R|),$$

which is infinite.

Now, suppose $p \neq 1$. Using the substitution $u = \ln x$, so that $du = \frac{1}{x}dx$, the integral becomes

$$\int_R^{1/2} \frac{dx}{x(\ln x)^p} = \int_{x=R}^{x=1/2} \frac{du}{u^p} = \int_{x=R}^{x=1/2} u^{-p}\, du = \frac{1}{p-1}u^{-p+1}\Bigg|_{x=R}^{x=1/2}$$
$$= \frac{1}{p-1}(\ln x)^{-p+1}\Bigg|_R^{1/2} = \frac{1}{p-1}(\ln(1/2))^{-p+1} - \frac{1}{p-1}(\ln(R))^{-p+1}.$$

By definition,

$$\int_0^{1/2} \frac{dx}{x(\ln x)^p} = \lim_{R\to 0+}\int_R^{1/2} \frac{dx}{x(\ln x)^p} = \lim_{R\to 0+}\left[\frac{1}{p-1}(\ln(1/2))^{-p+1} - \frac{1}{p-1}(\ln R)^{-p+1}\right].$$

If $p > 1$, $\lim_{R\to 0+}(\ln R)^{-p+1} = \lim_{R\to 0}\frac{1}{(\ln R)^{p-1}} = 0$. If $p < 1$, $\lim_{R\to 0+}(\ln R)^{1-p} = \infty$. Therefore, the integral diverges if $p < 1$ or $p = 1$, and converges if $p > 1$.

85. Conservation of Energy can be used to show that when a mass m oscillates at the end of a spring with spring constant k, the period of oscillation is

$$T = 4\sqrt{m}\int_0^{\sqrt{2E/k}} \frac{dx}{\sqrt{2E - kx^2}}$$

where E is the total energy of the mass. Show that this is an improper integral with value $T = 2\pi\sqrt{m/k}$.

SOLUTION The integrand is infinite at the upper limit of integration, $x = \sqrt{2E/k}$, so the integral is improper. Now, let

$$T(R) = 4\sqrt{m}\int_0^R \frac{dx}{\sqrt{2E - kx^2}} = 4\sqrt{m}\frac{1}{\sqrt{2E}}\int_0^R \frac{dx}{\sqrt{1 - (\frac{k}{2E})x^2}}$$
$$= 4\sqrt{\frac{m}{2E}}\sqrt{\frac{2E}{k}}\sin^{-1}\left(\sqrt{\frac{k}{2E}}R\right) = 4\sqrt{m/k}\sin^{-1}\left(\sqrt{\frac{k}{2E}}R\right).$$

Therefore

$$T = \lim_{R\to\sqrt{2E/k}} T(R) = 4\sqrt{\frac{m}{k}}\sin^{-1}(1) = 2\pi\sqrt{\frac{m}{k}}.$$

In Exercises 86–89, the ***Laplace transform*** *of a function $f(x)$ is the function $Lf(s)$ of the variable s defined by the improper integral (if it converges):*

$$Lf(s) = \int_0^\infty f(x)e^{-sx}\,dx$$

Laplace transforms are widely used in physics and engineering.

86. Show that if $f(x) = C$, where C is a constant, then $Lf(s) = C/s$ for $s > 0$.

SOLUTION If $f(x) = C$, a constant, then the Laplace transform of $f(x)$ is

$$Lf(s) = \int_0^\infty Ce^{-sx}\,dx = \lim_{R\to\infty} \frac{-C}{s}e^{-sx}\Big|_0^R = \lim_{R\to\infty} \frac{-C}{s}\left(e^{-sR} - 1\right) = \frac{-C}{s}(0-1) = \frac{C}{s}.$$

87. Show that if $f(x) = \sin \alpha x$, then $Lf(s) = \dfrac{\alpha}{s^2+\alpha^2}$.

SOLUTION If $f(x) = \sin\alpha x$, then the Laplace transform of $f(x)$ is

$$Lf(s) = \int_0^\infty e^{-sx}\sin\alpha x\,dx$$

First evaluate the indefinite integral using Integration by Parts, with $u = \sin\alpha x$ and $v' = e^{-sx}$. Then $u' = \alpha\cos\alpha x$, $v = -\frac{1}{s}e^{-sx}$, and

$$\int e^{-sx}\sin\alpha x\,dx = -\frac{1}{s}e^{-sx}\sin\alpha x + \frac{\alpha}{s}\int e^{-sx}\cos\alpha x\,dx.$$

Use Integration by Parts again, with $u = \cos\alpha x$, $v' = e^{-sx}$. Then $u' = -\alpha\sin\alpha x$, $v = -\frac{1}{s}e^{-sx}$, and

$$\int e^{-sx}\cos\alpha x\,dx = -\frac{1}{s}e^{-sx}\cos\alpha x - \frac{\alpha}{s}\int e^{-sx}\sin\alpha x\,dx.$$

Substituting this into the first equation and solving for $\int e^{-sx}\sin\alpha x\,dx$, we get

$$\int e^{-sx}\sin\alpha x\,dx = -\frac{1}{s}e^{-sx}\sin\alpha x - \frac{\alpha}{s^2}e^{-sx}\cos\alpha x - \frac{\alpha^2}{s^2}\int e^{-sx}\sin\alpha x\,dx$$

$$\int e^{-sx}\sin\alpha x\,dx = \frac{-e^{-sx}\left(\frac{1}{s}\sin\alpha x + \frac{\alpha}{s^2}\cos\alpha x\right)}{\left(1+\frac{\alpha^2}{s^2}\right)} = \frac{-e^{-sx}(s\sin\alpha x + \alpha\cos\alpha x)}{s^2+\alpha^2}$$

Thus,

$$\int_0^R e^{-sx}\sin\alpha x\,dx = \frac{1}{s^2+\alpha^2}\left[\frac{s\sin\alpha R + \alpha\cos\alpha R}{-e^{sR}} - \frac{0+\alpha}{-1}\right] = \frac{1}{s^2+\alpha^2}\left[\alpha - \frac{s\sin\alpha R+\alpha\cos\alpha R}{e^{sR}}\right].$$

Finally we take the limit, noting the fact that, for all values of R, $|s\sin\alpha R + \alpha\cos\alpha R| \le s + |\alpha|$

$$Lf(s) = \lim_{R\to\infty}\frac{1}{s^2+\alpha^2}\left[\alpha - \frac{s\sin\alpha R+\alpha\cos\alpha R}{e^{sR}}\right] = \frac{1}{s^2+\alpha^2}(\alpha - 0) = \frac{\alpha}{s^2+\alpha^2}.$$

88. Compute $Lf(s)$, where $f(x) = e^{\alpha x}$ and $s > \alpha$.

SOLUTION If $f(x) = e^{\alpha x}$, where $s > \alpha$, then the Laplace transform of $f(x)$ is

$$Lf(s) = \int_0^\infty e^{\alpha x}e^{-sx}\,dx = \int_0^\infty e^{-(s-\alpha)x}\,dx = \lim_{R\to\infty}\frac{-1}{s-\alpha}e^{-(s-\alpha)x}\Big|_0^R = \lim_{R\to\infty}\frac{-1}{s-\alpha}\left(e^{-(s-\alpha)R} - 1\right).$$

Because $s > \alpha$, $-(s-\alpha) < 0$, which gives us

$$\lim_{R\to\infty}\frac{1}{s-\alpha}\left(1 - e^{-(s-\alpha)R}\right) = \frac{1}{s-\alpha}(1-0) = \frac{1}{s-\alpha}.$$

The final answer is

$$Lf(s) = \frac{1}{s-\alpha}.$$

89. Compute $Lf(s)$, where $f(x) = \cos \alpha x$ and $s > 0$.

SOLUTION If $f(x) = \cos \alpha x$, then the Laplace transform of $f(x)$ is

$$Lf(x) = \int_0^\infty e^{-sx} \cos \alpha x \, dx$$

First evaluate the indefinite integral using Integration by Parts, with $u = \cos \alpha x$ and $v' - e^{-sx}$. Then $u' = -\alpha \sin \alpha x$, $v = -\frac{1}{s} e^{-sx}$, and

$$\int e^{-sx} \cos \alpha x \, dx = -\frac{1}{s} e^{-sx} \cos \alpha x - \frac{\alpha}{s} \int e^{-sx} \sin \alpha x \, dx.$$

Use Integration by Parts again, with $u = \sin \alpha x \, dx$ and $v' = -e^{-sx}$. Then $u' = \alpha \cos \alpha x$, $v = -\frac{1}{s} e^{-sx}$, and

$$\int e^{-sx} \sin \alpha x \, dx = -\frac{1}{s} e^{-sx} \sin \alpha x + \frac{\alpha}{s} \int e^{-sx} \cos \alpha x \, dx.$$

Substituting this into the first equation and solving for $\int e^{-sx} \cos \alpha x \, dx$, we get

$$\begin{aligned}
\int e^{-sx} \cos \alpha x \, dx &= -\frac{1}{s} e^{-sx} \cos \alpha x - \frac{\alpha}{s} \left[-\frac{1}{s} e^{-sx} \sin \alpha x + \frac{\alpha}{s} \int e^{-sx} \cos \alpha \, dx \right] \\
&= -\frac{1}{s} e^{-sx} \cos \alpha x + \frac{\alpha}{s^2} e^{-sx} \sin \alpha x - \frac{\alpha^2}{s^2} \int e^{-sx} \cos \alpha x \, dx \\
\int e^{-sx} \cos \alpha x \, dx &= \frac{e^{-sx} \left(\frac{\alpha}{s^2} \sin \alpha x - \frac{1}{s} \cos \alpha x \right)}{1 + \frac{\alpha^2}{s^2}} = \frac{e^{-sx}(\alpha \sin \alpha x - s \cos \alpha x)}{s^2 + \alpha^2}
\end{aligned}$$

Thus,

$$\int_0^R e^{-sx} \cos \alpha x \, dx = \frac{1}{s^2 + \alpha^2} \left[\frac{\alpha \sin \alpha R - s \cos \alpha R}{e^{sR}} - \frac{0 - s}{1} \right].$$

Finally we take the limit, noting the fact that, for all values of R, $|\alpha \sin \alpha R - s \cos \alpha R| \le |\alpha| + s$

$$Lf(s) = \lim_{R \to \infty} \frac{1}{s^2 + \alpha^2} \left[s + \frac{\alpha \sin \alpha R - s \cos \alpha R}{e^{sR}} \right] = \frac{1}{s^2 + \alpha^2}(s + 0) = \frac{s}{s^2 + \alpha^2}.$$

90. When a radioactive substance decays, the fraction of atoms present at time t is $f(t) = e^{-kt}$, where $k > 0$ is the decay constant. It can be shown that the *average* life of an atom (until it decays) is $A = -\int_0^\infty t f'(t) \, dt$. Use Integration by Parts to show that $A = \int_0^\infty f(t) \, dt$ and compute A. What is the average decay time of radon-222, whose half-life is 3.825 days?

SOLUTION Let $u = t$, $v' = f'(t)$. Then $u' = 1$, $v = f(t)$, and

$$A = -\int_0^\infty t f'(t) \, dt = -t f(t) \Big|_0^\infty + \int_0^\infty f(t) \, dt.$$

Since $f(t) = e^{-kt}$, we have

$$-t f(t) \Big|_0^\infty = \lim_{R \to \infty} -t e^{-kt} \Big|_0^R = \lim_{R \to \infty} -R e^{-Rt} + 0 = \lim_{R \to \infty} \frac{-R}{e^{Rt}} = \lim_{R \to \infty} \frac{-1}{R e^{Rt}} = 0.$$

Here we used L'Hôpital's Rule to compute the limit. Thus

$$A = \int_0^\infty f(t) \, dt = \int_0^\infty e^{-kt} \, dt.$$

Now,

$$\int_0^R e^{-kt} \, dt = -\frac{1}{k} e^{-kt} \Big|_0^R = -\frac{1}{k} \left(e^{-kR} - 1 \right) = \frac{1}{k} \left(1 - e^{-kR} \right),$$

so

$$A = \lim_{R \to \infty} \frac{1}{k} \left(1 - e^{-kR} \right) = \frac{1}{k}(1 - 0) = \frac{1}{k}.$$

Because k has units of $(\text{time})^{-1}$, A does in fact have the appropriate units of time. To find the average decay time of Radon-222, we need to determine the decay constant k, given the half-life of 3.825 days. Recall that

$$k = \frac{\ln 2}{t_n}$$

where t_n is the half-life. Thus,

$$A = \frac{1}{k} = \frac{t_n}{\ln 2} = \frac{3.825}{\ln 2} \approx 5.518 \text{ days.}$$

91. Let $J_n = \int_0^\infty x^n\, e^{-\alpha x}\, dx$, where $n \ge 1$ is an integer and $\alpha > 0$. Prove that

$$J_n = \frac{n}{\alpha} J_{n-1}$$

and $J_0 = 1/\alpha$. Use this to compute J_4. Show that $J_n = n!/\alpha^{n+1}$.

SOLUTION Using Integration by Parts, with $u = x^n$ and $v' = e^{-\alpha x}$, we get $u' = nx^{n-1}$, $v = -\frac{1}{\alpha} e^{-\alpha x}$, and

$$\int x^n e^{-\alpha x}\, dx = -\frac{1}{\alpha} x^n e^{-\alpha x} + \frac{n}{\alpha} \int x^{n-1} e^{-\alpha x}\, dx.$$

Thus,

$$J_n = \int_0^\infty x^n e^{-\alpha x}\, dx = \lim_{R\to\infty} \left(-\frac{1}{\alpha} x^n e^{-\alpha x} \right)\Bigg|_0^R + \frac{n}{\alpha} \int_0^\infty x^{n-1} e^{-\alpha x}\, dx = \lim_{R\to\infty} \frac{-R^n}{\alpha e^{\alpha R}} + 0 + \frac{n}{\alpha} J_{n-1}.$$

Use L'Hôpital's Rule repeatedly to compute the limit:

$$\lim_{R\to\infty} \frac{-R_n}{\alpha e^{\alpha R}} = \lim_{R\to\infty} \frac{-nR^{n-1}}{\alpha^2 e^{\alpha R}} = \lim_{R\to\infty} \frac{-n(n-1)R^{n-2}}{\alpha^3 e^{\alpha R}} = \cdots = \lim_{R\to\infty} \frac{-n(n-1)(n-2)\cdots(3)(2)(1)}{\alpha^{n+1} e^{\alpha R}} = 0.$$

Finally,

$$J_n = 0 + \frac{n}{\alpha} J_{n-1} = \frac{n}{\alpha} J_{n-1}.$$

J_0 can be computed directly:

$$J_0 = \int_0^\infty e^{-\alpha x}\, dx = \lim_{R\to\infty} \int_0^R e^{-\alpha x}\, dx = \lim_{R\to\infty} -\frac{1}{\alpha} e^{-\alpha x}\Bigg|_0^R = \lim_{R\to\infty} -\frac{1}{\alpha}\left(e^{-\alpha R} - 1\right) = -\frac{1}{\alpha}(0-1) = \frac{1}{\alpha}.$$

With this starting point, we can work up to J_4:

$$J_1 = \frac{1}{\alpha} J_0 = \frac{1}{\alpha}\left(\frac{1}{\alpha}\right) = \frac{1}{\alpha^2};$$

$$J_2 = \frac{2}{\alpha} J_1 = \frac{2}{\alpha}\left(\frac{1}{\alpha^2}\right) = \frac{2}{\alpha^3} = \frac{2!}{\alpha^{2+1}};$$

$$J_3 = \frac{3}{\alpha} J_2 = \frac{3}{\alpha}\left(\frac{2}{\alpha^3}\right) = \frac{6}{\alpha^4} = \frac{3!}{\alpha^{3+1}};$$

$$J_4 = \frac{4}{\alpha} J_3 = \frac{4}{\alpha}\left(\frac{6}{\alpha^4}\right) = \frac{24}{\alpha^5} = \frac{4!}{\alpha^{4+1}}.$$

We can use induction to prove the formula for J_n. If

$$J_{n-1} = \frac{(n-1)!}{\alpha^n},$$

then we have

$$J_n = \frac{n}{\alpha} J_{n-1} = \frac{n}{\alpha} \cdot \frac{(n-1)!}{\alpha^n} = \frac{n!}{\alpha^{n+1}}.$$

92. Let $a > 0$ and $n > 1$. Define $f(x) = \dfrac{x^n}{e^{ax} - 1}$ for $x \ne 0$ and $f(0) = 0$.

(a) Use L'Hôpital's Rule to show that $f(x)$ is continuous at $x = 0$.

(b) Show that $\int_0^\infty f(x)\, dx$ converges. *Hint:* Show that $f(x) \le 2x^n e^{-ax}$ if x is large enough. Then use the Comparison Test and Exercise 91.

SOLUTION

(a) Using L'Hôpital's Rule, we find

$$\lim_{x\to 0} \frac{x^n}{e^{\alpha x}-1} = \lim_{x\to 0} \frac{nx^{n-1}}{\alpha e^{\alpha x}} = \frac{0}{\alpha} = 0;$$

thus,

$$\lim_{x\to 0} f(x) = f(0),$$

and $f(x)$ is continuous at $x = 0$.

(b) Since $a > 0$, $\lim\limits_{x\to\infty} e^{ax} = \infty$. Therefore there will be some value of x, say $x = M$, such that, for all $x \geq M$, we'll have $e^{ax} \geq 2$. With this, we have

$$\frac{1}{e^{ax}} \leq \frac{1}{2} \quad \text{so} \quad \frac{1}{e^{ax}} + \frac{1}{2} \leq 1 \quad \text{and} \quad 1 - \frac{1}{e^{\alpha x}} \geq \frac{1}{2}.$$

Multiply this last inequality through by $e^{\alpha x}$ to obtain

$$e^{\alpha x} - 1 \geq \frac{e^{\alpha x}}{2} \quad \text{so} \quad \frac{1}{e^{\alpha x}-1} \leq \frac{2}{e^{\alpha x}} \quad \text{and} \quad \frac{x^n}{e^{\alpha x}-1} \leq \frac{2x^n}{e^{\alpha x}}.$$

From Exercise 91, we know that

$$\int_0^\infty x^n e^{-\alpha x}\,dx \text{ converges, so } \int_M^\infty 2x^n e^{-\alpha x}\,dx \text{ also converges.}$$

Therefore, by the comparison test,

$$\int_M^\infty \frac{x^n}{e^{\alpha x}-1}\,dx \text{ also converges.}$$

Now, from part (a), we know that $f(x)$ is continuous on $[0, M]$, so

$$\int_0^M \frac{x^n}{e^{\alpha x}-1}\,dx$$

exists and is finite. Thus we have shown

$$\int_0^\infty \frac{x^n}{e^{\alpha x}-1}\,dx = \int_0^M \frac{x^n}{e^{\alpha x}-1}\,dx + \int_M^\infty \frac{x^n}{e^{\alpha x}-1}\,dx \text{ converges.}$$

93. According to **Planck's Radiation Law**, the amount of electromagnetic energy with frequency between ν and $\nu + \Delta\nu$ that is radiated by a so-called black body at temperature T is proportional to $F(\nu)\,\Delta\nu$, where

$$F(\nu) = \left(\frac{8\pi h}{c^3}\right)\frac{\nu^3}{e^{h\nu/kT}-1}$$

where c, h, k are physical constants. Use Exercise 92 to show that the total radiated energy

$$E = \int_0^\infty F(\nu)\,d\nu$$

is finite. To derive his law, Planck introduced the quantum hypothesis in 1900, which marked the birth of quantum mechanics.

SOLUTION The total radiated energy E is given by

$$E = \int_0^\infty F(\nu)\,d\nu = \frac{8\pi h}{c^3}\int_0^\infty \frac{\nu^3}{e^{h\nu/kT}-1}\,d\nu.$$

Let $\alpha = h/kT$. Then

$$E = \frac{8\pi h}{c^3}\int_0^\infty \frac{\nu^3}{e^{\alpha\nu}-1}\,d\nu.$$

Because $\alpha > 0$ and $8\pi h/c^3$ is a constant, we know E is finite by Exercise 92.

Further Insights and Challenges

94. Let $I = \int_0^1 x^p \ln x\, dx$.

(a) Show that I diverges for $p = -1$.

(b) Show that if $p \neq -1$, then

$$\int x^p \ln x\, dx = \frac{x^{p+1}}{p+1}\left(\ln x - \frac{1}{p+1}\right) + C$$

(c) Use L'Hôpital's Rule to show that I converges if $p > -1$ and diverges if $p < -1$.

SOLUTION

(a) If $p = -1$, then

$$I = \int_0^1 x^{-1} \ln x\, dx = \int_0^1 \frac{\ln x}{x}\, dx.$$

Let $u = \ln x$, $du = (1/x)\, dx$. Then

$$\int \frac{\ln x}{x}\, dx = \int u\, du = \frac{u^2}{2} + C = \frac{1}{2}(\ln x)^2 + C.$$

Thus,

$$\int_R^1 \frac{\ln x}{x}\, dx = \frac{1}{2}(\ln 1)^2 - \frac{1}{2}(\ln R)^2 = -\frac{1}{2}(\ln R)^2,$$

and

$$I = \lim_{R\to 0^+} -\frac{1}{2}(\ln R)^2 = \infty.$$

The integral diverges for $p = -1$.

(b) If $p \neq 1$, then use Integration by Parts, with $u = \ln x$ and $v' = x^p$. Then $u' = 1/x$, $v = x^{p+1}/p + 1$, and

$$\begin{aligned}\int x^p \ln x\, dx &= \frac{x^{p+1}}{p+1}\ln x - \frac{1}{p+1}\int \left(x^{p+1}\right)\left(\frac{1}{x}\right) dx = \frac{x^{p+1}}{p+1}\ln x - \frac{1}{p+1}\int x^p\, dx \\ &= \frac{x^{p+1}}{p+1}\ln x - \frac{1}{p+1}\left(\frac{x^{p+1}}{p+1}\right) + C = \frac{x^{p+1}}{p+1}\left(\ln x - \frac{1}{p+1}\right) + C.\end{aligned}$$

(c) Let $p < -1$. Then

$$\begin{aligned}I &= \lim_{R\to 0^+}\int_R^1 x^p \ln x = \lim_{R\to 0^+}\left[\frac{1}{p+1}\left(\ln 1 - \frac{1}{p+1}\right) - \frac{R^{p+1}}{p+1}\left(\ln R - \frac{1}{p+1}\right)\right] \\ &= \lim_{R\to 0^+}\left(\frac{-1}{(p+1)^2} - \frac{R^{p+1}}{p+1}\ln R + \frac{R^{p+1}}{(p+1)^2}\right).\end{aligned}$$

Since $p < -1$, $p + 1 < 0$, and we have

$$I = \lim_{R\to 0^+}\left(\frac{-1}{(p+1)^2} - \frac{\ln R}{(p+1)R^{-p-1}} + \frac{1}{(p+1)^2 R^{-p-1}}\right) = \infty.$$

The integral diverges for $p < -1$. On the other hand, if $p > -1$, then $p + 1 > 0$, and

$$I = \frac{-1}{(p+1)^2} + \frac{1}{p+1}\lim_{R\to 0+} R^{p+1}\ln R + \frac{1}{(p+1)^2}\lim_{R\to 0^+} R^{p+1} = \frac{-1}{(p+1)^2} + 0 = \frac{-1}{(p+1)^2}.$$

95. Let

$$F(x) = \int_2^x \frac{dt}{\ln t} \qquad \text{and} \qquad G(x) = \frac{x}{\ln x}$$

Verify that L'Hôpital's Rule applies to the limit $L = \lim_{x\to\infty}\frac{F(x)}{G(x)}$ and evaluate L.

SOLUTION Because $\ln t < t$ for $t > 2$, we have $\frac{1}{\ln t} > \frac{1}{t}$ for $t > 2$, and so

$$F(x) = \int_2^x \frac{dt}{\ln t} > \int_2^x \frac{dt}{t} = \ln x - \ln 2$$

Thus, $F(x) \to \infty$ as $x \to \infty$. Moreover, by L'Hôpital's Rule

$$\lim_{x\to\infty} G(x) = \lim_{x\to\infty} \frac{1}{1/x} = \lim_{x\to\infty} x = \infty.$$

Thus, $\lim_{x\to\infty} \dfrac{F(x)}{G(x)}$ is of the form ∞/∞, and L'Hôpital's Rule applies. Finally,

$$L = \lim_{x\to\infty} \frac{F(x)}{G(x)} = \lim_{x\to\infty} \frac{\frac{1}{\ln x}}{\frac{\ln x - 1}{(\ln x)^2}} = \lim_{x\to\infty} \frac{\ln x}{\ln x - 1} = \lim_{x\to\infty} \frac{1}{1 - (1/\ln x)} = 1.$$

*In Exercises 96–98, an improper integral $I = \int_a^\infty f(x)\,dx$ is called **absolutely convergent** if $\int_a^\infty |f(x)|\,dx$ converges. It can be shown that if I is absolutely convergent, then it is convergent.*

96. Show that $\displaystyle\int_1^\infty \frac{\sin x}{x^2}\,dx$ is absolutely convergent.

SOLUTION For all x, $|\sin x| \le 1$. This implies

$$\left|\frac{\sin x}{x^2}\right| = \frac{|\sin x|}{x^2} \le \frac{1}{x^2}.$$

The integral $\displaystyle\int_1^\infty x^{-2}\,dx$ converges because $p = 2 > 1$. Therefore, by the comparison test,

$$\int_1^\infty \left|\frac{\sin x}{x^2}\right| dx \text{ also converges.}$$

Because the integral

$$\int_1^\infty \frac{\sin x}{x^2}\,dx$$

is absolutely convergent, it is also convergent.

97. Show that $\displaystyle\int_1^\infty e^{-x^2}\cos x\,dx$ is absolutely convergent.

SOLUTION By the result of Exercise 57, we know that $\displaystyle\int_0^\infty e^{-x^2}\,dx$ is convergent. Then $\displaystyle\int_1^\infty e^{-x^2}\,dx$ is also convergent. Because $|\cos x| \le 1$ for all x, we have

$$\left|e^{-x^2}\cos x\right| = |\cos x|\left|e^{-x^2}\right| \le \left|e^{-x^2}\right| = e^{-x^2}.$$

Therefore, by the comparison test, we have

$$\int_1^\infty \left|e^{-x^2}\cos x\right| dx \text{ also converges.}$$

Since $\displaystyle\int_1^\infty e^{-x^2}\cos x\,dx$ converges absolutely, it itself converges.

98. Let $f(x) = \sin x/x$ and $I = \int_0^\infty f(x)\,dx$. We define $f(0) = 1$. Then $f(x)$ is continuous and I is not improper at $x = 0$.

(a) Show that

$$\int_1^R \frac{\sin x}{x}\,dx = -\frac{\cos x}{x}\bigg|_1^R - \int_1^R \frac{\cos x}{x^2}\,dx$$

(b) Show that $\int_1^\infty (\cos x/x^2)\,dx$ converges. Conclude that the limit as $R \to \infty$ of the integral in (a) exists and is finite.

(c) Show that I converges.

It is known that $I = \frac{\pi}{2}$. However, I is *not* absolutely convergent. The convergence depends on cancellation, as shown in Figure 12.

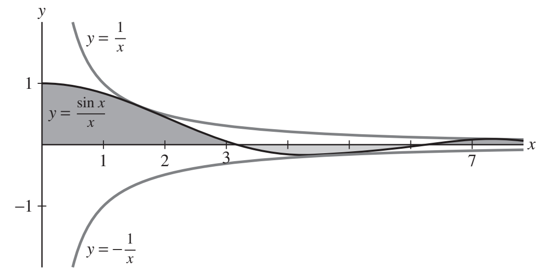

FIGURE 12 Convergence of $\int_1^\infty (\sin x/x)\,dx$ is due to the cancellation arising from the periodic change of sign.

SOLUTION

(a) Use Integration by Parts, with $u = \frac{1}{x}$ and $v' = \sin x$. Then $u' = -1/x^2$, $v = -\cos x$, and we have

$$\int_1^R \frac{\sin x}{x}\,dx = \frac{-\cos x}{x}\bigg|_1^R - \int_1^R \frac{\cos x}{x^2}\,dx.$$

(b) For all x, $|\cos x| \le 1$, and therefore

$$\left|\frac{\cos x}{x^2}\right| = \frac{|\cos x|}{x^2} \le \frac{1}{x^2}.$$

The integral $\displaystyle\int_1^\infty x^{-2}\,dx$ converges, because $p = 2 > 1$. Therefore, by the comparison test,

$$\int_1^\infty \left|\frac{\cos x}{x^2}\right| dx \text{ also converges.}$$

Because $\displaystyle\int_1^\infty (\cos x/x^2)\,dx$ converges absolutely, it also converges. By this result,

$$\lim_{R\to\infty} \int_1^R \frac{\sin x}{x}\,dx = \lim_{R\to\infty} \left[\frac{-\cos R}{R} + \frac{\cos 1}{1} - \int_1^R \frac{\cos x}{x^2}\,dx\right] = 0 + \frac{\cos 1}{1} - \int_0^\infty \frac{\cos x}{x^2}\,dx = \cos 1 - M,$$

where $M = \displaystyle\int_1^\infty (\cos x/x^2)\,dx$, the existence of which was shown in the argument above. Therefore the integral $\displaystyle\int_1^\infty (\sin x/x)\,dx$ converges to a finite value.

(c) The integral can be split up as follows:

$$\int_0^\infty \frac{\sin x}{x}\,dx = \int_0^1 \frac{\sin x}{x}\,dx + \int_1^\infty \frac{\sin x}{x}\,dx.$$

The second integral converges by part (b). For the first integral, if we define $f(0) = 1$, then the integrand is continuous on $[0, 1]$, and therefore

$$\int_0^1 \frac{\sin x}{x}\,dx = N$$

where N is some finite value. Thus, we have shown that I converges.

99. The **gamma function**, which plays an important role in advanced applications, is defined for $n \ge 1$ by

$$\Gamma(n) = \int_0^\infty t^{n-1}e^{-t}\,dt$$

(a) Show that the integral defining $\Gamma(n)$ converges for $n \ge 1$ (it actually converges for all $n > 0$). *Hint:* Show that $t^{n-1}e^{-t} < t^{-2}$ for t sufficiently large.

(b) Show that $\Gamma(n+1) = n\Gamma(n)$ using Integration by Parts.

(c) Show that $\Gamma(n+1) = n!$ if $n \ge 1$ is an integer. *Hint:* Use (a) repeatedly. Thus, $\Gamma(n)$ provides a way of defining n-factorial when n is not an integer.

SOLUTION
(a) By repeated use of L'Hôpital's Rule, we can compute the following limit:

$$\lim_{t\to\infty} \frac{e^t}{t^{n+1}} = \lim_{t\to\infty} \frac{e^t}{(n+1)t^n} = \cdots = \lim_{t\to\infty} \frac{e^t}{(n+1)!} = \infty.$$

This implies that, for t sufficiently large, we have

$$e^t \ge t^{n+1};$$

therefore

$$\frac{e^t}{t^{n-1}} \ge \frac{t^{n+1}}{t^{n-1}} = t^2 \quad \text{or} \quad t^{n-1}e^{-t} \le t^{-2}.$$

The integral $\int_1^\infty t^{-2}\,dt$ converges because $p = 2 > 1$. Therefore, by the comparison test,

$$\int_M^\infty t^{n-1}e^{-t}\,dt \text{ also converges,}$$

where M is the value above which the above comparisons hold. Finally, because the function $t^{n-1}e^{-t}$ is continuous for all t, we know that

$$\Gamma(n) = \int_0^\infty t^{n-1}e^{-t}\,dt \text{ converges} \quad \text{for all } n \ge 1.$$

(b) Using Integration by Parts, with $u = t^n$ and $v' - e^{-t}$, we have $u' = nt^{n-1}$, $v = -e^{-t}$, and

$$\Gamma(n+1) = \int_0^\infty t^n e^{-t}\,dt = -t^n e^{-t}\Big|_0^\infty + n\int_0^\infty t^{n-1}e^{-t}\,dt$$
$$= \lim_{R\to\infty}\left(\frac{-R^n}{e^R} - 0\right) + n\Gamma(n) = 0 + n\Gamma(n) = n\Gamma(n).$$

Here, we've computed the limit as in part (a) with repeated use of L'Hôpital's Rule.
(c) By the result of part (b), we have

$$\Gamma(n+1) = n\Gamma(n) = n(n-1)\Gamma(n-1) = n(n-1)(n-2)\Gamma(n-2) = \cdots = n!\,\Gamma(1).$$

If $n = 1$, then

$$\Gamma(1) = \int_0^\infty e^{-t}\,dt = \lim_{R\to\infty} -e^{-t}\Big|_0^R = \lim_{R\to\infty}\left(1 - e^{-R}\right) = 1.$$

Thus

$$\Gamma(n+1) = n!\,(1) = n!$$

100. Use the results of Exercise 99 to show that the Laplace transform (see Exercises 86–89 above) of x^n is $\frac{n!}{s^{n+1}}$.

SOLUTION If $f(x) = x^n$, then the Laplace transform of $f(x)$ is

$$Lf(s) = \int_0^\infty x^n e^{-sx}\,dx$$

Let $t = sx$. Then $dt = s\,dx$, and $x^n = t^n/s^n$. This gives us

$$Lf(s) = \int_0^\infty \frac{t^n}{s^n}e^{-t}\frac{dt}{s} = \frac{1}{s^{n+1}}\int_0^\infty t^n e^{-t}\,dt = \frac{1}{s^{n+1}}\Gamma(n+1) = \frac{n!}{s^{n+1}}.$$

7.7 Probability and Integration

Preliminary Questions

1. The function $p(x) = \cos x$ satisfies $\int_{-\pi/2}^{\pi} p(x)\,dx = 1$. Is $p(x)$ a probability density function on $[-\pi/2, \pi]$?

SOLUTION Since $p(x) = \cos x < 0$ for some points in $(-\pi/2, \pi)$, $p(x)$ is not a probability density function.

2. Estimate $P(2 \le X \le 2.1)$ assuming that the probability density function of X satisfies $p(2) = 0.2$.

SOLUTION $P(2 \le X \le 2.1) \approx p(2) \cdot (2.1 - 2) = 0.02$.

3. Which exponential probability density has mean $\mu = \frac{1}{4}$?

SOLUTION $\dfrac{1}{1/4} e^{-x/(1/4)} = 4e^{-4x}$.

Exercises

In Exercises 1–6, find a constant C such that $p(x)$ is a probability density function on the given interval, and compute the probability indicated.

1. $p(x) = \dfrac{C}{(x+1)^3}$ on $[0, \infty)$; $P(0 \le X \le 1)$

SOLUTION Compute the indefinite integral using the substitution $u = x + 1$, $du = dx$:

$$\int p(x)\,dx = \int \frac{C}{(x+1)^3}\,dx = -\frac{1}{2}C(x+1)^{-2} + K$$

For $p(x)$ to be a probability density function, we must have

$$1 = \int_0^\infty p(x)\,dx = -\frac{1}{2}C \lim_{R\to\infty} (x+1)^{-2}\Big|_0^R = \frac{1}{2}C - \frac{1}{2}C \lim_{R\to\infty}(R+1)^{-2} = \frac{1}{2}C$$

so that $C = 2$, and $p(x) = \frac{2}{(x+1)^3}$. Then using the indefinite integral above,

$$P(0 \le X \le 1) = \int_0^1 \frac{2}{(x+1)^3} = -\frac{1}{2} \cdot 2 \cdot (x+1)^{-2}\Big|_0^1 = -\frac{1}{4} + 1 = \frac{3}{4}$$

2. $p(x) = Cx(4-x)$ on $[0, 4]$; $P(3 \le X \le 4)$

SOLUTION Compute the indefinite integral:

$$\int p(x)\,dx = C\int x(4-x)\,dx = C\int 4x - x^2\,dx = C\left(2x^2 - \frac{1}{3}x^3\right) + K$$

For $p(x)$ to be a probability density function, we must have

$$1 = \int_0^4 p(x)\,dx = C\left(2x^2 - \frac{1}{3}x^3\right)\Big|_0^4 = C\left(32 - \frac{64}{3}\right) = \frac{32}{3}C$$

so that $C = \frac{3}{32}$ and $p(x) = \frac{3}{32}x(4-x)$. Then using the indefinite integral above,

$$P(3 \le X \le 4) = \int_3^4 p(x)\,dx = \frac{3}{32}\left(2x^2 - \frac{1}{3}x^3\right)\Big|_3^4 = \frac{3}{32}\left(32 - \frac{64}{3} - 18 + 9\right) = \frac{5}{32}$$

3. $p(x) = \dfrac{C}{\sqrt{1-x^2}}$ on $(-1, 1)$; $P\left(-\frac{1}{2} \le X \le \frac{1}{2}\right)$

SOLUTION Compute the indefinite integral:

$$\int p(x)\,dx = C\int \frac{1}{\sqrt{1-x^2}}\,dx = C\sin^{-1} x + K$$

valid for $-1 < x < 1$. For $p(x)$ to be a probability density function, we must have

$$\begin{aligned}1 = \int_{-1}^1 p(x)\,dx = \int_{-1}^0 p(x)\,dx + \int_0^1 p(x)\,dx &= C\left(\lim_{R\to -1^+} \sin^{-1} x\Big|_R^0 + \lim_{R\to 1^-} \sin^{-1} x\Big|_0^R\right) \\ &= C\left(\sin^{-1}(0) - \lim_{R\to -1^+} \sin^{-1}(R) + \lim_{R\to 1^-} \sin^{-1} R - \sin^{-1}(0)\right) \\ &= C\left(-\sin^{-1}(-1) + \sin^{-1}(1)\right) = \pi C\end{aligned}$$

so that $C = \frac{1}{\pi}$ and $p(x) = \frac{1}{\pi\sqrt{1-x^2}}$. Then using the indefinite integral above,

$$P\left(-\frac{1}{2} \le X \le \frac{1}{2}\right) = \int_{-1/2}^{1/2} p(x)\,dx = \frac{1}{\pi}\sin^{-1} x\Big|_{-1/2}^{1/2} = \frac{1}{\pi}\left(\frac{\pi}{6} - \frac{-\pi}{6}\right) = \frac{1}{3}$$

4. $p(x) = \dfrac{Ce^{-x}}{1+e^{-2x}}$ on $(-\infty, \infty)$; $P(X \le -4)$

SOLUTION Compute the indefinite integral using the substitution $u = e^{-x}$; then $du = -e^{-x}\,dx = -u\,dx$ so that $dx = -\frac{1}{u}\,du$:

$$\int p(x)\,dx = \int \frac{Ce^{-x}}{1+e^{-2x}}\,dx = C\int \frac{u\cdot\left(-\frac{1}{u}\right)}{1+u^2}\,du = -C\int \frac{1}{1+u^2}\,du$$
$$= -C\tan^{-1}u + K = -C\tan^{-1}(e^{-x}) + K = C\tan^{-1}(e^x) + K$$

For $p(x)$ to be a probability density function, we must have

$$1 = \int_{-\infty}^{\infty} p(x)\,dx = C\lim_{R\to\infty}\tan^{-1}(e^x)\Big|_{-R}^{R} = C\lim_{R\to\infty}\left(\tan^{-1}(e^R) - \tan^{-1}(e^{-R})\right) = C\left(\frac{\pi}{2} - 0\right) = \frac{\pi}{2}C$$

so that $C = \frac{2}{\pi}$ and $p(x) = \frac{2e^{-x}}{\pi(1+e^{-2x})}$. Then using the indefinite integral above,

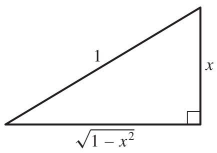
$$P(X \le -4) = \int_{-\infty}^{-4} p(x)\,dx = \lim_{R\to-\infty}\frac{2}{\pi}\tan^{-1}(e^x)\Big|_{R}^{-4} = \frac{2}{\pi}\tan^{-1}(e^{-4}) - \frac{2}{\pi}\lim_{R\to-\infty}\tan^{-1}(e^R)$$
$$= \frac{2}{\pi}\tan^{-1}(e^{-4}) \approx 0.0117$$

5. $p(x) = C\sqrt{1-x^2}$ on $(-1, 1)$; $P\left(-\frac{1}{2} \le X \le 1\right)$

SOLUTION Compute the indefinite integral using the substitution $x = \sin u$, so that $dx = \cos u\,du$:

$$\int p(x)\,dx = C\int\sqrt{1-x^2}\,dx = C\int\sqrt{1-\sin^2 u}\cos u\,du = C\int\cos^2 u\,du$$
$$= C\left(\frac{1}{2}u + \frac{1}{2}\cos u\sin u\right) + K$$

Since $x = \sin u$, we construct the following right triangle:



and we see that $\cos u = \sqrt{1-x^2}$, so that

$$\int p(x)\,dx = \frac{1}{2}C\left(\sin^{-1}x + x\sqrt{1-x^2}\right) + K$$

For $p(x)$ to be a probability density function, we must have

$$1 = \int_{-1}^{1} p(x)\,dx = \frac{1}{2}C\left(\sin^{-1}x + x\sqrt{1-x^2}\right)\Big|_{-1}^{1} = \frac{1}{2}C(\sin^{-1}1 - \sin^{-1}(-1)) = \frac{\pi}{2}C$$

so that $C = \frac{2}{\pi}$ and $p(x) = \frac{2}{\pi}\sqrt{1-x^2}$. Then using the indefinite integral above,

$$P\left(-\frac{1}{2} \le X \le 1\right) = \int_{-1/2}^{1}\frac{2}{\pi}\sqrt{1-x^2}\,dx = \frac{1}{\pi}\left(\sin^{-1}x + x\sqrt{1-x^2}\right)\Big|_{-1/2}^{1}$$
$$= \frac{1}{\pi}\left(\sin^{-1}1 + 0 - \sin^{-1}\left(-\frac{1}{2}\right) - \frac{-1}{2}\sqrt{1-\frac{1}{4}}\right)$$
$$= \frac{1}{\pi}\left(\frac{\pi}{2} - \frac{-\pi}{6} + \frac{\sqrt{3}}{4}\right) = \frac{2}{3} + \frac{\sqrt{3}}{4\pi} \approx 0.804$$

6. $p(x) = Ce^{-x}e^{-e^{-x}}$ on $(-\infty, \infty)$; $P(-4 \le X \le 4)$ This function, called the **Gumbel density**, is used to model extreme events such as floods and earthquakes.

SOLUTION Find the indefinite integral via the substitution $u = -e^{-x}$ so that $du = e^{-x}\,dx$; then

$$\int p(x)\,dx = C\int e^{-x}e^{-e^{-x}}\,dx = C\int e^u\,du = Ce^u = Ce^{-e^{-x}} + K$$

For $p(x)$ to be a probability density function, we must have

$$1 = \int_{-\infty}^{\infty} p(x)\,dx = C\lim_{R\to\infty} e^{-e^{-x}}\Big|_{-R}^{R} = C\lim_{R\to\infty}\left(e^{-e^{-R}} - e^{-e^{R}}\right) = C$$

since $e^{-R} \to 0$ so that the first term approaches $e^0 = 1$, and $e^R \to \infty$ so that the second term approaches $e^{-\infty} = 0$. Thus $C = 1$ and $p(x) = e^{-x}e^{-e^{-x}}$. Then using the indefinite integral above,

$$P(-4 \le X \le 4) = e^{-e^{-4}} - e^{-e^{4}} \approx 0.982$$

7. Verify that $p(x) = 3x^{-4}$ is a probability density function on $[1, \infty)$ and calculate its mean value.

SOLUTION We have

$$\int_1^{\infty} 3x^{-4}\,dx = \lim_{R\to\infty}\left(-x^{-3}\right)\Big|_1^R = \lim_{R\to\infty}\left(-\frac{1}{R^3}\right) + 1 = 1$$

so that $p(x)$ is a probability density function on $[1, \infty)$. Its mean value is

$$\int_1^{\infty} x\cdot 3x^{-4}\,dx = \int_1^{\infty} 3x^{-3}\,dx = -\frac{3}{2}x^{-2}\Big|_1^R = \lim_{R\to\infty}\left(-\frac{3}{2R^2}\right) + \frac{3}{2} = \frac{3}{2}$$

8. Show that the density function $p(x) = \dfrac{2}{\pi(x^2+1)}$ on $[0, \infty)$ has infinite mean.

SOLUTION To verify that $p(x)$ is a probability density function, note that

$$\int_0^{\infty} \frac{2}{\pi}\frac{1}{x^2+1}\,dx = \frac{2}{\pi}\lim_{R\to\infty}\tan^{-1}x\Big|_0^R = \frac{2}{\pi}\left(\frac{\pi}{2} - 0\right) = 1$$

Its average value is (using the substitution $u = x^2 + 1$, $du = 2x\,dx$):

$$\frac{2}{\pi}\int_0^{\infty}\frac{x}{x^2+1}\,dx = \frac{1}{\pi}\int_0^{\infty}\frac{1}{u}\,du$$

The indefinite integral is $\ln u$, so the definite integral approaches $\infty - (-\infty) = \infty$, so this integral diverges and the mean is infinite.

9. Verify that $p(t) = \frac{1}{50}e^{-t/50}$ satisfies the condition
$\int_0^{\infty} p(t)\,dt = 1$.

SOLUTION Use the substitution $u = \frac{t}{50}$, so that $du = \frac{1}{50}\,dt$. Then

$$\int_0^{\infty} p(t)\,dt = \int_0^{\infty}\frac{1}{50}e^{-t/50}\,dt = \int_0^{\infty} e^{-u}\,du = \lim_{R\to\infty}(-e^{-u})\Big|_0^R = \lim_{R\to\infty} 1 - e^{-R} = 1$$

10. Verify that for all $r > 0$, the exponential density function $p(t) = \frac{1}{r}e^{-t/r}$ satisfies the condition $\int_0^{\infty} p(t)\,dt = 1$.

SOLUTION This is similar to the preceding problem. Use the substitution $u = \frac{t}{r}$, so that $du = \frac{1}{r}\,dt$. Then

$$\int_0^{\infty} p(t)\,dt = \int_0^{\infty}\frac{1}{r}e^{-t/r}\,dt = \int_0^{\infty} e^{-u}\,du = \lim_{R\to\infty}(e^{-u})\Big|_0^R = \lim_{R\to\infty} 1 - e^{-R} = 1$$

11. The life X (in hours) of a battery in constant use is a random variable with exponential density. What is the probability that the battery will last more than 12 hours if the average life is 8 hours?

SOLUTION If the average life is 8 hours, then the mean of the exponential distribution is 8, so that the distribution is

$$p(x) = \frac{1}{8}e^{-x/8}$$

The probability that the battery will last more than 12 hours is given by (using the substitution $u = x/8$, so that $du = 1/8\,dx$ and $x = 12$ corresponds to $u = 3/2$)

$$P(X \geq 12) = \int_{12}^{\infty} p(x)\,dx = \int_{12}^{\infty} \frac{1}{8}e^{-x/8}\,dx = \int_{3/2}^{\infty} e^{-u}\,du = \lim_{R\to\infty}(-e^{-u})\Big|_{3/2}^{R}$$
$$= e^{-3/2} - \lim_{R\to\infty} e^{-R} = e^{-3/2} \approx 0.223$$

12. The time between incoming phone calls at a call center is a random variable with exponential density. There is a 50% probability of waiting 20 seconds or more between calls. What is the average time between calls?

SOLUTION The distribution is exponential, so $p(x) = \frac{1}{r}e^{-x/r}$. Since there is a 50% probability of waiting 20 seconds or more between calls, this means that

$$\int_{20}^{\infty} \frac{1}{r}e^{-x/r}\,dx = \frac{1}{2}$$

But

$$\int_{20}^{\infty} \frac{1}{r}e^{-x/r}\,dx = e^{-x/r}\Big|_{20}^{\infty} = e^{-20/r}$$

Thus $\frac{1}{2} = e^{-20/r}$, so that $-\frac{20}{r} = \ln\frac{1}{2} = -\ln 2$; it follows that $r = \frac{20}{\ln 2}$, which is the mean value.

13. The distance r between the electron and the nucleus in a hydrogen atom (in its lowest energy state) is a random variable with probability density $p(r) = 4a_0^{-3}r^2e^{-2r/a_0}$ for $r \geq 0$, where a_0 is the Bohr radius (Figure 7). Calculate the probability P that the electron is within one Bohr radius of the nucleus. The value of a_0 is approximately 5.29×10^{-11} m, but this value is not needed to compute P.

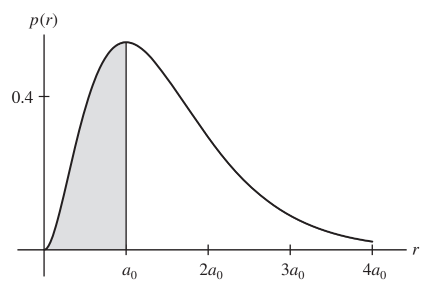


FIGURE 7 Probability density function $p(r) = 4a_0^{-3}r^2e^{-2r/a_0}$.

SOLUTION The probability P is the area of the shaded region in Figure 7. To calculate p, use the substitution $u = 2r/a_0$:

$$P = \int_0^{a_0} p(r)\,dr = \frac{4}{a_0^3}\int_0^{a_0} r^2e^{-2r/a_0}\,dr = \left(\frac{4}{a_0^3}\right)\left(\frac{a_0^3}{8}\right)\int_0^2 u^2e^{-u}\,du$$

The constant in front simplifies to $\frac{1}{2}$ and the formula in the margin gives us

$$P = \frac{1}{2}\int_0^2 u^2e^{-u}\,du = \frac{1}{2}\left(-(u^2+2u+2)e^{-u}\right)\Big|_0^2 = \frac{1}{2}\left(2 - 10e^{-2}\right) \approx 0.32$$

Thus, the electron within a distance a_0 of the nucleus with probability 0.32.

14. Show that the distance r between the electron and the nucleus in Exercise 13 has mean $\mu = 3a_0/2$.

SOLUTION The mean of the distribution is

$$\mu = \int_0^{\infty} rp(r)\,dr = \int_0^{\infty} r\cdot 4a_0^{-3}r^2e^{-2r/a_0}\,dr = \frac{4}{a_0^3}\int_0^{\infty} r^3e^{-2r/a_0}\,dr$$

To calculate this integral, use as before the substitution $x = 2r/a_0$ to get

$$\mu = \frac{4}{a_0^3}\cdot\frac{a_0^3}{8}\cdot\frac{a_0}{2}\int_0^{\infty} x^3e^{-x}\,dx = \frac{a_0}{4}\int_0^{\infty} x^3e^{-x}\,dx$$

To calculate this integral, we use integration by parts, with $u = x^3$, $v' = e^{-x}$, so that $u' = 3x^2$ and $v = -e^{-x}$; then

$$\mu = \frac{a_0}{4}\left(-x^3e^{-x}\Big|_0^{\infty} + 3\int_0^{\infty} x^2e^{-x}\,dx\right)$$

The first term is evaluated as follows, using L'Hôpital's Rule multiple times:

$$-x^3e^{-x}\Big|_0^{\infty} = \lim_{R\to\infty}\left(-x^3e^{-x}\right)\Big|_0^R = \lim_{R\to\infty}\left(-\frac{R^3}{e^R}\right)$$
$$= \lim_{R\to\infty}\left(-\frac{3R^2}{e^R}\right) = \lim_{R\to\infty}\left(-\frac{6R}{e^R}\right) = \lim_{R\to\infty}\left(-\frac{6}{e^R}\right) = 0$$

The second term, by the marginal note in the previous problem, is

$$\int_0^{\infty} x^2e^{-x}\,dx = \lim_{R\to\infty}\left((-u^2+2u+2)e^{-u}\right)\Big|_0^R = \lim_{R\to\infty}\left(2-\frac{-R^2+2R+2}{e^R}\right) = 2$$

using L'Hôpital's Rule as in the previous formulas. Thus, finally,

$$\mu = \frac{a_0}{4}(0+3\cdot 2) = \frac{3}{2}a_0$$

In Exercises 15–21, $F(z)$ denotes the cumulative normal distribution function. Refer to a calculator, computer algebra system, or online resource to obtain values of $F(z)$.

15. Express the area of region A in Figure 8 in terms of $F(z)$ and compute its value.

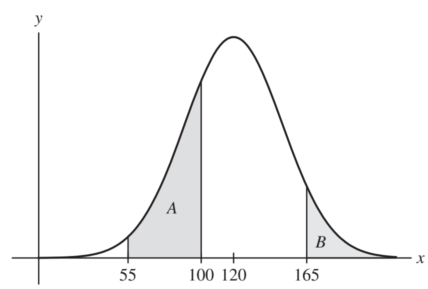

FIGURE 8 Normal density function with $\mu = 120$ and $\sigma = 30$.

SOLUTION The area of region A is $P(55 \le X \le 100)$. By Theorem 1, we have

$$P(55 \le X \le 100) = F\left(\frac{100-120}{30}\right) - F\left(\frac{55-120}{30}\right) = F\left(-\frac{2}{3}\right) - F\left(-\frac{13}{6}\right) \approx 0.237$$

16. Show that the area of region B in Figure 8 is equal to $1 - F(1.5)$ and compute its value. Verify numerically that this area is also equal to $F(-1.5)$ and explain why graphically.

SOLUTION The area of region B is $P(X \ge 165)$, and $P(X \ge 165) + P(X \le 165) = 1$. But by Theorem 1,

$$P(X \le 165) = F\left(\frac{165-120}{30}\right) = F(1.5)$$

so that

$$P(X \ge 165) = 1 - P(X \le 165) = 1 - F(1.5) \approx 0.0668$$

Using a computer algebra system, we also get $F(-1.5) \approx 0.0668$. Graphically, since the density function $p(x)$ is symmetric around $x = 120$, we see that the area to the right of $x = 165$ is equal to the area to the left of $x = 120 - (165 - 120) = 75$; this area is

$$F\left(\frac{75-120}{30}\right) = F\left(\frac{-45}{30}\right) = F(-1.5)$$

17. Assume X has a standard normal distribution ($\mu = 0, \sigma = 1$). Find:

(a) $P(X \le 1.2)$ **(b)** $P(X \ge -0.4)$

SOLUTION

(a) $P(X \le 1.2) = F(1.2) \approx 0.8849$

(b) $P(X \ge -0.4) = 1 - P(X \le -0.4) = 1 - F(-0.4) \approx 1 - 0.3446 \approx 0.6554$

18. Evaluate numerically: $\dfrac{1}{3\sqrt{2\pi}}\displaystyle\int_{14.5}^{\infty} e^{-(z-10)^2/18}\,dz$.

SOLUTION This is the area to the right of 14.5 under the cumulative distribution function for a normal distribution with $\mu = 10$ and $\sigma = 3$. In terms of the standard normal cumulative distribution function $F(z)$, this is

$$P(X \ge 14.5) = 1 - P(X \le 14.5) = 1 - F\left(\frac{14.5-10}{3}\right) = 1 - F(1.5) \approx 0.0668$$

19. Use a graph to show that $F(-z) = 1 - F(z)$ for all z. Then show that if $p(x)$ is a normal density function with mean μ and standard deviation σ, then for all $r \ge 0$,

$$P(\mu - r\sigma \le X \le \mu + r\sigma) = 2F(r) - 1$$

SOLUTION Consider the graph of the standard normal density function in Figure 5. This graph is symmetric around the y-axis, so that the area under the curve from z to ∞, which is $1 - F(z)$, is equal to the area under the curve from $-\infty$ to $-z$, which is $F(-z)$. Thus $1 - F(z) = F(-z)$. Now, if $p(x)$ is a normal density function with mean μ and standard deviation σ, then for $r \ge 0$ (so that the range $\mu - r\sigma \le X \le \mu + r\sigma$ is nonempty),

$$\begin{aligned} P(\mu - r\sigma \le X \le \mu + r\sigma) &= F\left(\frac{\mu + r\sigma - \mu}{\sigma}\right) - F\left(\frac{\mu - r\sigma - \mu}{\sigma}\right) \\ &= F(r) - F(-r) = F(r) - (1 - F(r)) = 2F(r) - 1 \end{aligned}$$

20. The average September rainfall in Erie, Pennsylvania, is a random variable X with mean $\mu = 102$ mm. Assume that the amount of rainfall is normally distributed with standard deviation $\sigma = 48$.

(a) Express $P(128 \le X \le 150)$ in terms of $F(z)$ and compute its value numerically.

(b) Let P be the probability that September rainfall will be at least 120 mm. Express P as an integral of an appropriate density function and compute its value numerically.

SOLUTION

(a)

$$P(128 \le X \le 150) = F\left(\frac{150-102}{48}\right) - F\left(\frac{128-102}{48}\right) = F(1) - F\left(\frac{13}{24}\right) \approx 0.135$$

(b) The cumulative density function associated with X is

$$f(z) = \frac{1}{48\sqrt{2\pi}}\int_{-\infty}^{z} e^{-(x-102)^2/(2\cdot 48^2)}\,dx$$

To compute the value numerically, we use the standard normal cumulative distribution $F(z)$. Recall that $P(X \ge 120) = 1 - P(X \le 120)$, and that

$$P(X \le 120) = F\left(\frac{120-102}{48}\right) = F\left(\frac{3}{8}\right) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{3/8} e^{-x^2/2}\,dx \approx 0.646$$

so that $P(X \ge 120) \approx 1 - 0.646 \approx 0.354$.

21. A bottling company produces bottles of fruit juice that are filled, on average, with 32 ounces of juice. Due to random fluctuations in the machinery, the actual volume of juice is normally distributed with a standard deviation of 0.4 ounce. Let P be the probability of a bottle having less than 31 ounces. Express P as an integral of an appropriate density function and compute its value numerically.

SOLUTION The associated cumulative distribution function is

$$f(z) = \frac{1}{0.4\sqrt{2\pi}}\int_{-\infty}^{z} e^{-(x-32)^2/(2\cdot 0.4^2)}\,dx$$

To compute the value numerically, we use the standard normal cumulative distribution function $F(z)$:

$$P(X \le 31) = F\left(\frac{31-32}{0.4}\right) = F\left(-\frac{5}{2}\right) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{-5/2} e^{-x^2/2}\,dx \approx 0.0062$$

22. According to **Maxwell's Distribution Law**, in a gas of molecular mass m, the speed v of a molecule in a gas at temperature T (kelvins) is a random variable with density

$$p(v) = 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2} v^2 e^{-mv^2/(2kT)} \qquad (v \ge 0)$$

where k is Boltzmann's constant. Show that the average molecular speed is equal to $(8kT/\pi m)^{1/2}$. The average speed of oxygen molecules at room temperature is around 450 m/s.

SOLUTION The average speed $\bar{v}$ is given by

$$\bar{v} = \int_0^\infty vp(v)\,dv = 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\int_0^\infty v^3 e^{-mv^2/2kT}\,dv.$$

Let $\alpha = -m/2kT$. We'll first compute the indefinite integral

$$\int v^3 e^{\alpha v^2}\,dv.$$

Using Integration by Parts, let $u = v^2$, $v' = ve^{\alpha v^2}$. Then $u' = 2v$ and $v = \frac{1}{2\alpha}e^{\alpha v^2}$. This gives us

$$\int v^3 e^{\alpha v^2}\,dv = \frac{1}{2\alpha}v^2 e^{\alpha v^2} - \frac{1}{\alpha}\int ve^{\alpha v^2}\,dv.$$

To compute the remaining integral, let $w = \alpha v^2$, $dw = 2\alpha v\,dv$. The result is

$$\int v^3 e^{\alpha v^2}\,dv = \frac{1}{2\alpha}v^2 e^{\alpha v^2} - \frac{1}{2\alpha^2}e^{\alpha v^2} + C.$$

Thus,

$$\int_0^R vp(v)\,dv = 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\left[\frac{e^{\alpha v^2}}{2\alpha}\left(v^2 - \frac{1}{\alpha}\right)\right]_0^R = 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\frac{1}{2\alpha}\left[e^{\alpha R^2}\left(R^2 - \frac{1}{\alpha}\right) + \frac{1}{\alpha}\right],$$

and

$$\bar{v} = \lim_{R\to\infty} 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\frac{1}{2\alpha}\left[e^{\alpha R^2}\left(R^2 - \frac{1}{\alpha}\right) + \frac{1}{\alpha}\right] = 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\frac{1}{2\alpha}\left[\lim_{R\to\infty} e^{\alpha R^2}\left(R^2 - \frac{1}{\alpha}\right) + \frac{1}{\alpha}\right].$$

Use L'Hôpital's Rule to compute the limit, recalling that $\alpha = -m/2kT < 0$:

$$\lim_{R\to\infty} e^{\alpha R^2}\left(R^2 - \frac{1}{\alpha}\right) = \lim_{R\to\infty}\frac{R^2 - \frac{1}{\alpha}}{e^{-\alpha R^2}} = \lim_{R\to\infty}\frac{2R}{-2\alpha Re^{-\alpha R^2}} = \lim_{R\to\infty}\frac{-1}{\alpha e^{-\alpha R^2}} = 0.$$

Thus

$$\bar{v} = 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\frac{1}{2\alpha}\left(0 + \frac{1}{\alpha}\right) = \frac{2\pi}{\alpha^2}\left(\frac{m}{2\pi kT}\right)^{3/2} = 2\pi\left(-\frac{2kT}{m}\right)^2\left(\frac{m}{2\pi kT}\right)\sqrt{\frac{m}{2\pi kT}}$$
$$= \frac{4kT}{m}\sqrt{\frac{m}{2\pi kT}} = \sqrt{\frac{8kT}{\pi m}}.$$

In Exercises 23–26, calculate μ and σ, where σ is the ***standard deviation****, defined by*

$$\sigma^2 = \int_{-\infty}^\infty (x-\mu)^2\,p(x)\,dx$$

The smaller the value of σ, the more tightly clustered are the values of the random variable X about the mean μ.

23. $p(x) = \dfrac{5}{2x^{7/2}}$ on $[1,\infty)$

SOLUTION The mean is

$$\int_1^\infty xp(x)\,dx = \int_1^\infty \frac{5}{2}x^{-5/2}\,dx = -\frac{5}{3}x^{-3/2}\Big|_1^\infty = \frac{5}{3}$$

and

$$\sigma^2 = \int_1^\infty (x-\mu)^2 p(x)\,dx = \int_1^\infty (x^2 - 2\mu x + \mu^2)\frac{5}{2}x^{-7/2}\,dx$$
$$= \frac{5}{2}\int_1^\infty x^{-3/2} - 2\mu x^{-5/2} + \mu^2 x^{-7/2}\,dx = \frac{5}{2}\left(-2x^{-1/2} + \frac{4}{3}\mu x^{-3/2} - \frac{2}{5}\mu^2 x^{-5/2}\right)\Big|_1^\infty$$
$$= \frac{5}{2}\left(2 - \frac{4}{3}\mu + \frac{2}{5}\mu^2\right) = \frac{5}{2}\left(2 - \frac{4}{3}\cdot\frac{5}{3} + \frac{2}{5}\cdot\frac{25}{9}\right) = \frac{20}{9}$$

24. $p(x) = \dfrac{1}{\pi\sqrt{1-x^2}}$ on $(-1, 1)$

SOLUTION Use the substituion $u = 1 - x^2$ so that $du = -2x\,dx$. The mean is

$$\mu = \int_{-1}^{1} \frac{x}{\pi\sqrt{1-x^2}}\,dx = -\frac{1}{2\pi}\int_{x=-1}^{1} \frac{-2x\,dx}{\sqrt{1-x^2}} = -\frac{1}{2\pi}\int_{x=-1}^{1} \frac{1}{\sqrt{u}}\,du$$
$$= -\frac{1}{\pi}\sqrt{u}\bigg|_{x=-1}^{x=1} = -\frac{1}{\pi}\sqrt{1-x^2}\bigg|_{-1}^{1} = 0$$

To compute the standard deviation, use the substitution $x = \sin u$, $dx = \cos u\,du$; then $x = -1$ corresponds to $u = -\pi/2$ and $x = 1$ to $u = \pi/2$:

$$\sigma^2 = \int_{-1}^{1} (x-\mu)^2 p(x) = \frac{1}{\pi}\int_{-1}^{1} \frac{x^2}{\sqrt{1-x^2}}\,dx = \frac{1}{\pi}\int_{-\pi/2}^{\pi/2} \frac{\sin^2 u}{\sqrt{1-\sin^2 u}}\cos u\,du$$
$$= \frac{1}{\pi}\int_{-\pi/2}^{\pi/2} \frac{\sin^2 u}{\cos u}\cos u\,du = \frac{1}{\pi}\int_{-\pi/2}^{\pi/2} \sin^2 u\,du = \frac{1}{2\pi}(u - \cos u \sin u)\bigg|_{-\pi/2}^{\pi/2}$$
$$= \frac{1}{2\pi}\left(\frac{\pi}{2} - \frac{-\pi}{2}\right) = \frac{1}{2}$$

25. $p(x) = \dfrac{1}{3}e^{-x/3}$ on $[0, \infty)$

SOLUTION This is an exponential density function with mean $\mu = 3$. The standard deviation is

$$\sigma^2 = \frac{1}{3}\int_0^\infty (x-3)^2 e^{-x/3}\,dx = \frac{1}{3}\int_0^\infty \left(x^2e^{-x/3} - 6xe^{-x/3} + 9e^{-x/3}\right)dx$$
$$= \frac{1}{3}\int_0^\infty x^2e^{-x/3}\,dx - 2\int_0^\infty xe^{-x/3}\,dx + 3\int_0^\infty e^{-x/3}\,dx$$

We tackle the third integral first:

$$\int_0^\infty e^{-x/3}\,dx = -3e^{-x/3}\bigg|_0^\infty = 3$$

For the second integral, use integration by parts with $u = x$, $v' = e^{-x/3}$ so that $u' = 1$ and $v = -3e^{-x/3}$. Then

$$\int_0^\infty xe^{-x/3}\,dx = -3xe^{-x/3}\bigg|_0^\infty + 3\int_0^\infty e^{-x/3}\,dx = 0 + 3\cdot 3 = 9$$

Finally, the first integral is solved using integration by parts with $u = x^2$, $v' = e^{-x/3}$ so that $u' = 2x$ and $v = -3e^{-x/3}$; then

$$\int_0^\infty x^2e^{-x/3}\,dx = -3x^2e^{-x/3}\bigg|_0^\infty + 6\int_0^\infty xe^{-x/3}\,dx = 0 + 6\cdot 9 = 54$$

and, finally,

$$\sigma^2 = \frac{1}{3}\int_0^\infty x^2e^{-x/3}\,dx - 2\int_0^\infty xe^{-x/3}\,dx + 3\int_0^\infty e^{-x/3}\,dx$$
$$= \frac{1}{3}\cdot 54 - 2\cdot 9 + 3\cdot 3 = 9$$

26. $p(x) = \dfrac{1}{r}e^{-x/r}$ on $[0, \infty)$, where $r > 0$

SOLUTION This is similar to the previous problem. We have an exponential density function with mean $\mu = r$. The standard deviation is

$$\sigma^2 = \frac{1}{r}\int_0^\infty (x-r)^2 e^{-x/r}\,dx = \frac{1}{r}\int_0^\infty \left(x^2e^{-x/r} - 2rxe^{-x/r} + r^2e^{-x/r}\right)dx$$
$$= \frac{1}{r}\int_0^\infty x^2e^{-x/r}\,dx - 2\int_0^\infty xe^{-x/r}\,dx + r\int_0^\infty e^{-x/r}\,dx$$

We tackle the third integral first:

$$\int_0^\infty e^{-x/r}\,dx = -re^{-x/r}\Big|_0^\infty = r$$

For the second integral, use integration by parts with $u = x$, $v' = e^{-x/r}$ so that $u' = 1$ and $v = -re^{-x/r}$. Then

$$\int_0^\infty xe^{-x/r}\,dx = -rxe^{-x/r}\Big|_0^\infty + r\int_0^\infty e^{-x/r}\,dx = 0 + r\cdot r = r^2$$

Finally, the first integral is solved using integration by parts with $u = x^2$, $v' = e^{-x/r}$ so that $u' = 2x$ and $v = -re^{-x/r}$; then

$$\int_0^\infty x^2e^{-x/r}\,dx = -rx^2e^{-x/r}\Big|_0^\infty + 2r\int_0^\infty xe^{-x/r}\,dx = 0 + 2r\cdot r^2 = 2r^3$$

and, finally,

$$\begin{aligned}\sigma^2 &= \frac{1}{r}\int_0^\infty x^2e^{-x/r}\,dx - 2\int_0^\infty xe^{-x/3}\,dx + r\int_0^\infty e^{-x/3}\,dx\\ &= \frac{1}{r}\cdot 2r^3 - 2\cdot r^2 + r\cdot r = r^2\end{aligned}$$

Further Insights and Challenges

27. The time to decay of an atom in a radioactive substance is a random variable X. The law of radioactive decay states that if N atoms are present at time $t = 0$, then $Nf(t)$ atoms will be present at time t, where $f(t) = e^{-kt}$ ($k > 0$ is the decay constant). Explain the following statements:

(a) The fraction of atoms that decay in a small time interval $[t, t + \Delta t]$ is approximately $-f'(t)\Delta t$.

(b) The probability density function of X is $-f'(t)$.

(c) The average time to decay is $1/k$.

SOLUTION

(a) The number of atoms that decay in the interval $[t, t + \Delta t]$ is just $f(t) - f(t + \Delta t)$; the statement simply says that $f(t) - f(t + \Delta t) \approx -f'(t)\Delta t$, which is the same as saying that

$$f'(t) \approx \frac{f(t) - f(t + \Delta t)}{\Delta t} = \frac{f(t + \Delta t) - f(t)}{\Delta t}$$

which is true by the definition of the derivative. Intuitively, since $f'(t)$ is the instantaneous rate of decay, we would expect that over a short interval, the number of atoms decaying is proportional to both $f'(t)$ and the size of the interval.

(b) The probability density function is defined by the property in (a): the probability that X lies in a small interval $[t, t + \Delta t]$ is approximately $p(t)\Delta t$, so that $p(t) = -f'(t)$.

(c) The average time to decay is the mean of the distribution, which is

$$\mu = \int_0^\infty t\cdot(-f'(t))\,dt = -\int_0^\infty tf'(t)\,dt$$

We compute this integral using integration by parts, with $u = t$, $v' = f'(t)$. Then $u' = 1$, $v = f(t)$, and

$$\mu = -\int_0^\infty tf'(t)\,dt = -tf(t)\Big|_0^\infty + \int_0^\infty f(t)\,dt.$$

Since $f(t) = e^{-kt}$, we have

$$-tf(t)\Big|_0^\infty = \lim_{R\to\infty} -te^{-kt}\Big|_0^R = \lim_{R\to\infty} -Re^{-Rt} + 0 = \lim_{R\to\infty}\frac{-R}{e^{Rt}} = \lim_{R\to\infty}\frac{-1}{Re^{Rt}} = 0.$$

Here we used L'Hôpital's Rule to compute the limit. Thus

$$\mu = \int_0^\infty f(t)\,dt = \int_0^\infty e^{-kt}\,dt.$$

Now,

$$\int_0^R e^{-kt}\,dt = -\frac{1}{k}e^{-kt}\Big|_0^R = -\frac{1}{k}\left(e^{-kR} - 1\right) = \frac{1}{k}\left(1 - e^{-kR}\right),$$

so

$$\mu = \lim_{R\to\infty} \frac{1}{k}\left(1 - e^{-kR}\right) = \frac{1}{k}(1-0) = \frac{1}{k}.$$

Because k has units of $(\text{time})^{-1}$, μ does in fact have the appropriate units of time.

28. The half-life of radon-222, is 3.825 days. Use Exercise 27 to compute:
(a) The average time to decay of a radon-222 atom.
(b) The probability that a given atom will decay in the next 24 hours.

SOLUTION
(a) The average decay time is just the mean, μ; to determine it, we must determine the decay constant k, given the half-life of 3.825 days. Recall that

$$k = \frac{\ln 2}{t_n}$$

where t_n is the half-life. Thus,

$$\mu = \frac{1}{k} = \frac{t_n}{\ln 2} = \frac{3.825}{\ln 2} \approx 5.518 \text{ days.}$$

(b) The probability that a particular atom will decay in the next 24 hours is the area under the probability density function between $t = 0$ and $t = 1$ (note that t is measured in days). Since $f(t) = e^{-kt}$, the probability density function is $-ke^{-kt}$; from part (a), $k \approx 0.1812$, so the required probability is

$$\int_0^1 (-f'(t))\,dt = f(0) - f(1) = 1 - e^{-0.1812} \approx 0.1657$$

7.8 Numerical Integration

Preliminary Questions

1. What are T_1 and T_2 for a function on $[0, 2]$ such that $f(0) = 3$, $f(1) = 4$, and $f(2) = 3$?

SOLUTION Using the given function values

$$T_1 = \frac{1}{2}(2)(3+3) = 6 \quad \text{and} \quad T_2 = \frac{1}{2}(1)(3+8+3) = 7.$$

2. For which graph in Figure 16 will T_N *overestimate* the integral? What about M_N?

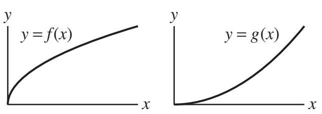

FIGURE 16

SOLUTION T_N overestimates the value of the integral when the integrand is concave up; thus, T_N will overestimate the integral of $y = g(x)$. On the other hand, M_N overestimates the value of the integral when the integrand is concave down; thus, M_N will overestimate the integral of $y = f(x)$.

3. How large is the error when the Trapezoidal Rule is applied to a linear function? Explain graphically.

SOLUTION The Trapezoidal Rule integrates linear functions exactly, so the error will be zero.

4. What is the maximum possible error if T_4 is used to approximate

$$\int_0^3 f(x)\,dx$$

where $|f''(x)| \le 2$ for all x.

SOLUTION The maximum possible error in T_4 is

$$\max|f''(x)|\frac{(b-a)^3}{12n^2} \le \frac{2(3-0)^3}{12(4)^2} = \frac{9}{32}.$$

5. What are the two graphical interpretations of the Midpoint Rule?

SOLUTION The two graphical interpretations of the Midpoint Rule are the sum of the areas of the midpoint rectangles and the sum of the areas of the tangential trapezoids.

Exercises

In Exercises 1–12, calculate T_N and M_N for the value of N indicated.

1. $\int_0^2 x^2\,dx, \quad N = 4$

SOLUTION Let $f(x) = x^2$. We divide $[0, 2]$ into 4 subintervals of width

$$\Delta x = \frac{2-0}{4} = \frac{1}{2}$$

with endpoints 0, 0.5, 1, 1.5, 2, and midpoints 0.25, 0.75, 1.25, 1.75. With this data, we get

$$T_4 = \frac{1}{2}\cdot\frac{1}{2}\left(0^2 + 2(0.5)^2 + 2(1)^2 + 2(1.5)^2 + 2^2\right) = 2.75; \text{ and}$$

$$M_4 = \frac{1}{2}\left(0.25^2 + 0.75^2 + 1.25^2 + 1.75^2\right) = 2.625.$$

2. $\int_0^4 \sqrt{x}\,dx, \quad N = 4$

SOLUTION Let $f(x) = \sqrt{x}$. We divide $[0, 4]$ into 4 subintervals of width

$$\Delta x = \frac{4-0}{4} = 1$$

with endpoints 0, 1, 2, 3, 4, and midpoints 0.5, 1.5, 2.5, 3.5. With this data, we get

$$T_4 = \frac{1}{2}\cdot 1\cdot\left(\sqrt{0} + 2\sqrt{1} + 2\sqrt{2} + 2\sqrt{3} + \sqrt{4}\right) \approx 5.14626; \text{ and}$$

$$M_4 = 1\cdot\left(\sqrt{0.5} + \sqrt{1.5} + \sqrt{2.5} + \sqrt{3.5}\right) \approx 5.38382.$$

3. $\int_1^4 x^3\,dx, \quad N = 6$

SOLUTION Let $f(x) = x^3$. We divide $[1, 4]$ into 6 subintervals of width

$$\Delta x = \frac{4-1}{6} = \frac{1}{2}$$

with endpoints 1, 1.5, 2, 2.5, 3, 3.5, 4, and midpoints 1.25, 1.75, 2.25, 2.75, 3.25, 3.75. With this data, we get

$$T_6 = \frac{1}{2}\left(\frac{1}{2}\right)\left(1^3 + 2(1.5)^3 + 2(2)^3 + 2(2.5)^3 + 2(3)^3 + 2(3.5)^3 + 4^3\right) = 64.6875; \text{ and}$$

$$M_6 = \frac{1}{2}\left(1.25^3 + 1.75^3 + 2.25^3 + 2.75^3 + 3.25^3 + 3.75^3\right) = 63.28125.$$

4. $\int_1^2 \sqrt{x^4+1}\,dx, \quad N = 5$

SOLUTION We divide $[1, 2]$ into 5 subintervals of width

$$\Delta x = \frac{2-1}{5} = \frac{1}{5} = 0.2$$

with endpoints 1, 1.2, 1.4, 1.6, 1.8, 2, and midpoints 1.1, 1.3, 1.5, 1.7, 1.9. With this data, we have

$$T_5 = \frac{1}{2}\cdot\frac{1}{5}\left(\sqrt{1^4+1} + 2\sqrt{1.2^4+1} + 2\sqrt{1.4^4+1} + 2\sqrt{1.6^4+1} + 2\sqrt{1.8^4+1} + \sqrt{2^2+1}\right) \approx 2.57228$$

$$M_5 = \frac{1}{5}\left(\sqrt{1.1^4+1} + \sqrt{1.3^4+1} + \sqrt{1.5^4+1} + \sqrt{1.7^4+1} + \sqrt{1.9^4+1}\right) \approx 2.55994$$

5. $\int_1^4 \frac{dx}{x}, \quad N = 6$

SOLUTION Let $f(x) = 1/x$. We divide $[1, 4]$ into 6 subintervals of width

$$\Delta x = \frac{4-1}{6} = \frac{1}{2}$$

with endpoints 1, 1.5, 2, 2.5, 3, 3.5, 4, and midpoints 1.25, 1.75, 2.25, 2.75, 3.25, 3.75. With this data, we get

$$T_6 = \frac{1}{2}\left(\frac{1}{2}\right)\left(\frac{1}{1} + \frac{2}{1.5} + \frac{2}{2} + \frac{2}{2.5} + \frac{2}{3} + \frac{2}{3.5} + \frac{1}{4}\right) \approx 1.40536; \text{ and}$$

$$M_6 = \frac{1}{2}\left(\frac{1}{1.25} + \frac{1}{1.75} + \frac{1}{2.25} + \frac{1}{2.75} + \frac{1}{3.25} + \frac{1}{3.75}\right) \approx 1.37693.$$

6. $\displaystyle\int_{-2}^{-1} \frac{dx}{x}, \quad N = 5$

SOLUTION Let $f(x) = 1/x$. We divide $[-2, -1]$ into 5 subintervals of width

$$\Delta x = \frac{-1 - (-2)}{5} = \frac{1}{5} = 0.2$$

with endpoints $-2, -1.8, -1.6, -1.4, -1.2, -1$, and midpoints $-1.9, -1.7, -1.5, -1.3, -1.1$. With this data, we get

$$T_5 = \frac{1}{2}\left(\frac{1}{5}\right)\left(\frac{1}{-2} + \frac{2}{-1.8} + \frac{2}{-1.6} + \frac{2}{-1.4} + \frac{2}{-1.2} + \frac{1}{-1}\right) \approx -0.695635; \text{ and}$$

$$M_5 = \frac{1}{5}\left(\frac{1}{-1.9} + \frac{1}{-1.7} + \frac{1}{-1.5} + \frac{1}{-1.3} + \frac{1}{-1.1}\right) \approx -0.691908.$$

7. $\displaystyle\int_{0}^{\pi/2} \sqrt{\sin x}\, dx, \quad N = 6$

SOLUTION Let $f(x) = \sqrt{\sin x}$. We divide $[0, \pi/2]$ into 6 subintervals of width

$$\Delta x = \frac{\frac{\pi}{2} - 0}{6} = \frac{\pi}{12}$$

with endpoints

$$0, \frac{\pi}{12}, \frac{2\pi}{12}, \ldots, \frac{6\pi}{12} = \frac{\pi}{2},$$

and midpoints

$$\frac{\pi}{24}, \frac{3\pi}{24}, \ldots, \frac{11\pi}{24}.$$

With this data, we get

$$T_6 = \frac{1}{2}\left(\frac{\pi}{12}\right)\left(\sqrt{\sin(0)} + 2\sqrt{\sin(\pi/12)} + \cdots + \sqrt{\sin(6\pi/12)}\right) \approx 1.17029; \text{ and}$$

$$M_6 = \frac{\pi}{12}\left(\sqrt{\sin(\pi/24)} + \sqrt{\sin(3\pi/24)} + \cdots + \sqrt{\sin(11\pi/24)}\right) \approx 1.20630.$$

8. $\displaystyle\int_{0}^{\pi/4} \sec x\, dx, \quad N = 6$

SOLUTION Let $f(x) = \sec x$. We divide $[0, \pi/4]$ into 6 subintervals of width

$$\Delta x = \frac{\frac{\pi}{4} - 0}{6} = \frac{\pi}{24}$$

with endpoints

$$0, \frac{\pi}{24}, \frac{2\pi}{24}, \ldots, \frac{6\pi}{24} = \frac{\pi}{4},$$

and midpoints

$$\frac{\pi}{48}, \frac{3\pi}{48}, \ldots, \frac{11\pi}{48}.$$

With this data, we get

$$T_6 = \frac{1}{2}\left(\frac{\pi}{24}\right)\left(\sec(0) + 2\sec(\pi/24) + 2\sec(2\pi/24) + \cdots + \sec(6\pi/24)\right) \approx 0.883387; \text{ and}$$

$$M_6 = \frac{\pi}{24}\left(\sec(\pi/48) + \sec(3\pi/48) + \sec(5\pi/48) + \cdots + \sec(11\pi/48)\right) \approx 0.880369.$$

9. $\int_1^2 \ln x\,dx, \quad N = 5$

SOLUTION Let $f(x) = \ln x$. We divide $[1, 2]$ into 5 subintervals of width

$$\Delta x = \frac{2-1}{5} = \frac{1}{5} = 0.2$$

with endpoints 1, 1.2, 1.4, 1.6, 1.8, 2, and midpoints 1.1, 1.3, 1.5, 1.7, 1.9. With this data, we get

$$T_5 = \frac{1}{2}\left(\frac{1}{5}\right)\left(\ln 1 + 2\ln 1.2 + 2\ln 1.4 + 2\ln 1.6 + 2\ln 1.8 + \ln 2\right) \approx 0.384632; \text{ and}$$

$$M_5 = \frac{1}{5}\left(\ln 1.1 + \ln 1.3 + \ln 1.5 + \ln 1.7 + \ln 1.9\right) \approx 0.387124.$$

10. $\int_2^3 \frac{dx}{\ln x}, \quad N = 5$

SOLUTION Let $f(x) = 1/\ln x$. We divide $[2, 3]$ into 5 subintervals of width

$$\Delta x = \frac{3-2}{5} = \frac{1}{5} = 0.2$$

with endpoints 2, 2.2, 2.4, 2.6, 2.8, 3, and midpoints 2.1, 2.3, 2.5, 2.7, 2.9. With this data, we get

$$T_5 = \frac{1}{2}\left(\frac{1}{5}\right)\left(\frac{1}{\ln 2} + \frac{2}{\ln 2.2} + \frac{2}{\ln 2.4} + \frac{2}{\ln 2.6} + \frac{2}{\ln 2.8} + \frac{1}{\ln 3}\right) \approx 1.12096; \text{ and}$$

$$M_5 = \frac{1}{5}\left(\frac{1}{\ln 2.1} + \frac{1}{\ln 2.3} + \frac{1}{\ln 2.5} + \frac{1}{\ln 2.7} + \frac{1}{\ln 2.9}\right) \approx 1.11716.$$

11. $\int_0^1 e^{-x^2}\,dx, \quad N = 5$

SOLUTION Let $f(x) = e^{-x^2}$. We divide $[0, 1]$ into 5 subintervals of width

$$\Delta x = \frac{1-0}{5} = \frac{1}{5} = 0.2$$

with endpoints

$$0, \frac{1}{5}, \frac{2}{5}, \frac{3}{5}, \frac{4}{5}, 1$$

and midpoints

$$\frac{1}{10}, \frac{3}{10}, \frac{5}{10}, \frac{7}{10}, \frac{9}{10}.$$

With this data, we get

$$T_5 = \frac{1}{2}\left(\frac{1}{5}\right)\left(e^{-0^2} + 2e^{-(1/5)^2} + 2e^{-(2/5)^2} + 2e^{-(3/5)^2} + 2e^{-(4/5)^2} + e^{-1^2}\right) \approx 0.74437; \text{ and}$$

$$M_5 = \frac{1}{5}\left(e^{-(1/10)^2} + e^{-(3/10)^2} + e^{-(5/10)^2} + e^{-(7/10)^2} + e^{-(9/10)^2}\right) \approx 0.74805.$$

12. $\int_{-2}^1 e^{x^2}\,dx, \quad N = 6$

SOLUTION Let $f(x) = e^{x^2}$. We divide $[-2, 1]$ into 6 subintervals of width

$$\Delta x = \frac{1-(-2)}{6} = \frac{3}{6} = \frac{1}{2} = 0.5$$

with endpoints $-2, -1.5, -1, -0.5, 0, 0.5, 1$, and midpoints $-1.75, -1.25, -0.75, -0.25, 0.25, 0.75$. With this data, we get

$$T_6 = \frac{1}{2}\left(\frac{1}{2}\right)\left(e^{(-2)^2} + 2e^{(-1.5)^2} + 2e^{(-1)^2} + 2e^{(-0.5)^2} + 2e^{0^2} + 2e^{(0.5)^2} + e^{1^2}\right) \approx 22.2161; \text{ and}$$

$$M_6 = \frac{1}{2}\left(e^{(-1.75)^2} + e^{(-1.25)^2} + e^{(-0.75)^2} + e^{(-0.25)^2} + e^{(0.25)^2} + e^{(0.75)^2}\right) \approx 15.8954.$$

In Exercises 13–22, calculate S_N given by Simpson's Rule for the value of N indicated.

13. $\int_0^4 \sqrt{x}\,dx, \quad N = 4$

SOLUTION Let $f(x) = \sqrt{x}$. We divide $[0, 4]$ into 4 subintervals of width

$$\Delta x = \frac{4-0}{4} = 1$$

with endpoints 0, 1, 2, 3, 4. With this data, we get

$$S_4 = \frac{1}{3}(1)\left(\sqrt{0} + 4\sqrt{1} + 2\sqrt{2} + 4\sqrt{3} + \sqrt{4}\right) \approx 5.25221.$$

14. $\int_3^5 (9 - x^2)\,dx, \quad N = 4$

SOLUTION Let $f(x) = 9 - x^2$. We divide $[3, 5]$ into 4 subintervals of length

$$\Delta x = \frac{5-3}{4} = \frac{2}{4} = \frac{1}{2} = 0.5$$

with endpoints 3, 3.5, 4, 4.5, 5. With this data, we get

$$S_4 = \frac{1}{3}\left(\frac{1}{2}\right)\left[(9-3^2) + 4(9-3.5^2) + 2(9-4^2) + 4(9-4.5^2) + (9-5^2)\right] \approx -14.6667.$$

15. $\int_0^3 \frac{dx}{x^4+1}, \quad N = 6$

SOLUTION Let $f(x) = 1/(x^4 + 1)$. We divide $[0, 3]$ into 6 subintervals of length

$$\Delta x = \frac{3-0}{6} = \frac{1}{2} = 0.5$$

with endpoints 0, 0.5, 1, 1.5, 2, 2.5, 3. With this data, we get

$$S_6 = \frac{1}{3}\left(\frac{1}{2}\right)\left[\frac{1}{0^4+1} + \frac{4}{0.5^4+1} + \frac{2}{1^4+1} + \frac{4}{1.5^4+1} + \frac{2}{2^4+1} + \frac{4}{2.5^4+1} + \frac{1}{3^4+1}\right] \approx 1.10903.$$

16. $\int_0^1 \cos(x^2)\,dx, \quad N = 6$

SOLUTION Let $f(x) = \cos(x^2)$. We divide $[0, 1]$ into 6 subintervals of length

$$\Delta x = \frac{1-0}{6} = \frac{1}{6}$$

with endpoints $0, \frac{1}{6}, \frac{2}{6}, \dots, \frac{6}{6} = 1$. With this data, we get

$$S_6 = \frac{1}{3}\left(\frac{1}{6}\right)\left[\cos\left(0^2\right) + 4\cos\left(\left(\frac{1}{6}\right)^2\right) + 2\cos\left(\left(\frac{2}{6}\right)^2\right) + \cdots + 4\cos\left(\left(\frac{5}{6}\right)^2\right) + \cos\left(1^2\right)\right] \approx 0.904523.$$

17. $\int_0^1 e^{-x^2}\,dx, \quad N = 4$

SOLUTION Let $f(x) = e^{-x^2}$. We divide $[0, 1]$ into 4 subintervals of length

$$\Delta x = \frac{1-0}{4} = \frac{1}{4}$$

with endpoints $0, \frac{1}{4}, \frac{2}{4}, \frac{3}{4}, \frac{4}{4} = 1$. With this data, we get

$$S_4 = \frac{1}{3}\left(\frac{1}{4}\right)\left[e^{-0^2} + 4e^{-(1/4)^2} + 2e^{-(2/4)^2} + 4e^{-(3/4)^2} + e^{-(1)^2}\right] \approx 0.746855.$$

18. $\int_1^2 e^{-x}\,dx, \quad N = 6$

SOLUTION Let $f(x) = e^{-x}$. We divide $[1, 2]$ into 6 subintervals of width

$$\Delta x = \frac{2-1}{6} = \frac{1}{6}$$

with endpoints $1, \frac{7}{6}, \frac{8}{6}, \frac{9}{6}, \ldots, \frac{12}{6} = 2$. With this data, we get

$$S_6 = \frac{1}{3}\left(\frac{1}{6}\right)\left[e^{-1} + 4e^{-7/6} + 2e^{-8/6} + 4e^{-9/6} + 2e^{-10/6} + 4e^{-11/6} + e^{-12/6}\right] \approx 0.232545.$$

19. $\int_1^4 \ln x\,dx, \quad N = 8$

SOLUTION Let $f(x) = \ln x$. We divide [1, 4] into 8 subintervals of length

$$\Delta x = \frac{4-1}{8} = \frac{3}{8} = 0.375$$

with endpoints 1, 1.375, 1.75, 2.125, 2.5, 2.875, 3.25, 3.625, 4. With this data, we get

$$S_8 = \frac{1}{3}\left(\frac{3}{8}\right)\left[\ln 1 + 4\ln(1.375) + 2\ln(1.75) + \cdots + 4\ln(3.625) + \ln 4\right] \approx 2.54499.$$

20. $\int_2^4 \sqrt{x^4+1}\,dx, \quad N = 8$

SOLUTION Let $f(x) = \sqrt{x^4+1}$. We divide [2, 4] into 8 subintervals of width

$$\Delta x = \frac{4-2}{8} = \frac{2}{8} = \frac{1}{4} = 0.25$$

with endpoints 2, 2.25, 2.5, 2.75, 3, 3.25, 3.5, 3.75, 4. With this data, we get

$$S_8 = \frac{1}{3}\left(\frac{1}{4}\right)\left[\sqrt{2^4+1} + 4\sqrt{(2.25)^4+1} + 2\sqrt{(2.5)^4+1} + \cdots + 4\sqrt{(3.75)^4+1} + \sqrt{4^4+1}\right] \approx 18.7909.$$

21. $\int_0^{\pi/4} \tan\theta\,d\theta, \quad N = 10$

SOLUTION Let $f(\theta) = \tan\theta$. We divide $[0, \frac{\pi}{4}]$ into 10 subintervals of width

$$\Delta\theta = \frac{\frac{\pi}{4} - 0}{10} = \frac{\pi}{40}$$

with endpoints $0, \frac{\pi}{40}, \frac{2\pi}{40}, \frac{3\pi}{40}, \ldots, \frac{10\pi}{40} = \frac{\pi}{4}$. With this data, we get

$$S_{10} = \frac{1}{3}\left(\frac{\pi}{40}\right)\left[\tan(0) + 4\tan\left(\frac{\pi}{40}\right) + 2\tan\left(\frac{2\pi}{40}\right) + \cdots + 4\tan\left(\frac{9\pi}{40}\right) + \tan\left(\frac{10\pi}{40}\right)\right] \approx 0.346576.$$

22. $\int_0^2 (x^2+1)^{-1/3}\,dx, \quad N = 10$

SOLUTION Let $f(x) = (x^2+1)^{-1/3}$. We divide [0, 2] into 10 subintervals of width

$$\Delta x = \frac{2-0}{10} = \frac{1}{5} = 0.2$$

with endpoints 0, 0.2, 0.4, 0.6, 0.8, 1, 1.2, 1.4, 1.6, 1.8, 2. With this data, we get

$$S_{10} = \frac{1}{3}\cdot\frac{1}{5}\Big[(0^2+1)^{-1/3} + 4(0.2^2+1)^{-1/3} + 2(0.4^2+1)^{-1/3} + \cdots + 4(1.8^2+1)^{-1/3} + (2^2+1)^{-1/3}\Big] \approx 1.598005$$

In Exercises 23–26, calculate the approximation to the volume of the solid obtained by rotating the graph around the given axis.

23. $y = \cos x; \quad [0, \frac{\pi}{2}]; \quad x\text{-axis}; \quad M_8$

SOLUTION Using the disk method, the volume is given by

$$V = \int_0^{\pi/2} \pi r^2\,dx = \pi\int_0^{\pi/2} (\cos x)^2\,dx$$

which can be estimated as

$$\pi \int_0^{\pi/2} (\cos x)^2\, dx \approx \pi[M_8].$$

Let $f(x) = \cos^2 x$. We divide $[0, \pi/2]$ into 8 subintervals of length

$$\Delta x = \frac{\frac{\pi}{2} - 0}{8} = \frac{\pi}{16}$$

with midpoints

$$\frac{\pi}{32}, \frac{3\pi}{32}, \frac{5\pi}{32}, \dots, \frac{15\pi}{32}.$$

With this data, we get

$$V \approx \pi[M_8] = \pi\left[\Delta x(y_1 + y_2 + \cdots + y_8)\right] = \frac{\pi^2}{16}\left[\cos^2\left(\frac{\pi}{32}\right) + \cos^2\left(\frac{3\pi}{32}\right) + \cdots + \cos^2\left(\frac{15\pi}{32}\right)\right] \approx 2.46740.$$

24. $y = \cos x$; $\left[0, \frac{\pi}{2}\right]$; y-axis; S_8

SOLUTION Using the cylindrical shell method, the volume is given by

$$V = \int_0^{\pi/2} 2\pi r h\, dx = 2\pi \int_0^{\pi/2} x \cos x\, dx$$

where the radius of the cylinder is $r = x$ and the height is $h = \cos x$. This can be approximated as

$$V = 2\pi \int_0^{\pi/2} x \cos x\, dx \approx 2\pi\left[\, S_8 \,\right],$$

where $f(x) = x \cos x$. We divide $[0, \pi/2]$ into 8 subintervals of length

$$\Delta x = \frac{\frac{\pi}{2} - 0}{8} = \frac{\pi}{16}$$

with endpoints

$$0, \frac{\pi}{16}, \frac{2\pi}{16}, \dots, \frac{8\pi}{16}.$$

With this data, we get

$$V \approx 2\pi[S_8] = 2\pi\left[\frac{1}{3} \cdot \frac{\pi}{16}(y_0 + 4y_1 + 2y_2 + \cdots + 4y_7 + y_8)\right]$$

$$= \frac{\pi^2}{24}\left[0(\cos 0) + 4\frac{\pi}{16}\left(\cos\frac{\pi}{16}\right) + \cdots + \frac{8\pi}{16}\left(\cos\frac{8\pi}{16}\right)\right] \approx 3.58666.$$

25. $y = e^{-x^2}$; $[0, 1]$; x-axis; T_8

SOLUTION Using the disk method, the volume is given by

$$V = \int_0^1 \pi r^2\, dx = \pi \int_0^1 \left(e^{-x^2}\right)^2 dx = \pi \int_0^1 e^{-2x^2}\, dx.$$

We can use the approximation

$$V = \pi \int_0^1 e^{-2x^2}\, dx \approx \pi[T_8],$$

where $f(x) = e^{-2x^2}$. Divide $[0, 1]$ into 8 subintervals of length

$$\Delta x = \frac{1 - 0}{8} = \frac{1}{8},$$

with endpoints

$$0, \frac{1}{8}, \frac{2}{8}, \dots, 1.$$

With this data, we get

$$V \approx \pi[T_8] = \pi\left[\frac{1}{2} \cdot \frac{1}{8}\left(e^{-2(0^2)} + 2e^{-2(1/8)^2} + \cdots + 2e^{-2(7/8)^2} + e^{-2(1)^2}\right)\right] \approx 1.87691.$$

26. $y = e^{-x^2}$; $[0, 1]$; y-axis; S_8

SOLUTION Using the cylindrical shell method, the volume is given by

$$V = \int_0^1 2\pi r h\, dx = 2\pi \int_0^1 x e^{-x^2}\, dx$$

where $r = x$ and $h = e^{-x^2}$. We can use the approximation

$$V = 2\pi \int_0^1 x e^{-x^2}\, dx \approx 2\pi[S_8],$$

where $f(x) = xe^{-x^2}$. Divide $[0, 1]$ into 8 subintervals of length

$$\Delta x = \frac{1-0}{8} = \frac{1}{8},$$

with endpoints

$$0,\ \frac{1}{8},\ \frac{2}{8}, \ldots, 1.$$

With this data, we get

$$V \approx 2\pi[S_8] = 2\pi\left(\frac{1}{3}\right)\left(\frac{1}{8}\right)\left[(0)e^{-(0^2)} + 4\left(\frac{1}{8}\right)e^{-(1/8)^2} + \cdots + 4\left(\frac{7}{8}\right)e^{-(7/8)^2} + e^{-1^2}\right] \approx 1.98595.$$

27. An airplane's velocity is recorded at 5-min intervals during a 1-hour period with the following results, in miles per hour:

550,	575,	600,	580,	610,	640,	625,
595,	590,	620,	640,	640,	630	

Use Simpson's Rule to estimate the distance traveled during the hour.

SOLUTION The distance traveled is equal to the integral $\int_0^1 v(t)\, dt$, where t is in hours. Since 5 minutes is $1/12$ of an hour, we have $\Delta t = 1/12$. Simpson's Rule gives us

$$S_{12} = \frac{1}{3} \cdot \frac{1}{12}\Big[550 + 4 \cdot 575 + 2 \cdot 600 + 4 \cdot 580 + 2 \cdot 610 + \cdots + 4 \cdot 640 + 630\Big] \approx 608.611.$$

The distance traveled during the hour is approximately 608.6 miles.

28. Use Simpson's Rule to determine the average temperature in a museum over a 3-hour period, if the temperatures (in degrees Celsius), recorded at 15-min intervals, are

21,	21.3,	21.5,	21.8,	21.6,	21.2,	20.8,
20.6,	20.9,	21.2,	21.1,	21.3,	21.2	

SOLUTION If $T(t)$ represents the temperature at time t, then the average temperature T_{ave} from $t = 0$ to $t = 3$ hours is given by

$$T_{\text{ave}} = \frac{1}{3-0}\int_0^3 T(t)\, dt.$$

To use Simpson's Rule to approximate this, let $\Delta t = 1/4$ (15 minute intervals). Then we have

$$T_{\text{ave}} = \frac{1}{3}[S_{12}] = \frac{1}{3} \cdot \frac{1}{3} \cdot \frac{1}{4}\Big[21 + 4 \cdot 21.3 + 2 \cdot 21.5 + \cdots + 4 \cdot 21.3 + 21.2\Big] \approx 21.2111.$$

The average temperature is approximately 21.2° C.

29. **Tsunami Arrival Times** Scientists estimate the arrival times of tsunamis (seismic ocean waves) based on the point of origin P and ocean depths. The speed s of a tsunami in miles per hour is approximately $s = \sqrt{15d}$, where d is the ocean depth in feet.

(a) Let $f(x)$ be the ocean depth x miles from P (in the direction of the coast). Argue using Riemann sums that the time T required for the tsunami to travel M miles toward the coast is

$$T = \int_0^M \frac{dx}{\sqrt{15 f(x)}}$$

(b) Use Simpson's Rule to estimate T if $M = 1000$ and the ocean depths (in feet), measured at 100-mile intervals starting from P, are

13,000, 11,500, 10,500, 9000, 8500,
7000, 6000, 4400, 3800, 3200, 2000

SOLUTION

(a) At a given distance from shore, say, x_i, the speed of the tsunami in mph is $s = \sqrt{15 f(x_i)}$. If we assume the speed s is constant over a small interval Δx, then the time to cover that interval at that speed is

$$t_i = \frac{\text{distance}}{\text{speed}} = \frac{\Delta x}{\sqrt{15 f(x_i)}}.$$

Now divide the interval $[0, M]$ into N subintervals of length Δx. The total time T is given by

$$T = \sum_{i=1}^{N} t_i = \sum_{i=1}^{N} \frac{\Delta x}{\sqrt{15 f(x_i)}}.$$

Taking the limit as $N \to \infty$, we get

$$T = \int_0^M \frac{dx}{\sqrt{15 f(x)}}.$$

(b) We have $\Delta x = 100$. Simpson's Rule gives us

$$S_{10} = \frac{1}{3} \cdot 100 \left[\frac{1}{\sqrt{15(13{,}000)}} + \frac{4}{\sqrt{15(11{,}500)}} + \cdots + \frac{1}{\sqrt{15(2000)}} \right] \approx 3.347.$$

It will take the tsunami about 3 hours and 21 minutes to reach shore.

30. Use S_8 to estimate $\displaystyle\int_0^{\pi/2} \frac{\sin x}{x}\, dx$, taking the value of $\dfrac{\sin x}{x}$ at $x = 0$ to be 1.

SOLUTION Divide $[0, \pi/2]$ into 8 subintervals of length

$$\Delta x = \frac{\frac{\pi}{2} - 0}{8} = \frac{\pi}{16}$$

with endpoints

$$0,\ \frac{\pi}{16},\ \frac{2\pi}{16},\ \ldots,\ \frac{8\pi}{16}.$$

Taking the value of $(\sin x)/x$ at $x = 0$ to be 1, we get

$$S_8 = \frac{1}{3}\left(\frac{\pi}{16}\right)\left[1 + 4\frac{\sin(\pi/16)}{\pi/16} + 2\frac{\sin(2\pi/16)}{2\pi/16} + \cdots + \frac{\sin(\pi/2)}{\pi/2}\right] \approx 1.37076.$$

31. Calculate T_6 for the integral $I = \displaystyle\int_0^2 x^3\, dx$.

(a) Is T_6 too large or too small? Explain graphically.

(b) Show that $K_2 = |f''(2)|$ may be used in the error bound and find a bound for the error.

(c) Evaluate I and check that the actual error is less than the bound computed in (b).

SOLUTION Let $f(x) = x^3$. Divide $[0, 2]$ into 6 subintervals of length $\Delta x = \frac{2-0}{6} = \frac{1}{3}$ with endpoints $0, \frac{1}{3}, \frac{2}{3}, \ldots, 2$. With this data, we get

$$T_6 = \frac{1}{2} \cdot \frac{1}{3}\left[0^3 + 2\left(\frac{1}{3}\right)^3 + 2\left(\frac{2}{3}\right)^3 + 2\left(\frac{3}{3}\right)^3 + 2\left(\frac{4}{3}\right)^3 + 2\left(\frac{5}{3}\right)^3 + (1)2^3\right] \approx 4.11111.$$

(a) Since x^3 is concave up on $[0, 2]$, T_6 is too large.

(b) We have $f'(x) = 3x^2$ and $f''(x) = 6x$. Since $|f''(x)| = |6x|$ is *increasing* on $[0, 2]$, its maximum value occurs at $x = 2$ and we may take $K_2 = |f''(2)| = 12$. Then

$$\text{Error}(T_6) \le \frac{K_2(b-a)^3}{12N^2} = \frac{12(2-0)^3}{12(6)^2} = \frac{2}{9} \approx 0.22222.$$

(c) The exact value is

$$\int_0^2 x^3\,dx = \frac{1}{4}x^4\Big|_0^2 = \frac{1}{4}(16-0) = 4.$$

We can use this to compute the actual error:

$$\text{Error}(T_6) = |T_6 - 4| \approx |4.11111 - 4| \approx 0.11111.$$

Since $0.11111 < 0.22222$, the actual error is indeed less than the maximum possible error.

32. Calculate M_4 for the integral $I = \int_0^1 x\sin(x^2)\,dx$.

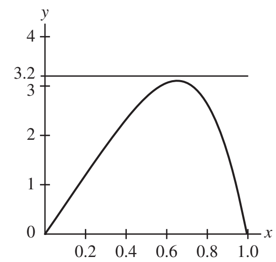
(a) GU Use a plot of $f''(x)$ to show that $K_2 = 3.2$ may be used in the error bound and find a bound for the error.

(b) CAS Evaluate I numerically and check that the actual error is less than the bound computed in (a).

SOLUTION Let $f(x) = x\sin(x^2)$. Divide [0, 1] into 4 subintervals of length $\Delta x = \frac{1-0}{4} = \frac{1}{4} = 0.25$, with endpoint 0, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and 1 and midpoints $\frac{1}{8}$, $\frac{3}{8}$, $\frac{5}{8}$, and $\frac{7}{8}$. With this data, we get

$$M_4 = \frac{1}{4}\left[\frac{1}{8}\sin((1/8)^2) + \frac{3}{8}\sin((3/8)^2) + \frac{5}{8}\sin((5/8)^2) + \frac{7}{8}\sin((7/8)^2)\right] \approx 0.224714$$

(a) Consider the following plot of $f''(x) = 6x\cos(x^2) - 4x^3\sin(x^2)$:



From this figure, it is clear that $f''(x)$ is bounded above (in absolute value) by 3.2, so we can choose $K_2 = 3.2$ in the error bound formula. With this choice, the bound for the error in the M_4 approximation is

$$\text{Error}(M_4) \le K_2 \cdot \frac{(b-a)^3}{24N^2} = 3.2 \cdot \frac{(1-0)^3}{24 \cdot 4^2} = \frac{3.2}{384} \approx 0.008333 \approx 8.333 \times 10^{-3}$$

(b) Using a computer algebra system, $I \approx 0.2298488$, so the actual error is

$$\approx 0.2298488 - 0.224714 = 0.005135 < 0.008333$$

In Exercises 33–36, state whether T_N or M_N underestimates or overestimates the integral and find a bound for the error (but do not calculate T_N or M_N).

33. $\int_1^4 \frac{1}{x}\,dx$, $\quad T_{10}$

SOLUTION Let $f(x) = \frac{1}{x}$. Then $f'(x) = \frac{-1}{x^2}$ and $f''(x) = \frac{2}{x^3} > 0$ on [1, 4], so $f(x)$ is concave up, and T_{10} overestimates the integral. Since $|f''(x)| = |\frac{2}{x^3}|$ has its maximum value on [1, 4] at $x = 1$, we can take $K_2 = \frac{2}{1^3} = 2$, and

$$\text{Error}(T_{10}) \le \frac{K_2(4-1)^3}{12N^2} = \frac{2(3)^3}{12(10)^2} = 0.045.$$

34. $\int_0^2 e^{-x/4}\,dx$, $\quad T_{20}$

SOLUTION Let $f(x) = e^{-x/4}$. Then $f'(x) = -(1/4)e^{-x/4}$ and

$$f''(x) = \frac{1}{16}e^{-x/4} > 0$$

on [0, 2], so $f(x)$ is concave up, and T_{20} overestimates the integral. Since $|f''(x)| = |(1/16)e^{-x/4}|$ has its maximum value on [0, 2] at $x = 0$, we can take $K_2 = |(1/16)e^0| = 1/16$, and

$$\text{Error}(T_{20}) \le \frac{K_2(2-0)^3}{12N^2} = \frac{\frac{1}{16}(2)^3}{12(20)^2} = 1.04167 \times 10^{-4}.$$

35. $\int_1^4 \ln x\,dx, \quad M_{10}$

SOLUTION Let $f(x) = \ln x$. Then $f'(x) = 1/x$ and

$$f''(x) = -\frac{1}{x^2} < 0$$

on $[1, 4]$, so $f(x)$ is concave down, and M_{10} overestimates the integral. Since $|f''(x)| = |-1/x^2|$ has its maximum value on $[1, 4]$ at $x = 1$, we can take $K_2 = |-1/1^2| = 1$, and

$$\text{Error}(M_{10}) \le \frac{K_2(4-1)^3}{24N^2} = \frac{(1)(3)^3}{24(10)^2} = 0.01125.$$

36. $\int_0^{\pi/4} \cos x, \quad M_{20}$

SOLUTION Let $f(x) = \cos x$. Then $f'(x) = -\sin x$ and $f''(x) = -\cos x < 0$ on $[0, \pi/4]$, so $f(x)$ is concave down, and M_{20} overestimates the integral. Since $|f''(x)| = |-\cos x|$ has its maximum value on $[0, \pi/4]$ at $x = 0$, we can take $K_2 = |-\cos(0)| = 1$, and

$$\text{Error}(M_{20}) \le \frac{K_2(\pi/4-0)^3}{24N^2} = \frac{(1)(\pi/4)^3}{24(20)^2} = 5.04659 \times 10^{-5}.$$

CAS *In Exercises 37–40, use the error bound to find a value of N for which Error(T_N) $\le 10^{-6}$. If you have a computer algebra system, calculate the corresponding approximation and confirm that the error satisfies the required bound.*

37. $\int_0^1 x^4\,dx$

SOLUTION Let $f(x) = x^4$. Then $f'(x) = 4x^3$ and $|f''(x)| = |12x^2|$, which has its maximum value on $[0, 1]$ at $x = 1$, so we can take $K_2 = |12(1)^2| = 12$. Then we have

$$\text{Error}(T_N) \le \frac{K_2(1-0)^3}{12N^2} = \frac{12}{12N^2} = \frac{1}{N^2}.$$

To ensure that the error is at most 10^{-6}, we must choose N such that

$$\frac{1}{N^2} \le \frac{1}{10^6}.$$

This gives $N^2 \ge 10^6$ or $N \ge 10^3$. Thus let $N = 1000$. The exact value of the integral is

$$\int_0^1 x^4\,dx = \left.\frac{x^5}{5}\right|_0^1 = \frac{1}{5} = 0.2.$$

Using a CAS, we find that

$$T_{1000} \approx 0.2000003333.$$

The actual error is approximately $|0.2000003333 - 0.2| \approx 3.333 \times 10^{-7}$, and is indeed less than 10^{-6}.

38. $\int_0^3 (5x^4 - x^5)\,dx$

SOLUTION Let $f(x) = 5x^4 - x^5$. Then $f'(x) = 20x^3 - 5x^4$ and $f''(x) = 60x^2 - 20x^3$. A plot reveals that $f''(x) \ge 0$ on $[0, 3]$; it achieves its maximum value where its derivative is zero, which is where $120x - 60x^2 = 0$, so $x = 2$. $|f''(2)| = |60 \cdot 2^2 - 20 \cdot 2^3| = 80$, so we may take $K_2 = 80$ in the error bound approximation. Then we have

$$\text{Error}(T_N) \le \frac{K_2(3-0)^3}{12N^2} = \frac{180}{N^2}$$

To ensure that the error is at most 10^{-6}, we must choose N such that

$$\frac{180}{N^2} \le 10^{-6}, \qquad \text{or} \quad N^2 \ge 180 \times 10^6 = 1.8 \times 10^8$$

Thus $N \ge \sqrt{1.8} \times 10^4 \approx 1.34164 \times 10^4$, so let $N = 13{,}417$. Using a computer algebra system, we get

$$T_{13417} \approx 121.5000006000$$

The true value of the integral is

$$I = \int_0^3 \left(5x^4 - x^5\right)\,dx = \left(x^5 - \frac{1}{6}x^6\right)\Big|_0^3 = 121.5$$

so that $T_{13417} - I \approx 0.0000006 = 6 \times 10^{-7} < 10^{-6}$.

39. $\displaystyle\int_2^5 \frac{1}{x}\,dx$

SOLUTION Let $f(x) = 1/x$. Then $f'(x) = -1/x^2$ and $|f''(x)| = |2/x^3|$, which has its maximum value on $[2, 5]$ at $x = 2$, so we can take $K_2 = |2/2^3| = 1/4$. Then we have

$$\text{Error}(T_N) \le \frac{K_2(5-2)^3}{12N^2} = \frac{(1/4)3^3}{12N^2} = \frac{9}{16N^2}.$$

To ensure that the error is at most 10^{-6}, we must choose N such that

$$\frac{9}{16N^2} \le \frac{1}{10^6}.$$

This gives us

$$N^2 \ge \frac{9 \cdot 10^6}{16} \Rightarrow N \ge \sqrt{\frac{9 \cdot 10^6}{16}} = 750.$$

Thus let $N = 750$. The exact value of the integral is

$$\int_2^5 \frac{1}{x}\,dx = \ln 5 - \ln 2 \approx 0.9162907314.$$

Using a CAS, we find that

$$T_{750} \approx 0.9162910119.$$

The error is approximately

$$|0.9162907314 - 0.9162910119| \approx 2.805 \times 10^{-7}$$

and is indeed less than 10^{-6}.

40. $\displaystyle\int_0^3 e^{-x}\,dx$

SOLUTION Let $f(x) = e^{-x}$. Then $f'(x) = -e^{-x}$ and $|f''(x)| = |e^{-x}| = e^{-x}$, which has its maximum value on $[0, 3]$ at $x = 0$, so we can take $K_2 = e^0 = 1$. Then we have

$$\text{Error}(T_N) \le \frac{K_2(3-0)^3}{12N^2} = \frac{(1)3^3}{12N^2} = \frac{9}{4N^2}.$$

To ensure that the error is at most 10^{-6}, we must choose N such that

$$\frac{9}{4N^2} \le \frac{1}{10^6}.$$

This gives us

$$N^2 \ge \frac{9 \cdot 10^6}{4} \Rightarrow N \ge \sqrt{\frac{9 \cdot 10^6}{4}} = 1500.$$

Thus let $N = 1500$. The exact value of the integral is

$$\int_0^3 e^{-x}\,dx = \left(-e^{-3}\right) - \left(-e^{-0}\right) = 1 - e^{-3} \approx 0.9502129316.$$

Using a CAS, we find that

$$T_{1500} \approx 0.9502132468.$$

The error is approximately

$$|0.9502129316 - 0.9502132468| \approx 3.152 \times 10^{-7}$$

and is indeed less than 10^{-6}.

41. Compute the error bound for the approximations T_{10} and M_{10} to $\int_0^3 (x^3+1)^{-1/2}\,dx$, using Figure 17 to determine a value of K_2. Then find a value of N such that the error in M_N is at most 10^{-6}.

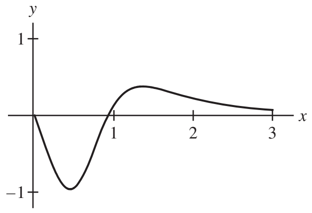


FIGURE 17 Graph of $f''(x)$, where $f(x) = (x^3+1)^{-1/2}$.

SOLUTION Clearly, in the range $0 \le x \le 3$, we have $|f''(x)| \le 1$, so we may choose $K_2 = 1$. Then

$$\text{Error}(T_{10}) \le \frac{K_2(3-0)^3}{12N^2} = \frac{27}{12\cdot 10^2} = \frac{27}{1200} = 0.0225$$

$$\text{Error}(M_{10}) \le \frac{K_2(3-0)^3}{24N^2} = \frac{27}{24\cdot 10^2} = \frac{27}{2400} = 0.01125$$

In order for the error in M_N to be at most 10^{-6}, we must have

$$\text{Error}(M_N) \le \frac{K_2(3-0)^3}{24N^2} = \frac{9}{8N^2} \le 10^{-6}$$

so that $8N^2 \ge 9\times 10^6$ and $N^2 \ge 1{,}125{,}000$. Thus we must choose $N \ge \sqrt{1{,}125{,}000} \approx 1060.7$, so that $N = 1061$.

42. (a) Compute S_6 for the integral $I = \displaystyle\int_0^1 e^{-2x}\,dx$.

(b) Show that $K_4 = 16$ may be used in the error bound and compute the error bound.

(c) Evaluate I and check that the actual error is less than the bound for the error computed in (b).

SOLUTION

(a) Let $f(x) = e^{-2x}$. We divide $[0,1]$ into six subintervals of length $\Delta x = (1-0)/6 = 1/6$, with endpoints $0, 1/6, \ldots, 5/6, 1$. With this data, we get

$$S_6 = \frac{1}{3}\cdot\frac{1}{6}\Big[e^{-2(0)} + 4e^{-2(1/6)} + 2e^{-2(2/6)} + \cdots + e^{-2(1)}\Big] \approx 0.432361.$$

(b) Taking derivatives, we get

$$f'(x) = -2e^{-2x},\ \ f''(x) = 4e^{-2x},\ \ f^{(3)}(x) = -8e^{-2x},\ \ f^{(4)}(x) = 16e^{-2x}.$$

Since $|f^{(4)}(x)| = |16e^{-2x}|$ assumes its maximum value on $[0,1]$ at $x=0$, we can set $K_4 = |16e^0| = 16$. Then we have

$$\text{Error}(S_6) \le \frac{K_4(1-0)^5}{180N^4} = \frac{16}{180\cdot 6^4} \approx 6.86\times 10^{-5}.$$

(c) The exact value of the integral is

$$\int_0^1 e^{-2x}\,dx = \left.\frac{e^{-2x}}{-2}\right|_0^1 = \frac{1-e^{-2}}{2} \approx 0.432332.$$

The actual error is

$$\text{Error}(S_6) \approx |0.432361 - 0.432332| \approx 2.9\times 10^{-5}.$$

The error is indeed less than the maximum possible error.

43. Calculate S_8 for $\int_1^5 \ln x\,dx$ and calculate the error bound. Then find a value of N such that S_N has an error of at most 10^{-6}.

SOLUTION Let $f(x) = \ln x$. We divide $[1,5]$ into eight subintervals of length $\Delta x = (5-1)/8 = 0.5$, with endpoints $1, 1.5, 2, \ldots, 5$. With this data, we get

$$S_8 = \frac{1}{3}\cdot\frac{1}{2}\Big[\ln 1 + 4\ln 1.5 + 2\ln 2 + \cdots + 4\ln 4.5 + \ln 5\Big] \approx 4.046655.$$

To find the maximum possible error, we first take derivatives:

$$f'(x) = \frac{1}{x},\ f''(x) = -\frac{1}{x^2},\ f^{(3)}(x) = \frac{2}{x^3},\ f^{(4)}(x) = -\frac{6}{x^4}.$$

Since $|f^{(4)}(x)| = |-6x^{-4}| = 6x^{-4}$, assumes its maximum value on $[1, 5]$ at $x = 1$, we can set $K_4 = 6(1)^{-4} = 6$. Then we have

$$\text{Error}(S_8) \le \frac{K_4(5-1)^5}{180N^4} = \frac{6 \cdot 4^5}{180 \cdot 8^4} \approx 0.0083333.$$

To ensure that S_N has error at most 10^{-6}, we must find N such that

$$\frac{6 \cdot 4^5}{180N^4} \le \frac{1}{10^6}.$$

This gives us

$$N^4 \ge \frac{6 \cdot 4^5 \cdot 10^6}{180} \Rightarrow N \ge \left(\frac{6 \cdot 4^5 \cdot 10^6}{180}\right)^{1/4} \approx 76.435.$$

Thus let $N = 78$ (remember that N must be even when using Simpson's Rule).

44. Find a bound for the error in the approximation S_{10} to $\int_0^3 e^{-x^2}\,dx$ (use Figure 18 to determine a value of K_4). Then find a value of N such that S_N has an error of at most 10^{-6}.

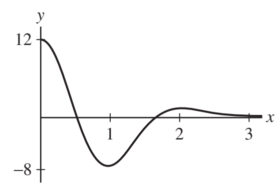

FIGURE 18 Graph of $f^{(4)}(x)$, where $f(x) = e^{-x^2}$.

SOLUTION From the graph, we see that $|f^{(4)}(x)| \le 12$, so we set $K_4 = 12$. This gives us

$$\text{Error}(S_{10}) \le \frac{K_4(3-0)^5}{180N^4} = \frac{12 \cdot 3^5}{180 \cdot 10^4} = 0.00162.$$

To ensure that S_N has error at most 10^{-6}, we must find N such that

$$\frac{12 \cdot 3^5}{180 \cdot N^4} \le \frac{1}{10^6}.$$

This gives us

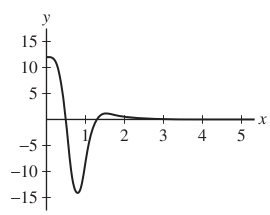
$$N^4 \ge \frac{12 \cdot 3^5 \cdot 10^6}{180} \Rightarrow N \ge \left(\frac{12 \cdot 3^5 \cdot 10^6}{180}\right)^{1/4} \approx 63.44.$$

Thus let $N = 64$.

45. CAS Use a computer algebra system to compute and graph $f^{(4)}(x)$ for $f(x) = \sqrt{1+x^4}$ and find a bound for the error in the approximation S_{40} to $\displaystyle\int_0^5 f(x)\,dx$.

SOLUTION From the graph of $f^{(4)}(x)$ shown below, we see that $|f^{(4)}(x)| \le 15$ on $[0, 5]$. Therefore we set $K_4 = 15$. Now we have

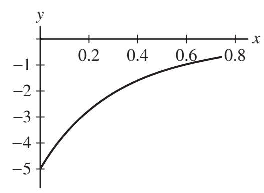
$$\text{Error}(S_{40}) \le \frac{15(5-0)^5}{180(40)^4} = \frac{5}{49152} \approx 1.017 \times 10^{-4}.$$



46. CAS Use a computer algebra system to compute and graph $f^{(4)}(x)$ for $f(x) = \tan x - \sec x$ and find a bound for the error in the approximation S_{40} to $\int_0^{\pi/4} f(x)\,dx$.

SOLUTION From the graph of $f^{(4)}(x)$ shown below, we see that $|f^{(x)}(x)| \le 5$ on $[0, \pi/4]$. Therefore we set $K_4 = 5$. Now we have

$$\text{Error}(S_{40}) \le \frac{5(\pi/4 - 0)^5}{180(40)^4} \approx 3.243 \times 10^{-9}.$$



In Exercises 47–50, use the error bound to find a value of N for which Error(S_N) $\le 10^{-9}$.

47. $\int_1^6 x^{4/3}\,dx$

SOLUTION Let $f(x) = x^{4/3}$. We start by taking derivatives:

$$f'(x) = \frac{4}{3}x^{1/3}$$
$$f''(x) = \frac{4}{9}x^{-2/3}$$
$$f'''(x) = -\frac{8}{27}x^{-5/3}$$
$$f^{(4)}(x) = \frac{40}{81}x^{-8/3}$$

For $x \ge 1$, $f^{(4)}(x)$ is a decreasing function of x, so it takes its maximum value on $[1, 6]$ at $x = 1$. That maximum value is $\frac{40}{81}$, which is quite close to (but smaller than) $\frac{1}{2}$. For simplicity, we take $K_4 = \frac{1}{2}$. Then

$$\text{Error}(S_N) \le \frac{K_4(b-a)^5}{180N^4} = \frac{(6-1)^5}{2 \cdot 180 \cdot N^4} = \frac{5^5}{360N^4} = \frac{625}{72N^4} \le 10^{-9}$$

Thus $72N^4 \ge 625 \times 10^9$, so that

$$N \ge \left(\frac{625 \times 10^9}{72}\right)^{1/4} \approx 305.24$$

so we can take $N = 306$.

48. $\int_0^4 xe^x\,dx$

SOLUTION Let $f(x) = xe^x$. To find K_4, we first take derivatives:

$$f'(x) = xe^x + e^x$$
$$f''(x) = xe^x + 2e^x$$
$$f^{(3)}(x) = xe^x + 3e^x$$
$$f^{(4)}(x) = xe^x + 4e^x.$$

On the interval $[0, 4]$,

$$|f^{(4)}(x)| = |xe^x + 4e^x| \le |4e^4 + 4e^4| = 8e^4.$$

Therefore we set $K_4 = 8e^4$, and we have

$$\text{Error}(S_N) \le \frac{K_4(4-0)^5}{180N^4} = \frac{8e^4 \cdot 4^5}{180N^4}.$$

To ensure that S_N has error at most 10^{-9}, we must find N such that

$$\frac{8e^4 \cdot 4^5}{180N^4} \le \frac{1}{10^9}.$$

This gives us

$$N^4 \ge \frac{8e^4 \cdot 4^5 \cdot 10^9}{180} \Rightarrow N \ge \left(\frac{8e^4 \cdot 4^5 \cdot 10^9}{180}\right)^{1/4} \approx 1255.52.$$

Thus let $N = 1256$.

49. $\int_0^1 e^{x^2}\,dx$

SOLUTION Let $f(x) = e^{x^2}$. To find K_4, we first take derivatives:

$$f'(x) = 2xe^{x^2}$$
$$f''(x) = 4x^2e^{x^2} + 2e^{x^2}$$
$$f^{(3)}(x) = 8x^3e^{x^2} + 12xe^{x^2}$$
$$f^{(4)}(x) = 16x^4e^{x^2} + 48x^2e^{x^2} + 12e^{x^2}.$$

On the interval [0, 1], $|f^{(4)}(x)|$ assumes its maximum value at $x = 1$. Therefore we set

$$K_4 = |f^{(4)}(1)| = 16e + 48e + 12e = 76e.$$

Now we have

$$\text{Error}(S_N) \le \frac{K_4(1-0)^5}{180N^4} = \frac{76e}{180N^4}.$$

To ensure that S_N has error at most 10^{-9}, we must find N such that

$$\frac{76e}{180N^4} \le \frac{1}{10^9}.$$

This gives us

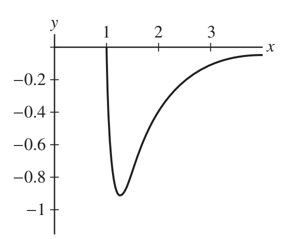
$$N^4 \ge \frac{76e \cdot 10^9}{180} \Rightarrow N \ge \left(\frac{76e \cdot 10^9}{180}\right)^{1/4} \approx 184.06.$$

Thus we let $N = 186$ (remember that N must be even when using Simpson's Rule).

50. $\int_1^4 \sin(\ln x)\,dx$

SOLUTION Let $f(x) = \sin(\ln x)$. To find K_4, we first take derivatives:

$$f'(x) = \frac{\cos(\ln x)}{x}$$
$$f''(x) = \frac{-\sin(\ln x) - \cos(\ln x)}{x^2}$$
$$f^{(3)}(x) = \frac{\cos(\ln x) + 3\sin(\ln x)}{x^3}$$
$$f^{(4)}(x) = \frac{-10\sin(\ln x)}{x^4}$$



From the graph of $y = f^{(4)}(x)$ shown above, we can see that on the interval $[1, 4]$, $|f^{(4)}(x)| \le 1$. Therefore we set $K_4 = 1$. Now we have

$$\text{Error}(S_N) \le \frac{(1)(4-1)^5}{180N^4} = \frac{3^5}{180N^4}.$$

To ensure that S_N has error at most 10^{-9}, we must find N such that

$$\frac{3^5}{180N^4} \le \frac{1}{10^9}.$$

This gives us

$$N^4 \ge \frac{3^5 \cdot 10^9}{180} \Rightarrow N \ge \left(\frac{3^5 \cdot 10^9}{180}\right)^{1/4} \approx 191.7.$$

Thus we let $N = 192$.

51. CAS Show that $\int_0^1 \frac{dx}{1+x^2} = \frac{\pi}{4}$ [use Eq. (3) in Section 5.7].

(a) Use a computer algebra system to graph $f^{(4)}(x)$ for $f(x) = (1+x^2)^{-1}$ and find its maximum on $[0, 1]$.

(b) Find a value of N such that S_N approximates the integral with an error of at most 10^{-6}. Calculate the corresponding approximation and confirm that you have computed $\frac{\pi}{4}$ to at least four places.

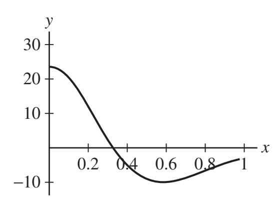
SOLUTION Recall from Section 3.9 that

$$\frac{d}{dx}\tan^{-1}(x) = \frac{1}{1+x^2}.$$

So then

$$\int_0^1 \frac{dx}{1+x^2} = \tan^{-1} x \Big|_0^1 = \tan^{-1}(1) - \tan^{-1}(0) = \frac{\pi}{4}.$$

(a) From the graph of $f^{(4)}(x)$ shown below, we can see that the maximum value of $|f^{(4)}(x)|$ on the interval $[0, 1]$ is 24.



(b) From part (a), we set $K_4 = 24$. Then we have

$$\text{Error}(S_N) \le \frac{24(1-0)^5}{180N^4} = \frac{2}{15N^4}.$$

To ensure that S_N has error at most 10^{-6}, we must find N such that

$$\frac{2}{15N^4} \le \frac{1}{10^6}.$$

This gives us

$$N^4 \ge \frac{2 \cdot 10^6}{15} \Rightarrow N \ge \left(\frac{2 \cdot 10^6}{15}\right)^{1/4} \approx 19.1.$$

Thus let $N = 20$. To compute S_{20}, let $\Delta x = (1-0)/20 = 0.05$. The endpoints of $[0, 1]$ are $0, \ 0.05, \ \dots, \ 1$. With this data, we get

$$S_{20} = \frac{1}{3}\left(\frac{1}{20}\right)\left[\frac{1}{1+0^2} + \frac{4}{1+(0.05)^2} + \frac{2}{1+(0.1)^2} + \cdots + \frac{1}{1+1^2}\right] \approx 0.785398163242.$$

The actual error is

$$|0.785398163242 - \pi/4| = |0.785398163242 - 0.785398163397| = 1.55 \times 10^{-10}.$$

52. Let $J = \int_0^\infty e^{-x^2}\,dx$ and $J_N = \int_0^N e^{-x^2}\,dx$. Although e^{-x^2} has no elementary antiderivative, it is known that $J = \sqrt{\pi}/2$. Let T_N be the Nth trapezoidal approximation to J_N. Calculate T_4 and show that T_4 approximates J to three decimal places.

SOLUTION T_4 is the 4$^{\text{th}}$ trapezoidal approximation to $J_4 = \int_0^4 e^{-x^2}\,dx$. We divide the interval [0, 4] into four subintervals, with endpoints 0, 1, 2, 3, and 4. Then

$$T_4 = \frac{1}{2}\cdot 1\left[e^{-0^2} + 2e^{-1^2} + 2e^{-2^2} + 2e^{-3^2} + e^{-4^2}\right] \approx 0.8863185$$

We have

$$T_4 - J \approx 0.8863185 - \frac{\sqrt{\pi}}{2} \approx 0.8863185 - 0.8862269 \approx 0.0000916$$

53. Let $f(x) = \sin(x^2)$ and $I = \int_0^1 f(x)\,dx$.

(a) Check that $f''(x) = 2\cos(x^2) - 4x^2\sin(x^2)$. Then show that $|f''(x)| \le 6$ for $x \in [0, 1]$. *Hint:* Note that $|2\cos(x^2)| \le 2$ and $|4x^2\sin(x^2)| \le 4$ for $x \in [0, 1]$.

(b) Show that Error(M_N) is at most $\dfrac{1}{4N^2}$.

(c) Find an N such that $|I - M_N| \le 10^{-3}$.

SOLUTION

(a) Taking derivatives, we get

$$f'(x) = 2x\cos(x^2)$$
$$f''(x) = 2x(-\sin(x^2)\cdot 2x) + 2\cos(x^2) = 2\cos(x^2) - 4x^2\sin(x^2).$$

On the interval [0, 1],

$$|f''(x)| = |2\cos(x^2) - 4x^2\sin(x^2)| \le |2\cos(x^2)| + |4x^2\sin(x^2)| \le 2 + 4 = 6.$$

(b) Using $K_2 = 6$, we get

$$\text{Error}(M_N) \le \frac{K_2(1-0)^3}{24N^2} = \frac{6}{24N^2} = \frac{1}{4N^2}.$$

(c) To ensure that M_N has error at most 10^{-3}, we must find N such that

$$\frac{1}{4N^2} \le \frac{1}{10^3}.$$

This gives us

$$N^2 \ge \frac{10^3}{4} = 250 \Rightarrow N \ge \sqrt{250} \approx 15.81.$$

Thus let $N = 16$.

54. CAS The error bound for M_N is proportional to $1/N^2$, so the error bound decreases by $\frac{1}{4}$ if N is increased to $2N$. Compute the actual error in M_N for $\int_0^\pi \sin x\,dx$ for $N = 4$, 8, 16, 32, and 64. Does the actual error seem to decrease by $\frac{1}{4}$ as N is doubled?

SOLUTION The exact value of the integral is

$$\int_0^\pi \sin x\,dx = -\cos x\Big|_0^\pi = -(-1) - (1) = 2.$$

To compute M_4, we have $\Delta x = (\pi - 0)/4 = \pi/4$, and midpoints $\pi/8,\ 3\pi/8,\ 5\pi/8,\ 7\pi/8$. With this data, we get

$$M_4 = \frac{\pi}{4}\left[\sin\left(\frac{\pi}{8}\right) + \sin\left(\frac{3\pi}{8}\right) + \sin\left(\frac{5\pi}{8}\right) + \sin\left(\frac{7\pi}{8}\right)\right] \approx 2.052344.$$

The values for M_8, M_{16}, M_{32}, and M_{64} are computed similarly:

$$M_8 = \frac{\pi}{8}\left[\sin\left(\frac{\pi}{16}\right) + \sin\left(\frac{3\pi}{16}\right) + \cdots + \sin\left(\frac{15\pi}{16}\right)\right] \approx 2.012909;$$
$$M_{16} = \frac{\pi}{16}\left[\sin\left(\frac{\pi}{32}\right) + \sin\left(\frac{3\pi}{32}\right) + \cdots + \sin\left(\frac{31\pi}{32}\right)\right] \approx 2.0032164;$$
$$M_{32} = \frac{\pi}{32}\left[\sin\left(\frac{\pi}{64}\right) + \sin\left(\frac{3\pi}{64}\right) + \cdots + \sin\left(\frac{63\pi}{64}\right)\right] \approx 2.00080342;$$
$$M_{64} = \frac{\pi}{64}\left[\sin\left(\frac{\pi}{128}\right) + \sin\left(\frac{3\pi}{128}\right) + \cdots + \sin\left(\frac{127\pi}{128}\right)\right] \approx 2.00020081.$$

Now we can compute the actual errors for each N:

$$\text{Error}(M_4) = |2 - 2.052344| = 0.052344$$
$$\text{Error}(M_8) = |2 - 2.012909| = 0.012909$$
$$\text{Error}(M_{16}) = |2 - 2.0032164| = 0.0032164$$
$$\text{Error}(M_{32}) = |2 - 2.00080342| = 0.00080342$$
$$\text{Error}(M_{64}) = |2 - 2.00020081| = 0.00020081$$

The actual error does in fact decrease by about 1/4 each time N is doubled.

55. CAS Observe that the error bound for T_N (which has 12 in the denominator) is twice as large as the error bound for M_N (which has 24 in the denominator). Compute the actual error in T_N for $\int_0^{\pi} \sin x\,dx$ for $N = 4, 8, 16, 32$, and 64 and compare with the calculations of Exercise 54. Does the actual error in T_N seem to be roughly twice as large as the error in M_N in this case?

SOLUTION The exact value of the integral is

$$\int_0^{\pi} \sin x\,dx = -\cos x\Big|_0^{\pi} = -(-1) - (1) = 2.$$

To compute T_4, we have $\Delta x = (\pi - 0)/4 = \pi/4$, and endpoints $0,\ \pi/4,\ 2\pi/4,\ 3\pi/4,\ \pi$. With this data, we get

$$T_4 = \frac{1}{2}\cdot\frac{\pi}{4}\left[\sin(0) + 2\sin\left(\frac{\pi}{4}\right) + 2\sin\left(\frac{2\pi}{4}\right) + 2\sin\left(\frac{3\pi}{4}\right) + \sin(\pi)\right] \approx 1.896119.$$

The values for T_8, T_{16}, T_{32}, and T_{64} are computed similarly:

$$T_8 = \frac{1}{2}\cdot\frac{\pi}{8}\left[\sin(0) + 2\sin\left(\frac{\pi}{8}\right) + 2\sin\left(\frac{2\pi}{8}\right) + \cdots + 2\sin\left(\frac{7\pi}{8}\right) + \sin(\pi)\right] \approx 1.974232;$$
$$T_{16} = \frac{1}{2}\cdot\frac{\pi}{16}\left[\sin(0) + 2\sin\left(\frac{\pi}{16}\right) + 2\sin\left(\frac{2\pi}{16}\right) + \cdots + 2\sin\left(\frac{15\pi}{16}\right) + \sin(\pi)\right] \approx 1.993570;$$
$$T_{32} = \frac{1}{2}\cdot\frac{\pi}{32}\left[\sin(0) + 2\sin\left(\frac{\pi}{32}\right) + 2\sin\left(\frac{2\pi}{32}\right) + \cdots + 2\sin\left(\frac{31\pi}{32}\right) + \sin(\pi)\right] \approx 1.998393;$$
$$T_{64} = \frac{1}{2}\cdot\frac{\pi}{64}\left[\sin(0) + 2\sin\left(\frac{\pi}{64}\right) + 2\sin\left(\frac{2\pi}{64}\right) + \cdots + 2\sin\left(\frac{63\pi}{64}\right) + \sin(\pi)\right] \approx 1.999598.$$

Now we can compute the actual errors for each N:

$$\text{Error}(T_4) = |2 - 1.896119| = 0.103881$$
$$\text{Error}(T_8) = |2 - 1.974232| = 0.025768$$
$$\text{Error}(T_{16}) = |2 - 1.993570| = 0.006430$$
$$\text{Error}(T_{32}) = |2 - 1.998393| = 0.001607$$
$$\text{Error}(T_{64}) = |2 - 1.999598| = 0.000402$$

Comparing these results with the calculations of Exercise 54, we see that the actual error in T_N is in fact about twice as large as the error in M_N.

56. CAS Explain why the error bound for S_N decreases by $\frac{1}{16}$ if N is increased to $2N$. Compute the actual error in S_N for $\int_0^\pi \sin x\,dx$ for $N = 4, 8, 16, 32$, and 64. Does the actual error seem to decrease by $\frac{1}{16}$ as N is doubled?

SOLUTION If we plug in $2N$ for N in the formula for the error bound for S_N, we get

$$\frac{K_4(b-a)^5}{180(2N)^4} = \frac{K_4(b-a)^5}{180 \cdot 2^4 \cdot N^4} = \frac{1}{16}\left(\frac{K_4(b-a)^5}{180N^4}\right).$$

Thus we see that, since N is raised to the fourth power in the denominator, the Error Bound for S_N decreases by $1/16$ if N is increased to $2N$. The exact value of the integral is

$$\int_0^\pi \sin x\,dx = -\cos x\Big|_0^\pi = -(-1) - (1) = 2.$$

To compute S_4, we have $\Delta x = (\pi - 0)/4 = \pi/4$, and endpoints $0,\ \pi/4,\ 2\pi/4,\ 3\pi/4,\ \pi$. With this data, we get

$$S_4 = \frac{1}{3}\cdot\frac{\pi}{4}\left[\sin(0) + 4\sin\left(\frac{\pi}{4}\right) + 2\sin\left(\frac{2\pi}{4}\right) + 4\sin\left(\frac{3\pi}{4}\right) + \sin(\pi)\right] \approx 2.004560.$$

The values for S_8, S_{16}, S_{32}, and S_{64} are computed similarly:

$$S_8 = \frac{1}{3}\cdot\frac{\pi}{8}\left[\sin(0) + 4\sin\left(\frac{\pi}{8}\right) + 2\sin\left(\frac{2\pi}{8}\right) + \cdots + 4\sin\left(\frac{7\pi}{8}\right) + \sin(\pi)\right] \approx 2.0002692;$$

$$S_{16} = \frac{1}{3}\cdot\frac{\pi}{16}\left[\sin(0) + 4\sin\left(\frac{\pi}{16}\right) + 2\sin\left(\frac{2\pi}{16}\right) + \cdots + 4\sin\left(\frac{15\pi}{16}\right) + \sin(\pi)\right] \approx 2.00001659;$$

$$S_{32} = \frac{1}{3}\cdot\frac{\pi}{32}\left[\sin(0) + 4\sin\left(\frac{\pi}{32}\right) + 2\sin\left(\frac{2\pi}{32}\right) + \cdots + 4\sin\left(\frac{31\pi}{32}\right) + \sin(\pi)\right] \approx 2.000001033;$$

$$S_{64} = \frac{1}{3}\cdot\frac{\pi}{64}\left[\sin(0) + 4\sin\left(\frac{\pi}{64}\right) + 2\sin\left(\frac{2\pi}{64}\right) + \cdots + 4\sin\left(\frac{63\pi}{64}\right) + \sin(\pi)\right] \approx 2.00000006453.$$

Now we can compute the actual errors for each N:

$$\text{Error}(S_4) = |2 - 2.004560| = 0.004560$$

$$\text{Error}(S_8) = |2 - 2.0002692| = 2.692 \times 10^{-4}$$

$$\text{Error}(S_{16}) = |2 - 2.00001659| = 1.659 \times 10^{-5}$$

$$\text{Error}(S_{32}) = |2 - 2.000001033| = 1.033 \times 10^{-6}$$

$$\text{Error}(S_{64}) = |2 - 2.00000006453| = 6.453 \times 10^{-8}$$

The actual error does in fact decrease by about $1/16$ each time N is doubled. For example, $0.004560/16 = 2.85 \times 10^{-4}$, which is roughly the same as 2.692×10^{-4}.

57. Verify that S_2 yields the exact value of $\displaystyle\int_0^1 (x - x^3)\,dx$.

SOLUTION Let $f(x) = x - x^3$. Clearly $f^{(4)}(x) = 0$, so we may take $K_4 = 0$ in the error bound estimate for S_2. Then

$$\text{Error}(S_2) \le \frac{K_4(1-0)^5}{180 \cdot 2^4} = 0 \cdot \frac{1}{2880} = 0$$

so that S_2 yields the exact value of the integral.

58. Verify that S_2 yields the exact value of $\displaystyle\int_a^b (x - x^3)\,dx$ for all $a < b$.

SOLUTION Let $f(x) = x - x^3$. Clearly $f^{(4)}(x) = 0$, so we may take $K_4 = 0$ in the error bound estimate for S_2. Then

$$\text{Error}(S_2) \le \frac{K_4(b-a)^5}{180 \cdot 2^4} = 0 \cdot \frac{(b-a)^5}{2880} = 0$$

so that S_2 yields the exact value of the integral.

Further Insights and Challenges

59. Show that if $f(x) = rx + s$ is a linear function (r, s constants), then $T_N = \int_a^b f(x)\,dx$ for all N and all endpoints a, b.

SOLUTION First, note that

$$\int_a^b (rx+s)\,dx = \frac{r(b^2-a^2)}{2} + s(b-a).$$

Now,

$$T_N(rx+s) = \frac{b-a}{2N}\left[f(a) + 2\sum_{i=1}^{N-1} f(x_i) + f(b)\right] = \frac{r(b-a)}{2N}\left[a + 2\sum_{i=1}^{N-1} a + 2\frac{b-a}{N}\sum_{i=1}^{N-1} i + b\right] + s\frac{b-a}{2N}(2N)$$

$$= \frac{r(b-a)}{2N}\left[(2N-1)a + 2\frac{b-a}{N}\frac{(N-1)N}{2} + b\right] + s(b-a) = \frac{r(b^2-a^2)}{2} + s(b-a).$$

60. Show that if $f(x) = px^2 + qx + r$ is a quadratic polynomial, then $S_2 = \int_a^b f(x)\,dx$. In other words, show that

$$\int_a^b f(x)\,dx = \frac{b-a}{6}\left(y_0 + 4y_1 + y_2\right)$$

where $y_0 = f(a)$, $y_1 = f\left(\frac{a+b}{2}\right)$, and $y_2 = f(b)$. *Hint:* Show this first for $f(x) = 1, x, x^2$ and use linearity.

SOLUTION For S_2, $\Delta x = (b-a)/2$, and the endpoints are $a,\ (a+b)/2,\ b$. Following the hint, let $f(x) = 1$. In this case,

$$S_2(1) = \frac{1}{3}\left(\frac{b-a}{2}\right)\left[f(a) + 4f\left(\frac{a+b}{2}\right) + f(b)\right] = \frac{b-a}{6}(1 + 4(1) + 1) = \frac{b-a}{6}(6)$$

$$= b - a = \int_a^b 1\,dx.$$

If $f(x) = x$, then

$$S_2(x) = \frac{1}{3}\left(\frac{b-a}{2}\right)\left[f(a) + 4f\left(\frac{a+b}{2}\right) + f(b)\right] = \frac{b-a}{6}\left(a + 4\left(\frac{a+b}{2}\right) + b\right) = \frac{b-a}{6}\left(\frac{6a+6b}{2}\right)$$

$$= \frac{b^2-a^2}{2} = \int_a^b x\,dx;$$

and if $f(x) = x^2$, then

$$S_2(x^2) = \frac{1}{3}\left(\frac{b-a}{2}\right)\left[f(a) + 4f\left(\frac{a+b}{2}\right) + f(b)\right] = \frac{b-a}{6}\left(a^2 + 4\left(\frac{a+b}{2}\right)^2 + b^2\right)$$

$$= \frac{b-a}{6}\left(a^2 + (a^2 + 2ab + b^2) + b^2\right) = \frac{b-a}{6}(2)(a^2 + ab + b^2) = \frac{b^3-a^3}{3} = \int_a^b x^2\,dx.$$

Now we use linearity:

$$\int_a^b (px^2 + qx + r)\,dx = p\int_a^b x^2\,dx + q\int_a^b x\,dx + r\int_a^b dx$$

$$= pS_2(x^2) + qS_2(x) + rS_2(1) = S_2(pa^2 + qa + r).$$

61. For N even, divide $[a, b]$ into N subintervals of width $\Delta x = \frac{b-a}{N}$. Set $x_j = a + j\,\Delta x$, $y_j = f(x_j)$, and

$$S_2^{2j} = \frac{b-a}{3N}\left(y_{2j} + 4y_{2j+1} + y_{2j+2}\right)$$

(a) Show that S_N is the sum of the approximations on the intervals $[x_{2j}, x_{2j+2}]$—that is, $S_N = S_2^0 + S_2^2 + \cdots + S_2^{N-2}$.

(b) By Exercise 60, $S_2^{2j} = \int_{x_{2j}}^{x_{2j+2}} f(x)\,dx$ if $f(x)$ is a quadratic polynomial. Use (a) to show that S_N is exact *for all N* if $f(x)$ is a quadratic polynomial.

SOLUTION

(a) This result follows because the even-numbered interior endpoints overlap:

$$\sum_{i=0}^{(N-2)/2} S_2^{2j} = \frac{b-a}{6}\left[(y_0 + 4y_1 + y_2) + (y_2 + 4y_3 + y_4) + \cdots\right]$$

$$= \frac{b-a}{6}\left[y_0 + 4y_1 + 2y_2 + 4y_3 + 2y_4 + \cdots + 4y_{N-1} + y_N\right] = S_N.$$

(b) If $f(x)$ is a quadratic polynomial, then by part (a) we have

$$S_N = S_2^0 + S_2^2 + \cdots + S_2^{N-2} = \int_{x_0}^{x_2} f(x)\,dx + \int_{x_2}^{x_4} f(x)\,dx + \cdots + \int_{x_{N-2}}^{x_N} f(x)\,dx = \int_a^b f(x)\,dx.$$

62. Show that S_2 also gives the exact value for $\int_a^b x^3\,dx$ and conclude, as in Exercise 61, that S_N is exact for all cubic polynomials. Show by counterexample that S_2 is not exact for integrals of x^4.

SOLUTION Let $f(x) = x^3$. Then $\Delta x = (b-a)/2$ and the endpoints are $a,\ (a+b)/2,\ b$. With this data, we get

$$S_2(x^3) = \frac{1}{3}\left(\frac{b-a}{2}\right)\left[a^3 + 4\left(\frac{a+b}{2}\right)^3 + b^3\right] = \frac{b-a}{6}\left[a^3 + \frac{1}{2}(a^3 + 3a^2b + 3ab^2 + b^3) + b^3\right]$$

$$= \frac{b-a}{6}\left(\frac{3}{2}\right)[a^3 + a^2b + ab^2 + b^3] = \frac{1}{4}(b-a)(a^3 + a^2b + ab^2 + b^3) = \frac{b^4 - a^4}{4} = \int_a^b x^3\,dx.$$

By linearity, and using the result from Exercise 60, we have that

$$\int_a^b (sx^3 + px^2 + qx + r)\,dx = s\int_a^b x^3\,dx + \int_a^b (px^2 + qx + r)\,dx$$

$$= s\left(S_2(x^3)\right) + S_2(px^2 + qx + r)$$

$$= S_2(sx^3 + px^2 + qx + r).$$

For N even, we can now follow the procedure of Exercise 61; that is, divide $[a,b]$ into N subintervals and on each subinterval compute S_2. Then, for any cubic polynomial $f(x)$, we have

$$\int_a^b f(x)\,dx = \int_a^{x_2} f(x)\,dx + \int_{x_2}^{x_4} f(x)\,dx + \cdots + \int_{x_{N-2}}^{b} f(x)\,dx = S_2^0 + S_2^2 + \cdots + S_2^{N-2} = S_N.$$

However, S_2 is not exact for polynomials of degree 4. For example,

$$\int_0^1 x^4\,dx = \frac{1}{5}$$

but

$$S_2 = \frac{1}{3}\left(\frac{1}{2}\right)\left[0^5 + 4(0.5)^5 + 1^5\right] = \frac{1}{6}\left(\frac{33}{32}\right) = \frac{11}{64} \neq \frac{1}{5}.$$

63. Use the error bound for S_N to obtain another proof that Simpson's Rule is exact for all cubic polynomials.

SOLUTION Let $f(x) = ax^3 + bx^2 + cx + d$, with $a \neq 0$, be any cubic polynomial. Then, $f^{(4)}(x) = 0$, so we can take $K_4 = 0$. This yields

$$\text{Error}(S_N) \le \frac{0}{180N^4} = 0.$$

In other words, S_N is exact for all cubic polynomials for all N.

64. **Sometimes, Simpson's Rule Performs Poorly** Calculate M_{10} and S_{10} for the integral $\int_0^1 \sqrt{1-x^2}\,dx$, whose value we know to be $\frac{\pi}{4}$ (one-quarter of the area of the unit circle).

(a) We usually expect S_N to be more accurate than M_N. Which of M_{10} and S_{10} is more accurate in this case?

(b) How do you explain the result of part (a)? *Hint:* The error bounds are not valid because $|f''(x)|$ and $|f^{(4)}(x)|$ tend to ∞ as $x \to 1$, but $|f^{(4)}(x)|$ goes to infinity faster.

SOLUTION Let $f(x) = \sqrt{1-x^2}$. Divide [0, 1] into 10 subintervals of length $\Delta x = (1-0)/10 = 0.1$ Then we have

$$M_{10} = \frac{1}{10}\left[\sqrt{1-(0.05)^2} + \sqrt{1-(0.15)^2} + \cdots + \sqrt{1-(0.95)^2}\right] \approx 0.788103;$$

$$S_{10} = \frac{1}{3}\left(\frac{1}{10}\right)\left[\sqrt{1-0^2} + 4\sqrt{1-(0.1)^2} + 2\sqrt{1-(0.2)^2} + \cdots + \sqrt{1-1^2}\right] \approx 0.781752.$$

(a) Since $\pi/4 = 0.785389$, we have

$$\text{Error}(M_{10}) = 0.0027;$$
$$\text{Error}(S_{10}) = 0.00365.$$

Thus, M_{10} is more accurate.

(b) These results can be explained by looking at the derivatives:

$$f'(x) = \frac{-x}{\sqrt{1-x^2}}$$
$$f''(x) = \frac{-1}{(1-x^2)^{3/2}}$$
$$f^{(3)}(x) = \frac{-3x}{(1-x^2)^{5/2}}$$
$$f^{(4)}(x) = \frac{-3(x^2+1)}{(1-x^2)^{7/2}}$$

Both $|f''(x)|$ and $|f^{(4)}(x)|$ tend to ∞ as $x \to 1$, but $|f^{(4)}(x)|$ tends to ∞ faster due to the $7/2$ exponent in the denominator.

CHAPTER REVIEW EXERCISES

1. Match the integrals (a)–(e) with their antiderivatives (i)–(v) on the basis of the general form (do not evaluate the integrals).

(a) $\displaystyle\int \frac{x\,dx}{x^2-4}$

(b) $\displaystyle\int \frac{(2x+9)\,dx}{x^2+4}$

(c) $\displaystyle\int \sin^3 x \cos^2 x\,dx$

(d) $\displaystyle\int \frac{dx}{x\sqrt{16x^2-1}}$

(e) $\displaystyle\int \frac{16\,dx}{x(x-4)^2}$

(i) $\sec^{-1} 4x + C$

(ii) $\log|x| - \log|x-4| - \dfrac{4}{x-4} + C$

(iii) $\dfrac{1}{30}(3\cos^5 x - 3\cos^3 x \sin^2 x - 7\cos^3 x) + C$

(iv) $\dfrac{9}{2}\tan^{-1}\dfrac{x}{2} + \ln(x^2+4) + C$

(v) $\sqrt{x^2-4} + C$

SOLUTION

(a) $\displaystyle\int \frac{x\,dx}{\sqrt{x^2-4}}$

Since x is a constant multiple of the derivative of x^2-4, the substitution method implies that the integral is a constant multiple of $\int \frac{du}{\sqrt{u}}$ where $u = x^2-4$, that is a constant multiple of $\sqrt{u} = \sqrt{x^2-4}$. It corresponds to the function in **(v)**.

(b) $\displaystyle\int \frac{(2x+9)\,dx}{x^2+4}$

The part $\int \frac{2x}{x^2+4}\,dx$ corresponds to $\ln(x^2+4)$ in **(iv)** and the part $\int \frac{9}{x^2+4}\,dx$ corresponds to $\frac{9}{2}\tan^{-1}\frac{x}{2}$. Hence the integral corresponds to the function in **(iv)**.

(c) $\displaystyle\int \sin^3 x \cos^2 x\,dx$

The reduction formula for $\int \sin^m x \cos^n x\,dx$ shows that this integral is equal to a sum of constant multiples of products in the form $\cos^i x \sin^j x$ as in **(iii)**.

(d) $\displaystyle\int \frac{dx}{x\sqrt{16x^2-1}}$

Since $\int \frac{dx}{|x|\sqrt{x^2-1}} = \sec^{-1} x + C$, we expect the integral $\int \frac{dx}{x\sqrt{16x^2-1}}$ to be equal to the function in **(i)**.

(e) $\displaystyle\int \frac{16\,dx}{x(x-4)^2}$

The partial fraction decomposition of the integrand has the form:

$$\frac{A}{x} + \frac{B}{x-4} + \frac{C}{(x-4)^2}$$

The term $\frac{A}{x}$ contributes the function $A\ln|x|$ to the integral, the term $\frac{B}{x-4}$ contributes $B\ln|x-4|$ and the term $\frac{C}{(x-4)^2}$ contributes $-\frac{C}{x-4}$. Therefore, we expect the integral to be equal to the function in **(ii)**.

2. Evaluate $\displaystyle\int \frac{x\,dx}{x+2}$ in two ways: using substitution and using the Method of Partial Fractions.

SOLUTION Using substitution, write $u = x+2$; then $du = dx$ and

$$\int \frac{x}{x+2}\,dx = \int \frac{u-2}{u}\,du = \int 1\,du - 2\int \frac{1}{u}\,du = u - 2\ln|u| + C_1$$
$$= x + 2 - 2\ln|x+2| + C_1 = x - 2\ln|x+2| + C$$

Using partial fractions, first do long division to get

$$\frac{x}{x+2} = 1 - \frac{2}{x+2}$$

Then

$$\int \frac{x}{x+2}\,dx = \int \left(1 - \frac{2}{x+2}\right)\,dx = \int 1\,dx - 2\int \frac{1}{x+2}\,dx = x - 2\ln|x+2| + C$$

In Exercises 3–12, evaluate using the suggested method.

3. $\displaystyle\int \cos^3\theta\sin^8\theta\,d\theta$ [write $\cos^3\theta$ as $\cos\theta(1-\sin^2\theta)$]

SOLUTION We use the identity $\cos^2\theta = 1 - \sin^2\theta$ to rewrite the integral:

$$\int \cos^3\theta\sin^8\theta\,d\theta = \int \cos^2\theta\sin^8\theta\cos\theta\,d\theta = \int \left(1-\sin^2\theta\right)\sin^8\theta\cos\theta\,d\theta.$$

Now, we use the substitution $u = \sin\theta$, $du = \cos\theta\,d\theta$:

$$\int \cos^3\theta\sin^8\theta\,d\theta = \int \left(1-u^2\right)u^8\,du = \int \left(u^8 - u^{10}\right)\,du = \frac{u^9}{9} - \frac{u^{11}}{11} + C = \frac{\sin^9\theta}{9} - \frac{\sin^{11}\theta}{11} + C.$$

4. $\displaystyle\int xe^{-12x}\,dx$ (Integration by Parts)

SOLUTION We use Integration by Parts with $u = x$ and $v' = e^{-12x}$. Then $u' = 1$, $v = -\frac{1}{12}e^{-12x}$, and we obtain:

$$\int xe^{-12x}\,dx = -\frac{xe^{-12x}}{12} + \int \frac{1}{12}e^{-12x}\,dx = -\frac{xe^{-12x}}{12} - \frac{1}{144}e^{-12x} + C = -\frac{e^{-12x}}{144}(12x+1) + C.$$

5. $\displaystyle\int \sec^3\theta\tan^4\theta\,d\theta$ (trigonometric identity, reduction formula)

SOLUTION We use the identity $1 + \tan^2\theta = \sec^2\theta$ to write $\tan^4\theta = \left(\sec^2\theta - 1\right)^2$ and to rewrite the integral as

$$\int \sec^3\theta\tan^4\theta\,d\theta \int \sec^3\theta\left(1-\sec^2\theta\right)^2 d\theta = \int \sec^3\theta\left(1 - 2\sec^2\theta + \sec^4\theta\right)\,d\theta$$
$$= \int \sec^7\theta\,d\theta - 2\int \sec^5\theta\,d\theta + \int \sec^3\theta\,d\theta.$$

Now we use the reduction formula

$$\int \sec^m\theta\, d\theta = \frac{\tan\theta \sec^{m-2}\theta}{m-1} + \frac{m-2}{m-1}\int \sec^{m-2}\theta\, d\theta.$$

We have

$$\int \sec^5\theta\, d\theta = \frac{\tan\theta\sec^3\theta}{4} + \frac{3}{4}\int \sec^3\theta\, d\theta + C,$$

and

$$\int \sec^7\theta\, d\theta = \frac{\tan\theta\sec^5\theta}{6} + \frac{5}{6}\int \sec^5\theta\, d\theta = \frac{\tan\theta\sec^5\theta}{6} + \frac{5}{6}\left(\frac{\tan\theta\sec^3\theta}{4} + \frac{3}{4}\int \sec^3\theta\, d\theta\right) + C$$

$$= \frac{\tan\theta\sec^5\theta}{6} + \frac{5}{24}\tan\theta\sec^3\theta + \frac{5}{8}\int \sec^3\theta\, d\theta + C.$$

Therefore,

$$\int \sec^3\theta\tan^4\theta\, d\theta = \left(\frac{\tan\theta\sec^5\theta}{6} + \frac{5}{24}\tan\theta\sec^3\theta + \frac{5}{8}\int \sec^3\theta\, d\theta\right)$$

$$- 2\left(\frac{\tan\theta\sec^3\theta}{4} + \frac{3}{4}\int \sec^3\theta\, d\theta\right) + \int \sec^3\theta\, d\theta$$

$$= \frac{\tan\theta\sec^5\theta}{6} - \frac{7\tan\theta\sec^3\theta}{24} + \frac{1}{8}\int \sec^3\theta\, d\theta.$$

We again use the reduction formula to compute

$$\int \sec^3\theta\, d\theta = \frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\int \sec\theta\, d\theta = \frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\ln|\sec\theta + \tan\theta| + C.$$

Finally,

$$\int \sec^3\theta\tan^4\theta\, d\theta = \frac{\tan\theta\sec^5\theta}{6} - \frac{7\tan\theta\sec^3\theta}{24} + \frac{\tan\theta\sec\theta}{16} + \frac{1}{16}\ln|\sec\theta + \tan\theta| + C.$$

6. $\displaystyle\int \frac{4x+4}{(x-5)(x+3)}\, dx$ (partial fractions)

SOLUTION The following partial fraction decomposition takes the form

$$\frac{4x+4}{(x-5)(x+3)} = \frac{A}{x-5} + \frac{B}{x+3}.$$

Clearing denominators gives us

$$4x + 4 = A(x+3) + B(x-5).$$

Setting $x = 5$ then yields $A = 3$, while setting $x = -3$ yields $B = 1$. Hence,

$$\int \frac{4x+4}{(x-5)(x+3)}\, dx = \int \frac{3}{x-5}\, dx + \int \frac{1}{x+3}\, dx = 3\ln|x-5| + \ln|x+3| + C.$$

7. $\displaystyle\int \frac{dx}{x(x^2-1)^{3/2}}\, dx$ (trigonometric substitution)

SOLUTION Substitute $x = \sec\theta$, $dx = \sec\theta\tan\theta\, d\theta$. Then,

$$\left(x^2-1\right)^{3/2} = \left(\sec^2\theta - 1\right)^{3/2} = \left(\tan^2\theta\right)^{3/2} = \tan^3\theta,$$

and

$$\int \frac{dx}{x\left(x^2-1\right)^{3/2}} = \int \frac{\sec\theta\tan\theta\, d\theta}{\sec\theta\tan^3\theta} = \int \frac{d\theta}{\tan^2\theta} = \int \cot^2\theta\, d\theta.$$

Using a reduction formula we find that:

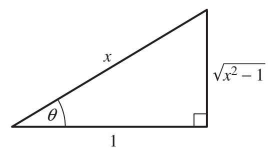
$$\int \cot^2\theta\, d\theta = -\cot\theta - \theta + C$$

so

$$\int \frac{dx}{x\left(x^2-1\right)^{3/2}} = -\cot\theta - \theta + C.$$

We now must return to the original variable x. We use the relation $x = \sec\theta$ and the figure to obtain:

$$\int \frac{dx}{x\left(x^2-1\right)^{3/2}} = -\frac{1}{\sqrt{x^2-1}} - \sec^{-1}x + C.$$

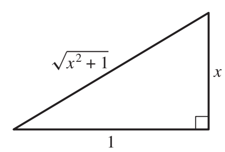


8. $\int (1+x^2)^{-3/2}dx$ (trigonometric substitution)

SOLUTION Use the substitution $x = \tan\theta$, $dx = \sec^2\theta\,d\theta$. Then

$$\int (1+x^2)^{-3/2}\,dx = \int (1+\tan^2\theta)^{-3/2}\sec^2\theta\,d\theta = \int (\sec^2\theta)^{-3/2}\sec^2\theta\,d\theta = \int \frac{1}{\sec\theta}\,d\theta$$
$$= \int \cos\theta\,d\theta = \sin\theta + C$$

Since $x = \tan\theta$, draw the following right triangle:



From the figure, we see that $\sin\theta = \frac{x}{\sqrt{x^2+1}}$, so that

$$\int (1+x^2)^{-3/2}\,dx = x(1+x^2)^{-1/2} + C$$

9. $\int \frac{dx}{x^{3/2}+x^{1/2}}$ (substitution)

SOLUTION Let $t = x^{1/2}$. Then $dt = \frac{1}{2}x^{-1/2}\,dx$ or $dx = 2x^{1/2}\,dt = 2t\,dt$. Therefore,

$$\int \frac{dx}{x^{3/2}+x^{1/2}} = \int \frac{2t\,dt}{t^3+t} = \int \frac{2\,dt}{t^2+1} = 2\tan^{-1}t + C = 2\tan^{-1}\sqrt{x} + C.$$

10. $\int \frac{dx}{x+x^{-1}}$ (rewrite integrand)

SOLUTION We rewrite the integrand as follows:

$$\int \frac{dx}{x+x^{-1}} = \int \frac{x\,dx}{x^2+1}.$$

Now, we substitute $u = x^2+1$. Then $du = 2x\,dx$ and

$$\int \frac{dx}{x+x^{-1}} = \int \frac{\frac{1}{2}\,du}{u} = \frac{1}{2}\int \frac{du}{u} = \frac{1}{2}\ln|u| + C = \frac{1}{2}\ln\left(1+x^2\right) + C.$$

11. $\int x^{-2}\tan^{-1}x\,dx$ (Integration by Parts)

SOLUTION We use Integration by Parts with $u = \tan^{-1}x$ and $v' = x^{-2}$. Then $u' = \frac{1}{1+x^2}$, $v = -x^{-1}$ and

$$\int x^{-2}\tan^{-1}x\,dx = -\frac{\tan^{-1}x}{x} + \int \frac{dx}{x\left(1+x^2\right)}.$$

For the remaining integral, the partial fraction decomposition takes the form

$$\frac{1}{x(1+x^2)} = \frac{A}{x} + \frac{Bx+C}{1+x^2}.$$

Clearing denominators gives us

$$1 = A(1+x^2) + (Bx+C)x.$$

Setting $x=0$ then yields $A=1$. Next, equating the x^2-coefficients gives

$$0 = A+B \qquad \text{so} \qquad B=-1,$$

while equating x-coefficients gives $C=0$. Hence,

$$\frac{1}{x\left(1+x^2\right)} = \frac{1}{x} - \frac{x}{1+x^2},$$

and

$$\int \frac{dx}{x(1+x^2)} = \int \frac{1}{x}\,dx - \int \frac{x\,dx}{1+x^2} = \ln|x| - \frac{1}{2}\ln\left(1+x^2\right) + C.$$

Therefore,

$$\int x^{-2}\tan^{-1}x\,dx = -\frac{\tan^{-1}x}{x} + \ln|x| - \frac{1}{2}\ln\left(1+x^2\right) + C.$$

12. $\displaystyle\int \frac{dx}{x^2+4x-5}$ (complete the square, substitution, partial fractions)

SOLUTION The partial fraction decomposition takes the form

$$\frac{1}{x^2+4x-5} = \frac{A}{x-1} + \frac{B}{x+5}.$$

Clearing denominators gives us

$$1 = A(x+5) + B(x-1).$$

Setting $x=1$ then yields $A=\frac{1}{6}$, while setting $x=-5$ yields $B=-\frac{1}{6}$. Therefore,

$$\int \frac{dx}{x^2+4x-5} = \frac{1}{6}\int \frac{dx}{x-1} - \frac{1}{6}\int \frac{dx}{x+5} = \frac{1}{6}\ln|x-1| - \frac{1}{6}\ln|x+5| + C = \frac{1}{6}\ln\left|\frac{x-1}{x+5}\right| + C.$$

In Exercises 13–64, evaluate using the appropriate method or combination of methods.

13. $\displaystyle\int_0^1 x^2 e^{4x}\,dx$

SOLUTION We evaluate the indefinite integral using Integration by Parts with $u=x^2$ and $v'=e^{4x}$. Then $u'=2x$, $v=\frac{1}{4}e^{4x}$ and

$$\int x^2 e^{4x}\,dx = \frac{x^2}{4}e^{4x} - \frac{1}{2}\int xe^{4x}\,dx.$$

We compute the resulting integral using Integration by Parts again, this time with $u=x$ and $v'=e^{4x}$. Then $u'=1$, $v=\frac{1}{4}e^{4x}$ and

$$\int xe^{4x}\,dx = x\cdot\frac{1}{4}e^{4x} - \int \frac{1}{4}e^{4x}\,dx = \frac{x}{4}e^{4x} - \frac{1}{16}e^{4x} + C.$$

Therefore,

$$\int x^2 e^{4x}\,dx = \frac{x^2}{4}e^{4x} - \frac{1}{2}\left(\frac{x}{4}e^{4x} - \frac{1}{16}e^{4x}\right) + C = \frac{e^{4x}}{32}\left(8x^2-4x+1\right) + C.$$

Finally,

$$\int_0^1 x^2 e^{4x}\,dx = \left(\frac{e^{4x}}{32}\left(8x^2-4x+1\right)\right)\Bigg|_0^1 = \frac{e^4}{32}(8-4+1) - \frac{1}{32}(1) = \frac{5e^4-1}{32}$$

14. $\displaystyle\int \frac{x^2}{\sqrt{9-x^2}}\,dx$

SOLUTION Substitute $x = 3\sin\theta$, $dx = 3\cos\theta\,d\theta$. Then

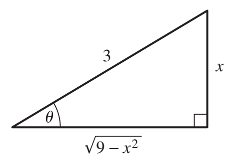
$$\sqrt{9-x^2} = \sqrt{9-9\sin^2\theta} = \sqrt{9\left(1-\sin^2\theta\right)} = \sqrt{9\cos^2\theta} = 3\cos\theta,$$

and

$$\int \frac{x^2}{\sqrt{9-x^2}}\,dx = \int \frac{9\sin^2\theta\cdot 3\cos\theta\,d\theta}{3\cos\theta} = 9\int \sin^2\theta\,d\theta$$
$$= 9\left(\frac{\theta}{2} - \frac{\sin 2\theta}{4}\right) + C = \frac{9\theta}{2} - \frac{9\sin\theta\cos\theta}{2} + C.$$

We now must return to the original variable x. Since $x = 3\sin\theta$, we have $t = \sin^{-1}\frac{x}{3}$. Using the figure we obtain

$$\int \frac{x^2}{\sqrt{9-x^2}}\,dx = \frac{9}{2}\sin^{-1}\left(\frac{x}{3}\right) - \frac{9}{2}\cdot\frac{x}{3}\cdot\frac{\sqrt{9-x^2}}{3} + C = \frac{9}{2}\sin^{-1}\left(\frac{x}{3}\right) - \frac{x\sqrt{9-x^2}}{2} + C.$$



15. $\displaystyle\int \cos^9 6\theta\sin^3 6\theta\,d\theta$

SOLUTION We use the identity $\sin^2 6\theta = 1 - \cos^2 6\theta$ to rewrite the integral:

$$\int \cos^9 6\theta \sin^3 6\theta\,d\theta = \int \cos^9 6\theta \sin^2 6\theta\sin 6\theta\,d\theta = \int \cos^9 6\theta\left(1-\cos^2 6\theta\right)\sin 6\theta\,d\theta.$$

Now, we use the substitution $u = \cos 6\theta$, $du = -6\sin 6\theta\,d\theta$:

$$\int \cos^9 6\theta\sin^3 6\theta\,d\theta = \int u^9\left(1-u^2\right)\left(-\frac{du}{6}\right) = -\frac{1}{6}\int\left(u^9 - u^{11}\right)du$$
$$= -\frac{1}{6}\left(\frac{u^{10}}{10} - \frac{u^{12}}{12}\right) + C = \frac{\cos^{12}6\theta}{72} - \frac{\cos^{10}6\theta}{60} + C.$$

16. $\displaystyle\int \sec^2\theta\tan^4\theta\,d\theta$

SOLUTION We substitute $u = \tan\theta$, $du = \sec^2\theta\,d\theta$ to obtain

$$\int \sec^2\theta\tan^4\theta\,d\theta = \int u^4\,du = \frac{u^5}{5} + C = \frac{\tan^5\theta}{5} + C.$$

17. $\displaystyle\int \frac{(6x+4)\,dx}{x^2-1}$

SOLUTION The partial fraction decomposition takes the form

$$\frac{6x+4}{(x-1)(x+1)} = \frac{A}{x-1} + \frac{B}{x+1}.$$

Clearing the denominators gives us

$$6x+4 = A(x+1) + B(x-1).$$

Setting $x = 1$ then yields $A = 5$, while setting $x = -1$ yields $B = 1$. Hence,

$$\int \frac{(6x+4)dx}{x^2-1} = \int \frac{5}{x-1}\,dx + \int \frac{1}{x+1}\,dx = 5\ln|x-1| + \ln|x+1| + C.$$

18. $\displaystyle\int_4^9 \frac{dt}{(t^2-1)^2}$

SOLUTION First evaluate the indefinite integral. Substitute $t = \sin\theta$, $dt = \cos\theta\, d\theta$. Then

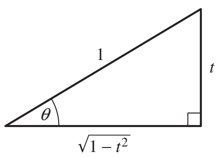
$$\left(t^2-1\right)^2 = \left(1-t^2\right)^2 = \left(1-\sin^2\theta\right)^2 = \left(\cos^2\theta\right)^2 = \cos^4\theta,$$

and

$$\int \frac{dt}{\left(t^2-1\right)^2} = \int \frac{\cos\theta\, d\theta}{\cos^4\theta} = \int \frac{d\theta}{\cos^3\theta} = \int \sec^3\theta\, d\theta.$$

We use a reduction formula to compute the resulting integral:

$$\int \frac{dt}{\left(t^2-1\right)^2} = \int \sec^3\theta\, d\theta = \frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\int \sec\theta\, d\theta = \frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\ln|\sec\theta + \tan\theta| + C.$$



We now must return to the original variable t. Using the relation $t = \sin\theta$ and the accompanying figure,

$$\begin{aligned}\int \frac{dt}{\left(t^2-1\right)^2} &= \frac{1}{2}\cdot\frac{t}{\sqrt{1-t^2}}\cdot\frac{1}{\sqrt{1-t^2}} + \frac{1}{2}\ln\left|\frac{1}{\sqrt{1-t^2}} + \frac{t}{\sqrt{1-t^2}}\right| + C \\ &= \frac{1}{2}\left(\frac{t}{1-t^2} + \ln\left|\frac{1+t}{\sqrt{1-t^2}}\right|\right) + C = \frac{1}{2}\left(\frac{t}{1-t^2} + \ln\left|\sqrt{\frac{1+t}{1-t}}\right|\right) + C \\ &= \frac{1}{2}\frac{t}{1-t^2} + \frac{1}{4}\ln\left|\frac{1+t}{1-t}\right| + C\end{aligned}$$

Finally,

$$\begin{aligned}\int_4^9 \frac{dt}{(t^2-1)^2} &= \left(\frac{1}{2}\frac{t}{1-t^2} + \frac{1}{4}\ln\left|\frac{1+t}{1-t}\right|\right)\Bigg|_4^9 \\ &= \frac{1}{2}\cdot\frac{9}{-80} + \frac{1}{4}\ln\frac{10}{8} - \frac{1}{2}\cdot\frac{4}{-15} - \frac{1}{4}\ln\frac{5}{3} = -\frac{9}{160} + \frac{2}{15} + \frac{1}{4}\left(\ln\frac{5}{4} - \ln\frac{5}{3}\right) \\ &= \frac{37}{480} + \frac{1}{4}\ln\frac{3}{4} = \frac{37}{480} + \frac{1}{4}\ln 3 - \frac{1}{2}\ln 2\end{aligned}$$

19. $\displaystyle\int \frac{d\theta}{\cos^4\theta}$

SOLUTION We use the identity $1 + \tan^2\theta = \sec^2\theta$ to rewrite the integral:

$$\int \frac{d\theta}{\cos^4\theta} = \int \sec^4\theta\, d\theta = \int \left(1+\tan^2\theta\right)\sec^2\theta\, d\theta.$$

Now, we substitute $u = \tan\theta$. Then, $du = \sec^2\theta\, d\theta$ and

$$\int \frac{d\theta}{\cos^4\theta} = \int \left(1+u^2\right) du = u + \frac{u^3}{3} + C = \frac{\tan^3\theta}{3} + \tan\theta + C.$$

20. $\displaystyle\int \sin 2\theta \sin^2\theta\, d\theta$

SOLUTION We use the trigonometric identity $\sin 2\theta = 2\sin\theta\cos\theta$ to rewrite the integral:

$$\int \sin 2\theta \sin^2\theta\, d\theta = \int 2\sin\theta\cos\theta\sin^2\theta\, d\theta = \int 2\sin^3\theta\cos\theta\, d\theta.$$

Now, we substitute $u = \sin\theta$. Then $du = \cos\theta\, d\theta$ and

$$\int \sin 2\theta\sin^2\theta\, d\theta = 2\int u^3\, du = \frac{u^4}{2} + C = \frac{\sin^4\theta}{2} + C.$$

21. $\int_0^1 \ln(4-2x)\,dx$

SOLUTION Note that $\ln(4-2x) = \ln(2(2-x)) = \ln 2 + \ln(2-x)$. Use integration by parts to integrate $\ln(2-x)$, with $u = \ln(2-x)$, $v' = 1$, so that $u' = -\frac{1}{2-x}$ and $v = x$. Then

$$I = \int_0^1 \ln(4-2x)\,dx = \int_0^1 \ln 2\,dx + \int_0^1 \ln(2-x)\,dx = \ln 2 + (x\ln(2-x))\Big|_0^1 + \int_0^1 \frac{x}{2-x}\,dx$$

Now use long division on the remaining integral, and the substitution $u = 2-x$:

$$\begin{aligned} I &= \ln 2 + (x\ln(2-x))\Big|_0^1 + \int_0^1 \left(-1 + \frac{2}{2-x}\right) dx \\ &= \ln 2 + 1\ln 1 - \int_0^1 1\,dx + 2\int_0^1 \frac{1}{2-x}\,dx = \ln 2 - 1 - 2\int_2^1 \frac{1}{u}\,du \\ &= \ln 2 - 1 - 2\ln u\Big|_2^1 = \ln 2 - 1 + 2\ln 2 = 3\ln 2 - 1 \end{aligned}$$

22. $\int (\ln(x+1))^2\,dx$

SOLUTION First, substitute $w = x+1$, $dw = dx$. Then

$$\int (\ln(x+1))^2\,dx = \int (\ln w)^2\,dw.$$

Now, we use Integration by Parts with $u = (\ln w)^2$ and $v' = 1$. We find $u' = 2\frac{\ln w}{w}$, $v = w$, and

$$\int (\ln w)^2\,dw = w(\ln w)^2 - 2\int \ln w\,dw.$$

We use Integration by Parts again, this time with $u = \ln w$ and $v' = 1$. We find $u' = \frac{1}{w}$, $v = w$, and

$$\int \ln w\,dx = w\ln w - \int dw = w\ln w - w + C.$$

Thus,

$$\int (\ln w)^2\,dw = w(\ln w)^2 - 2w\ln w + 2w + C,$$

and

$$\int (\ln(x+1))^2\,dx = (x+1)\,[\ln(x+1)]^2 - 2(x+1)\ln(x+1) + 2(x+1) + C.$$

23. $\int \sin^5\theta\,d\theta$

SOLUTION We use the trigonometric identity $\sin^2\theta = 1 - \cos^2\theta$ to rewrite the integral:

$$\int \sin^5\theta\,d\theta = \int \sin^4\theta\sin\theta\,d\theta = \int \left(1-\cos^2\theta\right)^2 \sin\theta\,d\theta.$$

Now, we substitute $u = \cos\theta$. Then $du = -\sin\theta\,d\theta$ and

$$\begin{aligned} \int \sin^5\theta\,d\theta &= \int \left(1-u^2\right)^2(-du) = -\int \left(1 - 2u^2 + u^4\right) du \\ &= -\left(u - \frac{2}{3}u^3 + \frac{u^5}{5}\right) + C = -\frac{\cos^5\theta}{5} + \frac{2\cos^3\theta}{3} - \cos\theta + C. \end{aligned}$$

24. $\int \cos^4(9x-2)\,dx$

SOLUTION We substitute $u = 9x-2$, $du = 9\,dx$ and then use a reduction formula to evaluate the resulting integral. We obtain:

$$\int \cos^4(9x-2)\,dx = \frac{1}{9}\int \cos^4 u\,du = \frac{1}{9}\left(\frac{\cos^3 u\sin u}{4} + \frac{3}{4}\int \cos^2 u\,du\right)$$

$$= \frac{\cos^3 u \sin u}{36} + \frac{1}{12}\int \cos^2 u\,du = \frac{\cos^3 u \sin u}{36} + \frac{1}{12}\left(\frac{u}{2} + \frac{\sin 2u}{4}\right) + C$$
$$= \frac{\cos^3(9x-2)\sin(9x-2)}{36} + \frac{9x-2}{24} + \frac{\sin(18x-4)}{48} + C.$$

25. $\displaystyle\int_0^{\pi/4} \sin 3x \cos 5x\,dx$

SOLUTION First compute the indefinite integral, using the trigonometric identity:

$$\sin\alpha\cos\beta = \frac{1}{2}\left(\sin(\alpha+\beta) + \sin(\alpha-\beta)\right).$$

For $\alpha = 3x$ and $\beta = 5x$ we get:

$$\sin 3x \cos 5x = \frac{1}{2}\left(\sin 8x + \sin(-2x)\right) = \frac{1}{2}(\sin 8x - \sin 2x).$$

Hence,

$$\int \sin 3x \cos 5x\,dx = \frac{1}{2}\int \sin 8x\,dx - \frac{1}{2}\int \sin 2x\,dx = -\frac{1}{16}\cos 8x + \frac{1}{4}\cos 2x + C.$$

Then

$$\int_0^{\pi/4} \sin 3x \cos 5x\,dx = \left(\frac{1}{4}\cos 2x - \frac{1}{16}\cos 8x\right)\Big|_0^{\pi/4} = \frac{1}{4}\cos\frac{\pi}{2} - \frac{1}{16}\cos 2\pi - \frac{1}{4}\cos 0 + \frac{1}{16}\cos 0 = -\frac{1}{4}$$

26. $\displaystyle\int \sin 2x \sec^2 x\,dx$

SOLUTION We use the trigonometric identity $\sin 2x = 2\cos x \sin x$ to rewrite the integrand:

$$\sin 2x \sec^2 x = 2\sin x \cos x \sec^2 x = \frac{2\sin x \cos x}{\cos^2 x} = \frac{2\sin x}{\cos x} = 2\tan x.$$

Hence,

$$\int \sin 2x \sec^2 x\,dx = \int 2\tan x\,dx = 2\ln|\sec x| + C.$$

27. $\displaystyle\int \sqrt{\tan x}\,\sec^2 x\,dx$

SOLUTION We substitute $u = \tan x$. Then $du = \sec^2 x\,dx$ and we obtain:

$$\int \sqrt{\tan x}\,\sec^2 x\,dx = \int \sqrt{u}\,du = \frac{2}{3}u^{3/2} + C = \frac{2}{3}(\tan x)^{3/2} + C.$$

28. $\displaystyle\int (\sec x + \tan x)^2\,dx$

SOLUTION We rewrite the integrand as

$$(\sec x + \tan x)^2 = \sec^2 x + 2\sec x \tan x + \tan^2 x = 2\sec x \tan x + 2\sec^2 x - 1.$$

Therefore,

$$\int (\sec x + \tan x)^2\,dx = 2\int \sec x \tan x\,dx + 2\int \sec^2 x\,dx - \int dx = 2\sec x + 2\tan x - x + C.$$

29. $\displaystyle\int \sin^5\theta \cos^3\theta\,d\theta$

SOLUTION We use the identity $\cos^2\theta = 1 - \sin^2\theta$ to rewrite the integral:

$$\int \sin^5\theta\cos^3\theta\,d\theta = \int \sin^5\theta\cos^2\theta\cos\theta\,d\theta = \int \sin^5\theta\left(1 - \sin^2\theta\right)\cos\theta\,d\theta.$$

Now, we use the substitution $u = \sin\theta$, $du = \cos\theta\,d\theta$:

$$\int \sin^5\theta\cos^3\theta\,d\theta = \int u^5\left(1 - u^2\right)du = \int\left(u^5 - u^7\right)du = \frac{u^6}{6} - \frac{u^8}{8} + C = \frac{\sin^6\theta}{6} - \frac{\sin^8\theta}{8} + C.$$

30. $\displaystyle\int \cot^3 x \csc x\, dx$

SOLUTION Use the identity $\cot^2 x = \csc^2 x - 1$ to write

$$\int \cot^3 x \csc x\, dx = \int \left(\csc^2 x - 1\right) \csc x \cot x\, dx.$$

Now use the substitution $u = \csc x$, $du = -\csc x \cot x\, dx$:

$$\int \cot^3 x \csc x\, dx = -\int \left(u^2 - 1\right) du = \int \left(1 - u^2\right) du = u - \frac{1}{3}u^3 + C = \csc x - \frac{1}{3}\csc^3 x + C.$$

31. $\displaystyle\int \cot^2 x \csc^2 x\, dx$

SOLUTION Use the substitution $u = \cot x$, $du = -\csc^2 x\, dx$:

$$\int \cot^2 x \csc^2 x\, dx = -\int \cot^2 x \left(-\csc^2 x\, dx\right) = -\int u^2\, du = -\frac{1}{3}u^3 + C = -\frac{1}{3}\cot^3 x + C.$$

32. $\displaystyle\int_{\pi/2}^{\pi} \cot^2 \frac{\theta}{2}\, d\theta$

SOLUTION To compute the indefinite integral, substitute $u = \frac{\theta}{2}$. Then $du = \frac{1}{2}\, d\theta$ and

$$\int \cot^2 \frac{\theta}{2}\, d\theta = 2\int \cot^2 u\, du.$$

Now, we use a reduction formula to compute

$$\int \cot^2 \frac{\theta}{2}\, d\theta = 2\int \cot^2 u\, du = 2(-\cot u - u) + C = -2\cot\frac{\theta}{2} - \theta + C.$$

Then

$$\int_{\pi/2}^{\pi} \cot^2 \frac{\theta}{2}\, d\theta = \left(-2\cot\frac{\theta}{2} - \theta\right)\Bigg|_{\pi/2}^{\pi} = -2\cot\frac{\pi}{2} - \pi + 2\cot\frac{\pi}{4} + \frac{\pi}{2} = 0 - \pi + 2 + \frac{\pi}{2} = 2 - \frac{\pi}{2}$$

33. $\displaystyle\int_{\pi/4}^{\pi/2} \cot^2 x \csc^3 x\, dx$

SOLUTION To compute the indefinite integral, use the identity $\cot^2 x = \csc^2 x - 1$ to write

$$\int \cot^2 x \csc^3 x\, dx = \int \left(\csc^2 x - 1\right) \csc^3 x\, dx = \int \csc^5 x\, dx - \int \csc^3 x\, dx.$$

Now use the reduction formula for $\csc^m x$:

$$\begin{aligned}
\int \cot^2 x \csc^3 x\, dx &= \left(-\frac{1}{4}\cot x \csc^3 x + \frac{3}{4}\int \csc^3 x\, dx\right) - \int \csc^3 x\, dx \\
&= -\frac{1}{4}\cot x \csc^3 x - \frac{1}{4}\int \csc^3 x\, dx \\
&= -\frac{1}{4}\cot x \csc^3 x - \frac{1}{4}\left(-\frac{1}{2}\cot x \csc x + \frac{1}{2}\int \csc x\, dx\right) \\
&= -\frac{1}{4}\cot x \csc^3 x + \frac{1}{8}\cot x \csc x - \frac{1}{8}\ln|\csc x - \cot x| + C.
\end{aligned}$$

Then

$$\begin{aligned}
\int_{\pi/4}^{\pi/2} \cos^2 x \csc^3 x\, dx &= \left(-\frac{1}{4}\cot x \csc^3 x + \frac{1}{8}\cot x \csc x - \frac{1}{8}\ln|\csc x - \cot x|\right)\Bigg|_{\pi/4}^{\pi/2} \\
&= -\frac{1}{4}\cot\frac{\pi}{2}\csc^3\frac{\pi}{2} + \frac{1}{8}\cot\frac{\pi}{2}\csc\frac{\pi}{2} - \frac{1}{8}\ln\left|\csc\frac{\pi}{2} - \cot\frac{\pi}{2}\right| \\
&\quad + \frac{1}{4}\cot\frac{\pi}{4}\csc^3\frac{\pi}{4} - \frac{1}{8}\cot\frac{\pi}{4}\csc\frac{\pi}{4} + \frac{1}{8}\ln\left|\csc\frac{\pi}{4} - \cot\frac{\pi}{4}\right| \\
&= 0 + 0 - \frac{1}{8}\ln|1 - 0| + \frac{1}{4}\cdot 1\cdot(\sqrt{2})^3 - \frac{1}{8}\cdot 1\cdot\sqrt{2} + \frac{1}{8}\ln\left|\sqrt{2} - 1\right| \\
&= \frac{\sqrt{2}}{2} - \frac{\sqrt{2}}{8} + \frac{1}{8}\ln(\sqrt{2} - 1) = \frac{3}{8}\sqrt{2} + \frac{1}{8}\ln(\sqrt{2} - 1)
\end{aligned}$$

34. $\displaystyle\int_4^6 \frac{dt}{(t-3)(t+4)}$

SOLUTION The partial fraction decomposition takes the form

$$\frac{1}{(t-3)(t+4)} = \frac{A}{t-3} + \frac{B}{t+4}.$$

Clearing denominators gives us

$$1 = A(t+4) + B(t-3) = (A+B)t + 4A - 3B.$$

Setting $t = 3$ then yields $A = \frac{1}{7}$, while setting $t = -4$ yields $B = -\frac{1}{7}$. Hence,

$$\int_4^6 \frac{dt}{(t-3)(t+4)} = \frac{1}{7}\int_4^6 \frac{dt}{t-3} - \frac{1}{7}\int_4^6 \frac{dt}{t+4} = \left(\frac{1}{7}\ln|t-3| - \frac{1}{7}\ln|t+4|\right)\Big|_4^6$$
$$= \left(\frac{1}{7}\ln\left|\frac{t-3}{t+4}\right|\right)\Big|_4^6 = \frac{1}{7}\left(\ln\frac{3}{10} - \ln\frac{1}{8}\right) = \frac{1}{7}\ln\frac{12}{5}$$

35. $\displaystyle\int \frac{dt}{(t-3)^2(t+4)}$

SOLUTION The partial fraction decomposition has the form

$$\frac{1}{(t-3)^2(t+4)} = \frac{A}{t+4} + \frac{B}{t-3} + \frac{C}{(t-3)^2}.$$

Clearing denominators gives us

$$1 = A(t-3)^2 + B(t-3)(t+4) + C(t+4).$$

Setting $t = 3$ then yields $C = \frac{1}{7}$, while setting $t = -4$ yields $A = \frac{1}{49}$. Lastly, setting $t = 0$ yields

$$1 = 9A - 12B + 4C \qquad \text{or} \qquad B = -\frac{1}{49}.$$

Hence,

$$\int \frac{dt}{(t-3)^2(t+4)} = \frac{1}{49}\int \frac{dt}{t+4} - \frac{1}{49}\int \frac{dt}{t-3} + \frac{1}{7}\int \frac{dt}{(t-3)^2}$$
$$= \frac{1}{49}\ln|t+4| - \frac{1}{49}\ln|t-3| + \frac{1}{7}\cdot\frac{-1}{t-3} + C = \frac{1}{49}\ln\left|\frac{t+4}{t-3}\right| - \frac{1}{7}\cdot\frac{1}{t-3} + C.$$

36. $\displaystyle\int \sqrt{x^2+9}\,dx$

SOLUTION Substitute $x = 3\tan\theta$, $dx = 3\sec^2\theta\,d\theta$. Then

$$\sqrt{x^2+9} = \sqrt{9\tan^2\theta + 9} = \sqrt{9\left(\tan^2\theta + 1\right)} = 3\sqrt{\sec^2\theta} = 3\sec\theta,$$

and

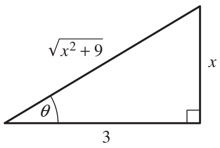
$$\int \sqrt{x^2+9}\,dx = \int 3\sec\theta \cdot 3\sec^2\theta\,d\theta = 9\int \sec^3\theta\,d\theta.$$

We use a reduction formula to compute the resulting integral:

$$\int \sqrt{x^2+9}\,dx = 9\int \sec^3\theta\,d\theta = 9\left(\frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\int \sec\theta\,d\theta\right) = \frac{9\tan\theta\sec\theta}{2} + \frac{9}{2}\ln|\sec\theta + \tan\theta| + C.$$

We now return to the original variable x. Since $x = 3\tan\theta$, we have $\theta = \tan^{-1}\frac{x}{3}$. We also use the figure to obtain:

$$\int \sqrt{x^2+9}\,dx = \frac{9}{2}\cdot\frac{x}{3}\cdot\frac{\sqrt{x^2+9}}{3} + \frac{9}{2}\ln\left|\frac{\sqrt{x^2+9}}{3} + \frac{x}{3}\right| + C = \frac{x\sqrt{x^2+9}}{2} + \frac{9}{2}\ln\left|\frac{x+\sqrt{x^2+9}}{3}\right| + C.$$



37. $\displaystyle\int \frac{dx}{x\sqrt{x^2-4}}$

SOLUTION Substitute $x = 2\sec\theta$, $dx = 2\sec\theta\tan\theta\, d\theta$. Then

$$\sqrt{x^2-4} = \sqrt{4\sec^2\theta - 4} = \sqrt{4\left(\sec^2\theta - 1\right)} = \sqrt{4\tan^2\theta} = 2\tan\theta,$$

and

$$\int \frac{dx}{x\sqrt{x^2-4}} = \int \frac{2\sec\theta\tan\theta\, d\theta}{2\sec\theta \cdot 2\tan\theta} = \frac{1}{2}\int d\theta = \frac{1}{2}\theta + C.$$

Now, return to the original variable x. Since $x = 2\sec\theta$, we have $\sec\theta = \frac{x}{2}$ or $\theta = \sec^{-1}\frac{x}{2}$. Thus,

$$\int \frac{dx}{x\sqrt{x^2-4}} = \frac{1}{2}\sec^{-1}\frac{x}{2} + C.$$

38. $\displaystyle\int_8^{27} \frac{dx}{x + x^{2/3}}$

SOLUTION We rewrite the integrand:

$$\int_8^{27} \frac{dx}{x + x^{2/3}} = \int_8^{27} \frac{dx}{x^{2/3}\left(x^{1/3}+1\right)} = \int_8^{27} t\,\frac{x^{-2/3}\,dx}{1 + x^{1/3}}.$$

Now, use the substitution $u = 1 + x^{1/3}$, $du = \frac{1}{3}x^{-2/3}\,dx$. $x = 8$ corresponds to $u = 3$, and $x = 27$ corresponds to $u = 4$. Then

$$\int_8^{27} \frac{dx}{x + x^{2/3}} = \int_8^{27} \frac{x^{-2/3}\,dx}{1 + x^{1/3}} = 3\int_3^4 \frac{du}{u} = 3\left(\ln|u|\right)\Big|_3^4 = 3(\ln 4 - \ln 3)$$

39. $\displaystyle\int \frac{dx}{x^{3/2} + ax^{1/2}}$

SOLUTION Let $u = x^{1/2}$ or $x = u^2$. Then $dx = 2u\,du$ and

$$\int \frac{dx}{x^{3/2} + ax^{1/2}} = \int \frac{2u\,du}{u^3 + au} = 2\int \frac{du}{u^2 + a}.$$

If $a > 0$, then

$$\int \frac{dx}{x^{3/2} + ax^{1/2}} = 2\int \frac{du}{u^2 + a} = \frac{2}{\sqrt{a}}\tan^{-1}\left(\frac{u}{\sqrt{a}}\right) + C = \frac{2}{\sqrt{a}}\tan^{-1}\sqrt{\frac{x}{a}} + C.$$

If $a = 0$, then

$$\int \frac{dx}{x^{3/2}} = -\frac{2}{\sqrt{x}} + C.$$

Finally, if $a < 0$, then

$$\int \frac{du}{u^2 + a} = \int \frac{du}{u^2 - \left(\sqrt{-a}\right)^2},$$

and the partial fraction decomposition takes the form

$$\frac{1}{u^2 - \left(\sqrt{-a}\right)^2} = \frac{A}{u - \sqrt{-a}} + \frac{B}{u + \sqrt{-a}}.$$

Clearing denominators gives us

$$1 = A(u + \sqrt{-a}) + B(u - \sqrt{-a}).$$

Setting $u = \sqrt{-a}$ then yields $A = \frac{1}{2\sqrt{-a}}$, while setting $u = -\sqrt{-a}$ yields $B = -\frac{1}{2\sqrt{-a}}$. Hence,

$$\begin{aligned}
\int \frac{dx}{x^{3/2} + ax^{1/2}} = 2\int \frac{du}{u^2 + a} &= \frac{1}{\sqrt{-a}}\int \frac{du}{u - \sqrt{-a}} - \frac{1}{\sqrt{-a}}\int \frac{du}{u + \sqrt{-a}} \\
&= \frac{1}{\sqrt{-a}}\ln|u - \sqrt{-a}| - \frac{1}{\sqrt{-a}}\ln\left|u + \sqrt{-a}\right| + C \\
&= \frac{1}{\sqrt{-a}}\ln\left|\frac{u - \sqrt{-a}}{u + \sqrt{-a}}\right| + C = \frac{1}{\sqrt{-a}}\ln\left|\frac{\sqrt{x} - \sqrt{-a}}{\sqrt{x} + \sqrt{-a}}\right| + C.
\end{aligned}$$

In summary,

$$\int \frac{dx}{x^{3/2}+ax^{1/2}} = \begin{cases} \frac{2}{\sqrt{a}}\tan^{-1}\sqrt{\frac{x}{a}}+C & a>0 \\ \frac{1}{\sqrt{-a}}\ln\left|\frac{\sqrt{x}-\sqrt{-a}}{\sqrt{x}+\sqrt{-a}}\right|+C & a<0 \\ -\frac{2}{\sqrt{x}}+C & a=0 \end{cases}$$

40. $\int \frac{dx}{(x-b)^2+4}$

SOLUTION Substitute $u = x - b$, $du = dx$. Then

$$\int \frac{dx}{(x-b)^2+4} = \int \frac{du}{u^2+4} = \frac{1}{2}\tan^{-1}\frac{u}{2} + C = \frac{1}{2}\tan^{-1}\left(\frac{x-b}{2}\right) + C.$$

41. $\int \frac{(x^2-x)\,dx}{(x+2)^3}$

SOLUTION The partial fraction decomposition has the form

$$\frac{x^2-x}{(x+2)^3} = \frac{A}{x+2} + \frac{B}{(x+2)^2} + \frac{C}{(x+2)^3}.$$

Clearing denominators gives us

$$x^2 - x = A(x+2)^2 + B(x+2) + C.$$

Setting $x = -2$ then yields $C = 6$. Equating x^2-coefficients gives us $A = 1$, and equating x-coefficients yields $4A + B = -1$, or $B = -5$. Thus,

$$\int \frac{x^2-x}{(x+2)^3}\,dx = \int \frac{dx}{x+2} + \int \frac{-5\,dx}{(x+2)^2} + \int \frac{6\,dx}{(x+2)^3} = \ln|x+2| + \frac{5}{x+2} - \frac{3}{(x+2)^2} + C.$$

42. $\int \frac{(7x^2+x)\,dx}{(x-2)(2x+1)(x+1)}$

SOLUTION The partial fraction decomposition has the form

$$\frac{7x^2+x}{(x-2)(2x+1)(x+1)} = \frac{A}{x-2} + \frac{B}{2x+1} + \frac{C}{x+1}.$$

Clearing denominators gives us

$$7x^2 + x = A(2x+1)(x+1) + B(x-2)(x+1) + C(x-2)(2x+1).$$

Setting $x = 2$ then yields $A = 2$, while setting $x = -\frac{1}{2}$ yields $B = -1$, and setting $x = -1$ yields $C = 2$. Hence,

$$\int \frac{7x^2+x}{(x-2)(2x+1)(x+1)}\,dx = 2\int \frac{dx}{x-2} - \int \frac{dx}{2x+1} + 2\int \frac{dx}{x+1}$$

$$= 2\ln|x-2| - \frac{1}{2}\ln|2x+1| + 2\ln|x+1| + C.$$

43. $\int \frac{16\,dx}{(x-2)^2(x^2+4)}$

SOLUTION The partial fraction decomposition has the form

$$\frac{16}{(x-2)^2\left(x^2+4\right)} = \frac{A}{x-2} + \frac{B}{(x-2)^2} + \frac{Cx+D}{x^2+4}.$$

Clearing denominators gives us

$$16 = A(x-2)\left(x^2+4\right) + B\left(x^2+4\right) + (Cx+D)(x-2)^2.$$

Setting $x = 2$ then yields $B = 2$. With $B = 2$,

$$16 = A\left(x^3 - 2x^2 + 4x - 8\right) + 2\left(x^2+4\right) + Cx^3 + (D-4C)x^2 + (4C-4D)x + 4D$$

$$16 = (A+C)x^3 + (-2A + 2 + D - 4C)\,x^2 + (4A + 4C - 4D)x + (-8A + 8 + 4D)$$

Equating coefficients of like powers of x now gives us the system of equations

$$\begin{aligned} A + C &= 0 \\ -2A - 4C + D + 2 &= 0 \\ 4A + 4C - 4D &= 0 \\ -8A + 4D + 8 &= 1 \end{aligned}$$

whose solution is

$$A = -1,\ C = 1,\ D = 0.$$

Thus,

$$\begin{aligned} \int \frac{dx}{(x-2)^2\left(x^2+4\right)} &= -\int \frac{dx}{x-2} + 2\int \frac{dx}{(x-2)^2} + \int \frac{x}{x^2+4}\,dx \\ &= -\ln|x-2| - 2\frac{1}{x-2} + \frac{1}{2}\ln\left(x^2+4\right) + C. \end{aligned}$$

44. $\displaystyle\int \frac{dx}{(x^2+25)^2}$

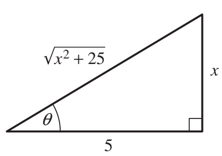
SOLUTION Use the trigonometric substitution $x = 5\tan\theta$, $dx = 5\sec^2\theta\,d\theta$,

$$x^2 + 25 = (5\tan\theta)^2 + 25 = 25\left(\tan^2\theta + 1\right) = 25\sec^2\theta.$$

Then,

$$\begin{aligned} \int \frac{dx}{\left(x^2+25\right)^2} &= \int \frac{5\sec^2\theta\,d\theta}{\left(25\sec^2\theta\right)^2} = \int \frac{d\theta}{125\sec^2\theta} = \frac{1}{125}\int \cos^2\theta\,d\theta \\ &= \frac{1}{125}\left(\frac{\cos\theta\sin\theta}{2} + \frac{1}{2}\theta\right) + C = \frac{1}{250}(\cos\theta\sin\theta + \theta) + C. \end{aligned}$$

To return to the original variable x we use the relation $x = 5\tan\theta$ and the accompanying figure.



Thus,

$$\int \frac{dx}{\left(x^2+25\right)^2} = \frac{1}{250}\left(\frac{5}{\sqrt{x^2+25}} \cdot \frac{x}{\sqrt{x^2+25}} + \tan^{-1}\left(\frac{x}{5}\right)\right) + C = \frac{1}{50}\frac{x}{x^2+25} + \frac{1}{250}\tan^{-1}\left(\frac{x}{5}\right) + C.$$

45. $\displaystyle\int \frac{dx}{x^2+8x+25}$

SOLUTION Complete the square to rewrite the denominator as

$$x^2 + 8x + 25 = (x+4)^2 + 9.$$

Now, let $u = x + 4$, $du = dx$. Then,

$$\int \frac{dx}{x^2+8x+25} = \int \frac{du}{u^2+9} = \frac{1}{3}\tan^{-1}\frac{u}{3} + C = \frac{1}{3}\tan^{-1}\left(\frac{x+4}{3}\right) + C.$$

46. $\displaystyle\int \frac{dx}{x^2+8x+4}$

SOLUTION Use the method of partial fractions. To facilitate the computations we first complete the square in the denominator:

$$\frac{1}{x^2+8x+4} = \frac{1}{(x+4)^2 - 12}.$$

Now we substitute $t = x + 4$. Then $dt = dx$ and

$$\int \frac{dx}{x^2 + 8x + 4} = \int \frac{dt}{t^2 - 12} = \int \frac{dt}{\left(t - 2\sqrt{3}\right)\left(t + 2\sqrt{3}\right)}.$$

We use the following partial fraction decomposition of the integrand:

$$\frac{1}{\left(t - 2\sqrt{3}\right)\left(t + 2\sqrt{3}\right)} = \frac{A}{t - 2\sqrt{3}} + \frac{B}{t + 2\sqrt{3}}.$$

Clearing denominators gives us

$$1 = A\left(t + 2\sqrt{3}\right) + B\left(t - 2\sqrt{3}\right).$$

Setting $t = 2\sqrt{3}$ then yields $A = \frac{1}{4\sqrt{3}}$, while setting $t = -2\sqrt{3}$ yields $B = -\frac{1}{4\sqrt{3}}$. Hence,

$$\int \frac{dx}{x^2 + 8x + 4} = \frac{1}{4\sqrt{3}} \int \frac{dt}{t - 2\sqrt{3}} - \frac{1}{4\sqrt{3}} \int \frac{dt}{t + 2\sqrt{3}} = \frac{1}{4\sqrt{3}} \ln|t - 2\sqrt{3}| - \frac{1}{4\sqrt{3}} \ln|t + 2\sqrt{3}| + C$$

$$= \frac{1}{4\sqrt{3}} \ln\left|\frac{t - 2\sqrt{3}}{t + 2\sqrt{3}}\right| + C = \frac{1}{4\sqrt{3}} \ln\left|\frac{x + 42\sqrt{3}}{x + 4 + 2\sqrt{3}}\right| + C.$$

47. $\displaystyle\int \frac{(x^2 - x)\,dx}{(x + 2)^3}$

SOLUTION The partial fraction decomposition has the form

$$\frac{x^2 - x}{(x + 2)^3} = \frac{A}{x + 2} + \frac{B}{(x + 2)^2} + \frac{C}{(x + 2)^3}.$$

Clearing denominators gives us

$$x^2 - x = A(x + 2)^2 + B(x + 2) + C.$$

Setting $x = -2$ then yields $C = 6$. Equating x^2-coefficients gives us $A = 1$, and equating x-coefficients yields $4A + B = -1$, or $B = -5$. Thus,

$$\int \frac{x^2 - x}{(x + 2)^3}\,dx = \int \frac{dx}{x + 2} + \int \frac{-5\,dx}{(x + 2)^2} + \int \frac{6\,dx}{(x + 2)^3} = \ln|x + 2| + \frac{5}{x + 2} - \frac{3}{(x + 2)^2} + C.$$

48. $\displaystyle\int_0^1 t^2\sqrt{1 - t^2}\,dt$

SOLUTION First compute the indefinite integral by using the substitution $t = \sin\theta$, $dt = \cos\theta\,d\theta$. We have

$$\sqrt{1 - t^2} = \sqrt{1 - \sin^2\theta} = \sqrt{\cos^2\theta} = \cos\theta,$$

and

$$\int t^2\sqrt{1 - t^2}\,dt = \int \sin^2\theta\cos\theta\cos\theta\,d\theta = \int \sin^2\theta\cos^2\theta\,d\theta$$

$$= \int (1 - \cos^2\theta)\cos^2\theta\,d\theta = \int \cos^2\theta\,d\theta - \int \cos^4\theta\,d\theta$$

$$= \int \cos^2\theta\,d\theta - \left(\frac{1}{4}\cos^3\theta\sin\theta + \frac{3}{4}\int \cos^2\theta\,d\theta\right)$$

$$= -\frac{1}{4}\cos^3\theta\sin\theta + \frac{1}{4}\int \cos^2\theta\,d\theta$$

$$= -\frac{1}{4}\cos^3\theta\sin\theta + \frac{1}{4}\left(\frac{1}{2}\cos\theta\sin\theta + \frac{1}{2}\theta\right) + C$$

$$= -\frac{1}{4}\cos^3\theta\sin\theta + \frac{1}{8}\cos\theta\sin\theta + \frac{1}{8}\theta + C.$$

Now, return to the original variable t. Since $t = \sin\theta$, $\cos\theta = \sqrt{1 - t^2}$ and

$$\int t^2\sqrt{1 - t^2}\,dt = -\frac{t(1 - t^2)^{3/2}}{4} + \frac{t\sqrt{1 - t^2}}{8} + \frac{\sin^{-1} t}{8} + C = \frac{t^3\sqrt{1 - t^2}}{4} + \frac{\sin^{-1} t}{8} - \frac{t\sqrt{1 - t^2}}{8} + C.$$

Then

$$\int_0^1 t^2\sqrt{1-t^2}\,dt = \left(\frac{t^3\sqrt{1-t^2}}{4} + \frac{\sin^{-1} t}{8} - \frac{t\sqrt{1-t^2}}{8}\right)\Bigg|_0^1$$

$$= 0 + \frac{1}{8}\sin^{-1} 1 - 0 - 0 + \frac{1}{8}\sin^{-1} 0 + 0 = \frac{\sin^{-1} 1}{8} = \frac{\pi}{16}$$

49. $\int \frac{dx}{x^4\sqrt{x^2+4}}$

SOLUTION Substitute $x = 2\tan\theta$, $dx = 2\sec^2\theta\,d\theta$. Then

$$\sqrt{x^2+4} = \sqrt{4\tan^2\theta + 4} = \sqrt{4\left(\tan^2\theta + 1\right)} = 2\sqrt{\sec^2\theta} = 2\sec\theta,$$

and

$$\int \frac{dx}{x^4\sqrt{x^2+4}} = \int \frac{2\sec^2\theta\,d\theta}{16\tan^4\theta \cdot 2\sec\theta} = \int \frac{\sec\theta\,d\theta}{16\tan^4\theta}.$$

We have

$$\frac{\sec\theta}{\tan^4\theta} = \frac{\cos^3\theta}{\sin^4\theta}.$$

Hence,

$$\int \frac{dx}{x^4\sqrt{x^2+4}} = \frac{1}{16}\int \frac{\cos^3\theta\,d\theta}{\sin^4\theta} = \frac{1}{16}\int \frac{\cos^2\theta\cos\theta\,d\theta}{\sin^4\theta} = \frac{1}{16}\int \frac{\left(1-\sin^2\theta\right)\cos\theta\,d\theta}{\sin^4\theta}.$$

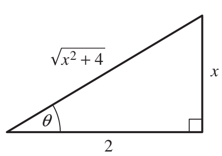
Now substitute $u = \sin\theta$ and $du = \cos\theta\,d\theta$ to obtain

$$\int \frac{dx}{x^4\sqrt{x^2+4}} = \frac{1}{16}\int \frac{1-u^2}{u^4}\,du = \frac{1}{16}\int \left(u^{-4} - u^{-2}\right)du = -\frac{1}{48u^3} + \frac{1}{16}\frac{1}{u} + C$$

$$= -\frac{1}{48}\cdot\frac{1}{\sin^3\theta} + \frac{1}{16}\frac{1}{\sin\theta} + C = -\frac{1}{48}\csc^3\theta + \frac{1}{16}\csc\theta + C.$$

Finally, return to the original to the original variable x using the relation $x = 2\tan\theta$ and the figure below.

$$\int \frac{dx}{x^4\sqrt{x^2+4}} = -\frac{1}{48}\left(\frac{\sqrt{x^2+4}}{x}\right)^3 + \frac{1}{16}\frac{\sqrt{x^2+4}}{x} + C = -\frac{\left(x^2+4\right)^{3/2}}{48x^3} + \frac{\sqrt{x^2+4}}{16x} + C.$$



50. $\int \frac{dx}{(x^2+5)^{3/2}}$

SOLUTION Substitute $x = \sqrt{5}\tan\theta$. Then $dx = \sqrt{5}\sec^2\theta\,d\theta$,

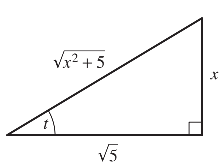
$$x^2 + 5 = 5\tan^2\theta + 5 = 5(\tan^2\theta + 1) = 5\sec^2\theta,$$

and

$$\int \frac{dx}{\left(x^2+5\right)^{3/2}} = \frac{1}{5}\int \frac{\sec^2\theta}{\sec^3\theta}\,d\theta = \frac{1}{5}\int \cos\theta\,d\theta = \frac{1}{5}\sin\theta + C.$$

We now return to the original variable x using the relation $x = \sqrt{5}\tan\theta$ and the figure below. Thus,

$$\int \frac{dx}{\left(x^2+5\right)^{3/2}} = \frac{1}{5}\cdot\frac{x}{\sqrt{x^2+5}} + C.$$



51. $\int (x+1)e^{4-3x}\,dx$

SOLUTION We compute the integral using Integration by Parts with $u = x+1$ and $v' = e^{4-3x}$. Then $u' = 1$, $v = -\frac{1}{3}e^{4-3x}$ and

$$\int (x+1)e^{4-3x}\,dx = -\frac{1}{3}(x+1)e^{4-3x} + \frac{1}{3}\int e^{4-3x}\,dx = -\frac{1}{3}(x+1)e^{4-3x} + \frac{1}{3}\cdot\left(-\frac{1}{3}\right)e^{4-3x} + C$$
$$= -\frac{1}{9}e^{4-3x}(3x+4) + C.$$

52. $\int x^{-2}\tan^{-1}x\,dx$

SOLUTION We use Integration by Parts with $u = \tan^{-1}x$ and $v' = x^{-2}$. Then $u' = \frac{1}{1+x^2}$, $v = -x^{-1}$ and

$$\int x^{-2}\tan^{-1}x\,dx = -\frac{\tan^{-1}x}{x} + \int \frac{dx}{x\left(1+x^2\right)}.$$

For the remaining integral, the partial fraction decomposition takes the form

$$\frac{1}{x(1+x^2)} = \frac{A}{x} + \frac{Bx+C}{1+x^2}.$$

Clearing denominators gives us

$$1 = A(1+x^2) + (Bx+C)x.$$

Setting $x = 0$ then yields $A = 1$. Next, equating the x^2-coefficients gives

$$0 = A + B \qquad \text{so} \qquad B = -1,$$

while equating x-coefficients gives $C = 0$. Hence,

$$\frac{1}{x\left(1+x^2\right)} = \frac{1}{x} - \frac{x}{1+x^2},$$

and

$$\int \frac{dx}{x\left(1+x^2\right)} = \int \frac{1}{x}\,dx - \int \frac{x\,dx}{1+x^2} = \ln|x| - \frac{1}{2}\ln\left(1+x^2\right) + C.$$

Therefore,

$$\int x^{-2}\tan^{-1}x\,dx = -\frac{\tan^{-1}x}{x} + \ln|x| - \frac{1}{2}\ln\left(1+x^2\right) + C.$$

53. $\int x^3\cos(x^2)\,dx$

SOLUTION Substitute $t = x^2$, $dt = 2x\,dx$. Then

$$\int x^3\cos\left(x^2\right)\,dx = \frac{1}{2}\int t\cos t\,dt.$$

We compute the resulting integral using Integration by Parts with $u = t$ and $v' = \cos t$. Then $u' = 1$, $v = \sin t$ and

$$\int t\cos t\,dt = t\sin t - \int \sin t\,dt = t\sin t + \cos t + C.$$

Thus,

$$\int x^3\cos\left(x^2\right)\,dx = \frac{1}{2}x^2\sin x^2 + \frac{1}{2}\cos x^2 + C.$$

54. $\int x^2(\ln x)^2\,dx$

SOLUTION We use Integration by Parts with $u = (\ln x)^2$ and $v' = x^2$. Then $u' = \frac{2\ln x}{x}$, $v = \frac{x^3}{3}$ and

$$\int x^2(\ln x)^2dx = \frac{x^3}{3}(\ln x)^2 - \frac{2}{3}\int x^2\ln x\,dx.$$

To calculate the resulting integral, we again use Integration by Parts, this time with $u = \ln x$ and $v' = x^2$. Then, $u' = \frac{1}{x}$, $v = \frac{x^3}{3}$, and

$$\int x^2 \ln x\, dx = \frac{x^3}{3} \ln x - \frac{1}{3} \int x^2\, dx = \frac{x^3}{3} \ln x - \frac{x^3}{9} + C.$$

Finally,

$$\int x^2 (\ln x)^2 dx = \frac{x^3}{3} (\ln x)^2 - \frac{2}{3} \left(\frac{x^3}{3} \ln x - \frac{x^3}{9} \right) + C = \frac{x^3}{3} \left((\ln x)^2 - \frac{2}{3} \ln x + \frac{2}{9} \right) + C.$$

55. $\int x \tanh^{-1} x\, dx$

SOLUTION We use Integration by Parts with $u = \tanh^{-1} x$ and $v' = x$. Then $u' = \frac{1}{1-x^2}$, $v = \frac{x^2}{2}$ and

$$\int x \tanh^{-1} x\, dx = \frac{x^2}{2} \tanh^{-1} x - \frac{1}{2} \int \frac{x^2}{1 - x^2}\, dx.$$

Now

$$\frac{x^2}{1-x^2} = \frac{x^2 - 1 + 1}{1 - x^2} = -1 + \frac{1}{1-x^2},$$

and the partial fraction decomposition for the remaining fraction takes the form

$$\frac{1}{1-x^2} = \frac{A}{1-x} + \frac{B}{1+x}.$$

Clearing denominators gives us

$$1 = A(1+x) + B(1-x).$$

Setting $x = 1$ then yields $A = \frac{1}{2}$, while setting $x = -1$ yields $B = \frac{1}{2}$. Thus,

$$\begin{aligned} \int \frac{x^2}{1-x^2} &= -\int dx + \frac{1}{2} \int \frac{1}{1-x}\, dx + \frac{1}{2} \int \frac{1}{1+x}\, dx \\ &= -x - \frac{1}{2} \ln |1-x| + \frac{1}{2} \ln |1+x| + C = -x + \frac{1}{2} \ln \left| \frac{1+x}{1-x} \right| + C. \end{aligned}$$

Therefore,

$$\int x \tanh^{-1} x\, dx = \frac{x^2}{2} \tanh^{-1} x - \frac{1}{2} \left(-x + \frac{1}{2} \ln \left| \frac{1+x}{1-x} \right| \right) + C = \frac{x^2}{2} \tanh^{-1} x + \frac{x}{2} - \frac{1}{4} \ln \left| \frac{1+x}{1-x} \right| + C.$$

56. $\int \frac{\tan^{-1} t\, dt}{1+t^2}$

SOLUTION Substitute $u = \tan^{-1} t$. Then, $du = \frac{dt}{1+t^2}$ and

$$\int \frac{\tan^{-1} t\, dt}{1+t^2} = \int u\, du = \frac{1}{2} u^2 + C = \frac{1}{2} \left(\tan^{-1} t \right)^2 + C.$$

57. $\int \ln(x^2 + 9)\, dx$

SOLUTION We compute the integral using Integration by Parts with $u = \ln \left(x^2 + 9 \right)$ and $v' = 1$. Then $u' = \frac{2x}{x^2+9}$, $v = x$, and

$$\int \ln \left(x^2 + 9 \right)\, dx = x \ln \left(x^2 + 9 \right) - \int \frac{2x^2}{x^2 + 9}\, dx.$$

To compute this integral we write:

$$\frac{x^2}{x^2+9} = \frac{\left(x^2 + 9 \right) - 9}{x^2 + 9} = 1 - \frac{9}{x^2+9};$$

hence,

$$\int \frac{x^2}{x^2+9}\,dx = \int 1\,dx - 9\int \frac{dx}{x^2+9} = x - 3\tan^{-1}\frac{x}{3} + C.$$

Therefore,

$$\int \ln\left(x^2+9\right)\,dx = x\ln\left(x^2+9\right) - 2x + 6\tan^{-1}\left(\frac{x}{3}\right) + C.$$

58. $\int (\sin x)(\cosh x)\,dx$

SOLUTION We compute the integral using Integration by Parts with $u = \sin x$ and $v' = \cosh x$. Then $u' = \cos x$, $v = \sinh x$ and

$$\int \sin x \cosh x\,dx = \sin x \sinh x - \int \cos x \sinh x\,dx.$$

We compute the resulting integral using Integration by Parts, this time with $u = \cos x$ and $v' = \sinh x$. Then $u' = -\sin x$, $v = \cosh x$ and

$$\int \cos x \sinh x\,dx = \cos x \cosh x + \int \sin x \cosh x\,dx.$$

Therefore,

$$\int \sin x \cosh x\,dx = \sin x \sinh x - \cos x \cosh x - \int \sin x \cosh x\,dx.$$

Solving for $\int (\sin x)(\cosh x)\,dx$, we find

$$2\int \sin x \cosh x\,dx = \sin x \sinh x - \cos x \cosh x + C$$
$$\int \sin x \cosh x\,dx = \frac{1}{2}\sin x \sinh x - \frac{1}{2}\cos x \cosh x + C$$

59. $\int_0^1 \cosh 2t\,dt$

SOLUTION $\int_0^1 \cosh 2t\,dt = \frac{1}{2}\sinh 2t\Big|_0^1 = \frac{1}{2}\sinh 2.$

60. $\int \sinh^3 x \cosh x\,dx$

SOLUTION Let $u = \sinh x$. Then $du = \cosh x\,dx$ and

$$\int \sinh^3 x \cosh x\,dx = \int u^3\,du = \frac{1}{4}u^4 + C = \frac{1}{4}\sinh^4 x + C.$$

61. $\int \coth^2(1-4t)\,dt$

SOLUTION $\int \coth^2(1-4t)\,dt = \int \left(1 + \operatorname{csch}^2(1-4t)\right)\,dt = t + \frac{1}{4}\coth(1-4t) + C.$

62. $\int_{-0.3}^{0.3} \frac{dx}{1-x^2}$

SOLUTION $\int_{-0.3}^{0.3} \frac{dx}{1-x^2} = \tanh^{-1} x\Big|_{-0.3}^{0.3} = 2\tanh^{-1}(0.3).$

63. $\int_0^{3\sqrt{3}/2} \frac{dx}{\sqrt{9-x^2}}$

SOLUTION $\int_0^{3\sqrt{3}/2} \frac{dx}{\sqrt{9-x^2}} = \sin^{-1}\frac{x}{3}\Big|_0^{3\sqrt{3}/2} = \sin^{-1}\frac{\sqrt{3}}{2} = \frac{\pi}{3}.$

64. $\displaystyle\int \frac{\sqrt{x^2+1}\,dx}{x^2}$

SOLUTION Let $x = \sinh t$. Then $dx = \cosh t\,dt$ and

$$\int \frac{\sqrt{x^2+1}\,dx}{x^2} = \int \frac{\cosh^2 t}{\sinh^2 t}\,dt = \int \coth^2 t\,dt = \int (1+\operatorname{csch}^2 t)\,dt = t - \coth t + C$$
$$= \sinh^{-1} x - \frac{\sqrt{x^2+1}}{x} + C.$$

65. Use the substitution $u = \tanh t$ to evaluate $\displaystyle\int \frac{dt}{\cosh^2 t + \sinh^2 t}$.

SOLUTION Let $u = \tanh t$. Then $du = \operatorname{sech}^2 t\,dt$ and

$$\int \frac{dt}{\cosh^2 t + \sinh^2 t} = \int \frac{\operatorname{sech}^2 t}{1+\tanh^2 t}\,dt = \int \frac{du}{1+u^2} = \tan^{-1} u + C = \tan^{-1}(\tanh x) + C.$$

66. Find the volume obtained by rotating the region enclosed by $y = \ln x$ and $y = (\ln x)^2$ about the y-axis.

SOLUTION The curves meet at $(1, 0)$ and at $(e, 1)$. We compute the volume of the solid using the method of cylindrical shells:

$$V = \int_1^e 2\pi x \cdot (\ln x - (\ln x)^2)\,dx = 2\pi \int_1^e x \ln x\,dx - 2\pi \int_0^1 x(\ln x)^2\,dx$$

For the second integral, use integration by parts, with $u = (\ln x)^2$ and $v' = x$, so that $u' = \frac{2\ln x}{x}$ and $v = \frac{1}{2}x^2$. Then

$$V = 2\pi \int_1^e x \ln x\,dx - 2\pi \left(\frac{1}{2}x^2(\ln x)^2 \Big|_1^e - \int_1^e x \ln x\,dx \right) = -\pi e^2 + 4\pi \int_1^e x \ln x\,dx$$

Again apply integration by parts, with $u = \ln x$ and $v' = x$, so that $u' = \frac{1}{x}$ and $v = \frac{1}{2}x^2$. Then

$$V = -\pi e^2 + 4\pi \int_1^e x \ln x\,dx = -\pi e^2 + 4\pi \left(\frac{1}{2}x^2 \ln x \Big|_1^e - \frac{1}{2}\int_1^e x\,dx \right) = -\pi e^2 + 4\pi \left(\frac{1}{2}e^2 - \frac{1}{4}e^2 + \frac{1}{4} \right) = \pi$$

67. Let $I_n = \displaystyle\int \frac{x^n\,dx}{x^2+1}$.

(a) Prove that $I_n = \dfrac{x^{n-1}}{n-1} - I_{n-2}$.

(b) Use (a) to calculate I_n for $0 \le n \le 5$.

(c) Show that, in general,

$$I_{2n+1} = \frac{x^{2n}}{2n} - \frac{x^{2n-2}}{2n-2} + \cdots + (-1)^{n-1}\frac{x^2}{2} + (-1)^n \frac{1}{2}\ln(x^2+1) + C$$
$$I_{2n} = \frac{x^{2n-1}}{2n-1} - \frac{x^{2n-3}}{2n-3} + \cdots + (-1)^{n-1}x + (-1)^n \tan^{-1} x + C$$

SOLUTION

(a) $I_n = \displaystyle\int \frac{x^n}{x^2+1}\,dx = \int \frac{x^{n-2}(x^2+1-1)}{x^2+1}\,dx = \int x^{n-2}\,dx - \int \frac{x^{n-2}}{x^2+1}\,dx = \frac{x^{n-1}}{n-1} - I_{n-2}.$

(b) First compute I_0 and I_1 directly:

$$I_0 = \int \frac{x^0\,dx}{x^2+1} = \int \frac{dx}{x^2+1} = \tan^{-1}x + C \quad \text{and} \quad I_1 = \int \frac{x\,dx}{x^2+1} = \frac{1}{2}\ln\left(x^2+1\right) + C.$$

We now use the equality obtained in part (a) to compute I_2, I_3, I_4 and I_5:

$$I_2 = \frac{x^{2-1}}{2-1} - I_{2-2} = x - I_0 = x - \tan^{-1}x + C;$$
$$I_3 = \frac{x^{3-1}}{3-1} - I_{3-2} = \frac{x^2}{2} - I_1 = \frac{x^2}{2} - \frac{1}{2}\ln\left(x^2+1\right) + C;$$
$$I_4 = \frac{x^{4-1}}{4-1} - I_{4-2} = \frac{x^3}{3} - I_2 = \frac{x^3}{3} - \left(x - \tan^{-1}x\right) + C = \frac{x^3}{3} - x + \tan^{-1}x + C;$$
$$I_5 = \frac{x^{5-1}}{5-1} - I_{5-2} = \frac{x^4}{4} - I_3 = \frac{x^4}{4} - \left(\frac{x^2}{2} - \frac{1}{2}\ln\left(x^2+1\right)\right) + C = \frac{x^4}{4} - \frac{x^2}{2} + \frac{1}{2}\ln\left(x^2+1\right) + C.$$

(c) We prove the two identities using mathematical induction. We first prove that for $n \geq 1$:

$$I_{2n+1} = \frac{x^{2n}}{2n} - \frac{x^{2n-2}}{2n-2} + \cdots + (-1)^n \cdot \frac{1}{2} \ln\left(x^2+1\right) + C.$$

We verify the equality for $n = 1$. Setting $n = 1$, we find

$$I_3 = \frac{x^2}{2} + (-1)^1 \cdot \frac{1}{2} \ln\left(x^2+1\right) + C = \frac{x^2}{2} - \frac{1}{2} \ln\left(x^2+1\right) + C,$$

which agrees with the value obtained in part (b). We now assume that for $n = k$:

$$I_{2k+1} = \frac{x^{2k}}{2k} - \frac{x^{2k-2}}{2k-2} + \cdots + (-1)^k \cdot \frac{1}{2} \ln\left(x^2+1\right) + C.$$

We use this assumption to prove the equality for $n = k + 1$. By part (a) and the induction hypothesis

$$\begin{aligned} I_{2k+3} = \frac{x^{2k+2}}{2k+2} - I_{2k+1} &= \frac{x^{2k+2}}{2k+2} - \frac{x^{2k}}{2k} + \frac{x^{2k-2}}{2k-2} - \cdots - (-1)^k \cdot \frac{1}{2} \ln\left(x^2+1\right) + C \\ &= \frac{x^{2k+2}}{2k+2} - \frac{x^{2k}}{2k} + \cdots + (-1)^{k+1} \cdot \frac{1}{2} \ln\left(x^2+1\right) + C \end{aligned}$$

as required. We now prove the second identity for $n \geq 1$:

$$I_{2n} = \frac{x^{2n-1}}{2n-1} - \frac{x^{2n-3}}{2n-3} + \cdots + (-1)^n \tan^{-1} x + C.$$

We verify this equality for $n = 1$:

$$I_2 = x - \tan^{-1} x + C,$$

which agrees with the value obtained in part (b). We now assume that for $n = k$

$$I_{2k} = \frac{x^{2k-1}}{2k-1} - \frac{x^{2k-3}}{2k-3} + \cdots + (-1)^k \tan^{-1} x + C.$$

We use this assumption to prove the equality for $n = k + 1$. By part (a) and the induction hypothesis

$$\begin{aligned} I_{2k+2} = \frac{x^{2k+1}}{2k+1} - I_{2k} &= \frac{x^{2k+1}}{2k+1} - \frac{x^{2k-1}}{2k-1} + \frac{x^{2k-3}}{2k-3} - \cdots - (-1)^k \cdot \tan^{-1} x + C \\ &= \frac{x^{2k+1}}{2k+1} - \frac{x^{2k-1}}{2k-1} + \cdots + (-1)^{k+1} \cdot \tan^{-1} x + C \end{aligned}$$

as required.

68. Let $J_n = \int x^n e^{-x^2/2}\, dx$.

(a) Show that $J_1 = -e^{-x^2/2}$.

(b) Prove that $J_n = -x^{n-1} e^{-x^2/2} + (n-1) J_{n-2}$.

(c) Use (a) and (b) to compute J_3 and J_5.

SOLUTION

(a) Let $u = -\frac{x^2}{2}$. Then $du = -x\, dx$ and

$$J_1 = \int x e^{-x^2/2}\, dx = -\int e^u\, du = -e^u + C = -e^{-x^2/2} + C.$$

(b) Using Integration by Parts with $u = x^{n-1}$ and $v' = x e^{-x^2/2}$, we find

$$J_n = -x^{n-1} e^{-x^2/2} + (n-1) \int x^{n-2} e^{-x^2/2}\, dx = -x^{n-1} e^{-x^2/2} + (n-1) J_{n-2}.$$

(c) Using the results from parts (a) and (b),

$$\begin{aligned} J_3 &= -x^{3-1} e^{-x^2/2} + (3-1) J_{3-2} = -x^2 e^{-x^2/2} + 2 J_1 \\ &= -x^2 e^{-x^2/2} - 2e^{-x^2/2} + C = -e^{-x^2/2}(x^2+2) + C \end{aligned}$$

and then

$$J_5 = -x^{5-1}e^{-x^2/2} + (5-1)J_{5-2} = -x^4e^{-x^2/2} + 4J_3$$
$$= -x^4e^{-x^2/2} - 4e^{-x^2/2}(x^2+2) + C = -e^{-x^2/2}(x^4+4x^2+8) + C.$$

69. Compute $p(X \le 1)$, where X is a continuous random variable with probability density $p(x) = \dfrac{1}{\pi(x^2+1)}$.

SOLUTION

$$P(X \le 1) = \int_{-\infty}^{1} p(x)\,dx = \frac{1}{\pi}\int_{-\infty}^{1} \frac{1}{x^2+1}\,dx = \frac{1}{\pi}\tan^{-1} x\Big|_{-\infty}^{1} = \frac{1}{\pi}\cdot\left(\frac{\pi}{4} - \frac{-\pi}{2}\right) = \frac{3}{4}$$

70. Show that $p(x) = \frac{1}{4}e^{-x/2} + \frac{1}{6}e^{-x/3}$ is a probability density on $[0, \infty)$ and find its mean.

SOLUTION To show that $p(x)$ is a probability density, we must show that its integral over $[0, \infty)$ is 1:

$$\int_0^\infty p(x)\,dx = \int_0^\infty \left(\frac{1}{4}e^{-x/2} + \frac{1}{6}e^{-x/3}\right)dx = \left(-\frac{1}{2}e^{-x/2} - \frac{1}{2}e^{-x/3}\right)\Big|_0^\infty = 0 + 0 + \frac{1}{2} + \frac{1}{2} = 1$$

The mean of $p(x)$ is

$$\mu = \int_0^\infty xp(x)\,dx = \int_0^\infty \left(\frac{1}{4}xe^{-x/2} + \frac{1}{6}xe^{-x/3}\right)dx$$

Now, for a positive constant a, using integration by parts with $u = x$, $v' = e^{-x/a}$, we have $u' = 1$, $v = -ae^{-x/a}$, and

$$\int_0^\infty xe^{-x/a}\,dx = -axe^{-x/a}\Big|_0^\infty + a\int_0^\infty e^{-x/a}\,dx = -a^2\left(e^{-x/a}\right)\Big|_0^\infty = a^2$$

so that

$$\mu = \frac{1}{4}\int_0^\infty xe^{-x/2}\,dx + \frac{1}{6}\int_0^\infty xe^{-x/3}\,dx = \frac{1}{4}\cdot 4 + \frac{1}{6}\cdot 9 = \frac{5}{2}$$

71. Find a constant C such that $p(x) = Cx^3e^{-x^2}$ is a probability density and compute $p(0 \le X \le 1)$.

SOLUTION We first find the indefinite integral of $p(x)$ using integration by parts, with $u = x^2$, $v' = xe^{-x^2}$, so that $u' = 2x$ and $v = -\frac{1}{2}e^{-x^2}$:

$$\int Cx^3e^{-x^2}\,dx = C\left(-\frac{1}{2}x^2e^{-x^2} + \int xe^{-x^2}\,dx\right) = C\left(-\frac{1}{2}x^2e^{-x^2} - \frac{1}{2}e^{-x^2}\right) = -\frac{C}{2}e^{-x^2}(x^2+1)$$

To determine the constant C, the value of the integral on the interval $[0, \infty)$ must be 1:

$$1 = \int_0^\infty Cx^3e^{-x^2}\,dx = -\frac{C}{2}e^{-x/2}(x^2+1)\Big|_0^\infty = -\frac{C}{2}\left(\lim_{R\to\infty}\frac{x^2+1}{e^{x/2}} - 1\right) = \frac{C}{2}$$

so that $C = 2$. Then

$$P(0 \le X \le 1) = \int_0^1 2x^3e^{-x^2}\,dx = -e^{-x^2}(x^2+1)\Big|_0^1 = 1 - 2e^{-1} \approx 0.13212$$

72. The interval between patient arrivals in an emergency room is a random variable with exponential density function $p(t) = 0.125e^{-0.125t}$ (t in minutes). What is the average time between patient arrivals? What is the probability of two patients arriving within 3 minutes of each other?

SOLUTION The mean of the distribution is (using integration by parts with $u = t$, $v' = 0.125e^{-0.125t}$):

$$\int_0^\infty tp(t)\,dt = \int_0^\infty 0.125te^{-0.125t}\,dt = te^{-0.125t}\Big|_0^\infty + \int_0^\infty e^{-0.125t}\,dt = -8e^{-0.125t}\Big|_0^\infty = 8$$

Since the distribution gives the waiting time between arrivals, it follows that the probability of two patients arriving within 3 minutes of each other is

$$\int_0^3 p(t)\,dt = \int_0^3 0.125e^{-0.125t}\,dt = -e^{-0.125t}\Big|_0^3 = 1 - e^{-0.375} \approx 1 - 0.68729 \approx 0.31271$$

73. Calculate the following probabilities, assuming that X is normally distributed with mean $\mu = 40$ and $\sigma = 5$.

(a) $p(X \geq 45)$ **(b)** $p(0 \leq X \leq 40)$

SOLUTION Let F be the standard normal cumulative distribution function. Then by Theorem 1 in Section 7.7,

(a)

$$p(X \geq 45) = 1 - p(X \leq 45) = 1 - F\left(\frac{45-40}{5}\right) = 1 - F(1) \approx 1 - 0.8413 \approx 0.1587$$

(b)

$$p(0 \leq X \leq 40) = p(X \leq 40) - p(X \leq 0) = F\left(\frac{40-40}{5}\right) - F\left(\frac{0-40}{5}\right)$$
$$= F(0) - F(-8) = \frac{1}{2} - F(-8) \approx \frac{1}{2} - 0 = \frac{1}{2}$$

Note that $p(X \leq 40)$ is exactly $\frac{1}{2}$ since 40 is the mean. Also, since -8 is so far to the left in the standard normal distribution, the probability of its occurrence is quite small (approximately 8×10^{-11}).

74. According to kinetic theory, the molecules of ordinary matter are in constant random motion. The energy E of a molecule is a random variable with density function $p(E) = \frac{1}{kT}e^{-E/(kT)}$, where T is the temperature (in kelvins) and k is Boltzmann's constant. Compute the *mean* kinetic energy $\overline{E}$ in terms of k and T.

SOLUTION By definition,

$$\int_0^\infty Ee^{-E/kT}\,dE = \lim_{R\to\infty}\int_0^R Ee^{-E/kT}\,dE.$$

We compute the definite integral using Integration by Parts with $u = E$, $v' = e^{-E/kT}$. Then $u' = 1$, $v = -kTe^{-E/kT}$ and

$$\int_0^R Ee^{-E/kT}\,dE = -kTe^{-E/kT}E\Big|_{E=0}^R + \int_0^R kTe^{-E/kT}\,dE = -kTe^{-R/kT}R - (kT)^2e^{-E/kT}\Big|_{E=0}^R$$
$$= -kTRe^{-R/kT} - \left(k^2T^2e^{-R/kT} - k^2T^2e^0\right) = k^2T^2 - kTRe^{-R/kT} - k^2T^2e^{-R/kT}.$$

We now let $R \to \infty$, obtaining:

$$\int_0^\infty Ee^{-E/RT}\,dE = \lim_{R\to\infty}\int_0^R Ee^{-E/RT}\,dE = \lim_{R\to\infty}\left(k^2T^2 - kTRe^{-R/kT} - k^2T^2e^{-R/kT}\right)$$
$$= k^2T^2 - kT\lim_{R\to\infty} Re^{-R/kT} - 0 = k^2T^2 - kT\lim_{R\to\infty} Re^{-R/kT}.$$

We compute the remaining limit using L'Hôpital's Rule:

$$\lim_{R\to\infty} Re^{-R/kT} = \lim_{R\to\infty}\frac{R}{e^{R/kT}} = \lim_{R\to\infty}\frac{\frac{dR}{dR}}{\frac{d}{dR}\left(e^{R/kT}\right)} = \lim_{R\to\infty}\frac{1}{\frac{1}{kT}e^{R/kT}} = 0.$$

Thus,

$$\int_0^\infty Ee^{-E/RT}\,dE = k^2T^2,$$

and

$$\overline{E} = \frac{1}{kT}\int_0^\infty Ee^{-E/kT}\,dE = \frac{1}{kT}\cdot k^2T^2 = kT.$$

In Exercises 75–84, determine whether the improper integral converges and, if so, evaluate it.

75. $\displaystyle\int_0^\infty \frac{dx}{(x+2)^2}$

SOLUTION

$$\int_0^\infty \frac{dx}{(x+2)^2} = \lim_{R\to\infty}\int_0^R \frac{dx}{(x+2)^2} = \lim_{R\to\infty} -\frac{1}{x+2}\Big|_0^R$$
$$= \lim_{R\to\infty}\left(-\frac{1}{R+2} + \frac{1}{0+2}\right) = \lim_{R\to\infty}\left(-\frac{1}{R+2} + \frac{1}{2}\right) = 0 + \frac{1}{2} = \frac{1}{2}.$$

76. $\displaystyle\int_4^\infty \frac{dx}{x^{2/3}}$

SOLUTION The integral $\displaystyle\int_a^\infty \frac{dx}{x^p}$ $(a > 0)$ converges if $p > 1$ and diverges if $p \le 1$. Here, $p = \frac{2}{3} < 1$, hence the integral diverges.

77. $\displaystyle\int_0^4 \frac{dx}{x^{2/3}}$

SOLUTION

$$\int_0^4 \frac{dx}{x^{2/3}} = \lim_{R\to 0+} \int_R^4 \frac{dx}{x^{2/3}} = \lim_{R\to 0+} 3x^{1/3}\Big|_R^4 = \lim_{R\to 0+} \left(3\cdot 4^{1/3} - 3\cdot R^{1/3}\right) = 3\sqrt[3]{4}.$$

78. $\displaystyle\int_9^\infty \frac{dx}{x^{12/5}}$

SOLUTION

$$\int_9^\infty \frac{dx}{x^{12/5}} = \lim_{R\to\infty} \int_9^R \frac{dx}{x^{12/5}} = \lim_{R\to\infty} -\frac{5}{7}x^{-7/5}\Big|_9^R = \lim_{R\to\infty}\left(-\frac{5}{7}R^{-7/5} + \frac{5}{7}\cdot 9^{-7/5}\right)$$
$$= 0 + \frac{5}{7}\cdot 9^{-7/5} = \frac{5}{7\cdot 9\cdot 9^{2/5}} = \frac{5}{63\cdot 9^{2/5}}.$$

79. $\displaystyle\int_{-\infty}^0 \frac{dx}{x^2+1}$

SOLUTION

$$\int_{-\infty}^0 \frac{dx}{x^2+1} = \lim_{R\to-\infty} \int_R^0 \frac{dx}{x^2+1} = \lim_{R\to-\infty} \tan^{-1}x\Big|_R^0 = \lim_{R\to-\infty}\left(\tan^{-1}0 - \tan^{-1}R\right)$$
$$= \lim_{R\to-\infty}\left(-\tan^{-1}R\right) = -\left(-\frac{\pi}{2}\right) = \frac{\pi}{2}.$$

80. $\displaystyle\int_{-\infty}^9 e^{4x}\,dx$

SOLUTION

$$\int_{-\infty}^9 e^{4x}\,dx = \lim_{R\to-\infty}\int_R^9 e^{4x}\,dx = \lim_{R\to-\infty}\frac{1}{4}e^{4x}\Big|_R^9 = \lim_{R\to-\infty}\frac{1}{4}e^{36} - \frac{1}{4}e^{4R} = \frac{e^{36}}{4}.$$

81. $\displaystyle\int_0^{\pi/2} \cot\theta\,d\theta$

SOLUTION

$$\int_0^{\pi/2}\cot\theta\,d\theta = \lim_{R\to 0+}\int_R^{\pi/2}\cot\theta\,d\theta = \lim_{R\to 0+}\ln|\sin\theta|\Big|_R^{\pi/2} = \lim_{R\to 0+}\left(\ln\left(\sin\frac{\pi}{2}\right) - \ln(\sin R)\right)$$
$$= \lim_{R\to 0+}(\ln 1 - \ln(\sin R)) = \lim_{R\to 0+}\ln\left(\frac{1}{\sin R}\right) = \infty.$$

We conclude that the improper integral diverges.

82. $\displaystyle\int_1^\infty \frac{dx}{(x+2)(2x+3)}$

SOLUTION First, evaluate the indefinite integral. The following partial fraction decomposition has the form

$$\frac{1}{(x+2)(2x+3)} = -\frac{1}{x+2} + \frac{2}{2x+3}.$$

Clearing denominators gives us

$$1 = A(2x+3) + B(x+2).$$

Setting $x = -2$ then yields $A = -1$, while setting $x = -\frac{3}{2}$ yields $B = 2$. Hence,

$$\int \frac{dx}{(x+2)(2x+3)} = -\int \frac{dx}{x+2} + 2\int \frac{dx}{2x+3} = -\ln|x+2| + \ln|2x+3| + C = \ln\left|\frac{2x+3}{x+2}\right| + C.$$

Now, for $R > 1$,

$$\int_1^R \frac{dx}{(x+2)(2x+3)} = \ln\left|\frac{2x+3}{x+2}\right|\Bigg|_1^R = \ln\frac{2R+3}{R+2} - \ln\frac{5}{3},$$

and

$$\int_1^\infty \frac{dx}{(x+2)(2x+3)} = \lim_{R\to\infty}\left(\ln\frac{2R+3}{R+2}\right) - \ln\frac{5}{3} = \ln 2 + \ln\frac{3}{5} = \ln\frac{6}{5}.$$

83. $\int_0^\infty (5+x)^{-1/3}\,dx$

SOLUTION

$$\int_0^\infty (5+x)^{-1/3}\,dx = \lim_{R\to\infty}\int_0^R (5+x)^{-1/3}\,dx = \lim_{R\to\infty} \frac{3}{2}(5+x)^{2/3}\Big|_0^R$$
$$= \lim_{R\to\infty}\left(\frac{3}{2}(5+R)^{2/3} - \frac{3}{2}5^{2/3}\right) = \infty.$$

We conclude that the improper integral diverges.

84. $\int_2^5 (5-x)^{-1/3}\,dx$

SOLUTION

$$\int_2^5 (5-x)^{-1/3}\,dx = \lim_{R\to 5-}\int_2^R (5-x)^{-1/3}\,dx = \lim_{R\to 5-} -\frac{3}{2}(5-x)^{2/3}\Big|_2^R$$
$$= \lim_{R\to 5-} -\frac{3}{2}\left((5-R)^{2/3} - 3^{2/3}\right) = -\frac{3}{2}\left(0 - 3^{2/3}\right) = \frac{3^{5/3}}{2}.$$

In Exercises 85–90, use the Comparison Test to determine whether the improper integral converges or diverges.

85. $\int_8^\infty \frac{dx}{x^2-4}$

SOLUTION For $x \ge 8$, $\frac{1}{2}x^2 \ge 4$, so that

$$-\frac{1}{2}x^2 \le -4$$
$$\frac{1}{2}x^2 \le x^2 - 4$$

and

$$\frac{1}{x^2-4} \le \frac{2}{x^2}.$$

Now, $\int_1^\infty \frac{dx}{x^2}$ converges, so $\int_8^\infty \frac{2}{x^2}\,dx$ also converges. Therefore, by the comparison test,

$$\int_8^\infty \frac{dx}{x^2-4} \text{ converges.}$$

86. $\int_8^\infty (\sin^2 x)e^{-x}\,dx$

SOLUTION The following inequality holds for all x,

$$0 \le \left(\sin^2 x\right)e^{-x} \le e^{-x}.$$

We use direct computation to show that the improper integral of e^{-x} over the interval $[8, \infty)$ converges:

$$\int_8^\infty e^{-x}\,dx = \lim_{R\to\infty}\int_8^R e^{-x}\,dx = \lim_{R\to\infty} -e^{-x}\Big|_8^R = \lim_{R\to\infty}\left(-e^{-R}+e^{-8}\right) = 0 + e^{-8} = e^{-8}.$$

Therefore, by the Comparison Test, the improper integral $\int_8^\infty (\sin^2 x)e^{-x}\,dx$ also converges.

87. $\displaystyle\int_3^\infty \frac{dx}{x^4+\cos^2 x}$

SOLUTION For $x \ge 1$, we have

$$\frac{1}{x^4+\cos^2 x} \le \frac{1}{x^4}.$$

Since $\int_1^\infty \frac{dx}{x^4}$ converges, the Comparison Test guarantees that $\int_1^\infty \frac{dx}{x^4+\cos^2 x}$ also converges. The integral $\int_1^3 \frac{dx}{x^4+\cos^2 x}$ has a finite value (notice that $x^4+\cos^2 x \ne 0$) hence we conclude that the integral $\int_3^\infty \frac{dx}{x^4+\cos^2 x}$ also converges.

88. $\displaystyle\int_1^\infty \frac{dx}{x^{1/3}+x^{2/3}}$

SOLUTION If $x \ge 1$, then $x^{1/3} \ge 1$; therefore,

$$x^{1/3}+x^{2/3} = x^{1/3}\left(1+x^{1/3}\right) \le x^{1/3}\left(x^{1/3}+x^{1/3}\right) = x^{1/3}\cdot 2x^{1/3} = 2x^{2/3}.$$

Hence,

$$\frac{1}{x^{1/3}+x^{2/3}} \ge \frac{1}{2x^{2/3}}.$$

The integral $\int_1^\infty \frac{dx}{x^{2/3}}$ diverges; hence $\int_1^\infty \frac{dx}{2x^{2/3}}$ also diverges. Therefore, by the Comparison Test, the improper integral $\int_1^\infty \frac{dx}{x^{1/3}+x^{2/3}}$ also diverges.

89. $\displaystyle\int_0^1 \frac{dx}{x^{1/3}+x^{2/3}}$

SOLUTION For $0 \le x \le 1$,

$$x^{1/3}+x^{2/3} \ge x^{1/3} \quad \text{so} \quad \frac{1}{x^{1/3}+x^{2/3}} \le \frac{1}{x^{1/3}}.$$

Now, $\int_0^1 x^{-1/3}\,dx$ converges. Therefore, by the Comparison Test, the improper integral $\int_0^1 \frac{dx}{x^{1/3}+x^{2/3}}$ also converges.

90. $\displaystyle\int_0^\infty e^{-x^3}\,dx$

SOLUTION For $x > 1$, $e^x \ge x$; hence $e^{x^3} \ge x^3$, therefore $0 \le e^{-x^3} \le x^{-3}$. Since $\int_1^\infty \frac{dx}{x^3}$ converges, the integral $\int_1^\infty e^{-x^3}\,dx$ also converges by the Comparison Test. We write

$$\int_0^\infty e^{-x^3}\,dx = \int_0^1 e^{-x^3}\,dx + \int_1^\infty e^{-x^3}\,dx.$$

The first integral on the right hand side has a finite value and the second integral converges. We conclude that the integral $\int_0^\infty e^{-x^3}\,dx$ converges.

91. Calculate the volume of the infinite solid obtained by rotating the region under $y = (x^2+1)^{-2}$ for $0 \le x < \infty$ about the y-axis.

SOLUTION Using the Shell Method, the volume of the infinite solid obtained by rotating the region under the graph of $y = \left(x^2+1\right)^{-2}$ over the interval $[0, \infty)$ about the y-axis is

$$V = 2\pi\int_0^\infty \frac{x}{\left(x^2+1\right)^2}\,dx.$$

Now,

$$\int_0^\infty \frac{x}{\left(x^2+1\right)^2}\,dx = \lim_{R\to\infty}\int_0^R \frac{x\,dx}{\left(x^2+1\right)^2}$$

We substitute $t = x^2 + 1$, $dt = 2x\,dx$. The new limits of integration are $t = 1$ and $t = R^2 + 1$. Thus,

$$\int_0^R \frac{x\,dx}{\left(x^2+1\right)^2} = \int_1^{R^2+1} \frac{\frac{1}{2}\,dt}{t^2} = -\frac{1}{2t}\bigg|_1^{R^2+1} = \frac{1}{2}\left(1 - \frac{1}{R^2+1}\right).$$

Taking the limit as $R \to \infty$ yields:

$$\int_0^\infty \frac{x\,dx}{\left(x^2+1\right)^2} = \lim_{R\to\infty}\frac{1}{2}\left(1-\frac{1}{R^2+1}\right) = \frac{1}{2}(1-0) = \frac{1}{2}.$$

Therefore,

$$V = 2\pi\cdot\frac{1}{2} = \pi.$$

92. Let R be the region under the graph of $y = (x+1)^{-1}$ for $0 \le x < \infty$. Which of the following quantities is finite?

(a) The area of R

(b) The volume of the solid obtained by rotating R about the x-axis

(c) The volume of the solid obtained by rotating R about the y-axis

SOLUTION

(a) The area of R is

$$\int_0^\infty \frac{dx}{x+1} = \lim_{R\to\infty}\int_0^R \frac{dx}{x+1} = \lim_{R\to\infty} \ln|x+1|\,\bigg|_0^R = \lim_{R\to\infty}\big(\ln(R+1) - \ln 1\big) = \infty.$$

Hence, the area of R is not finite.

(b) Using the Disk Method, the volume of the solid obtained by rotating R about the x-axis is

$$\pi\int_0^\infty \frac{dx}{(x+1)^2} = \pi\lim_{R\to\infty}\int_0^R \frac{dx}{(x+1)^2} = \pi\lim_{R\to\infty} -\frac{1}{x+1}\bigg|_0^R = \pi\lim_{R\to\infty}\left(-\frac{1}{R+1}+1\right) = \pi.$$

Hence, the volume of the solid obtained by rotating R about the x-axis is finite.

(c) Using the Shell Method, the volume of the solid obtained by rotating R about the y-axis is

$$2\pi\int_0^\infty \frac{x}{x+1}\,dx = 2\pi\lim_{R\to\infty}\int_0^R \frac{x\,dx}{x+1}.$$

Now,

$$\int_0^R \frac{x\,dx}{x+1} = \int_0^R \frac{(x+1)-1}{x+1}\,dx = \int_0^R \left(1 - \frac{1}{x+1}\right)dx = (x - \ln(x+1))\bigg|_0^R$$
$$= R - (\ln(R+1) - \ln 1) = R - \ln(R+1).$$

Thus,

$$2\pi\lim_{R\to\infty}\int_0^R \frac{x\,dx}{x+1} = 2\pi\lim_{R\to\infty}(R - \ln(R+1)) = 2\pi\lim_{R\to\infty} R\left(1 - \frac{\ln(R+1)}{R}\right) = \infty.$$

Hence, the volume of the solid obtained by rotating R about the y-axis is not finite.

93. Show that $\int_0^\infty x^n e^{-x^2}\,dx$ converges for all $n > 0$. *Hint:* First observe that $x^n e^{-x^2} < x^n e^{-x}$ for $x > 1$. Then show that $x^n e^{-x} < x^{-2}$ for x sufficiently large.

SOLUTION For $x > 1$, $x^2 > x$; hence $e^{x^2} > e^x$, and $0 < e^{-x^2} < e^{-x}$. Therefore, for $x > 1$ the following inequality holds:

$$x^{n+2}e^{-x^2} < x^{n+2}e^{-x}.$$

Now, using L'Hôpital's Rule $n+2$ times, we find

$$\lim_{x\to\infty} x^{n+2}e^{-x} = \lim_{x\to\infty} \frac{x^{n+2}}{e^x} = \lim_{x\to\infty} \frac{(n+2)x^{n+1}}{e^x} = \lim_{x\to\infty} \frac{(n+2)(n+1)x^n}{e^x}$$
$$= \cdots = \lim_{x\to\infty} \frac{(n+2)!}{e^x} = 0.$$

Therefore,

$$\lim_{x\to\infty} x^{n+2}e^{-x^2} = 0$$

by the Squeeze Theorem, and there exists a number $R > 1$ such that, for all $x > R$:

$$x^{n+2}e^{-x^2} < 1 \quad \text{or} \quad x^n e^{-x^2} < x^{-2}.$$

Finally, write

$$\int_0^\infty x^n e^{-x^2}\,dx = \int_0^R x^n e^{-x^2}\,dx + \int_R^\infty x^n e^{-x^2}\,dx.$$

The first integral on the right-hand side has finite value since the integrand is a continuous function. The second integral converges since on the interval of integration, $x^n e^{-x^2} < x^{-2}$ and we know that $\int_R^\infty x^{-2}\,dx = \int_R^\infty \frac{dx}{x^2}$ converges. We conclude that the integral $\int_0^\infty x^n e^{-x^2}\,dx$ converges.

94. Compute the Laplace transform $Lf(s)$ of the function $f(x) = x$ for $s > 0$. See Exercises 86–89 in Section 7.6 for the definition of $Lf(s)$.

SOLUTION The Laplace transform of $f(x) = x$ is the following integral:

$$L(x)(s) = \int_0^\infty xe^{-sx}\,dx = \lim_{R\to\infty}\int_0^R xe^{-sx}\,dx.$$

We compute the definite integral using Integration by Parts with $u = x$ and $v' = e^{-sx}$. Then $u' = 1$, $v = -\frac{1}{s}e^{-sx}$ and

$$\int_0^R xe^{-sx}\,dx = -\frac{1}{s}xe^{-sx}\Big|_0^R + \int_0^R \frac{1}{s}e^{-sx}\,dx = \left(-\frac{1}{s}Re^{-sR} - \frac{1}{s^2}e^{-sx}\right)\Big|_0^R$$
$$= -\frac{1}{s}Re^{-sR} - \frac{1}{s^2}\left(e^{-sR} - e^0\right) = \frac{1}{s^2} - \frac{1}{s^2}e^{-sR} - \frac{1}{s}Re^{-sR}.$$

Therefore,

$$L(x)(s) = \lim_{R\to\infty}\left(\frac{1}{s^2} - \frac{1}{s^2}e^{-sR} - \frac{1}{s}Re^{-sR}\right) = \frac{1}{s^2} - \frac{1}{s^2}\lim_{R\to\infty} e^{-sR} - \frac{1}{s}\lim_{R\to\infty} Re^{-sR}.$$

Since $s > 0$, we have $\lim_{R\to\infty} e^{-sR} = 0$. Also by L'Hôpital's Rule:

$$\lim_{R\to\infty} Re^{-sR} = \lim_{R\to\infty}\frac{R}{e^{sR}} = \lim_{R\to\infty}\frac{1}{se^{sR}} = 0.$$

Finally,

$$L(x)(s) = \frac{1}{s^2} - 0 - 0 = \frac{1}{s^2}.$$

95. Compute the Laplace transform $Lf(s)$ of the function $f(x) = x^2e^{\alpha x}$ for $s > \alpha$.

SOLUTION The Laplace transform is the following integral:

$$L\left(x^2e^{\alpha x}\right)(s) = \int_0^\infty x^2e^{\alpha x}e^{-sx}\,dx = \int_0^\infty x^2e^{(\alpha-s)x}\,dx = \lim_{R\to\infty}\int_0^R x^2e^{(\alpha-s)x}\,dx.$$

We compute the definite integral using Integration by Parts with $u = x^2$, $v' = e^{(\alpha-s)x}$. Then $u' = 2x$, $v = \frac{1}{\alpha-s}e^{(\alpha-s)x}$ and

$$\int_0^R x^2e^{(\alpha-s)x}\,dx = \frac{1}{\alpha-s}x^2e^{(\alpha-s)x}\Big|_{x=0}^R - \int_0^R 2x\cdot\frac{1}{\alpha-s}e^{(\alpha-s)x}\,dx$$
$$= \frac{1}{\alpha-s}R^2e^{(\alpha-s)R} - \frac{2}{\alpha-s}\int_0^R xe^{(\alpha-s)x}\,dx.$$

We compute the resulting integral using Integration by Parts again, this time with $u = x$ and $v' = e^{(\alpha-s)x}$. Then $u' = 1$, $v = \frac{1}{\alpha-s}e^{(\alpha-s)x}$ and

$$\int_0^R xe^{(\alpha-s)x}\,dx = x \cdot \frac{1}{\alpha-s}e^{(\alpha-s)x}\Big|_{x=0}^{R} - \frac{1}{\alpha-s}\int_0^R e^{(\alpha-s)x}\,dx = \left(\frac{x}{\alpha-s}e^{(\alpha-s)x} - \frac{1}{(\alpha-s)^2}e^{(\alpha-s)x}\right)\Big|_{x=0}^{R}$$

$$= \frac{R}{\alpha-s}e^{(\alpha-s)R} - \frac{1}{(\alpha-s)^2}\left(e^{(\alpha-s)R} - e^0\right) = \frac{1}{(\alpha-s)^2} - \frac{1}{(\alpha-s)^2}e^{(\alpha-s)R} + \frac{R}{\alpha-s}e^{(\alpha-s)R}.$$

Thus,

$$\int_0^R x^2e^{(\alpha-s)x}\,dx = \frac{1}{\alpha-s}R^2e^{(\alpha-s)R} - \frac{2}{\alpha-s}\left(\frac{1}{(\alpha-s)^2} - \frac{1}{(\alpha-s)^2}e^{(\alpha-s)R} + \frac{R}{\alpha-s}e^{(\alpha-s)R}\right)$$

$$= \frac{1}{\alpha-s}R^2e^{(\alpha-s)R} - \frac{2}{(\alpha-s)^3} + \frac{2}{(\alpha-s)^3}e^{(\alpha-s)R} - \frac{2R}{(\alpha-s)^2}e^{(\alpha-s)R},$$

and

$$L\left(x^2e^{\alpha x}\right)(s) = \frac{2}{(s-\alpha)^3} - \frac{1}{s-\alpha}\lim_{R\to\infty} R^2e^{-(s-\alpha)R} - \frac{2}{(s-\alpha)^3}\lim_{R\to\infty} e^{-(s-\alpha)R} - \frac{2}{(s-\alpha)^2}\lim_{R\to\infty} Re^{-(s-\alpha)R}.$$

Now, since $s > \alpha$, $\lim_{R\to\infty} e^{-(s-\alpha)R} = 0$. We use L'Hôpital's Rule to compute the other two limits:

$$\lim_{R\to\infty} Re^{-(s-\alpha)R} = \lim_{R\to\infty} \frac{R}{e^{(s-\alpha)R}} = \lim_{R\to\infty} \frac{1}{(s-\alpha)e^{(s-\alpha)R}} = 0;$$

$$\lim_{R\to\infty} R^2e^{-(s-\alpha)R} = \lim_{R\to\infty} \frac{R^2}{e^{(s-\alpha)R}} = \lim_{R\to\infty} \frac{2R}{(s-\alpha)e^{(s-\alpha)R}} = \lim_{R\to\infty} \frac{2}{(s-\alpha)^2e^{(s-\alpha)R}} = 0.$$

Finally,

$$L\left(x^2e^{\alpha x}\right)(s) = \frac{2}{(s-\alpha)^3} - 0 - 0 - 0 = \frac{2}{(s-\alpha)^3}.$$

96. Estimate $\int_2^5 f(x)\,dx$ by computing T_2, M_3, T_6, and S_6 for a function $f(x)$ taking on the values in the following table:

x	2	2.5	3	3.5	4	4.5	5
$f(x)$	$\frac{1}{2}$	2	1	0	$-\frac{3}{2}$	-4	-2

SOLUTION To calculate T_2, divide [2, 5] into two subintervals of length $\Delta x = \frac{3}{2}$ with endpoints $x_0 = 2$, $x_1 = 3.5$, $x_2 = 5$. Then

$$T_2 = \frac{1}{2}\cdot\frac{3}{2}\left(f(2) + 2f(3.5) + f(5)\right) = 0.75\left(\frac{1}{2} + 2\cdot 0 + (-2)\right) = -\frac{9}{8}.$$

To calculate M_3, divide [2, 5] into three subintervals of length $\Delta x = 1$ with midpoints $c_1 = 2.5$, $c_2 = 3.5$, $c_3 = 4.5$. Then

$$M_3 = 1\cdot\left(f(2.5) + f(3.5) + f(4.5)\right) = 2 + 0 - 4 = -2.$$

To calculate T_6, divide [2, 5] into 6 subintervals of length $\frac{5-2}{6} = \frac{1}{2}$ with endpoints $x_0 = 2$, $x_1 = 2.5$, $x_2 = 3$, $x_3 = 3.5$, $x_4 = 4$, $x_5 = 4.5$, $x_6 = 5$. Then

$$T_6 = \frac{1}{2}\cdot\frac{1}{2}\left(f(2) + 2f(2.5) + 2f(3) + 2f(3.5) + 2f(4) + 2f(4.5) + f(5)\right)$$

$$= \frac{1}{4}\left(\frac{1}{2} + 2\cdot 2 + 2\cdot 1 + 2\cdot 0 + 2\cdot\left(-\frac{3}{2}\right) + 2(-4) + (-2)\right) = -\frac{13}{8}.$$

Finally, to calculate S_6, divide [2, 5] into 6 subintervals of length $\Delta x = \frac{5-2}{6} = \frac{1}{2}$ with endpoints $x_0 = 2$, $x_1 = 2.5$, $x_2 = 3$, $x_3 = 3.5$, $x_4 = 4$, $x_5 = 4.5$, $x_6 = 5$. Then

$$S_6 = \frac{1}{3}\cdot\frac{1}{2}\left(f(2) + 4f(2.5) + 2f(3) + 4f(3.5) + 2f(4) + 4f(4.5) + f(5)\right)$$

$$= \frac{1}{6}\left(\frac{1}{2} + 4\cdot 2 + 2\cdot 1 + 4\cdot 0 + 2\cdot\left(-\frac{3}{2}\right) + 4(-4) + (-2)\right) = -\frac{7}{4}.$$

97. State whether the approximation M_N or T_N is larger or smaller than the integral.

(a) $\int_0^\pi \sin x\,dx$ **(b)** $\int_\pi^{2\pi} \sin x\,dx$

(c) $\int_1^8 \frac{dx}{x^2}$ **(d)** $\int_2^5 \ln x\,dx$

SOLUTION

(a) Because $f(x) = \sin x$ is concave down on the interval $[0, \pi]$,

$$T_N \le \int_0^\pi \sin x\,dx \le M_N;$$

that is, T_N is smaller and M_N is larger than the integral.

(b) On the interval $[\pi, 2\pi]$, the function $f(x) = \sin x$ is concave up, therefore

$$M_N \le \int_\pi^{2\pi} \sin x\,dx \le T_N;$$

that is, M_N is smaller and T_N is larger than the integral.

(c) The function $f(x) = \frac{1}{x^2}$ is concave up on the interval $[1, 8]$; therefore,

$$M_N \le \int_1^8 \frac{dx}{x^2} \le T_N;$$

that is, M_N is smaller and T_N is larger than the integral.

(d) The integrand $y = \ln x$ is concave down on the interval $[2, 5]$; hence,

$$T_N \le \int_2^5 \ln x\,dx \le M_N;$$

that is, T_N is smaller and M_N is larger than the integral.

98. The rainfall rate (in inches per hour) was measured hourly during a 10-hour thunderstorm with the following results:

0, 0.41, 0.49, 0.32, 0.3, 0.23,
0.09, 0.08, 0.05, 0.11, 0.12

Use Simpson's Rule to estimate the total rainfall during the 10-hour period.

SOLUTION We have 10 subintervals of length $\Delta x = 1$. Thus, the total rainfall during the 10-hour period is approximately

$$\begin{aligned} S_{10} &= \frac{1}{3} \cdot 1[0 + 4 \cdot 0.41 + 2 \cdot 0.49 + 4 \cdot 0.32 + 2 \cdot 0.3 + 4 \cdot 0.23 + 2 \cdot 0.09 + 4 \cdot 0.08 + 2 \cdot 0.05 \\ &\qquad + 4 \cdot 0.11 + 0.12] \\ &= 2.19 \text{ inches.} \end{aligned}$$

In Exercises 99–104, compute the given approximation to the integral.

99. $\int_0^1 e^{-x^2}\,dx, \quad M_5$

SOLUTION Divide the interval $[0, 1]$ into 5 subintervals of length $\Delta x = \frac{1-0}{5} = \frac{1}{5}$, with midpoints $c_1 = \frac{1}{10}$, $c_2 = \frac{3}{10}$, $c_3 = \frac{1}{2}$, $c_4 = \frac{7}{10}$, and $c_5 = \frac{9}{10}$. Then

$$\begin{aligned} M_5 &= \Delta x \left[f\left(\frac{1}{10}\right) + f\left(\frac{3}{10}\right) + f\left(\frac{1}{2}\right) + f\left(\frac{7}{10}\right) + f\left(\frac{9}{10}\right) \right] \\ &= \frac{1}{5} \left[e^{-(1/10)^2} + e^{-(3/10)^2} + e^{-(1/2)^2} + e^{-(7/10)^2} + e^{-(9/10)^2} \right] = 0.748053. \end{aligned}$$

100. $\displaystyle\int_2^4 \sqrt{6t^3+1}\,dt, \quad T_3$

SOLUTION Divide the interval [2, 4] into 3 subintervals of length $\Delta x = \frac{4-2}{3} = \frac{2}{3}$, with endpoints 2, $\frac{8}{3}$, $\frac{10}{3}$, 4. Then,

$$T_3 = \frac{1}{2}\Delta x\left(f(2) + 2f\left(\frac{8}{3}\right) + 2f\left(\frac{10}{3}\right) + f(4)\right)$$
$$= \frac{1}{2}\cdot\frac{2}{3}\left(\sqrt{6\cdot 2^3+1} + 2\sqrt{6\cdot\left(\frac{8}{3}\right)^3+1} + 2\sqrt{6\cdot\left(\frac{10}{3}\right)^3+1} + \sqrt{6\cdot 4^3+1}\right) = 25.976514.$$

101. $\displaystyle\int_{\pi/4}^{\pi/2} \sqrt{\sin\theta}\,d\theta, \quad M_4$

SOLUTION Divide the interval $\left[\frac{\pi}{4}, \frac{\pi}{2}\right]$ into 4 subintervals of length $\Delta x = \frac{\frac{\pi}{2}-\frac{\pi}{4}}{4} = \frac{\pi}{16}$ with midpoints $\frac{9\pi}{32}$, $\frac{11\pi}{32}$, $\frac{13\pi}{32}$, and $\frac{15\pi}{32}$. Then

$$M_4 = \Delta x\left(f\left(\frac{9\pi}{32}\right) + f\left(\frac{11\pi}{32}\right) + f\left(\frac{13\pi}{32}\right) + f\left(\frac{15\pi}{32}\right)\right)$$
$$= \frac{\pi}{16}\left(\sqrt{\sin\frac{9\pi}{32}} + \sqrt{\sin\frac{11\pi}{32}} + \sqrt{\sin\frac{13\pi}{32}} + \sqrt{\sin\frac{15\pi}{32}}\right) = 0.744978.$$

102. $\displaystyle\int_1^4 \frac{dx}{x^3+1}, \quad T_6$

SOLUTION Divide the interval [1, 4] into 6 subintervals of length $\Delta x = \frac{4-1}{6} = \frac{1}{2}$ with endpoints 1, $\frac{3}{2}$, 2, $\frac{5}{2}$, 3, $\frac{7}{2}$, 4. Then

$$T_6 = \frac{1}{2}\Delta x\left(f(1) + 2f\left(\frac{3}{2}\right) + 2f(2) + 2f\left(\frac{5}{2}\right) + 2f(3) + 2f\left(\frac{7}{2}\right) + f(4)\right)$$
$$= \frac{1}{2}\cdot\frac{1}{2}\left(\frac{1}{1^3+1} + 2\frac{1}{\left(\frac{3}{2}\right)^3+1} + 2\frac{1}{2^3+1} + 2\frac{1}{\left(\frac{5}{2}\right)^3+1} + 2\frac{1}{3^3+1} + 2\frac{1}{(\frac{7}{2})^2+1} + \frac{1}{4^3+1}\right) = 0.358016.$$

103. $\displaystyle\int_0^1 e^{-x^2}\,dx, \quad S_4$

SOLUTION Divide the interval [0, 1] into 4 subintervals of length $\Delta x = \frac{1}{4}$ with endpoints 0, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, 1. Then

$$S_6 = \frac{1}{3}\Delta x\left(f(0) + 4f\left(\frac{1}{4}\right) + 2f\left(\frac{1}{2}\right) + 4f\left(\frac{3}{4}\right) + f(1)\right)$$
$$= \frac{1}{3}\cdot\frac{1}{4}\left(e^{-0^2} + 4e^{-(1/4)^2} + 2e^{-(1/2)^2} + 4e^{-(3/4)^2} + e^{-1^2}\right) = 0.746855.$$

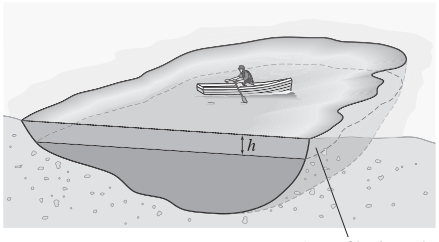
104. $\displaystyle\int_5^9 \cos(x^2)\,dx, \quad S_8$

SOLUTION Divide the interval [5, 9] into 8 subintervals of length $\Delta x = \frac{9-5}{8} = \frac{1}{2}$ with endpoints 5, $\frac{11}{2}$, 6, $\frac{13}{2}$, 7, $\frac{15}{2}$, 8, $\frac{17}{2}$, 9. Then

$$S_8 = \frac{1}{3}\Delta x\left(f(5) + 4f\left(\frac{11}{2}\right) + 2f(6) + 4f\left(\frac{13}{2}\right) + 2f(7) + 4f\left(\frac{15}{2}\right) + 2f(8) + 4f\left(\frac{17}{2}\right) + f(9)\right)$$
$$= \frac{1}{3}\cdot\frac{1}{2}\left(\cos(5^2) + 4\cos(5.5^2) + 2\cos(6^2) + 4\cos(6.5^2)\right.$$
$$\left. + 2\cos(7^2) + 4\cos(7.5^2) + 2\cos(8^2) + 4\cos(8.5^2) + \cos(9^2)\right)$$
$$= 0.608711.$$

105. The following table gives the area $A(h)$ of a horizontal cross section of a pond at depth h. Use the Trapezoidal Rule to estimate the volume V of the pond (Figure 1).

h (ft)	$A(h)$ (acres)	h (ft)	$A(h)$ (acres)
0	2.8	10	0.8
2	2.4	12	0.6
4	1.8	14	0.2
6	1.5	16	0.1
8	1.2	18	0



Area of horizontal cross section is $A(h)$

FIGURE 1

SOLUTION The volume of the pond is the following integral:

$$V = \int_0^{18} A(h)dh$$

We approximate the integral using the trapezoidal approximation T_9. The interval of depth [0, 18] is divided to 9 subintervals of length $\Delta x = 2$ with endpoints 0, 2, 4, 6, 8, 10, 12, 14, 16, 18. Thus,

$$\begin{aligned} V \approx T_9 &= \frac{1}{2} \cdot 2(2.8 + 2 \cdot 2.4 + 2 \cdot 1.8 + 2 \cdot 1.5 + 2 \cdot 1.2 + 2 \cdot 0.8 + 2 \cdot 0.6 + 2 \cdot 0.2 + 2 \cdot 0.1 + 0) \\ &= 20 \text{ acre} \cdot \text{ft} = 871{,}200 \text{ ft}^3, \end{aligned}$$

where we have used the fact that 1 acre $= 43{,}560$ ft^2.

106. Suppose that the second derivative of the function $A(h)$ in Exercise 105 satisfies $|A''(h)| \le 1.5$. Use the error bound to find the maximum possible error in your estimate of the volume V of the pond.

SOLUTION The Error Bound for the Trapezoidal Rule states that

$$\text{Error } (T_N) \le \frac{K_2(b-a)^3}{12N^2},$$

where K_2 is a number such that $\left|f''(x)\right| \le K_2$ for all $x \in [a, b]$. We estimated the volume of the pond by T_9; hence $N = 9$. The interval of depth is [0, 18] hence $b - a = 18 - 0 = 18$. Since $\left|A''(h)\right| \le 1.5$ acres/ft^2 we may take $K_2 = 1.5$, to find that the error cannot exceed

$$\frac{K_2(b-a)^3}{12N^2} = \frac{1.5 \cdot 18^3}{12 \cdot 9^2} = 9 \text{ acre} \cdot \text{ft} = 392{,}040 \text{ ft}^3,$$

where we have used the fact that 1 acre $= 43{,}560$ ft^2.

107. Find a bound for the error $\left|M_{16} - \int_1^3 x^3\,dx\right|$.

SOLUTION The Error Bound for the Midpoint Rule states that

$$\left|M_N - \int_a^b f(x)\,dx\right| \le \frac{K_2(b-a)^3}{24N^2},$$

where K_2 is a number such that $\left|f''(x)\right| \le K_2$ for all $x \in [1, 3]$. Here $b - a = 3 - 1 = 2$ and $N = 16$. Therefore,

$$\left|M_{16} - \int_1^3 x^3\,dx\right| \le \frac{K_2 \cdot 2^3}{24 \cdot 16^2} = \frac{K_2}{768}.$$

To find K_2, we differentiate $f(x) = x^3$ twice:

$$f'(x) = 3x^2 \qquad \text{and} \qquad f''(x) = 6x.$$

On the interval $[1, 3]$ we have $\left|f''(x)\right| = 6x \le 6 \cdot 3 = 18$; hence, we may take $K_2 = 18$. Thus,

$$\left|M_{16} - \int_1^3 x^3\,dx\right| \le \frac{18}{768} = \frac{3}{128} = 0.0234375.$$

108. $\boxed{\text{GU}}$ Let $f(x) = \sin(x^3)$. Find a bound for the error

$$\left|T_{24} - \int_0^{\pi/2} f(x)\,dx\right|$$

Hint: Find a bound K_2 for $|f''(x)|$ by plotting $f''(x)$ with a graphing utility.

SOLUTION Using the error bound for T_{24} we obtain:

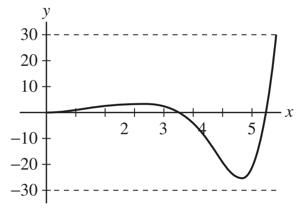
$$\left|T_{24} - \int_0^{\pi/2} f(x)\,dx\right| \le \frac{K_2\left(\frac{\pi}{2} - 0\right)^3}{12 \cdot 24^2} = \frac{K_2\pi^3}{55,296},$$

where K_2 is a number such that $\left|f''(x)\right| < k_2$ for all $x \in \left[0, \frac{\pi}{2}\right]$. We compute the first and second derivative of $f(x) = \sin(x^3)$:

$$f'(x) = 3x^2\cos(x^3)$$
$$f''(x) = 6x\cos(x^3) + 3x^2 \cdot 3x^2\left(-\sin(x^3)\right) = 6x\cos(x^3) - 9x^4\sin(x^3)$$

The graph of $f''(x) = 6x\cos(x^3) - 9x^4\sin(x^3)$ on the interval $\left[0, \frac{\pi}{2}\right]$ shows that $\left|f''(x)\right| \le 30$ on this interval. We may choose $K_2 = 30$ and find

$$\left|T_{24} - \int_0^{\pi/2} f(x)\,dx\right| \le \frac{30\pi^3}{55,296} = \frac{5\pi^3}{9216} = 0.0168220.$$



109. Find a value of N such that

$$\left|M_N - \int_0^{\pi/4} \tan x\,dx\right| \le 10^{-4}$$

SOLUTION To use the Error Bound we must find the second derivative of $f(x) = \tan x$. We differentiate f twice to obtain:

$$f'(x) = \sec^2 x$$
$$f''(x) = 2\sec x\tan x = \frac{2\sin x}{\cos^2 x}$$

For $0 \le x \le \frac{\pi}{4}$, we have $\sin x \le \sin\frac{\pi}{4} = \frac{1}{\sqrt{2}}$ and $\cos x \ge \frac{1}{\sqrt{2}}$ or $\cos^2 x \ge \frac{1}{2}$. Therefore, for $0 \le x \le \frac{\pi}{4}$ we have:

$$f''(x) = \frac{2\sin x}{\cos^2 x} \le \frac{2 \cdot \frac{1}{\sqrt{2}}}{\frac{1}{2}} = 2\sqrt{2}.$$

Using the Error Bound with $b = \frac{\pi}{4}$, $a = 0$ and $K_2 = 2\sqrt{2}$ we have:

$$\left|M_N - \int_0^{\pi/4} \tan x\,dx\right| \le \frac{2\sqrt{2} \cdot \left(\frac{\pi}{4} - 0\right)^3}{24N^2} = \frac{\pi^3\sqrt{2}}{768N^2}.$$

We must choose a value of N such that:

$$\frac{\pi^3\sqrt{2}}{768N^2} \le 10^{-4}$$

$$N^2 \ge \frac{10^4 \cdot \sqrt{2}\pi^3}{768}$$

$$N \ge 23.9$$

The smallest integer that is needed to obtain the required precision is $N = 24$.

110. Find a value of N such that S_N approximates $\int_2^5 x^{-1/4}\,dx$ with an error of at most 10^{-2} (but do not calculate S_N).

SOLUTION To use the error bound we must find the fourth derivative $f^{(4)}(x)$. We differentiate $f(x) = x^{-1/4}$ four times to obtain:

$$f'(x) = -\frac{1}{4}x^{-5/4}, \ f''(x) = \frac{5}{16}x^{-9/4}, \ f'''(x) = -\frac{45}{64}x^{-13/4}, \ f^{(4)}(x) = \frac{585}{256}x^{-17/4}.$$

For $2 \le x \le 5$ we have:

$$\left|f^{(4)}(x)\right| = \frac{585}{256x^{17/4}} \le \frac{585}{256 \cdot 2^{17/4}} = 0.120099.$$

Using the error bound with $b = 5$, $a = 2$ and $K_4 = 0.120099$ we have:

$$\text{Error}\,(S_N) \le \frac{0.120099(5-2)^5}{180N^4} = \frac{0.162134}{N^4}.$$

We must choose a value of N such that:

$$\frac{0.162134}{N^4} \le 10^{-2}$$

$$N^4 \ge 16.2134$$

$$N \ge 2.00664$$

The smallest even value of N that is needed to obtain the required precision is $N = 4$.

8 FURTHER APPLICATIONS OF THE INTEGRAL AND TAYLOR POLYNOMIALS

8.1 Arc Length and Surface Area

Preliminary Questions

1. Which integral represents the length of the curve $y = \cos x$ between 0 and π?

$$\int_0^{\pi} \sqrt{1+\cos^2 x}\, dx, \qquad \int_0^{\pi} \sqrt{1+\sin^2 x}\, dx$$

SOLUTION Let $y = \cos x$. Then $y' = -\sin x$, and $1 + (y')^2 = 1 + \sin^2 x$. Thus, the length of the curve $y = \cos x$ between 0 and π is

$$\int_0^{\pi} \sqrt{1+\sin^2 x}\, dx.$$

2. Use the formula for arc length to show that for any constant C, the graphs $y = f(x)$ and $y = f(x) + C$ have the same length over every interval $[a, b]$. Explain geometrically.

SOLUTION The graph of $y = f(x) + C$ is a vertical translation of the graph of $y = f(x)$; hence, the two graphs should have the same arc length. We can explicitly establish this as follows:

$$\text{length of } y = f(x) + C = \int_a^b \sqrt{1 + \left[\frac{d}{dx}(f(x)+C)\right]^2}\, dx = \int_a^b \sqrt{1+[f'(x)]^2}\, dx = \text{length of } y = f(x).$$

3. Use the formula for arc length to show that the length of a graph over $[1, 4]$ cannot be less than 3.

SOLUTION Note that $f'(x)^2 \geq 0$, so that $\sqrt{1+[f'(x)]^2} \geq \sqrt{1} = 1$. Then the arc length of the graph of $f(x)$ on $[1, 4]$ is

$$\int_1^4 \sqrt{1+[f'(x)]^2}\, dx \geq \int_1^4 1\, dx = 3$$

Exercises

1. Express the arc length of the curve $y = x^4$ between $x = 2$ and $x = 6$ as an integral (but do not evaluate).

SOLUTION Let $y = x^4$. Then $y' = 4x^3$ and

$$s = \int_2^6 \sqrt{1+(4x^3)^2}\, dx = \int_2^6 \sqrt{1+16x^6}\, dx.$$

2. Express the arc length of the curve $y = \tan x$ for $0 \leq x \leq \frac{\pi}{4}$ as an integral (but do not evaluate).

SOLUTION Let $y = \tan x$. Then $y' = \sec^2 x$, and

$$s = \int_0^{\pi/4} \sqrt{1+(\sec^2 x)^2}\, dx = \int_0^{\pi/4} \sqrt{1+\sec^4 x}\, dx.$$

3. Find the arc length of $y = \frac{1}{12}x^3 + x^{-1}$ for $1 \leq x \leq 2$. *Hint:* Show that $1 + (y')^2 = \left(\frac{1}{4}x^2 + x^{-2}\right)^2$.

SOLUTION Let $y = \dfrac{1}{12}x^3 + x^{-1}$. Then $y' = \dfrac{x^2}{4} x^{-2}$, and

$$(y')^2 + 1 = \left(\frac{x^2}{4} - x^{-2}\right)^2 + 1 = \frac{x^4}{16} - \frac{1}{2} + x^{-4} + 1 = \frac{x^4}{16} + \frac{1}{2} + x^{-4} = \left(\frac{x^2}{4} + x^{-2}\right)^2.$$

Thus,

$$s=\int_1^2\sqrt{1+(y')^2}\,dx=\int_1^2\sqrt{\left(\frac{x^2}{4}+\frac{1}{x^2}\right)^2}\,dx=\int_1^2\left|\frac{x^2}{4}+\frac{1}{x^2}\right|dx$$
$$=\int_1^2\left(\frac{x^2}{4}+\frac{1}{x^2}\right)dx\quad\text{since}\quad\frac{x^2}{4}+\frac{1}{x^2}>0$$
$$=\left(\frac{x^3}{12}-\frac{1}{x}\right)\bigg|_1^2=\frac{13}{12}.$$

4. Find the arc length of $y=\left(\frac{x}{2}\right)^4+\frac{1}{2x^2}$ over $[1,4]$. *Hint:* Show that $1+(y')^2$ is a perfect square.

SOLUTION Let $y=\left(\frac{x}{2}\right)^4+\frac{1}{2x^2}$. Then

$$y'=4\left(\frac{x}{2}\right)^3\left(\frac{1}{2}\right)-\frac{1}{x^3}=\frac{x^3}{4}-\frac{1}{x^3}$$

and

$$(y')^2+1=\left(\frac{x^3}{4}-\frac{1}{x^3}\right)^2+1=\frac{x^6}{16}-\frac{1}{2}+\frac{1}{x^6}+1=\frac{x^6}{16}+\frac{1}{2}+\frac{1}{x^6}=\left(\frac{x^3}{4}+\frac{1}{x^3}\right)^2.$$

Hence,

$$s=\int_1^4\sqrt{1+y'^2}\,dx=\int_1^4\sqrt{\left(\frac{x^3}{4}+\frac{1}{x^3}\right)^2}\,dx=\int_1^4\left|\frac{x^3}{4}+\frac{1}{x^3}\right|dx$$
$$=\int_1^4\left(\frac{x^3}{4}+\frac{1}{x^3}\right)dx\quad\text{since}\quad\frac{x^3}{4}+\frac{1}{x^3}>0\text{ on }[1,4]$$
$$=\left(\frac{x^4}{16}+\frac{x^{-2}}{-2}\right)\bigg|_1^4=\frac{525}{32}.$$

In Exercises 5–10, calculate the arc length over the given interval.

5. $y=3x+1,\quad[0,3]$

SOLUTION Let $y=3x+1$. Then $y'=3$, and $s=\int_0^3\sqrt{1+9}\,dx=3\sqrt{10}$.

6. $y=9-3x,\quad[1,3]$

SOLUTION Let $y=9-3x$. Then $y'=-3$, and $s=\int_1^3\sqrt{1+9}\,dx=3\sqrt{10}-\sqrt{10}=2\sqrt{10}$.

7. $y=x^{3/2},\quad[1,2]$

SOLUTION Let $y=x^{3/2}$. Then $y'=\frac{3}{2}x^{1/2}$, and

$$s=\int_1^2\sqrt{1+\frac{9}{4}x}\,dx=\frac{8}{27}\left(1+\frac{9}{4}x\right)^{3/2}\bigg|_1^2=\frac{8}{27}\left(\left(\frac{11}{2}\right)^{3/2}-\left(\frac{13}{4}\right)^{3/2}\right)=\frac{1}{27}\left(22\sqrt{22}-13\sqrt{13}\right).$$

8. $y=\frac{1}{3}x^{3/2}-x^{1/2},\quad[2,8]$

SOLUTION Let $y=\frac{1}{3}x^{3/2}-x^{1/2}$. Then

$$y'=\frac{1}{2}x^{1/2}-\frac{1}{2}x^{-1/2},$$

and

$$1+(y')^2=1+\left(\frac{1}{2}x^{1/2}-\frac{1}{2}x^{-1/2}\right)^2=\frac{1}{4}x+\frac{1}{2}+\frac{1}{4}x^{-1}=\left(\frac{1}{2}x^{1/2}+\frac{1}{2}x^{-1/2}\right)^2.$$

Hence,

$$\begin{aligned} s &= \int_2^8 \sqrt{1+(y')^2}\,dx = \int_2^8 \sqrt{\left(\frac{1}{2}x^{1/2}+\frac{1}{2}x^{-1/2}\right)^2}\,dx = \int_2^8 \left|\frac{1}{2}x^{1/2}+\frac{1}{2}x^{-1/2}\right|\,dx \\ &= \int_2^8 \left(\frac{1}{2}x^{1/2}+\frac{1}{2}x^{-1/2}\right)dx \quad \text{since} \quad \frac{1}{2}x^{1/2}+\frac{1}{2}x^{-1/2} > 0 \\ &= \left(\frac{1}{3}x^{3/2}+x^{1/2}\right)\Big|_2^8 = \frac{17\sqrt{2}}{3}. \end{aligned}$$

9. $y = \frac{1}{4}x^2 - \frac{1}{2}\ln x, \quad [1, 2e]$

SOLUTION Let $y = \frac{1}{4}x^2 - \frac{1}{2}\ln x$. Then

$$y' = \frac{x}{2} - \frac{1}{2x},$$

and

$$1+(y')^2 = 1 + \left(\frac{x}{2}-\frac{1}{2x}\right)^2 = \frac{x^2}{4}+\frac{1}{2}+\frac{1}{4x^2} = \left(\frac{x}{2}+\frac{1}{2x}\right)^2.$$

Hence,

$$\begin{aligned} s &= \int_1^{2e} \sqrt{1+(y')^2}\,dx = \int_1^{2e} \sqrt{\left(\frac{x}{2}+\frac{1}{2x}\right)^2}\,dx = \int_1^{2e} \left|\frac{x}{2}+\frac{1}{2x}\right|\,dx \\ &= \int_1^{2e} \left(\frac{x}{2}+\frac{1}{2x}\right)dx \quad \text{since} \quad \frac{x}{2}+\frac{1}{2x} > 0 \text{ on } [1, 2e] \\ &= \left(\frac{x^2}{4}+\frac{1}{2}\ln x\right)\Big|_1^{2e} = e^2 + \frac{\ln 2}{2} + \frac{1}{4}. \end{aligned}$$

10. $y = \ln(\cos x), \quad \left[0, \frac{\pi}{4}\right]$

SOLUTION Let $y = \ln(\cos x)$. Then $y' = -\tan x$ and $1+(y')^2 = 1+\tan^2 x = \sec^2 x$. Hence,

$$\begin{aligned} s &= \int_0^{\pi/4} \sqrt{1+(y')^2}\,dx = \int_0^{\pi/4} \sqrt{\sec^2 x}\,dx = \int_0^{\pi/4} |\sec x|\,dx \\ &= \int_0^{\pi/4} \sec x\,dx \quad \text{since} \quad \sec x > 0 \text{ on } \left[0, \frac{\pi}{4}\right] \\ &= \ln|\sec x + \tan x|\Big|_0^{\pi/4} = \ln(\sqrt{2}+1). \end{aligned}$$

In Exercises 11–14, approximate the arc length of the curve over the interval using the Trapezoidal Rule T_N, the Midpoint Rule M_N, or Simpson's Rule S_N as indicated.

11. $y = \frac{1}{4}x^4, \quad [1, 2], \quad T_5$

SOLUTION Let $y = \frac{1}{4}x^4$. Then

$$1+(y')^2 = 1+(x^3)^2 = 1+x^6.$$

Therefore, the arc length over $[1, 2]$ is

$$\int_1^2 \sqrt{1+x^6}\,dx.$$

Now, let $f(x) = \sqrt{1+x^6}$. With $n = 5$,

$$\Delta x = \frac{2-1}{5} = \frac{1}{5} \quad \text{and} \quad \{x_i\}_{i=0}^5 = \left\{1, \frac{6}{5}, \frac{7}{5}, \frac{8}{5}, \frac{9}{5}, 2\right\}.$$

Using the Trapezoidal Rule,

$$\int_1^2 \sqrt{1+x^6}\,dx \approx \frac{\Delta x}{2}\left[f(x_0)+2\sum_{i=1}^{4} f(x_i)+f(x_5)\right]=3.957736.$$

The arc length is approximately 3.957736 units.

12. $y=\sin x$, $\left[0,\frac{\pi}{2}\right]$, M_8

SOLUTION Let $y=\sin x$. Then

$$1+y'^2=1+\cos^2 x.$$

Therefore, the arc length over $[0,\pi/2]$ is

$$\int_0^{\pi/2}\sqrt{1+\cos^2 x}\,dx.$$

Now, let $f(x)=\sqrt{1+\cos^2 x}$. With $n=8$, we have:

$$\Delta x=\frac{\pi/2}{8}=\frac{\pi}{16} \quad\text{and}\quad \{x_i^*\}_{i=1}^8=\left\{\frac{\pi}{32},\frac{3\pi}{32},\frac{5\pi}{32},\frac{7\pi}{32},\frac{9\pi}{32},\frac{11\pi}{32},\frac{13\pi}{32},\frac{15\pi}{32}\right\}.$$

Using the Midpoint Rule,

$$\int_0^{\pi/2}\sqrt{1+\cos^2 x}\,dx \approx \Delta x\sum_{i=1}^{8} f(x_i^*)=1.910099.$$

The arc length is approximately 1.910099 units.

13. $y=x^{-1}$, $[1,2]$, S_8

SOLUTION Let $y=x^{-1}$. Then $y'=-x^{-2}$ and

$$1+(y')^2=1+\frac{1}{x^4}.$$

Therefore, the arc length over $[1,2]$ is

$$\int_1^2\sqrt{1+\frac{1}{x^4}}\,dx.$$

Now, let $f(x)=\sqrt{1+\frac{1}{x^4}}$. With $n=8$,

$$\Delta x=\frac{2-1}{8}=\frac{1}{8} \quad\text{and}\quad \{x_i\}_{i=0}^8=\left\{1,\frac{9}{8},\frac{5}{4},\frac{11}{8},\frac{3}{2},\frac{13}{8},\frac{7}{4},\frac{15}{8},2\right\}.$$

Using Simpson's Rule,

$$\int_1^2\sqrt{1+\frac{1}{x^4}}\,dx \approx \frac{\Delta x}{3}\left[f(x_0)+4\sum_{i=1}^{4} f(x_{2i-1})+2\sum_{i=1}^{3} f(x_{2i})+f(x_8)\right]=1.132123.$$

The arc length is approximately 1.132123 units.

14. $y=e^{-x^2}$, $[0,2]$, S_8

SOLUTION Let $y=e^{-x^2}$. Then

$$1+(y')^2=1+4x^2e^{-2x^2}.$$

Therefore, the arc length over $[0,2]$ is

$$\int_0^2\sqrt{1+4x^2e^{-2x^2}}\,dx.$$

Now, let $f(x)=\sqrt{1+4x^2e^{-2x^2}}$. With $n=8$,

$$\Delta x=\frac{2-0}{8}=\frac{1}{4} \quad\text{and}\quad \{x_i\}_{i=0}^8=\left\{0,\frac{1}{4},\frac{1}{2},\frac{3}{4},1,\frac{5}{4},\frac{3}{2},\frac{7}{4},2\right\}.$$

Using Simpson's Rule,

$$\int_0^2 \sqrt{1+4x^2e^{-2x^2}}\,dx \approx \frac{\Delta x}{3}\left[f(x_0)+4\sum_{i=1}^{4} f(x_{2i-1})+2\sum_{i=1}^{3} f(x_{2i})+f(x_8)\right]=2.280718.$$

The arc length is approximately 2.280718 units.

15. Calculate the length of the astroid $x^{2/3}+y^{2/3}=1$ (Figure 11).

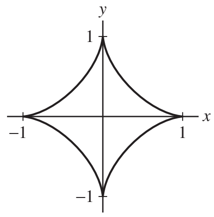


FIGURE 11 Graph of $x^{2/3}+y^{2/3}=1$.

SOLUTION We will calculate the arc length of the portion of the asteroid in the first quadrant and then multiply by 4. By implicit differentiation

$$\frac{2}{3}x^{-1/3}+\frac{2}{3}y^{-1/3}y'=0,$$

so

$$y'=-\frac{x^{-1/3}}{y^{-1/3}}=-\frac{y^{1/3}}{x^{1/3}}.$$

Thus

$$1+(y')^2=1+\frac{y^{2/3}}{x^{2/3}}=\frac{x^{2/3}+y^{2/3}}{x^{2/3}}=\frac{1}{x^{2/3}},$$

and

$$s=\int_0^1 \frac{1}{x^{1/3}}\,dx=\frac{3}{2}.$$

The total arc length is therefore $4\cdot\frac{3}{2}=6$.

16. Show that the arc length of the asteroid $x^{2/3}+y^{2/3}=a^{2/3}$ (for $a>0$) is proportional to a.

SOLUTION We will calculate the arc length of the portion of the asteroid in the first quadrant and then multiply by 4. By implicit differentiation

$$\frac{2}{3}x^{-1/3}+\frac{2}{3}y^{-1/3}y'=0,$$

so

$$y'=-\frac{x^{-1/3}}{y^{-1/3}}=-\frac{y^{1/3}}{x^{1/3}}.$$

Thus

$$1+(y')^2=1+\frac{y^{2/3}}{x^{2/3}}=\frac{x^{2/3}+y^{2/3}}{x^{2/3}}=\frac{a^{2/3}}{x^{2/3}},$$

and

$$s=\int_0^a \frac{a^{1/3}}{x^{1/3}}\,dx=a^{1/3}\left(\frac{3}{2}a^{2/3}\right)=\frac{3}{2}a.$$

The total arc length is therefore $4\cdot\frac{3}{2}a=6a$, which is proportional to a.

17. Let $a, r>0$. Show that the arc length of the curve $x^r+y^r=a^r$ for $0\le x\le a$ is proportional to a.

SOLUTION Using implicit differentiation, we find $y'=-(x/y)^{r-1}$ and

$$1+(y')^2=1+(x/y)^{2r-2}=\frac{x^{2r-1}+y^{2r-2}}{y^{2r-2}}=\frac{x^{2r-2}+(a^r-x^r)^{2-2/r}}{(a^r-x^r)^{2-2/r}}.$$

The arc length is then

$$s = \int_0^a \sqrt{\frac{x^{2r-2} + (a^r - x^r)^{2-2/r}}{(a^r - x^r)^{2-2/r}}}\, dx.$$

Using the substitution $x = au$, we obtain

$$s = a\int_0^1 \sqrt{\frac{u^{2r-2} + (1 - u^r)^{2-2/r}}{(1 - u^r)^{2-2/r}}}\, du,$$

where the integral is independent of a.

18. Find the arc length of the curve shown in Figure 12.

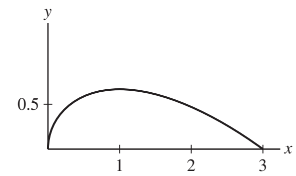

FIGURE 12 Graph of $9y^2 = x(x-3)^2$.

SOLUTION Using implicit differentiation,

$$18yy' = x(2)(x-3) + (x-3)^2 = 3(x-3)(x-1)$$

Hence,

$$(y')^2 = \frac{(x-3)^2(x-1)^2}{36y^2} = \frac{(x-3)^2(x-1)^2}{4(9y^2)} = \frac{(x-3)^2(x-1)^2}{4x(x-3)^2} = \frac{(x-1)^2}{4x}$$

and

$$1 + (y')^2 = \frac{(x-1)^2 + 4x}{4x} = \frac{(x+1)^2}{4x}.$$

Finally,

$$\begin{aligned} s &= \int_0^3 \sqrt{\frac{(x+1)^2}{4x}}\, dx = \int_0^3 \frac{|x+1|}{2\sqrt{x}}\, dx \\ &= \int_0^3 \frac{x+1}{2\sqrt{x}}\, dx \quad \text{since} \quad x+1 > 0 \text{ on } [0,3] \\ &= \int_0^3 \left(\frac{1}{2}x^{1/2} + \frac{1}{2}x^{-1/2}\right) dx = \left(\frac{1}{3}x^{3/2} + x^{1/2}\right)\Big|_0^3 = 2\sqrt{3}. \end{aligned}$$

19. Find the value of a such that the arc length of the *catenary* $y = \cosh x$ for $-a \le x \le a$ equals 10.

SOLUTION Let $y = \cosh x$. Then $y' = \sinh x$ and

$$1 + (y')^2 = 1 + \sinh^2 x = \cosh^2 x.$$

Thus,

$$s = \int_{-a}^{a} \cosh x\, dx = \sinh(a) - \sinh(-a) = 2\sinh a.$$

Setting this expression equal to 10 and solving for a yields $a = \sinh^{-1}(5) = \ln(5 + \sqrt{26})$.

20. Calculate the arc length of the graph of $f(x) = mx + r$ over $[a, b]$ in two ways: using the Pythagorean theorem (Figure 13) and using the arc length integral.

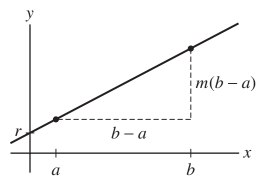

FIGURE 13

SOLUTION Let h denote the length of the hypotenuse. Then, by Pythagoras' Theorem,

$$h^2 = (b-a)^2 + m^2(b-a)^2 = (b-a)^2(1+m^2),$$

or

$$h = (b-a)\sqrt{1+m^2}$$

since $b > a$. Moreover, $(f'(x))^2 = m^2$, so

$$s = \int_a^b \sqrt{1+m^2}\,dx = (b-a)\sqrt{1+m^2} = h.$$

21. Show that the circumference of the unit circle is equal to

$$2\int_{-1}^{1} \frac{dx}{\sqrt{1-x^2}} \quad \text{(an improper integral)}$$

Evaluate, thus verifying that the circumference is 2π.

SOLUTION Note the circumference of the unit circle is twice the arc length of the upper half of the curve defined by $x^2 + y^2 = 1$. Thus, let $y = \sqrt{1-x^2}$. Then

$$y' = -\frac{x}{\sqrt{1-x^2}} \quad \text{and} \quad 1 + (y')^2 = 1 + \frac{x^2}{1-x^2} = \frac{1}{1-x^2}.$$

Finally, the circumference of the unit circle is

$$2\int_{-1}^{1} \frac{dx}{\sqrt{1-x^2}} = 2\sin^{-1} x\Big|_{-1}^{1} = \pi - (-\pi) = 2\pi.$$

22. Generalize the result of Exercise 21 to show that the circumference of the circle of radius r is $2\pi r$.

SOLUTION Let $y = \sqrt{r^2 - x^2}$ denote the upper half of a circle of radius r centered at the origin. Then

$$1 + (y')^2 = 1 + \frac{x^2}{r^2 - x^2} = \frac{r^2}{r^2 - x^2} = \frac{1}{1 - \frac{x^2}{r^2}},$$

and the circumference of the circle is given by

$$C = 2\int_{-r}^{r} \frac{dx}{\sqrt{1 - x^2/r^2}}.$$

Using the substitution $u = x/r$, $du = dx/r$, we find

$$C = 2r\int_{-1}^{1} \frac{du}{\sqrt{1-u^2}} = 2r\sin^{-1} u\Big|_{-1}^{1}$$
$$= 2r\left(\frac{\pi}{2} - \left(-\frac{\pi}{2}\right)\right) = 2\pi r$$

23. Calculate the arc length of $y = x^2$ over $[0, a]$. *Hint:* Use trigonometric substitution. Evaluate for $a = 1$.

SOLUTION Let $y = x^2$. Then $y' = 2x$ and

$$s = \int_0^a \sqrt{1+4x^2}\,dx.$$

Using the substitution $2x = \tan\theta$, $2\,dx = \sec^2\theta\,d\theta$, we find

$$s = \frac{1}{2}\int_{x=0}^{x=a} \sec^3\theta\,d\theta.$$

Next, using a reduction formula for the integral of $\sec^3\theta$, we see that

$$s = \left(\frac{1}{4}\sec\theta\tan\theta + \frac{1}{4}\ln|\sec\theta + \tan\theta|\right)\Big|_{x=0}^{x=a} = \left(\frac{1}{2}x\sqrt{1+4x^2} + \frac{1}{4}\ln|\sqrt{1+4x^2} + 2x|\right)\Big|_0^a$$
$$= \frac{a}{2}\sqrt{1+4a^2} + \frac{1}{4}\ln|\sqrt{1+4a^2} + 2a|$$

Thus, when $a = 1$,

$$s = \frac{1}{2}\sqrt{5} + \frac{1}{4}\ln(\sqrt{5} + 2) \approx 1.478943.$$

24. Express the arc length of $g(x) = \sqrt{x}$ over $[0, 1]$ as a definite integral. Then use the substitution $u = \sqrt{x}$ to show that this arc length is equal to the arc length of x^2 over $[0, 1]$ (but do not evaluate the integrals). Explain this result graphically.

SOLUTION Let $g(x) = \sqrt{x}$. Then

$$1 + g'(x)^2 = \frac{1 + 4x}{4x} \quad \text{and} \quad s = \int_0^1 \sqrt{\frac{1 + 4x}{4x}}\, dx = \int_0^1 \frac{\sqrt{1 + 4x}}{2\sqrt{x}}\, dx.$$

With the substitution $u = \sqrt{x}$, $du = \dfrac{1}{2\sqrt{x}}\, dx$, this becomes

$$s = \int_0^1 \sqrt{1 + 4u^2}\, du.$$

Now, let $f(x) = x^2$. Then $1 + f'(x)^2 = 1 + 4x^2$, and

$$s = \int_0^1 \sqrt{1 + 4x^2}\, dx.$$

Thus, the two arc lengths are equal. This is explained graphically by the fact that for $x \geq 0$, x^2 and $\sqrt{x}$ are inverses of each other. This means that the two graphs are symmetric with respect to the line $y = x$. Moreover, the graphs of x^2 and $\sqrt{x}$ intersect at $x = 0$ and at $x = 1$. Thus, it is clear that the arc length of the two graphs on $[0, 1]$ are equal.

25. Find the arc length of $y = e^x$ over $[0, a]$. *Hint:* Try the substitution $u = \sqrt{1 + e^{2x}}$ followed by partial fractions.

SOLUTION Let $y = e^x$. Then $1 + (y')^2 = 1 + e^{2x}$, and the arc length over $[0, a]$ is

$$\int_0^a \sqrt{1 + e^{2x}}\, dx.$$

Now, let $u = \sqrt{1 + e^{2x}}$. Then

$$du = \frac{1}{2} \cdot \frac{2e^{2x}}{\sqrt{1 + e^{2x}}}\, dx = \frac{u^2 - 1}{u}\, dx$$

and the arc length is

$$\begin{aligned}
\int_0^a \sqrt{1 + e^{2x}}\, dx &= \int_{x=0}^{x=a} u \cdot \frac{u}{u^2 - 1}\, du = \int_{x=0}^{x=a} \frac{u^2}{u^2 - 1}\, du = \int_{x=0}^{x=a} \left(1 + \frac{1}{u^2 - 1}\right) du \\
&= \int_{x=0}^{x=a} \left(1 + \frac{1}{2}\frac{1}{u - 1} - \frac{1}{2}\frac{1}{u + 1}\right) du = \left(u + \frac{1}{2}\ln(u - 1) - \frac{1}{2}\ln(u + 1)\right)\Bigg|_{x=0}^{x=a} \\
&= \left[\sqrt{1 + e^{2x}} + \frac{1}{2}\ln\left(\frac{\sqrt{1 + e^{2x}} - 1}{\sqrt{1 + e^{2x}} + 1}\right)\right]\Bigg|_0^a \\
&= \sqrt{1 + e^{2a}} + \frac{1}{2}\ln\frac{\sqrt{1 + e^{2a}} - 1}{\sqrt{1 + e^{2a}} + 1} - \sqrt{2} + \frac{1}{2}\ln\frac{1 + \sqrt{2}}{\sqrt{2} - 1} \\
&= \sqrt{1 + e^{2a}} + \frac{1}{2}\ln\frac{\sqrt{1 + e^{2a}} - 1}{\sqrt{1 + e^{2a}} + 1} - \sqrt{2} + \ln(1 + \sqrt{2}).
\end{aligned}$$

26. Show that the arc length of $y = \ln(f(x))$ for $a \leq x \leq b$ is

$$\int_a^b \frac{\sqrt{f(x)^2 + f'(x)^2}}{f(x)}\, dx$$ 4

SOLUTION Let $y = \ln(f(x))$. Then

$$y' = \frac{f'(x)}{f(x)} \qquad \text{and} \qquad 1 + (y')^2 = \frac{f(x)^2 + f'(x)^2}{f(x)^2}.$$

Therefore,

$$s = \int_a^b \frac{\sqrt{f(x)^2 + f'(x)^2}}{f(x)}\,dx$$

since $f(x) > 0$ in order for $y = \ln(f(x))$ to be defined on $[a, b]$.

27. Use Eq. (4) to compute the arc length of $y = \ln(\sin x)$ for $\frac{\pi}{4} \le x \le \frac{\pi}{2}$.

SOLUTION With $f(x) = \sin x$, Eq. (4) yields

$$s = \int_{\pi/4}^{\pi/2} \frac{\sqrt{\sin^2 x + \cos^2 x}}{\sin x}\,dx = \int_{\pi/4}^{\pi/2} \csc x\,dx = \ln(\csc x - \cot x)\Big|_{\pi/4}^{\pi/2}$$

$$= \ln 1 - \ln(\sqrt{2} - 1) = \ln \frac{1}{\sqrt{2} - 1} = \ln(\sqrt{2} + 1).$$

28. Use Eq. (4) to compute the arc length of $y = \ln\left(\frac{e^x + 1}{e^x - 1}\right)$ over $[1, 3]$.

SOLUTION With $f(x) = \frac{e^x + 1}{e^x - 1}$,

$$f'(x) = \frac{(e^x - 1)e^x - (e^x + 1)e^x}{(e^x - 1)^2} = -\frac{2e^x}{(e^x - 1)^2}$$

and

$$f(x)^2 + f'(x)^2 = \left(\frac{e^x + 1}{e^x - 1}\right)^2 + \frac{4e^{2x}}{(e^x - 1)^4} = \frac{(e^{2x} - 1)^2 + 4e^{2x}}{(e^x - 1)^4} = \frac{(e^{2x} + 1)^2}{(e^x - 1)^4}.$$

Thus, by Eq. (4),

$$s = \int_1^3 \frac{e^{2x} + 1}{(e^x - 1)^2} \cdot \frac{e^x - 1}{e^x + 1}\,dx = \int_1^3 \frac{e^{2x} + 1}{e^{2x} - 1}\,dx.$$

Observe that

$$\frac{e^{2x} + 1}{e^{2x} - 1} = \frac{e^x + e^{-x}}{e^x - e^{-x}} = \frac{(e^x + e^{-x})/2}{(e^x - e^{-x})/2} = \frac{\cosh x}{\sinh x}.$$

Therefore,

$$s = \int_1^3 \frac{\cosh x}{\sinh x}\,dx = \ln(\sinh x)\Big|_1^3 = \ln(\sinh 3) - \ln(\sinh 1).$$

29. Show that if $0 \le f'(x) \le 1$ for all x, then the arc length of $y = f(x)$ over $[a, b]$ is at most $\sqrt{2}(b - a)$. Show that for $f(x) = x$, the arc length equals $\sqrt{2}(b - a)$.

SOLUTION If $0 \le f'(x) \le 1$ for all x, then

$$s = \int_a^b \sqrt{1 + f'(x)^2}\,dx \le \int_a^b \sqrt{1 + 1}\,dx = \sqrt{2}(b - a).$$

If $f(x) = x$, then $f'(x) = 1$ and

$$s = \int_a^b \sqrt{1 + 1}\,dx = \sqrt{2}(b - a).$$

30. Use the Comparison Theorem (Section 5.2) to prove that the arc length of $y = x^{4/3}$ over $[1, 2]$ is not less than $\frac{5}{3}$.

SOLUTION Note that $f'(x) = \frac{4}{3}x^{1/3}$; for $x \in [1, 2]$, we have $x^{1/3} \ge 1$ so that $f'(x) \ge \frac{4}{3}$. Then

$$\sqrt{1 + f'(x)^2} \ge \sqrt{1 + \left(\frac{4}{3}\right)^2} = \sqrt{\frac{25}{9}} = \frac{5}{3}$$

and then the arc length is

$$\int_1^2 \sqrt{1 + f'(x)^2}\,dx \ge \int_1^2 \frac{5}{3}\,dx = \frac{5}{3}$$

31. Approximate the arc length of one-quarter of the unit circle (which we know is $\frac{\pi}{2}$) by computing the length of the polygonal approximation with $N = 4$ segments (Figure 14).

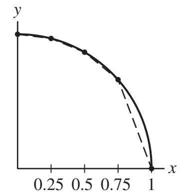

FIGURE 14 One-quarter of the unit circle

SOLUTION With $y = \sqrt{1-x^2}$, the five points along the curve are

$$P_0(0,1),\ P_1(1/4, \sqrt{15}/4),\ P_2(1/2, \sqrt{3}/2),\ P_3(3/4, \sqrt{7}/4),\ P_4(1,0)$$

Then

$$\overline{P_0P_1} = \sqrt{\frac{1}{16} + \left(\frac{4-\sqrt{15}}{4}\right)^2} \approx 0.252009$$

$$\overline{P_1P_2} = \sqrt{\frac{1}{16} + \left(\frac{2\sqrt{3}-\sqrt{15}}{4}\right)^2} \approx 0.270091$$

$$\overline{P_2P_3} = \sqrt{\frac{1}{16} + \left(\frac{2\sqrt{3}-\sqrt{7}}{4}\right)^2} \approx 0.323042$$

$$\overline{P_3P_4} = \sqrt{\frac{1}{16} + \frac{7}{16}} \approx 0.707108$$

and the total approximate distance is 1.552250 whereas $\pi/2 \approx 1.570796$.

32. CAS A merchant intends to produce specialty carpets in the shape of the region in Figure 15, bounded by the axes and graph of $y = 1 - x^n$ (units in yards). Assume that material costs \$50/yd^2 and that it costs $50L$ dollars to cut the carpet, where L is the length of the curved side of the carpet. The carpet can be sold for $150A$ dollars, where A is the carpet's area. Using numerical integration with a computer algebra system, find the whole number n for which the merchant's profits are maximal.

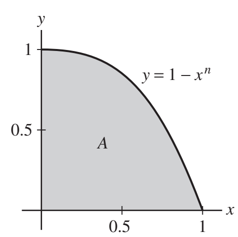

FIGURE 15

SOLUTION The area of the carpet is

$$A = \int_0^1 (1 - x^n)dx = \left(x - \frac{x^{n+1}}{n+1}\right)\bigg|_0^1 = 1 - \frac{1}{n+1} = \frac{n}{n+1},$$

while the length of the curved side of the carpet is

$$L = \int_0^1 \sqrt{1 + (nx^{n-1})^2}\,dx = \int_0^1 \sqrt{1 + n^2x^{2n-2}}\,dx.$$

Using these formulas, we find that the merchant's profit is given by

$$150A - (50A + 50L) = 100A - 50L = \frac{100n}{n+1} - 50\int_0^1 \sqrt{1 + n^2x^{2n-2}}\,dx.$$

Using a CAS, we find that the merchant's profit is maximized (approximately \$3.31 per carpet) when $n = 13$. The table below lists the profit for $1 \le n \le 15$.

n	Profit	n	Profit
1	−20.71067810	9	3.06855532
2	−7.28047621	10	3.18862208
3	−2.39328273	11	3.25953632
4	−0.01147138	12	3.29668137
5	1.30534545	13	3.31024566
6	2.08684099	14	3.30715476
7	2.57017349	15	3.29222024
8	2.87535925		

In Exercises 33–40, compute the surface area of revolution about the x-axis over the interval.

33. $y = x$, $[0, 4]$

SOLUTION $1 + (y')^2 = 2$ so that

$$SA = 2\pi \int_0^4 x\sqrt{2}\,dx = 2\pi\sqrt{2}\frac{1}{2}x^2\bigg|_0^4 = 16\pi\sqrt{2}$$

34. $y = 4x + 3$, $[0, 1]$

SOLUTION Let $y = 4x + 3$. Then $1 + (y')^2 = 17$ and

$$SA = 2\pi \int_0^1 (4x+3)\sqrt{17}\,dx = 2\pi\sqrt{17}\left(2x^2 + 3x\right)\bigg|_0^1 = 10\pi\sqrt{17}.$$

35. $y = x^3$, $[0, 2]$

SOLUTION $1 + (y')^2 = 1 + 9x^4$, so that

$$SA = 2\pi \int_0^2 x^3\sqrt{1+9x^4}\,dx = \frac{2\pi}{36}\int_0^2 36x^3\sqrt{1+9x^4}\,dx = \frac{\pi}{18}(1+9x^4)^{3/2}\bigg|_0^2 = \frac{\pi}{18}\left(145^{3/2} - 1\right)$$

36. $y = x^2$, $[0, 4]$

SOLUTION Let $y = x^2$. Then $y' = 2x$ and

$$SA = 2\pi \int_0^4 x^2\sqrt{1+4x^2}\,dx.$$

Using the substitution $2x = \tan\theta$, $2\,dx = \sec^2\theta\,d\theta$, we find that

$$\begin{aligned}
\int x^2\sqrt{1+4x^2}\,dx &= \frac{1}{8}\int \sec^3\theta\tan^2\theta\,d\theta = \frac{1}{8}\int\left(\sec^5\theta - \sec^3\theta\right)d\theta \\
&= \frac{1}{8}\left(\frac{1}{4}\sec^3\theta\tan\theta + \frac{3}{8}\sec\theta\tan\theta + \frac{3}{8}\ln|\sec\theta + \tan\theta| - \frac{1}{2}\sec\theta\tan\theta - \frac{1}{2}\ln|\sec\theta+\tan\theta|\right) + C \\
&= \frac{x}{16}(1+4x^2)^{3/2} - \frac{x}{32}\sqrt{1+4x^2} - \frac{1}{64}\ln|\sqrt{1+4x^2} + 2x| + C.
\end{aligned}$$

Finally,

$$\begin{aligned}
SA &= 2\pi\left(\frac{x}{16}(1+4x^2)^{3/2} - \frac{x}{32}\sqrt{1+4x^2} - \frac{1}{64}\ln|\sqrt{1+4x^2}+2x|\right)\bigg|_0^4 \\
&= 2\pi\left(\frac{1}{4}65^{3/2} - \frac{\sqrt{65}}{8} - \frac{1}{64}\ln(8+\sqrt{65})\right) = \frac{129\sqrt{65}}{4}\pi - \frac{\pi}{32}\ln(8+\sqrt{65}).
\end{aligned}$$

37. $y = (4 - x^{2/3})^{3/2}$, $[0, 8]$

SOLUTION Let $y = (4 - x^{2/3})^{3/2}$. Then

$$y' = -x^{-1/3}(4 - x^{2/3})^{1/2},$$

and

$$1 + (y')^2 = 1 + \frac{4 - x^{2/3}}{x^{2/3}} = \frac{4}{x^{2/3}}.$$

Therefore,

$$SA = 2\pi \int_0^8 (4 - x^{2/3})^{3/2} \left(\frac{2}{x^{1/3}}\right) dx.$$

Using the substitution $u = 4 - x^{2/3}$, $du = -\frac{2}{3}x^{-1/3}\,dx$, we find

$$SA = 2\pi \int_4^0 u^{3/2}(-3)\,du = 6\pi \int_0^4 u^{3/2}\,du = \frac{12}{5}\pi u^{5/2}\Big|_0^4 = \frac{384\pi}{5}.$$

38. $y = e^{-x}$, $[0, 1]$

SOLUTION Let $y = e^{-x}$. Then $y' = -e^{-x}$ and

$$SA = 2\pi \int_0^1 e^{-x}\sqrt{1 + e^{-2x}}\,dx.$$

Using the substitution $e^{-x} = \tan\theta$, $-e^{-x}\,dx = \sec^2\theta\,d\theta$, we find that

$$\begin{aligned}\int e^{-x}\sqrt{1+e^{-2x}}\,dx &= -\int \sec^3\theta\,d\theta = -\frac{1}{2}\sec\theta\tan\theta - \frac{1}{2}\ln|\sec\theta + \tan\theta| + C\\ &= -\frac{1}{2}e^{-x}\sqrt{1+e^{-2x}} - \frac{1}{2}\ln|\sqrt{1+e^{-2x}} + e^{-x}| + C.\end{aligned}$$

Finally,

$$\begin{aligned}SA &= \left(-\pi e^{-x}\sqrt{1+e^{-2x}} - \pi\ln|\sqrt{1+e^{-2x}} + e^{-x}|\right)\Big|_0^1\\ &= -\pi e^{-1}\sqrt{1+e^{-2}} - \pi\ln(\sqrt{1+e^{-2}} + e^{-1}) + \pi\sqrt{2} + \pi\ln(\sqrt{2}+1)\\ &= \pi\sqrt{2} - \pi e^{-1}\sqrt{1+e^{-2}} + \pi\ln\left(\frac{\sqrt{2}+1}{\sqrt{1+e^{-2}}+e^{-1}}\right).\end{aligned}$$

39. $y = \frac{1}{4}x^2 - \frac{1}{2}\ln x$, $[1, e]$

SOLUTION We have $y' = \frac{x}{2} - \frac{1}{2x}$, and

$$1 + (y')^2 = 1 + \left(\frac{x}{2} - \frac{1}{2x}\right)^2 = 1 + \frac{x^2}{4} - \frac{1}{2} + \frac{1}{4x^2} = \frac{x^2}{4} + \frac{1}{2} + \frac{1}{4x^2} = \left(\frac{x}{2} + \frac{1}{2x}\right)^2.$$

Thus,

$$\begin{aligned}SA &= 2\pi \int_1^e \left(\frac{x^2}{4} - \frac{\ln x}{2}\right)\left(\frac{x}{2} + \frac{1}{2x}\right) dx = 2\pi \int_1^e \frac{x^3}{8} + \frac{x}{8} - \frac{x\ln x}{4} - \frac{\ln x}{4x}\,dx\\ &= 2\pi\left(\frac{x^4}{32} + \frac{x^2}{16} - \frac{x^2\ln x}{8} + \frac{x^2}{16} - \frac{(\ln x)^2}{8}\right)\Big|_1^e\\ &= 2\pi\left(\frac{e^4}{32} + \frac{e^2}{16} - \frac{e^2}{8} + \frac{e^2}{16} - \frac{1}{8} - \left(\frac{1}{32} + \frac{1}{16} + 0 + \frac{1}{16} - 0\right)\right)\\ &= 2\pi\left(\frac{e^4}{32} - \frac{1}{8} - \frac{1}{32} - \frac{1}{16} - \frac{1}{16}\right)\\ &= \frac{\pi}{16}(e^4 - 9)\end{aligned}$$

40. $y = \sin x$, $[0, \pi]$

SOLUTION Let $y = \sin x$. Then $y' = \cos x$, and

$$SA = 2\pi \int_0^\pi \sin x\sqrt{1 + \cos^2 x}\,dx.$$

Using the substitution $\cos x = \tan\theta$, $-\sin x\,dx = \sec^2\theta\,d\theta$, we find that

$$\int \sin x\sqrt{1+\cos^2 x}\,dx = -\int \sec^3\theta\,d\theta = -\frac{1}{2}\sec\theta\tan\theta - \frac{1}{2}\ln|\sec\theta + \tan\theta| + C$$

$$= -\frac{1}{2}\cos x\sqrt{1+\cos^2 x} - \frac{1}{2}\ln\left|\sqrt{1+\cos^2 x} + \cos x\right| + C.$$

Finally,

$$SA = 2\pi\left(-\frac{1}{2}\cos x\sqrt{1+\cos^2 x} - \frac{1}{2}\ln\left|\sqrt{1+\cos^2 x} + \cos x\right|\right)\Big|_0^{\pi}$$
$$= 2\pi\left(\frac{1}{2}\sqrt{2} - \frac{1}{2}\ln(\sqrt{2}-1) + \frac{1}{2}\sqrt{2} + \frac{1}{2}\ln(\sqrt{2}+1)\right) = 2\pi\left(\sqrt{2} + \ln(\sqrt{2}+1)\right).$$

CAS *In Exercises 41–44, use a computer algebra system to find the approximate surface area of the solid generated by rotating the curve about the x-axis.*

41. $y = x^{-1}$, $[1, 3]$

SOLUTION

$$SA = 2\pi\int_1^3 \frac{1}{x}\sqrt{1+\left(-\frac{1}{x^2}\right)^2}\,dx = 2\pi\int_1^3 \frac{1}{x}\sqrt{1+\frac{1}{x^4}}\,dx \approx 7.603062807$$

using Maple.

42. $y = x^4$, $[0, 1]$

SOLUTION

$$SA = 2\pi\int_0^1 x^4\sqrt{1+(4x^3)^2}\,dx = 2\pi\int_0^1 x^4\sqrt{1+16x^6}\,dx \approx 3.436526697$$

using Maple.

43. $y = e^{-x^2/2}$, $[0, 2]$

SOLUTION

$$SA = 2\pi\int_0^2 e^{-x^2/2}\sqrt{1+(-xe^{-x^2/2})^2}\,dx = 2\pi\int_0^2 e^{-x^2/2}\sqrt{1+x^2e^{-x^2}}\,dx \approx 8.222695606$$

using Maple.

44. $y = \tan x$, $\left[0, \frac{\pi}{4}\right]$

SOLUTION Let $y = \tan x$. Then $y' = \sec^2 x$, $1 + (y')^2 = 1 + \sec^4 x$, and

$$SA = 2\pi\int_0^{\pi/4} \tan x\sqrt{1+\sec^4 x}\,dx.$$

Using a computer algebra system to approximate the value of the definite integral, we find

$$SA \approx 3.83908.$$

45. Find the area of the surface obtained by rotating $y = \cosh x$ over $[-\ln 2, \ln 2]$ around the x-axis.

SOLUTION Let $y = \cosh x$. Then $y' = \sinh x$, and

$$\sqrt{1+(y')^2} = \sqrt{1+\sinh^2 x} = \sqrt{\cosh^2 x} = \cosh x.$$

Therefore,

$$SA = 2\pi\int_{-\ln 2}^{\ln 2} \cosh^2 x\,dx = \pi\int_{-\ln 2}^{\ln 2} (1+\cosh 2x)\,dx = \pi\left(x + \frac{1}{2}\sinh 2x\right)\Big|_{-\ln 2}^{\ln 2}$$
$$= \pi\left(\ln 2 + \frac{1}{2}\sinh(2\ln 2) + \ln 2 - \frac{1}{2}\sinh(-2\ln 2)\right) = 2\pi\ln 2 + \pi\sinh(2\ln 2).$$

We can simplify this answer by recognizing that

$$\sinh(2\ln 2) = \frac{e^{2\ln 2} - e^{-2\ln 2}}{2} = \frac{4-\frac{1}{4}}{2} = \frac{15}{8}.$$

Thus,

$$SA = 2\pi\ln 2 + \frac{15\pi}{8}.$$

46. Show that the surface area of a spherical cap of height h and radius R (Figure 16) has surface area $2\pi Rh$.

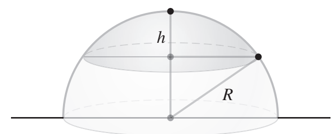

FIGURE 16

SOLUTION To determine the surface area of the cap, we will rotate a portion of a circle of radius R, centered at the origin, about the y-axis. Since the equation of the right half of the circle is $x = \sqrt{R^2 - y^2}$,

$$1 + (x')^2 = 1 + \frac{y^2}{R^2 - y^2} = \frac{R^2}{R^2 - y^2},$$

and

$$SA = 2\pi \int_{R-h}^{R} \sqrt{R^2 - y^2}\left(\frac{R}{\sqrt{R^2 - y^2}}\right) dy = 2\pi R\,(R - (R - h)) = 2\pi Rh.$$

47. Find the surface area of the torus obtained by rotating the circle $x^2 + (y - b)^2 = a^2$ about the x-axis (Figure 17).

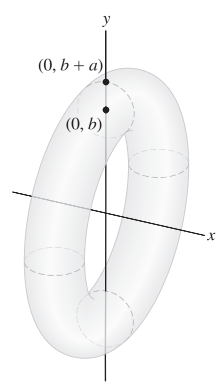

FIGURE 17 Torus obtained by rotating a circle about the x-axis.

SOLUTION $y = b + \sqrt{a^2 - x^2}$ gives the top half of the circle and $y = b - \sqrt{a^2 - x^2}$ gives the bottom half. Note that in each case,

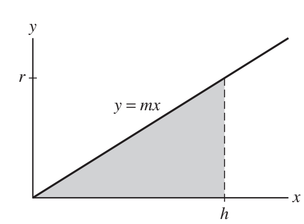
$$1 + (y')^2 = 1 + \frac{x^2}{a^2 - x^2} = \frac{a^2}{a^2 - x^2}.$$

Rotating the two halves of the circle around the x-axis then yields

$$\begin{aligned} SA &= 2\pi \int_{-a}^{a} (b + \sqrt{a^2 - x^2})\frac{a}{\sqrt{a^2 - x^2}}\,dx + 2\pi \int_{-a}^{a} (b - \sqrt{a^2 - x^2})\frac{a}{\sqrt{a^2 - x^2}}\,dx \\ &= 2\pi \int_{-a}^{a} 2b\frac{a}{\sqrt{a^2 - x^2}}\,dx = 4\pi ba \int_{-a}^{a} \frac{1}{\sqrt{a^2 - x^2}}\,dx \\ &= 4\pi ba \cdot \sin^{-1}\left(\frac{x}{a}\right)\Big|_{-a}^{a} = 4\pi ba\left(\frac{\pi}{2} - \left(-\frac{\pi}{2}\right)\right) = 4\pi^2 ba. \end{aligned}$$

48. Show that the surface area of a right circular cone of radius r and height h is $\pi r\sqrt{r^2 + h^2}$. *Hint:* Rotate a line $y = mx$ about the x-axis for $0 \le x \le h$, where m is determined suitably by the radius r.

SOLUTION



From the figure, we see that $m = \frac{r}{h}$, so $y = \frac{rx}{h}$. Thus

$$SA = 2\pi \int_0^h \frac{rx}{h}\sqrt{1+\frac{r^2}{h^2}}\,dx = \frac{2\pi r}{h}\sqrt{1+\frac{r^2}{h^2}}\int_0^h x\,dx = \pi r\sqrt{h^2+r^2}.$$

Further Insights and Challenges

49. Find the surface area of the ellipsoid obtained by rotating the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$ about the x-axis.

SOLUTION Taking advantage of symmetry, we can find the surface area of the ellipsoid by doubling the surface area obtained by rotating the portion of the ellipse in the first quadrant about the x-axis. The equation for the portion of the ellipse in the first quadrant is

$$y = \frac{b}{a}\sqrt{a^2-x^2}.$$

Thus,

$$1+(y')^2 = 1+\frac{b^2x^2}{a^2(a^2-x^2)} = \frac{a^4+(b^2-a^2)x^2}{a^2(a^2-x^2)},$$

and

$$SA = 4\pi\int_0^a \frac{b}{a}\sqrt{a^2-x^2}\,\frac{\sqrt{a^4+(b^2-a^2)x^2}}{a\sqrt{a^2-x^2}}\,dx = 4\pi b\int_0^a \sqrt{1+\left(\frac{b^2-a^2}{a^4}\right)x^2}\,dx.$$

We now consider two cases. If $b^2 > a^2$, then we make the substitution

$$\frac{\sqrt{b^2-a^2}}{a^2}x = \tan\theta, \quad dx = \frac{a^2}{\sqrt{b^2-a^2}}\sec^2\theta\,d\theta,$$

and find that

$$\begin{aligned} SA &= 4\pi b\frac{a^2}{\sqrt{b^2-a^2}}\int_{x=0}^{x=a}\sec^3\theta\,d\theta = 2\pi b\frac{a^2}{\sqrt{b^2-a^2}}\left(\sec\theta\tan\theta + \ln|\sec\theta+\tan\theta|\right)\Big|_{x=0}^{x=a} \\ &= \left(2\pi bx\sqrt{1+\left(\frac{b^2-a^2}{a^4}\right)x^2} + 2\pi b\frac{a^2}{\sqrt{b^2-a^2}}\ln\left|\sqrt{1+\left(\frac{b^2-a^2}{a^4}\right)x^2}+\frac{\sqrt{b^2-a^2}}{a^2}x\right|\right)\Bigg|_0^a \\ &= 2\pi b^2 + 2\pi b\frac{a^2}{\sqrt{b^2-a^2}}\ln\left(\frac{b}{a}+\frac{\sqrt{b^2-a^2}}{a}\right). \end{aligned}$$

On the other hand, if $a^2 > b^2$, then we make the substitution

$$\frac{\sqrt{a^2-b^2}}{a^2}x = \sin\theta, \quad dx = \frac{a^2}{\sqrt{a^2-b^2}}\cos\theta\,d\theta,$$

and find that

$$\begin{aligned} SA &= 4\pi b\frac{a^2}{\sqrt{a^2-b^2}}\int_{x=0}^{x=a}\cos^2\theta\,d\theta = 2\pi b\frac{a^2}{\sqrt{a^2-b^2}}\left(\theta+\sin\theta\cos\theta\right)\Big|_{x=0}^{x=a} \\ &= \left[2\pi bx\sqrt{1-\left(\frac{a^2-b^2}{a^4}\right)x^2} + 2\pi b\frac{a^2}{\sqrt{a^2-b^2}}\sin^{-1}\left(\frac{\sqrt{a^2-b^2}}{a^2}x\right)\right]\Bigg|_0^a \\ &= 2\pi b^2 + 2\pi b\frac{a^2}{\sqrt{a^2-b^2}}\sin^{-1}\left(\frac{\sqrt{a^2-b^2}}{a}\right). \end{aligned}$$

Observe that in both cases, as a approaches b, the value of the surface area of the ellipsoid approaches $4\pi b^2$, the surface area of a sphere of radius b.

50. Show that if the arc length of $f(x)$ over $[0, a]$ is proportional to a, then $f(x)$ must be a linear function.

SOLUTION

$$s = \int_0^a \sqrt{1 + f'(x)^2}\,dx$$

For s to be proportional to a, $\sqrt{1 + f'(x)^2}$ must be a constant, which implies $f'(x)$ is a constant. This, in turn, requires $f(x)$ be linear.

51. CAS Let L be the arc length of the upper half of the ellipse with equation

$$y = \frac{b}{a}\sqrt{a^2 - x^2}$$

(Figure 18) and let $\eta = \sqrt{1 - (b^2/a^2)}$. Use substitution to show that

$$L = a\int_{-\pi/2}^{\pi/2} \sqrt{1 - \eta^2 \sin^2\theta}\,d\theta$$

Use a computer algebra system to approximate L for $a = 2$, $b = 1$.

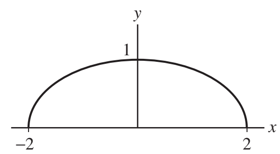


FIGURE 18 Graph of the ellipse $y = \frac{1}{2}\sqrt{4 - x^2}$.

SOLUTION Let $y = \frac{b}{a}\sqrt{a^2 - x^2}$. Then

$$1 + (y')^2 = \frac{b^2x^2 + a^2(a^2 - x^2)}{a^2(a^2 - x^2)}$$

and

$$s = \int_{-a}^a \sqrt{\frac{b^2x^2 + a^2(a^2 - x^2)}{a^2(a^2 - x^2)}}\,dx.$$

With the substitution $x = a\sin t$, $dx = a\cos t\,dt$, $a^2 - x^2 = a^2\cos^2 t$ and

$$s = a\int_{-\pi/2}^{\pi/2} \cos t\sqrt{\frac{a^2b^2\sin^2 t + a^2a^2\cos^2 t}{a^2(a^2\cos^2 t)}}\,dt = a\int_{\pi/2}^{\pi/2} \sqrt{\frac{b^2\sin^2 t}{a^2} + \cos^2 t}\,dt$$

Because

$$\eta = \sqrt{1 - \frac{b^2}{a^2}},\ \eta^2 = 1 - \frac{b^2}{a^2}$$

we then have

$$1 - \eta^2\sin^2 t = 1 - \left(1 - \frac{b^2}{a^2}\right)\sin^2 t = 1 - \sin^2 t + \frac{b^2}{a^2}\sin^2 t = \cos^2 t + \frac{b^2}{a^2}\sin^2 t$$

which is the same as the expression under the square root above. Substituting, we get

$$s = a\int_{-\pi/2}^{\pi/2} \sqrt{1 - \eta^2\sin^2 t}\,dt$$

When $a = 2$ and $b = 1$, $\eta^2 = \frac{3}{4}$. Using a computer algebra system to approximate the value of the definite integral, we find $s \approx 4.84422$.

52. Prove that the portion of a sphere of radius R seen by an observer located at a distance d above the North Pole has area $A = 2\pi d R^2/(d+R)$. *Hint:* According to Exercise 46, the cap has surface area is $2\pi Rh$. Show that $h = dR/(d+R)$ by applying the Pythagorean Theorem to the three right triangles in Figure 19.

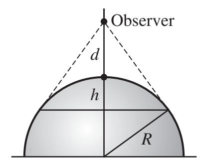

FIGURE 19 Spherical cap observed from a distance d above the North Pole.

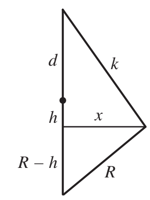
SOLUTION Label distances as shown in the figure below.



By repeated application of the Pythagorean Theorem, we find

$$(d+R)^2 = R^2 + k^2 = R^2 + (d+h)^2 + x^2 = R^2 + (d+h)^2 + R^2 - (R-h)^2.$$

Solving for h yields

$$\begin{aligned} d^2 + 2dR + R^2 &= R^2 + d^2 + 2dh + h^2 + R^2 - R^2 + 2Rh - h^2 \\ 2dR &= 2dh + 2Rh \\ dR &= (d+R)h \\ h &= \frac{dR}{d+R} \end{aligned}$$

and thus

$$SA = 2\pi R\left(\frac{dR}{d+R}\right).$$

53. Suppose that the observer in Exercise 52 moves off to infinity—that is, $d \to \infty$. What do you expect the limiting value of the observed area to be? Check your guess by calculating the limit using the formula for the area in the previous exercise.

SOLUTION We would assume the observed surface area would approach $2\pi R^2$ which is the surface area of a hemisphere of radius R. To verify this, observe:

$$\lim_{d\to\infty} SA = \lim_{d\to\infty} \frac{2\pi R^2 d}{R+d} = \lim_{d\to\infty} \frac{2\pi R^2}{1} = 2\pi R^2.$$

54. Let M be the total mass of a metal rod in the shape of the curve $y = f(x)$ over $[a,b]$ whose mass density $\rho(x)$ varies as a function of x. Use Riemann sums to justify the formula

$$M = \int_a^b \rho(x)\sqrt{1 + f'(x)^2}\,dx$$

SOLUTION Divide the interval $[a,b]$ into n subintervals, which we shall denote by $[x_{j-1}, x_j]$ for $j = 1, 2, 3, \ldots, n$. On each subinterval, we will assume that the mass density of the rod is constant; hence, the mass of the corresponding segment of the rod will be approximately equal to the product of the mass density of the segment and the length of the segment. Specifically, let c_j be any point in the jth subinterval and approximate the mass of the segment by

$$\rho(c_j)\sqrt{1 + f'(c_j)^2}\,\Delta x,$$

where $\sqrt{1 + f'(c_j)^2}\,\Delta x$ is the approximate length of the segment. Thus,

$$M \approx \sum_{j=1}^{n} \rho(c_j)\sqrt{1 + f'(c_j)^2}\,\Delta x.$$

As $n \to \infty$, this Riemann sum approaches a definite integral, and we have

$$M = \int_a^b \rho(x)\sqrt{1 + f'(x)^2}\, dx.$$

55. Let $f(x)$ be an increasing function on $[a, b]$ and let $g(x)$ be its inverse. Argue on the basis of arc length that the following equality holds:

$$\int_a^b \sqrt{1 + f'(x)^2}\, dx = \int_{f(a)}^{f(b)} \sqrt{1 + g'(y)^2}\, dy \qquad \boxed{5}$$

Then use the substitution $u = f(x)$ to prove Eq. (5).

SOLUTION Since the graphs of $f(x)$ and $g(x)$ are symmetric with respect to the line $y = x$, the arc length of the curves will be equal on the respective domains. Since the domain of g is the range of f, on $f(a)$ to $f(b)$, $g(x)$ will have the same arc length as $f(x)$ on a to b. If $g(x) = f^{-1}(x)$ and $u = f(x)$, then $x = g(u)$ and $du = f'(x)\, dx$. But

$$g'(u) = \frac{1}{f'(g(u))} = \frac{1}{f'(x)} \Rightarrow f'(x) = \frac{1}{g'(u)}$$

Now substituting $u = f(x)$,

$$s = \int_a^b \sqrt{1 + f'(x)^2}\, dx = \int_{f(a)}^{f(b)} \sqrt{1 + \left(\frac{1}{g'(u)}\right)^2}\, g'(u)\, du = \int_{f(a)}^{f(b)} \sqrt{g'(u)^2 + 1}\, du$$

8.2 Fluid Pressure and Force

Preliminary Questions

1. How is pressure defined?

SOLUTION Pressure is defined as force per unit area.

2. Fluid pressure is proportional to depth. What is the factor of proportionality?

SOLUTION The factor of proportionality is the weight density of the fluid, $w = \rho g$, where ρ is the mass density of the fluid.

3. When fluid force acts on the side of a submerged object, in which direction does it act?

SOLUTION Fluid force acts in the direction perpendicular to the side of the submerged object.

4. Why is fluid pressure on a surface calculated using thin horizontal strips rather than thin vertical strips?

SOLUTION Pressure depends only on depth and does not change horizontally at a given depth.

5. If a thin plate is submerged horizontally, then the fluid force on one side of the plate is equal to pressure times area. Is this true if the plate is submerged vertically?

SOLUTION When a plate is submerged vertically, the pressure is not constant along the plate, so the fluid force is not equal to the pressure times the area.

Exercises

1. A box of height 6 m and square base of side 3 m is submerged in a pool of water. The top of the box is 2 m below the surface of the water.

(a) Calculate the fluid force on the top and bottom of the box.

(b) Write a Riemann sum that approximates the fluid force on a side of the box by dividing the side into N horizontal strips of thickness $\Delta y = 6/N$.

(c) To which integral does the Riemann sum converge?

(d) Compute the fluid force on a side of the box.

SOLUTION

(a) At a depth of 2 m, the pressure on the top of the box is $\rho g h = 10^3 \cdot 9.8 \cdot 2 = 19{,}600$ Pa. The top has area 9 m^2, and the pressure is constant, so the force on the top of the box is $19{,}600 \cdot 9 = 176{,}400 N$. At a depth of 8 m, the pressure on the bottom of the box is $\rho g h = 10^3 \cdot 9.8 \cdot 8 = 78{,}400$ Pa, so the force on the bottom of the box is $78{,}400 \cdot 9 = 705{,}600 N$.

(b) Let y_j denote the depth of the j^{th} strip, for $j = 1, 2, 3, \ldots, N$; the pressure at this depth is $10^3 \cdot 9.8 \cdot y_j = 9800 y_j$ Pa. The strip has thickness Δy m and length 3 m, so has area $3\Delta y$ m^2. Thus the force on the strip is $29{,}400 y_j \Delta y$ N. Sum over all the strips to conclude that the force on one side of the box is approximately

$$F \approx \sum_{j=1}^{N} 29{,}400 y_j \Delta y.$$

(c) As $N \to \infty$, the Riemann sum in part (b) converges to the definite integral $29{,}400 \int_2^8 y\,dy$.

(d) Using the result from part (c), the fluid force on one side of the box is

$$29{,}400 \int_2^8 y\,dy = 14{,}700 y^2 \Big|_2^8 = 882{,}000\ N$$

2. A plate in the shape of an isosceles triangle with base 1 m and height 2 m is submerged vertically in a tank of water so that its vertex touches the surface of the water (Figure 7).

(a) Show that the width of the triangle at depth y is $f(y) = \frac{1}{2}y$.

(b) Consider a thin strip of thickness Δy at depth y. Explain why the fluid force on a side of this strip is approximately equal to $\rho g \frac{1}{2} y^2 \Delta y$.

(c) Write an approximation for the total fluid force F on a side of the plate as a Riemann sum and indicate the integral to which it converges.

(d) Calculate F.

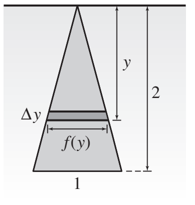


FIGURE 7

SOLUTION

(a) By similar triangles, $\frac{y}{2} = \frac{f(y)}{1}$ so $f(y) = \frac{y}{2}$.

(b) The pressure at a depth of y feet is $\rho g y$ Pa, and the area of the strip is approximately $f(y)\,\Delta y = \frac{1}{2} y \Delta y$ m^2. Therefore, the fluid force on this strip is approximately

$$\rho g y \left(\frac{1}{2} y \Delta y\right) = \frac{1}{2} \rho g y^2 \Delta y.$$

(c) $F \approx \sum_{j=1}^{N} \rho g \frac{y_j^2}{2} \Delta y$. As $N \to \infty$, the Riemann sum converges to the definite integral

$$\frac{\rho g}{2} \int_0^2 y^2\,dy.$$

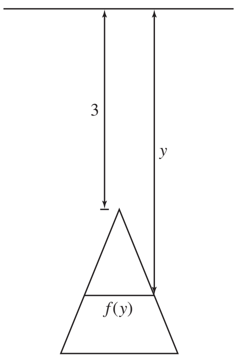
(d) Using the result of part (c),

$$F = \frac{\rho g}{2} \int_0^2 y^2\,dy = \frac{\rho g}{2}\left(\frac{y^3}{3}\right)\Bigg|_0^2 = \frac{9800}{2} \cdot \frac{8}{3} = \frac{39200}{3}\ \text{N}.$$

3. Repeat Exercise 2, but assume that the top of the triangle is located 3 m below the surface of the water.

SOLUTION

(a) Examine the figure below. By similar triangles, $\frac{y-3}{2} = \frac{f(y)}{1}$ so $f(y) = \frac{y-3}{2}$.



(b) The pressure at a depth of y feet is $\rho g y$ lb/ Pa, and the area of the strip is approximately $f(y)\,\Delta y = \frac{1}{2}(y-3)\Delta y$ m^2. Therefore, the fluid force on this strip is approximately

$$\rho g y\left(\frac{1}{2}(y-3)\Delta y\right) = \frac{1}{2}\rho g y(y-3)\Delta y \text{ N}.$$

(c) $F \approx \sum_{j=1}^{N} \rho g \frac{y_j^2 - 3y_j}{2}\Delta y$. As $N \to \infty$, the Riemann sum converges to the definite integral

$$\frac{\rho g}{2}\int_3^5 (y^2 - 3y)\,dy.$$

(d) Using the result of part (c),

$$F = \frac{\rho g}{2}\int_3^5 (y^2-3y)\,dy = \frac{\rho g}{2}\left(\frac{y^3}{3} - \frac{3y^2}{2}\right)\Bigg|_3^5 = \frac{9800}{2}\left[\left(\frac{125}{3} - \frac{75}{2}\right) - \left(9 - \frac{27}{2}\right)\right] = \frac{127{,}400}{3} \text{ N}.$$

4. The plate R in Figure 8, bounded by the parabola $y = x^2$ and $y = 1$, is submerged vertically in water (distance in meters).

(a) Show that the width of R at height y is $f(y) = 2\sqrt{y}$ and the fluid force on a side of a horizontal strip of thickness Δy at height y is approximately $(\rho g)2y^{1/2}(1-y)\Delta y$.

(b) Write a Riemann sum that approximates the fluid force F on a side of R and use it to explain why

$$F = \rho g \int_0^1 2y^{1/2}(1-y)\,dy$$

(c) Calculate F.

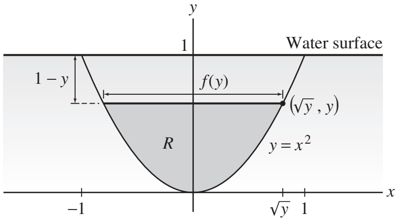


FIGURE 8

SOLUTION

(a) At height y, the thin plate R extends from the point $(-\sqrt{y}, y)$ on the left to the point $(\sqrt{y}, y)$ on the right; thus, the width of the plate is $f(y) = \sqrt{y} - (-\sqrt{y}) = 2\sqrt{y}$. Moreover, the area of a horizontal strip of thickness Δy at height y is $f(y)\,\Delta y = 2\sqrt{y}\,\Delta y$. Because the water surface is at height $y = 1$, the horizontal strip at height y is at a depth of $1 - y$. Consequently, the fluid force on the strip is approximately

$$\rho g(1-y) \times 2\sqrt{y}\Delta y = 2\rho g y^{1/2}(1-y)\Delta y.$$

(b) If the plate is divided into N strips with y_j being the representative height of the jth strip (for $j = 1, 2, 3, \ldots, N$), then the total fluid force exerted on the plate is

$$F \approx 2\rho g \sum_{j=1}^{N} (1 - y_j)\sqrt{y_j}\Delta y.$$

As $N \to \infty$, the Riemann sum converges to the definite integral

$$2\rho g \int_0^1 (1-y)\sqrt{y}\,dy.$$

(c) Using the result from part (b),

$$F = 2\rho g \int_0^1 (1-y)\sqrt{y}\,dy = 2\rho g\left(\frac{2}{3}y^{3/2} - \frac{2}{5}y^{5/2}\right)\Big|_0^1 = \frac{8}{15}\rho g.$$

Now, $\rho g = 9800\ \text{N/m}^3$ so that $F = \frac{15680}{3}$ N.

5. Let F be the fluid force on a side of a semicircular plate of radius r meters, submerged vertically in water so that its diameter is level with the water's surface (Figure 9).

(a) Show that the width of the plate at depth y is $2\sqrt{r^2 - y^2}$.

(b) Calculate F as a function of r using Eq. (2).

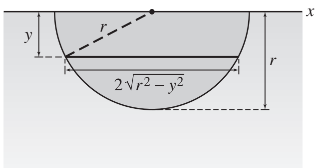

FIGURE 9

SOLUTION

(a) Place the origin at the center of the semicircle and point the positive y-axis downward. The equation for the edge of the semicircular plate is then $x^2 + y^2 = r^2$. At a depth of y, the plate extends from the point $(-\sqrt{r^2 - y^2}, y)$ on the left to the point $(\sqrt{r^2 - y^2}, y)$ on the right. The width of the plate at depth y is then

$$\sqrt{r^2 - y^2} - \left(-\sqrt{r^2 - y^2}\right) = 2\sqrt{r^2 - y^2}.$$

(b) With $w = 9800\ \text{N/m}^3$,

$$F = 2w \int_0^r y\sqrt{r^2 - y^2}\,dy = -\frac{19{,}600}{3}(r^2 - y^2)^{3/2}\Big|_0^r = \frac{19{,}600 r^3}{3}\ \text{N}.$$

6. Calculate the force on one side of a circular plate with radius 2 m, submerged vertically in a tank of water so that the top of the circle is tangent to the water surface.

SOLUTION Place the origin at the point where the top of the circle is tangent to the water surface and orient the positive y-axis pointing downward. The equation of the circle is then $x^2 + (y-2)^2 = 4$, and the width at any depth y is $2\sqrt{4 - (y-2)^2}$. Thus,

$$F = 2\rho g \int_0^4 y\sqrt{4 - (y-2)^2}\,dy,$$

Using the substitution $y - 2 = 2\sin\theta$, $dy = 2\cos\theta\,d\theta$, the limits of integration become $-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$, so we find

$$\begin{aligned}
F &= 2\rho g \int_0^4 y\sqrt{4 - (y-2)^2}\,dy \\
&= 2\rho g \int_{-\pi/2}^{\pi/2} (2 + 2\sin\theta)(2\cos\theta)(2\cos\theta\,d\theta) = 16\rho g \int_{-\pi/2}^{\pi/2} \cos^2\theta + \sin\theta\cos^2\theta\,d\theta \\
&= 16\rho g\left(\frac{1}{2}\theta + \frac{1}{2}\sin\theta\cos\theta - \frac{1}{3}\cos^3\theta\right)\Big|_{-\pi/2}^{\pi/2} \\
&= 16\rho g\left(\frac{\pi}{4} + 0 - 0 - (-\frac{\pi}{4} + 0 - 0)\right) = 8\rho g\pi = 78{,}400\pi\ \text{N}.
\end{aligned}$$

7. A semicircular plate of radius r meters, oriented as in Figure 9, is submerged in water so that its diameter is located at a depth of m meters. Calculate the fluid force on one side of the plate in terms of m and r.

SOLUTION Place the origin at the center of the semicircular plate with the positive y-axis pointing downward. The water surface is then at $y = -m$. Moreover, at location y, the width of the plate is $2\sqrt{r^2 - y^2}$ and the depth is $y + m$. Thus,

$$F = 2\rho g \int_0^r (y+m)\sqrt{r^2 - y^2}\,dy.$$

Now,

$$\int_0^r y\sqrt{r^2 - y^2}\,dy = -\frac{1}{3}(r^2 - y^2)^{3/2}\Big|_0^r = \frac{1}{3}r^3.$$

Geometrically,

$$\int_0^r \sqrt{r^2 - y^2}\,dy$$

represents the area of one quarter of a circle of radius r, and thus has the value $\frac{\pi r^2}{4}$. Bringing these results together, we find that

$$F = 2\rho g\left(\frac{1}{3}r^3 + \frac{\pi}{4}r^2\right) = \frac{19{,}600}{3}r^3 + 4900mr^2 \text{ N}.$$

8. A plate extending from depth $y = 2$ m to $y = 5$ m is submerged in a fluid of density $\rho = 850$ kg/m^3. The horizontal width of the plate at depth y is $f(y) = 2(1 + y^2)^{-1}$. Calculate the fluid force on one side of the plate.

SOLUTION The fluid force on one side of the plate is given by

$$F = \rho g \int_2^5 y f(y)\,dy = \rho g \int_2^5 2y(1 + y^2)^{-1}\,dy = \rho g \ln(1 + y^2)\Big|_2^5 = \rho g(\ln 26 - \ln 5)$$
$$= 8330 \ln \frac{26}{5} \approx 13733.32 \text{ N}.$$

9. Figure 10 shows the wall of a dam on a water reservoir. Use the Trapezoidal Rule and the width and depth measurements in the figure to estimate the fluid force on the wall.

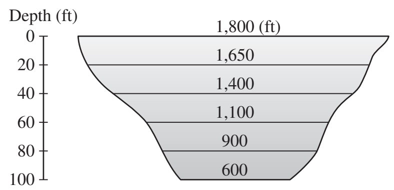

FIGURE 10

SOLUTION Let $f(y)$ denote the width of the dam wall at depth y feet. Then the force on the dam wall is

$$F = w\int_0^{100} y f(y)\,dy.$$

Using the Trapezoidal Rule and the width and depth measurements in the figure,

$$F \approx w\frac{20}{2}[0 \cdot f(0) + 2 \cdot 20 \cdot f(20) + 2 \cdot 40 \cdot f(40) + 2 \cdot 60 \cdot f(60) + 2 \cdot 80 \cdot f(80) + 100 \cdot f(100)]$$
$$= 10w(0 + 66{,}000 + 112{,}000 + 132{,}000 + 144{,}000 + 60{,}000) = 321{,}250{,}000 \text{ lb}.$$

10. Calculate the fluid force on a side of the plate in Figure 11(A), submerged in water.

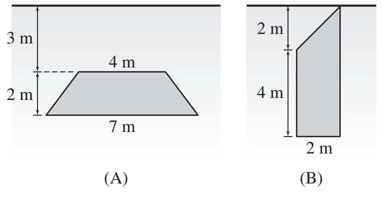

FIGURE 11

SOLUTION The width of the plate varies linearly from 4 meters at a depth of 3 meters to 7 meters at a depth of 5 meters. Thus, at depth y, the width of the plate is

$$4 + \frac{3}{2}(y - 3) = \frac{3}{2}y - \frac{1}{2}.$$

Finally, the force on a side of the plate is

$$F = w\int_3^5 y\left(\frac{3}{2}y - \frac{1}{2}\right)dy = w\left(\frac{1}{2}y^3 - \frac{1}{4}y^2\right)\Big|_3^5 = 45w = 441{,}000 \text{ N}.$$

11. Calculate the fluid force on a side of the plate in Figure 11(B), submerged in a fluid of mass density $\rho = 800$ kg/m^3.

SOLUTION Because the fluid has a mass density of $\rho = 800$ kg/m^3,

$$w = (800)(9.8) = 7840 \text{ N/m}^3.$$

For depths up to 2 meters, the width of the plate at depth y is y; for depths from 2 meters to 6 meters, the width of the plate is a constant 2 meters. Thus,

$$F = w\int_0^2 y(y)\,dy + w\int_2^6 2y\,dy = w\frac{y^3}{3}\bigg|_0^2 + wy^2\Big|_2^6 = \frac{8w}{3} + 32w = \frac{104w}{3} = \frac{815{,}360}{3} \text{ N}.$$

12. Find the fluid force on the side of the plate in Figure 12, submerged in a fluid of density $\rho = 1200$ kg/m^3. The top of the place is level with the fluid surface. The edges of the plate are the curves $y = x^{1/3}$ and $y = -x^{1/3}$.

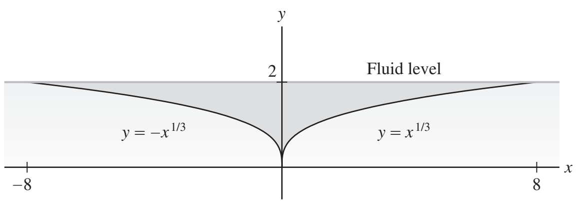

FIGURE 12

SOLUTION At height y, the plate extends from the point $(-y^3, y)$ on the left to the point (y^3, y) on the right; thus, the width of the plate is $f(y) = y^3 - (-y^3) = 2y^3$. Because the water surface is at height $y = 2$, the horizontal strip at height y is at a depth of $2 - y$. Consequently,

$$F = \rho g\int_0^2 (2-y)(2y^3)\,dy = 2\rho g\left(\frac{1}{2}y^4 - \frac{1}{5}y^5\right)\bigg|_0^2 = \frac{16\rho g}{5} = \frac{16\cdot 1200\cdot 9.8}{5} = 37{,}632 \text{ N}.$$

13. Let R be the plate in the shape of the region under $y = \sin x$ for $0 \le x \le \frac{\pi}{2}$ in Figure 13(A). Find the fluid force on a side of R if it is rotated counterclockwise by 90° and submerged in a fluid of density 1100 kg/m^3 with its top edge level with the surface of the fluid as in (B).

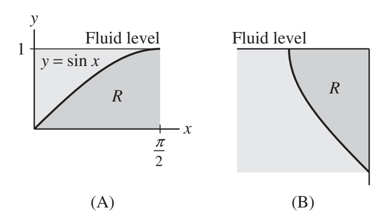

FIGURE 13

SOLUTION Place the origin at the bottom corner of the plate with the positive y-axis pointing upward. The fluid surface is then at height $y = \frac{\pi}{2}$, and the horizontal strip of the plate at height y is at a depth of $\frac{\pi}{2} - y$ and has a width of $\sin y$. Now, using integration by parts we find

$$F = \rho g\int_0^{\pi/2}\left(\frac{\pi}{2} - y\right)\sin y\,dy = \rho g\left[-\left(\frac{\pi}{2} - y\right)\cos y - \sin y\right]\bigg|_0^{\pi/2} = \rho g\left(\frac{\pi}{2} - 1\right)$$
$$= 1100\cdot 9.8\left(\frac{\pi}{2} - 1\right) \approx 6153.184 \text{ N}.$$

14. In the notation of Exercise 13, calculate the fluid force on a side of the plate R if it is oriented as in Figure 13(A). You may need to use Integration by Parts and trigonometric substitution.

SOLUTION Place the origin at the lower left corner of the plate. Because the fluid surface is at height $y = 1$, the horizontal strip at height y is at a depth of $1 - y$. Moreover, this strip has a width of

$$\frac{\pi}{2} - \sin^{-1} y = \cos^{-1} y.$$

Thus,

$$F = \rho g\int_0^1 (1-y)\cos^{-1} y\,dy.$$

Starting with integration by parts, we find

$$\int_0^1 (1-y)\cos^{-1} y\,dy = \left(y - \frac{1}{2}y^2\right)\cos^{-1} y\Big|_0^1 + \int_0^1 \frac{y - \frac{1}{2}y^2}{\sqrt{1-y^2}}\,dy$$

$$= \frac{1}{2}\cos^{-1} 1 + \int_0^1 \frac{y - \frac{1}{2}y^2}{\sqrt{1-y^2}}\,dy = \int_0^1 \frac{y}{\sqrt{1-y^2}}\,dy - \frac{1}{2}\int_0^1 \frac{y^2}{\sqrt{1-y^2}}\,dy.$$

Now,

$$\int_0^1 \frac{y}{\sqrt{1-y^2}}\,dy = \; -\sqrt{1-y^2}\Big|_0^1 = 1.$$

For the remaining integral, we use the trigonometric substitution $y = \sin\theta$, $dy = \cos\theta\,d\theta$ and find

$$\frac{1}{2}\int_0^1 \frac{y^2}{\sqrt{1-y^2}}\,dy = \frac{1}{2}\int_{y=0}^{y=1} \sin^2\theta\,d\theta = \frac{1}{4}(\theta - \sin\theta\cos\theta)\Big|_{y=0}^{y=1}$$

$$= \frac{1}{4}\left(\sin^{-1} y - y\sqrt{1-y^2}\right)\Big|_0^1 = \frac{\pi}{8}.$$

Finally,

$$F = \rho g\left(1 - \frac{\pi}{8}\right) = 1100 \cdot 9.8\left(1 - \frac{\pi}{8}\right) \approx 6546.70 \text{ N}.$$

15. Calculate the fluid force on one side of a plate in the shape of region A shown Figure 14. The water surface is at $y = 1$, and the fluid has density $\rho = 900$ kg/m^3.

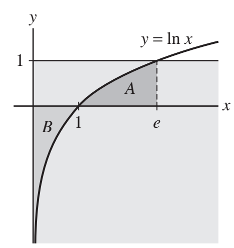

FIGURE 14

SOLUTION Because the fluid surface is at height $y = 1$, the horizontal strip at height y is at a depth of $1 - y$. Moreover, this strip has a width of $e - e^y$. Thus,

$$F = \rho g \int_0^1 (1-y)(e - e^y)\,dy = e\rho g \int_0^1 (1-y)\,dy - \rho g \int_0^1 (1-y)e^y\,dy.$$

Now,

$$\int_0^1 (1-y)\,dy = \left(y - \frac{1}{2}y^2\right)\Big|_0^1 = \frac{1}{2},$$

and using integration by parts

$$\int_0^1 (1-y)e^y\,dy = \left((1-y)e^y + e^y\right)\Big|_0^1 = e - 2.$$

Combining these results, we find that

$$F = \rho g\left(\frac{1}{2}e - (e-2)\right) = \rho g\left(2 - \frac{1}{2}e\right) = 900 \cdot 9.8\left(2 - \frac{1}{2}e\right) \approx 5652.37 \text{ N}.$$

16. Calculate the fluid force on one side of the “infinite” plate B in Figure 14, assuming the fluid has density $\rho = 900$ kg/m^3.

SOLUTION Because the fluid surface is at height $y = 1$, the horizontal strip at height y is at a depth of $1 - y$. Moreover, this strip has a width of e^y. Thus,

$$F = \rho g \int_{-\infty}^0 (1-y)e^y\,dy.$$

Using integration by parts, we find

$$\int_{-\infty}^{0} (1-y)e^y \, dy = \left[(1-y)e^y + e^y\right]\Big|_{-\infty}^{0} = 2.$$

Thus, $F = 2\rho g = 2 \cdot 900 \cdot 9.8 = 17{,}640$ N.

17. Figure 15(A) shows a ramp inclined at 30° leading into a swimming pool. Calculate the fluid force on the ramp.

SOLUTION A horizontal strip at depth y has length 6 and width

$$\frac{\Delta y}{\sin 30^\circ} = 2\Delta y.$$

Thus,

$$F = 2\rho g \int_0^4 6y \, dy = 96\rho g.$$

If distances are in feet, then $\rho g = w = 62.5$ lb/ft^3 and $F = 6000$ lb; if distances are in meters, then $\rho g = 9800$ N/m^3 and $F = 940{,}800$ N.

18. Calculate the fluid force on one side of the plate (an isosceles triangle) shown in Figure 15(B).

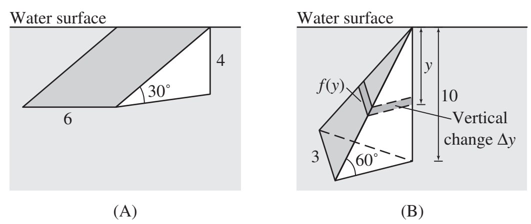

FIGURE 15

SOLUTION A horizontal strip at depth y has length $f(y) = \frac{3}{10}y$ and width

$$\frac{\Delta y}{\sin 60^\circ} = \frac{2}{\sqrt{3}}\Delta y.$$

Thus,

$$F = \frac{\sqrt{3}}{5} w \int_0^{10} y^2 \, dy = \frac{200\sqrt{3}}{3} w.$$

If distances are in feet, then $w = 62.5$ lb/ft^3 and $F \approx 7216.88$ lb; if distances are in meters, then $w = 9800$ N/m^3 and $F \approx 1{,}131{,}606.5$ N.

19. The massive Three Gorges Dam on China's Yangtze River has height 185 m (Figure 16). Calculate the force on the dam, assuming that the dam is a trapezoid of base 2000 m and upper edge 3000 m, inclined at an angle of 55° to the horizontal (Figure 17).

FIGURE 16 Three Gorges Dam on the Yangtze River

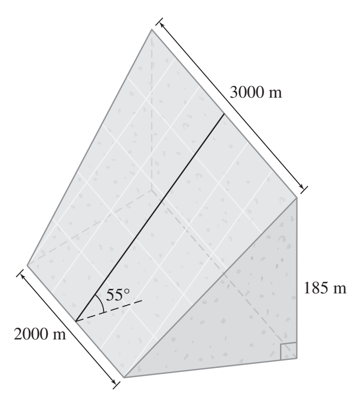

FIGURE 17

SOLUTION Let $y = 0$ be at the bottom of the dam, so that the top of the dam is at $y = 185$. Then the width of the dam at height y is $2000 + \frac{1000y}{185}$. The dam is inclined at an angle of 55° to the horizontal, so the height of a horizontal strip is

$$\frac{\Delta y}{\sin 55^\circ} \approx 1.221\Delta y$$

so that the area of such a strip is

$$1.221\left(2000+\frac{1000y}{185}\right)\Delta y$$

Then

$$F=\rho g\int_0^{185}1.221y\left(2000+\frac{1000y}{185}\right)dy=\rho g\int_0^{185}2442y+6.6y^2\,dy=\rho g(1221y^2+2.2y^3)\Big|_0^{185}$$
$$=55{,}718{,}300\rho g=55{,}718{,}300\cdot 9800=5.460393400\times 10^{11}\text{ N}.$$

20. A square plate of side 3 m is submerged in water at an incline of 30° with the horizontal. Calculate the fluid force on one side of the plate if the top edge of the plate lies at a depth of 6 m.

SOLUTION Because the plate is 3 meters on a side, is submerged at a horizontal angle of 30°, and has its top edge located at a depth of 6 meters, the bottom edge of the plate is located at a depth of $6+3\sin 30°=\frac{15}{2}$ meters. Let y denote the depth at any point of the plate. The width of each horizontal strip of the plate is then

$$\frac{\Delta y}{\sin 30°}=2\Delta y,$$

and

$$F=\rho g\int_6^{15/2}(2)3y\,dy=(\rho g)\frac{243}{4}=595{,}350\text{ N}.$$

21. The trough in Figure 18 is filled with corn syrup, whose weight density is 90 lb/ft^3. Calculate the force on the front side of the trough.

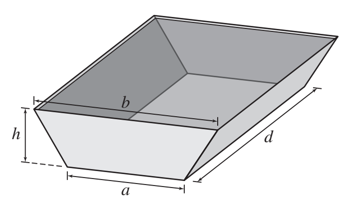

FIGURE 18

SOLUTION Place the origin along the top edge of the trough with the positive y-axis pointing downward. The width of the front side of the trough varies linearly from b when $y=0$ to a when $y=h$; thus, the width of the front side of the trough at depth y feet is given by

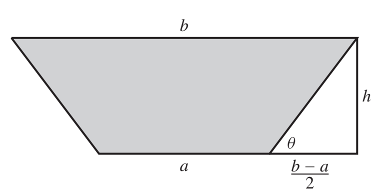
$$b+\frac{a-b}{h}y.$$

Now,

$$F=w\int_0^h y\left(b+\frac{a-b}{h}y\right)dy=w\left(\frac{1}{2}by^2+\frac{a-b}{3h}y^3\right)\Big|_0^h=w\left(\frac{b}{6}+\frac{a}{3}\right)h^2=(15b+30a)h^2\text{ lb}.$$

22. Calculate the fluid pressure on one of the slanted sides of the trough in Figure 18 when it is filled with corn syrup as in Exercise 21.

SOLUTION



The diagram above displays a side view of the trough. From this diagram, we see that

$$\sin\theta=\frac{h}{\sqrt{\left(\frac{b-a}{2}\right)^2+h^2}}.$$

Thus,

$$F=\frac{w}{\sin\theta}\int_0^h d\cdot y\,dy=\frac{90\sqrt{\left(\frac{b-a}{2}\right)^2+h^2}}{h}\frac{dh^2}{2}=45dh\sqrt{\left(\frac{b-a}{2}\right)^2+h^2}.$$

Further Insights and Challenges

23. The end of the trough in Figure 19 is an equilateral triangle of side 3. Assume that the trough is filled with water to height H. Calculate the fluid force on each side of the trough as a function of H and the length l of the trough.

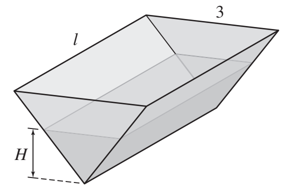


FIGURE 19

SOLUTION Place the origin at the lower vertex of the trough and orient the positive y-axis pointing upward. First, consider the faces at the front and back ends of the trough. A horizontal strip at height y has a length of $\frac{2y}{\sqrt{3}}$ and is at a depth of $H - y$. Thus,

$$F = w\int_0^H (H-y)\frac{2y}{\sqrt{3}}\,dy = w\left(\frac{H}{\sqrt{3}}y^2 - \frac{2}{3\sqrt{3}}y^3\right)\Big|_0^H = \frac{\sqrt{3}}{9}wH^3.$$

For the slanted sides, we note that each side makes an angle of 60° with the horizontal. If we let ℓ denote the length of the trough, then

$$F = \frac{2w\ell}{\sqrt{3}}\int_0^H (H-y)\,dy = \frac{\sqrt{3}}{3}\ell w H^2.$$

24. A rectangular plate of side ℓ is submerged vertically in a fluid of density w, with its top edge at depth h. Show that if the depth is increased by an amount Δh, then the force on a side of the plate increases by $wA\Delta h$, where A is the area of the plate.

SOLUTION Let F_1 be the force on a side of the plate when its top edge is at depth h and F_2 be the force on a side of the plate when its top edge is at depth $h + \Delta h$. Further, let b denote the width of the rectangular plate. Then

$$F_1 = w\int_h^{h+\ell} yb\,dy = bw\left(\frac{y^2}{2}\right)\Big|_h^{h+\ell} = bw\left(\frac{\ell^2 + 2\ell h}{2}\right)$$

$$F_2 = w\int_{h+\Delta h}^{h+\ell+\Delta h} yb\,dy = bw\left(\frac{y^2}{2}\right)\Big|_{h+\Delta h}^{h+\ell+\Delta h} = bw\frac{\ell^2 + 2\ell h + 2\ell\Delta h}{2}$$

and $F_2 - F_1 = bw\ell\Delta h = wA\Delta h$.

25. Prove that the force on the side of a rectangular plate of area A submerged vertically in a fluid is equal to $p_0 A$, where p_0 is the fluid pressure at the center point of the rectangle.

SOLUTION Let ℓ denote the length of the vertical side of the rectangle, x denote the length of the horizontal side of the rectangle, and suppose the top edge of the rectangle is at depth $y = m$. The pressure at the center of the rectangle is then

$$p_0 = w\left(m + \frac{\ell}{2}\right),$$

and the force on the side of the rectangular plate is

$$F = \int_m^{\ell+m} wxy\,dy = \frac{wx}{2}\left[(\ell+m)^2 - m^2\right] = \frac{wx\ell}{2}(\ell + 2m) = Aw\left(\frac{\ell}{2} + m\right) = Ap_0.$$

26. If the density of a fluid varies with depth, then the pressure at depth y is a function $p(y)$ (which need not equal wy as in the case of constant density). Use Riemann sums to argue that the total force F on the flat side of a submerged object submerged vertically is $F = \int_a^b f(y)p(y)\,dy$, where $f(y)$ is the width of the side at depth y.

SOLUTION Suppose the object extends from a depth of $y = a$ to a depth of $y = b$. Divide the object into N horizontal strips, each of width Δy. Let $p(y)$ denote the pressure within the fluid at depth y and $f(y)$ denote the width of the flat side of the submerged object at depth y. The approximate force on the jth strip ($j = 1, 2, 3, \ldots, N$) is

$$p(y_j)f(y_j)\Delta y,$$

where y_j is a depth associated with the jth strip. Summing over all of the strips,

$$F \approx \sum_{j=1}^{N} p(y_j) f(y_j) \Delta y.$$

As $N \to \infty$, this Riemann sum converges to a definite integral, and

$$F = \int_a^b p(y) f(y)\, dy.$$

8.3 Center of Mass

Preliminary Questions

1. What are the x- and y-moments of a lamina whose center of mass is located at the origin?

SOLUTION Because the center of mass is located at the origin, it follows that $M_x = M_y = 0$.

2. A thin plate has mass 3. What is the x-moment of the plate if its center of mass has coordinates $(2, 7)$?

SOLUTION The x-moment of the plate is the product of the mass of the plate and the y-coordinate of the center of mass. Thus, $M_x = 3(7) = 21$.

3. The center of mass of a lamina of total mass 5 has coordinates $(2, 1)$. What are the lamina's x- and y-moments?

SOLUTION The x-moment of the plate is the product of the mass of the plate and the y-coordinate of the center of mass, whereas the y-moment is the product of the mass of the plate and the x-coordinate of the center of mass. Thus, $M_x = 5(1) = 5$, and $M_y = 5(2) = 10$.

4. Explain how the Symmetry Principle is used to conclude that the centroid of a rectangle is the center of the rectangle.

SOLUTION Because a rectangle is symmetric with respect to both the vertical line and the horizontal line through the center of the rectangle, the Symmetry Principle guarantees that the centroid of the rectangle must lie along both of these lines. The only point in common to both lines of symmetry is the center of the rectangle, so the centroid of the rectangle must be the center of the rectangle.

Exercises

1. Four particles are located at points $(1, 1)$, $(1, 2)$, $(4, 0)$, $(3, 1)$.

(a) Find the moments M_x and M_y and the center of mass of the system, assuming that the particles have equal mass m.

(b) Find the center of mass of the system, assuming the particles have masses 3, 2, 5, and 7, respectively.

SOLUTION

(a) Because each particle has mass m,

$$M_x = m(1) + m(2) + m(0) + m(1) = 4m;$$
$$M_y = m(1) + m(1) + m(4) + m(3) = 9m;$$

and the total mass of the system is $4m$. Thus, the coordinates of the center of mass are

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(\frac{9m}{4m}, \frac{4m}{4m}\right) = \left(\frac{9}{4}, 1\right).$$

(b) With the indicated masses of the particles,

$$M_x = 3(1) + 2(2) + 5(0) + 7(1) = 14;$$
$$M_y = 3(1) + 2(1) + 5(4) + 7(3) = 46;$$

and the total mass of the system is 17. Thus, the coordinates of the center of mass are

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(\frac{46}{17}, \frac{14}{17}\right).$$

2. Find the center of mass for the system of particles of masses 4, 2, 5, 1 located at $(1, 2)$, $(-3, 2)$, $(2, -1)$, $(4, 0)$.

SOLUTION With the indicated masses and locations of the particles

$$M_x = 4(2) + 2(2) + 5(-1) + 1(0) = 7;$$

$$M_y = 4(1) + 2(-3) + 5(2) + 1(4) = 12;$$

and the total mass of the system is 12. Thus, the coordinates of the center of mass are

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(1, \frac{7}{12}\right).$$

3. Point masses of equal size are placed at the vertices of the triangle with coordinates $(a, 0)$, $(b, 0)$, and $(0, c)$. Show that the center of mass of the system of masses has coordinates $\left(\frac{1}{3}(a+b), \frac{1}{3}c\right)$.

SOLUTION Let each particle have mass m. The total mass of the system is then $3m$. and the moments are

$$M_x = 0(m) + 0(m) + c(m) = cm; \text{ and}$$

$$M_y = a(m) + b(m) + 0(m) = (a+b)m.$$

Thus, the coordinates of the center of mass are

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(\frac{(a+b)m}{3m}, \frac{cm}{3m}\right) = \left(\frac{a+b}{3}, \frac{c}{3}\right).$$

4. Point masses of mass m_1, m_2, and m_3 are placed at the points $(-1, 0)$, $(3, 0)$, and $(0, 4)$.

(a) Suppose that $m_1 = 6$. Find m_2 such that the center of mass lies on the y-axis.

(b) Suppose that $m_1 = 6$ and $m_2 = 4$. Find the value of m_3 such that $y_{CM} = 2$.

SOLUTION With the given masses and locations, we find

$$M_x = m_1(0) + m_2(0) + m_3(4) = 4m_3;$$

$$M_y = m_1(-1) + m_2(3) + m_3(0) = 3m_2 - m_1;$$

and the total mass of the system is $m_1 + m_2 + m_3$. Thus, the coordinates of the center of mass are

$$\left(\frac{3m_2 - m_1}{m_1 + m_2 + m_3}, \frac{4m_3}{m_1 + m_2 + m_3}\right).$$

(a) For the center of mass to lie on the y-axis, we must have $3m_2 - m_1 = 0$, or $m_2 = \frac{1}{3}m_1$. Given $m_1 = 6$, it follows that $m_2 = 2$.

(b) To have $y_{CM} = 2$ requires

$$\frac{4m_3}{m_1 + m_2 + m_3} = 2 \quad \text{or} \quad m_3 = m_1 + m_2.$$

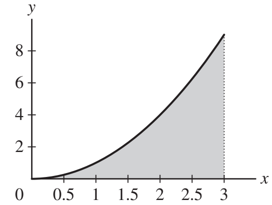
Given $m_1 = 6$ and $m_2 = 4$, it follows that $m_3 = 10$.

5. Sketch the lamina S of constant density $\rho = 3$ g/cm^2 occupying the region beneath the graph of $y = x^2$ for $0 \le x \le 3$.

(a) Use Eqs. (1) and (2) to compute M_x and M_y.

(b) Find the area and the center of mass of S.

SOLUTION A sketch of the lamina is shown below



(a) Using Eq. (2),

$$M_x = 3\int_0^9 y(3 - \sqrt{y})\, dy = \left(\frac{9y^2}{2} - \frac{6}{5}y^{5/2}\right)\Bigg|_0^9 = \frac{729}{10}.$$

Using Eq. (1),

$$M_y = 3\int_0^3 x(x^2)\, dx = \frac{3x^4}{4}\Bigg|_0^3 = \frac{243}{4}.$$

(b) The area of the lamina is

$$A = \int_0^3 x^2\,dx = \left.\frac{x^3}{3}\right|_0^3 = 9\text{ cm}^2.$$

With a constant density of $\rho = 3\text{ g/cm}^2$, the mass of the lamina is $M = 27$ grams, and the coordinates of the center of mass are

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(\frac{243/4}{27}, \frac{729/10}{27}\right) = \left(\frac{9}{4}, \frac{27}{10}\right).$$

6. Use Eqs. (1) and (3) to find the moments and center of mass of the lamina S of constant density $\rho = 2\text{ g/cm}^2$ occupying the region between $y = x^2$ and $y = 9x$ over $[0, 3]$. Sketch S, indicating the location of the center of mass.

SOLUTION With $\rho = 2\text{ g/cm}^2$,

$$M_x = \frac{1}{2}(2)\int_0^3 \left((9x)^2 - (x^2)^2\right)dx = \frac{3402}{5},$$

and

$$M_y = 2\int_0^3 x(9x - x^2)\,dx = \frac{243}{2}.$$

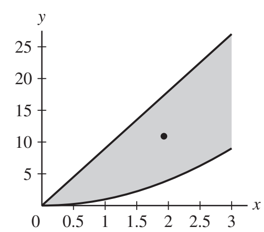
The mass of the lamina is

$$M = 2\int_0^3 (9x - x^2)\,dx = 63\text{ g},$$

so the coordinates of the center of mass are

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(\frac{243}{126}, \frac{3402}{315}\right).$$

A sketch of the lamina, with the location of the center of mass indicated, is shown below.



7. Find the moments and center of mass of the lamina of uniform density ρ occupying the region underneath $y = x^3$ for $0 \le x \le 2$.

SOLUTION With uniform density ρ,

$$M_x = \frac{1}{2}\rho\int_0^2 (x^3)^2\,dx = \frac{64\rho}{7} \quad\text{and}\quad M_y = \rho\int_0^2 x(x^3)\,dx = \frac{32\rho}{5}.$$

The mass of the lamina is

$$M = \rho\int_0^2 x^3\,dx = 4\rho,$$

so the coordinates of the center of mass are

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(\frac{8}{5}, \frac{16}{7}\right).$$

8. Calculate M_x (assuming $\rho = 1$) for the region underneath the graph of $y = 1 - x^2$ for $0 \le x \le 1$ in two ways, first using Eq. (2) and then using Eq. (3).

SOLUTION By Eq. (2),

$$M_x = \int_0^1 y\sqrt{1-y}\,dy.$$

Using the substitution $u = 1 - y$, $du = -dy$, we find

$$M_x = \int_0^1 (1-u)\sqrt{u}\,du = \left(\frac{2}{3}u^{3/2} - \frac{2}{5}u^{5/2}\right)\Big|_0^1 = \frac{4}{15}.$$

By Eq. (3),

$$M_x = \frac{1}{2}\int_0^1 (1-x^2)^2\,dx = \frac{1}{2}\left(x - \frac{2}{3}x^3 + \frac{1}{5}x^5\right)\Big|_0^1 = \frac{4}{15}.$$

9. Let T be the triangular lamina in Figure 17.

(a) Show that the horizontal cut at height y has length $4 - \frac{2}{3}y$ and use Eq. (2) to compute M_x (with $\rho = 1$).

(b) Use the Symmetry Principle to show that $M_y = 0$ and find the center of mass.

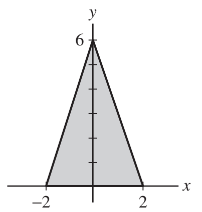


FIGURE 17 Isosceles triangle.

SOLUTION

(a) The equation of the line from (2, 0) to (0, 6) is $y = -3x + 6$, so

$$x = 2 - \frac{1}{3}y.$$

The length of the horizontal cut at height y is then

$$2\left(2 - \frac{1}{3}y\right) = 4 - \frac{2}{3}y,$$

and

$$M_x = \int_0^6 y\left(4 - \frac{2}{3}y\right)dy = 24.$$

(b) Because the triangular lamina is symmetric with respect to the y-axis, $x_{cm} = 0$, which implies that $M_y = 0$. The total mass of the lamina is

$$M = 2\int_0^2 (-3x+6)\,dx = 12,$$

so $y_{cm} = 24/12$. Finally, the coordinates of the center of mass are (0, 2).

In Exercises 10–17, find the centroid of the region lying underneath the graph of the function over the given interval.

10. $f(x) = 6 - 2x$, $[0, 3]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^3 (6-2x)^2\,dx = 18 \quad \text{and} \quad M_y = \int_0^3 x(6-2x)\,dx = 9.$$

The area of the region is

$$A = \int_0^3 (6-2x)\,dx = 9,$$

so the coordinates of the centroid are

$$\left(\frac{M_y}{A}, \frac{M_x}{A}\right) = (1, 2).$$

11. $f(x) = \sqrt{x}$, $[1, 4]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_1^4 x\,dx = \frac{15}{4} \quad \text{and} \quad M_y = \int_1^4 x\sqrt{x}\,dx = \frac{62}{5}.$$

The area of the region is

$$A = \int_1^4 \sqrt{x}\,dx = \frac{14}{3},$$

so the coordinates of the centroid are

$$\left(\frac{M_y}{A}, \frac{M_x}{A}\right) = \left(\frac{93}{35}, \frac{45}{56}\right).$$

12. $f(x) = x^3$, $[0, 1]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^1 x^6\,dx = \frac{1}{14} \quad \text{and} \quad M_y = \int_0^1 x^4\,dx = \frac{1}{5}.$$

The area of the region is

$$A = \int_0^1 x^3\,dx = \frac{1}{4},$$

so the coordinates of the centroid are

$$\left(\frac{M_y}{A}, \frac{M_x}{A}\right) = \left(\frac{4}{5}, \frac{2}{7}\right).$$

13. $f(x) = 9 - x^2$, $[0, 3]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^3 (9 - x^2)^2\,dx = \frac{324}{5} \quad \text{and} \quad M_y = \int_0^3 x(9 - x^2)\,dx = \frac{81}{4}.$$

The area of the region is

$$A = \int_0^3 (9 - x^2)\,dx = 18,$$

so the coordinates of the centroid are

$$\left(\frac{M_y}{A}, \frac{M_x}{A}\right) = \left(\frac{9}{8}, \frac{18}{5}\right).$$

14. $f(x) = (1 + x^2)^{-1/2}$, $[0, 3]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^3 \frac{1}{1 + x^2}\,dx = \left.\frac{\tan^{-1} x}{2}\right|_0^3 = \frac{1}{2}\tan^{-1} 3 \quad \text{and} \quad M_y = \int_0^3 \frac{x}{\sqrt{1 + x^2}}\,dx = \sqrt{10} - 1.$$

The area of the region is

$$A = \int_0^3 \frac{1}{\sqrt{1 + x^2}}\,dx = \ln|x + \sqrt{1 + x^2}|\Big|_0^3 = \ln(3 + \sqrt{10}),$$

so the coordinates of the centroid are

$$\left(\frac{M_y}{A}, \frac{M_x}{A}\right) = \left(\frac{\sqrt{10} - 1}{\ln(3 + \sqrt{10})}, \frac{\tan^{-1} 3}{2\ln(3 + \sqrt{10})}\right).$$

15. $f(x) = e^{-x}$, $[0, 4]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^4 e^{-2x}\,dx = \frac{1}{4}\left(1 - e^{-8}\right) \quad \text{and} \quad M_y = \int_0^4 xe^{-x}\,dx = -e^{-x}(x + 1)\Big|_0^4 = 1 - 5e^{-4}.$$

The area of the region is

$$A = \int_0^4 e^{-x}\,dx = 1 - e^{-4},$$

so the coordinates of the centroid are

$$\left(\frac{M_y}{A}, \frac{M_x}{A}\right) = \left(\frac{1-5e^{-4}}{1-e^{-4}}, \frac{1-e^{-8}}{4(1-e^{-4})}\right).$$

16. $f(x) = \ln x, \quad [1, 2]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_1^2 (\ln x)^2\,dx = \frac{1}{2}(x(\ln x)^2 - 2x\ln x + 2x)\Big|_1^2 = (\ln 2)^2 - 2\ln 2 + 1; \text{ and}$$

$$M_y = \int_1^2 x\ln x\,dx = \left(\frac{1}{2}x^2\ln x - \frac{1}{4}x^2\right)\Big|_1^2 = 2\ln 2 - \frac{3}{4}.$$

The area of the region is

$$A = \int_1^2 \ln x\,dx = (x\ln x - x)\Big|_1^2 = 2\ln 2 - 1,$$

so the coordinates of the centroid are

$$\left(\frac{M_y}{A}, \frac{M_x}{A}\right) = \left(\frac{2\ln 2 - \frac{3}{4}}{2\ln 2 - 1}, \frac{(\ln 2)^2 - 2\ln 2 + 1}{2\ln 2 - 1}\right).$$

17. $f(x) = \sin x, \quad [0, \pi]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^\pi \sin^2 x\,dx = \frac{1}{4}(x - \sin x\cos x)\Big|_0^\pi = \frac{\pi}{4}; \text{ and}$$

$$M_y = \int_0^\pi x\sin x\,dx = (-x\cos x + \sin x)\Big|_0^\pi = \pi.$$

The area of the region is

$$A = \int_0^\pi \sin x\,dx = 2,$$

so the coordinates of the centroid are

$$\left(\frac{M_y}{A}, \frac{M_x}{A}\right) = \left(\frac{\pi}{2}, \frac{\pi}{8}\right).$$

18. Calculate the moments and center of mass of the lamina occupying the region between the curves $y = x$ and $y = x^2$ for $0 \le x \le 1$.

SOLUTION The moments of the lamina are

$$M_x = \frac{1}{2}\int_0^1 (x^2 - x^4)\,dx = \frac{1}{15} \quad \text{and} \quad M_y = \int_0^1 x(x - x^2)\,dx = \frac{1}{12}.$$

The area of the lamina is

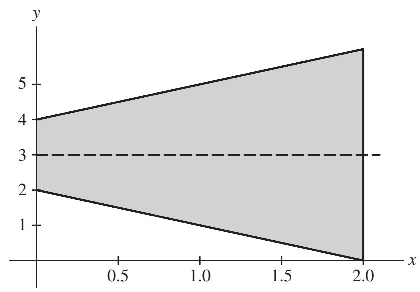
$$A = \int_0^1 (x - x^2)\,dx = \frac{1}{6},$$

so the coordinates of the centroid are

$$\left(\frac{M_y}{A}, \frac{M_x}{A}\right) = \left(\frac{1}{2}, \frac{2}{5}\right).$$

19. Sketch the region between $y = x + 4$ and $y = 2 - x$ for $0 \le x \le 2$. Using symmetry, explain why the centroid of the region lies on the line $y = 3$. Verify this by computing the moments and the centroid.

SOLUTION A sketch of the region is shown below.



The region is clearly symmetric about the line $y = 3$, so we expect the centroid of the region to lie along this line. We find

$$M_x = \frac{1}{2}\int_0^2 \left((x+4)^2 - (2-x)^2\right) dx = 24;$$

$$M_y = \int_0^2 x\,((x+4) - (2-x))\,dx = \frac{28}{3}; \text{ and}$$

$$A = \int_0^2 ((x+4) - (2-x))\,dx = 8.$$

Thus, the coordinates of the centroid are $\left(\frac{7}{6}, 3\right)$.

In Exercises 20–25, find the centroid of the region lying between the graphs of the functions over the given interval.

20. $y = x, \quad y = \sqrt{x}, \quad [0, 1]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^1 (x - x^2)\,dx = \frac{1}{12} \quad \text{and} \quad M_y = \int_0^1 x(\sqrt{x} - x)\,dx = \frac{1}{15}.$$

The area of the region is

$$A = \int_0^1 (\sqrt{x} - x)\,dx = \frac{1}{6},$$

so the coordinates of the centroid are

$$\left(\frac{6}{15}, \frac{1}{2}\right).$$

21. $y = x^2, \quad y = \sqrt{x}, \quad [0, 1]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^1 (x - x^4)\,dx = \frac{3}{20} \quad \text{and} \quad M_y = \int_0^1 x(\sqrt{x} - x^2)\,dx = \frac{3}{20}.$$

The area of the region is

$$A = \int_0^1 (\sqrt{x} - x^2)\,dx = \frac{1}{3},$$

so the coordinates of the centroid are

$$\left(\frac{9}{20}, \frac{9}{20}\right).$$

Note: This makes sense, since the functions are inverses of each other. This makes the region symmetric with respect to the line $y = x$. Thus, by the symmetry principle, the center of mass must lie on that line.

22. $y = x^{-1}, \quad y = 2 - x, \quad [1, 2]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_1^2 \left[\left(\frac{1}{x}\right)^2 - (2-x)^2\right] dx = \frac{1}{12} \quad \text{and} \quad M_y = \int_1^2 x\left(\frac{1}{x} - (2-x)\right) dx = \frac{1}{3}.$$

The area of the region is

$$A = \int_1^2 \left(\frac{1}{x} - (2-x)\right) dx = \ln 2 - \frac{1}{2},$$

so the coordinates of the centroid are

$$\left(\frac{2}{6\ln 2 - 3}, \frac{1}{12\ln 2 - 6}\right).$$

23. $y = e^x, \quad y = 1, \quad [0, 1]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^1 (e^{2x} - 1)\, dx = \frac{e^2 - 3}{4} \quad \text{and} \quad M_y = \int_0^1 x(e^x - 1)\, dx = \left(xe^x - e^x - \frac{1}{2}x^2\right)\Big|_0^1 = \frac{1}{2}.$$

The area of the region is

$$A = \int_0^1 (e^x - 1)\, dx = e - 2,$$

so the coordinates of the centroid are

$$\left(\frac{1}{2(e-2)}, \frac{e^2 - 3}{4(e-2)}\right).$$

24. $y = \ln x, \quad y = x - 1, \quad [1, 3]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_1^3 \left[(x-1)^2 - (\ln x)^2\right] dx = \left(\frac{1}{3}x^3 - x^2 - x - x(\ln x)^2 + 2x\ln x\right)\Big|_1^3 = 3\ln 3 - \frac{3}{2}(\ln 3)^2 - \frac{2}{3}; \text{ and}$$

$$M_y = \int_1^3 x((x-1) - \ln x)\, dx = \left(\frac{1}{3}x^3 - \frac{1}{2}x^2\ln x - \frac{1}{4}x^2\right)\Big|_1^3 = \frac{20}{3} - \frac{9}{2}\ln 3.$$

The area of the region is

$$A = \int_1^3 (x - 1 - \ln x)\, dx = \left(\frac{1}{2}x^2 - x\ln x\right)\Big|_1^3 = 4 - 3\ln 3,$$

so the coordinates of the centroid are

$$\left(\frac{40 - 27\ln 3}{24 - 18\ln 3}, \frac{18\ln 3 - 9(\ln 3)^2 - 4}{24 - 18\ln 3}\right).$$

25. $y = \sin x, \quad y = \cos x, \quad [0, \pi/4]$

SOLUTION The moments of the region are

$$M_x = \frac{1}{2}\int_0^{\pi/4} (\cos^2 x - \sin^2 x)\, dx = \frac{1}{2}\int_0^{\pi/4} \cos 2x\, dx = \frac{1}{4}; \text{ and}$$

$$M_y = \int_0^{\pi/4} x(\cos x - \sin x)\, dx = [(x-1)\sin x + (x+1)\cos x]\Big|_0^{\pi/4} = \frac{\pi\sqrt{2}}{4} - 1.$$

The area of the region is

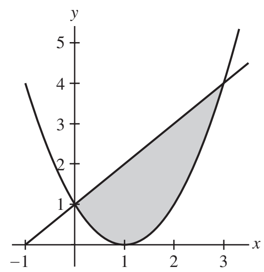
$$A = \int_0^{\pi/4} (\cos x - \sin x)\, dx = \sqrt{2} - 1,$$

so the coordinates of the centroid are

$$\left(\frac{\pi\sqrt{2} - 4}{4(\sqrt{2} - 1)}, \frac{1}{4(\sqrt{2} - 1)}\right).$$

26. Sketch the region enclosed by $y = x + 1$, and $y = (x - 1)^2$, and find its centroid.

SOLUTION A sketch of the region is shown below.



The moments of the region are

$$M_x = \frac{1}{2}\int_0^3 (x+1)^2 - (x-1)^4\,dx = \frac{1}{2}\left(\frac{1}{3}(x+1)^3 - \frac{1}{5}(x-1)^5\right)\Big|_0^3 = \frac{1}{2}\left(\frac{64}{3} - \frac{32}{5} - \frac{1}{3} - \frac{1}{5}\right) = \frac{36}{5}$$

$$M_y = \int_0^3 x((x+1) - (x-1)^2)\,dx = \int_0^3 3x^2 - x^3\,dx = \left(x^3 - \frac{1}{4}x^4\right)\Big|_0^3 = \frac{27}{4}$$

The area of the region is

$$A = \int_0^3 (x+1) - (x-1)^2\,dx = \int_0^3 -x^2 + 3x\,dx = \left(-\frac{1}{3}x^3 + \frac{3}{2}x^2\right)\Big|_0^3 = \frac{9}{2}$$

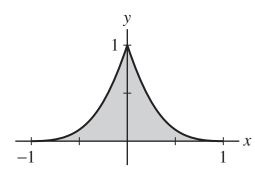
so that the coordinates of the centroid are

$$\left(\frac{27}{4}\cdot\frac{2}{9}, \frac{36}{5}\cdot\frac{2}{9}\right) = \left(\frac{3}{2}, \frac{8}{5}\right)$$

s

27. Sketch the region enclosed by $y = 0$, $y = (x + 1)^3$, and $y = (1 - x)^3$, and find its centroid.

SOLUTION A sketch of the region is shown below.



The moments of the region are

$$M_x = \frac{1}{2}\left(\int_{-1}^0 (x+1)^6\,dx + \int_0^1 (1-x)^6\,dx\right) = \frac{1}{7};\ \text{and}$$

$M_y = 0$ by the Symmetry Principle.

The area of the region is

$$A = \int_{-1}^0 (x+1)^3\,dx + \int_0^1 (1-x)^3\,dx = \frac{1}{2},$$

so the coordinates of the centroid are $\left(0, \frac{2}{7}\right)$.

In Exercises 28–32, find the centroid of the region.

28. Top half of the ellipse $\left(\frac{x}{2}\right)^2 + \left(\frac{y}{4}\right)^2 = 1$

SOLUTION The equation of the top half of the ellipse is $y = \sqrt{16 - 4x^2}$. Thus,

$$M_x = \frac{1}{2}\int_{-2}^2 \left(\sqrt{16 - 4x^2}\right)^2\,dx = \frac{64}{3}.$$

By the Symmetry Principle, $M_y = 0$. The area of the region is one-half the area of an ellipse with major axis 4 and minor axis 2; i.e., $\frac{1}{2}\pi(4)(2) = 4\pi$. Finally, the coordinates of the centroid are

$$\left(0, \frac{16}{3\pi}\right).$$

29. Top half of the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$ for arbitrary $a, b > 0$

SOLUTION The equation of the top half of the ellipse is

$$y = \sqrt{b^2 - \frac{b^2x^2}{a^2}}$$

Thus,

$$M_x = \frac{1}{2}\int_{-a}^{a}\left(\sqrt{b^2 - \frac{b^2x^2}{a^2}}\right)^2 dx = \frac{2ab^2}{3}.$$

By the Symmetry Principle, $M_y = 0$. The area of the region is one-half the area of an ellipse with axes of length a and b; i.e., $\frac{1}{2}\pi ab$. Finally, the coordinates of the centroid are

$$\left(0, \frac{4b}{3\pi}\right).$$

30. Semicircle of radius r with center at the origin

SOLUTION The equation of the top half of the circle is $y = \sqrt{r^2 - x^2}$. Thus,

$$M_x = \frac{1}{2}\int_{-r}^{r}\left(\sqrt{r^2 - x^2}\right)^2 dx = \frac{2r^3}{3}.$$

By the Symmetry Principle, $M_y = 0$. The area of the region is one-half the area of a circle of radius r; i.e., $\frac{1}{2}\pi r^2$. Finally, the coordinates of the centroid are

$$\left(0, \frac{4r}{3\pi}\right).$$

31. Quarter of the unit circle lying in the first quadrant

SOLUTION By the Symmetry Principle, the center of mass must lie on the line $y = x$ in the first quadrant. Therefore, we need only calculate one of the moments of the region. With $y = \sqrt{1 - x^2}$, we find

$$M_y = \int_0^1 x\sqrt{1 - x^2}\, dx = \frac{1}{3}.$$

The area of the region is one-quarter of the area of a unit circle; i.e., $\frac{1}{4}\pi$. Thus, the coordinates of the centroid are

$$\left(\frac{4}{3\pi}, \frac{4}{3\pi}\right).$$

32. Triangular plate with vertices $(-c, 0)$, $(0, c)$, (a, b), where $a, b, c > 0$, and $b < c$

SOLUTION By symmetry, the center of mass must lie on the line connecting $(-c, 0)$ and the midpoint $(a/2, (b + c)/2)$ of the opposite side:

$$\ell_1 : y = \frac{b + c}{a + 2c}(x + c)$$

Also by symmetry, the center of mass must lie on the line connecting $(0, c)$ and the midpoint $((a - c)/2, b/2)$ of the opposite side:

$$\ell_2 : y = \frac{b - 2c}{a - c}x + c$$

These lines intersect at one point (x_{cm}, y_{cm}). Equating the formulas for the two lines and solving for x yields

$$x = \frac{a - c}{3}.$$

Substituting this value for x into the equation for ℓ_2 gives

$$y = \frac{b - 2c}{a - c}\frac{a - c}{3} + c = \frac{b + c}{3}.$$

Hence, the coordinates of the centroid are

$$\left(\frac{a - c}{3}, \frac{b + c}{3}\right).$$

33. Find the centroid for the shaded region of the semicircle of radius r in Figure 18. What is the centroid when $r = 1$ and $h = \frac{1}{2}$? *Hint:* Use geometry rather than integration to show that the *area* of the region is $r^2 \sin^{-1}(\sqrt{1 - h^2/r^2}) - h\sqrt{r^2 - h^2}$).

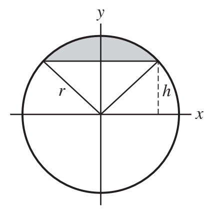


FIGURE 18

SOLUTION From the symmetry of the region, it is obvious that the centroid lies along the y-axis. To determine the y-coordinate of the centroid, we must calculate the moment about the x-axis and the area of the region. Now, the length of the horizontal cut of the semicircle at height y is

$$\sqrt{r^2 - y^2} - \left(-\sqrt{r^2 - y^2}\right) = 2\sqrt{r^2 - y^2}.$$

Therefore, taking $\rho = 1$, we find

$$M_x = 2\int_h^r y\sqrt{r^2 - y^2}\,dy = \frac{2}{3}(r^2 - h^2)^{3/2}.$$

Observe that the region is comprised of a sector of the circle with the triangle between the two radii removed. The angle of the sector is 2θ, where $\theta = \sin^{-1}\sqrt{1 - h^2/r^2}$, so the area of the sector is $\frac{1}{2}r^2(2\theta) = r^2\sin^{-1}\sqrt{1 - h^2/r^2}$. The triangle has base $2\sqrt{r^2 - h^2}$ and height h, so the area is $h\sqrt{r^2 - h^2}$. Therefore,

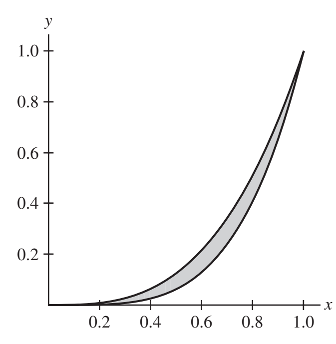
$$Y_{CM} = \frac{M_x}{A} = \frac{\frac{2}{3}(r^2 - h^2)^{3/2}}{r^2\sin^{-1}\sqrt{1 - h^2/r^2} - h\sqrt{r^2 - h^2}}.$$

When $r = 1$ and $h = 1/2$, we find

$$Y_{CM} = \frac{\frac{2}{3}(3/4)^{3/2}}{\sin^{-1}\frac{\sqrt{3}}{2} - \frac{\sqrt{3}}{4}} = \frac{3\sqrt{3}}{4\pi - 3\sqrt{3}}.$$

34. Sketch the region between $y = x^n$ and $y = x^m$ for $0 \le x \le 1$, where $m > n \ge 0$ and find the COM of the region. Find a pair (n, m) such that the COM lies outside the region.

SOLUTION A sketch of the region for x^3 and x^4 is below.



Since $m > n \ge 0$, the graph of x^n lies above that of x^m for x between 0 and 1. Thus the moments are

$$\begin{aligned} M_x &= \frac{1}{2}\int_0^1 x^{2n} - x^{2m}\,dx = \frac{1}{2}\left(\frac{1}{2n+1}x^{2n+1} - \frac{1}{2m+1}x^{2m+1}\right)\Big|_0^1 \\ &= \frac{1}{2}\left(\frac{1}{2n+1} - \frac{1}{2m+1}\right) = \frac{m-n}{(2n+1)(2m+1)} \\ M_y &= \int_0^1 x(x^n - x^m)\,dx = \int_0^1 x^{n+1} - x^{m+1}\,dx = \left(\frac{1}{n+2}x^{n+2} - \frac{1}{m+2}x^{m+2}\right)\Big|_0^1 \\ &= \frac{1}{n+2} - \frac{1}{m+2} = \frac{m-n}{(n+2)(m+2)} \end{aligned}$$

The area of the region is

$$A = \int_0^1 x^n - x^m \, dx = \frac{1}{n+1} - \frac{1}{m+1} = \frac{m-n}{(n+1)(m+1)}$$

Thus the center of mass has coordinates

$$\left(\frac{(n+1)(m+1)}{(n+2)(m+2)}, \frac{(n+1)(m+1)}{(2n+1)(2m+1)} \right)$$

In the case graphed above, for $n = 3$, $m = 4$, the center of mass is

$$\left(\frac{20}{30}, \frac{20}{63} \right) = \left(\frac{2}{3}, \frac{20}{63} \right)$$

and

$$\left(\frac{2}{3} \right)^3 = \frac{8}{27} < \frac{20}{63}$$

Thus the point $\left(\frac{2}{3}, \frac{8}{27} \right)$ lies on $y = x^3$ and then the curve $y = x^3$ lies below the center of mass of the region.

In Exercises 35–37, use the additivity of moments to find the COM of the region.

35. Isosceles triangle of height 2 on top of a rectangle of base 4 and height 3 (Figure 19)

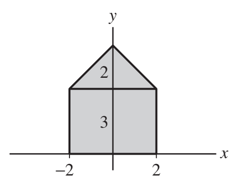


FIGURE 19

SOLUTION The region is symmetric with respect to the y-axis, so $M_y = 0$ by the Symmetry Principle. The moment about the x-axis for the rectangle is

$$M_x^{\text{rect}} = \frac{1}{2} \int_{-2}^{2} 3^2 \, dx = 18,$$

whereas the moment about the x-axis for the triangle is

$$M_x^{\text{triangle}} = \int_3^5 y(10 - 2y) \, dy = \frac{44}{3}.$$

The total moment about the x-axis is then

$$M_x = M_x^{\text{rect}} + M_x^{\text{triangle}} = 18 + \frac{44}{3} = \frac{98}{3}.$$

Because the area of the region is $12 + 4 = 16$, the coordinates of the center of mass are

$$\left(0, \frac{49}{24} \right).$$

36. An ice cream cone consisting of a semicircle on top of an equilateral triangle of side 6 (Figure 20)

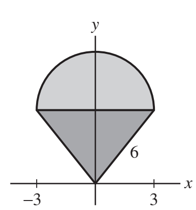

FIGURE 20

SOLUTION The region is symmetric with respect to the y-axis, so $M_y = 0$ by the Symmetry Principle. The moment about the x-axis for the triangle is

$$M_x^{\text{triangle}} = \frac{2}{\sqrt{3}} \int_0^{3\sqrt{3}} y^2\,dy = 54.$$

For the semicircle, first note that the center is $(0, 3\sqrt{3})$, so the equation is $x^2 + (y - 3\sqrt{3})^2 = 9$, and

$$M_x^{\text{semi}} = 2\int_{3\sqrt{3}}^{3+3\sqrt{3}} y\sqrt{9 - (y - 3\sqrt{3})^2}\,dy.$$

Using the substitution $w = y - 3\sqrt{3}$, $dw = dy$, we find

$$\begin{aligned} M_x^{\text{semi}} &= 2\int_0^3 (w + 3\sqrt{3})\sqrt{9 - w^2}\,dw \\ &= 2\int_0^3 w\sqrt{9 - w^2}\,dw + 6\sqrt{3}\int_0^3 \sqrt{9 - w^2}\,dw = 18 + \frac{27\pi\sqrt{3}}{2}, \end{aligned}$$

where we have used the fact that $\int_0^3 \sqrt{9 - w^2}\,dw$ represents the area of one-quarter of a circle of radius 3. The total moment about the x-axis is then

$$M_x = M_x^{\text{triangle}} + M_x^{\text{semi}} = 72 + \frac{27\pi\sqrt{3}}{2}.$$

Because the area of the region is $9\sqrt{3} + \frac{9\pi}{2}$, the coordinates of the center of mass are

$$\left(0, \frac{16 + 3\pi\sqrt{3}}{\pi + 2\sqrt{3}}\right).$$

37. Three-quarters of the unit circle (remove the part in the fourth quadrant)

SOLUTION By the Symmetry Principle, the center of mass must lie on the line $y = -x$. Let region 1 be the semicircle above the x-axis and region 2 be the quarter circle in the third quadrant. Because region 1 is symmetric with respect to the y-axis, $M_y^1 = 0$ by the Symmetry Principle. Furthermore

$$M_y^2 = \int_{-1}^0 x\sqrt{1 - x^2}\,dx = -\frac{1}{3}.$$

Thus, $M_y = M_y^1 + M_y^2 = 0 + (-\frac{1}{3}) = -\frac{1}{3}$. The area of the region is $3\pi/4$, so the coordinates of the centroid are

$$\left(-\frac{4}{9\pi}, \frac{4}{9\pi}\right).$$

38. Let S be the lamina of mass density $\rho = 1$ obtained by removing a circle of radius r from the circle of radius $2r$ shown in Figure 21. Let M_x^S and M_y^S denote the moments of S. Similarly, let M_y^{big} and M_y^{small} be the y-moments of the larger and smaller circles.

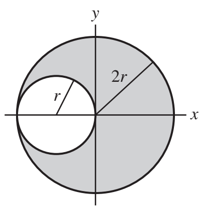

FIGURE 21

(a) Use the Symmetry Principle to show that $M_x^S = 0$.

(b) Show that $M_y^S = M_y^{\text{big}} - M_y^{\text{small}}$ using the additivity of moments.

(c) Find M_y^{big} and M_y^{small} using the fact that the COM of a circle is its center. Then compute M_y^S using (b).

(d) Determine the COM of S.

SOLUTION

(a) Because S is symmetric with respect to the x-axis, $M_x^S = 0$.

(b) Because the small circle together with the region S comprise the big circle, by the additivity of moments,

$$M_y^S + M_y^{\text{small}} = M_y^{\text{big}}.$$

Thus $M_y^S = M_y^{\text{big}} - M_y^{\text{small}}$.

(c) The center of the big circle is the origin, so $x_{\text{cm}}^{\text{big}} = 0$; consequently, $M_y^{\text{big}} = 0$. On the other hand, the center of the small circle is $(-r, 0)$, so $x_{\text{cm}}^{\text{small}} = -r$; consequently

$$M_y^{\text{small}} = x_{\text{cm}}^{\text{small}} \cdot A^{\text{small}} = -r \cdot \pi r^2 = -\pi r^3.$$

By the result of part (b), it follows that $M_y^S = 0 - (-\pi r^3) = \pi r^3$.

(d) The area of the region S is $4\pi r^2 - \pi r^2 = 3\pi r^2$. The coordinates of the center of mass of the region S are then

$$\left(\frac{\pi r^3}{3\pi r^2}, 0\right) = \left(\frac{r}{3}, 0\right).$$

39. Find the COM of the laminas in Figure 22 obtained by removing squares of side 2 from a square of side 8.

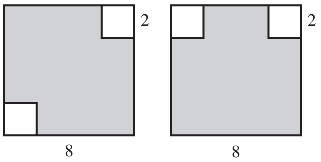

FIGURE 22

SOLUTION Start with the square on the left. Place the square so that the bottom left corner is at (0, 0). By the Symmetry Principle, the center of mass must lie on the lines $y = x$ and $y = 8 - x$. The only point in common to these two lines is (4, 4), so the center of mass is (4, 4).

Now consider the square on the right. Place the square as above. By the symmetry principle, $x_{cm} = 4$. Now, let $s1$ denote the square in the upper left, $s2$ denote the square in the upper right, and B denote the entire square. Then

$$M_x^{s1} = \frac{1}{2}\int_0^2 (8^2 - 6^2)\,dx = 28;$$

$$M_x^{s2} = \frac{1}{2}\int_6^8 (8^2 - 6^2)\,dx = 28; \text{ and}$$

$$M_x^{B} = \frac{1}{2}\int_0^8 8^2\,dx = 256.$$

By the additivity of moments, $M_x = 256 - 28 - 28 = 200$. Finally, the area of the region is $A = 64 - 4 - 4 = 56$, so the coordinates of the center of mass are

$$\left(4, \frac{200}{56}\right) = \left(4, \frac{25}{7}\right).$$

Further Insights and Challenges

40. A **median** of a triangle is a segment joining a vertex to the midpoint of the opposite side. Show that the centroid of a triangle lies on each of its medians, at a distance two-thirds down from the vertex. Then use this fact to prove that the three medians intersect at a single point. *Hint:* Simplify the calculation by assuming that one vertex lies at the origin and another on the x-axis.

SOLUTION Orient the triangle by placing one vertex at (0, 0) and the long side of the triangle along the x-axis. Label the vertices $(0, 0)$, $(a, 0)$, (b, c). Thus, the equations of the short sides are $y = \frac{cx}{b}$ and $y = \frac{cx}{b-a} - \frac{ac}{b-a}$. Now,

$$M_x = \frac{1}{2}\int_0^b (cx/b)^2\,dx + \frac{1}{2}\int_b^a \left(\frac{cx - ac}{b - a}\right)^2 dx = \frac{ac^2}{6};$$

$$M_y = \int_0^b x(cx/b)\,dx + \int_b^a x\left(\frac{cx - ac}{b - a}\right) dx = \frac{ac(a + b)}{6}; \text{ and}$$

$$M = \frac{ac}{2}.$$

so the center of mass is $\left(\dfrac{a+b}{3}, \dfrac{c}{3}\right)$. To show that the centroid lies on each median, let y_1 be the median from (b, c), y_2 the median from $(0, 0)$ and y_3 the median from $(a, 0)$. We find

$$y_1(x) = \frac{2c}{2b-a}(x - a/2), \qquad \text{so} \qquad y_1\left(\frac{a+b}{3}\right) = \frac{c}{3};$$

$$y_2(x) = \frac{c}{a+b}x, \qquad \text{so} \qquad y_2\left(\frac{a+b}{3}\right) = \frac{c}{3};$$

$$y_3(x) = \frac{c}{b-2a}(x - a), \qquad \text{so} \qquad y_3\left(\frac{a+b}{3}\right) = \frac{c}{3}.$$

This shows that the center of mass lies on each median. We now show that the center of mass is $\frac{2}{3}$ of the way from each vertex. For y_1, note that $x = b$ gives the vertex and $x = \frac{a}{2}$ gives the midpoint of the opposite side, so two-thirds of this distance is

$$x = b + \frac{2}{3}\left(\frac{a}{2} - b\right) = \frac{a+b}{3},$$

the x-coordinate of the center of mass. Likewise, for y_2, two-thirds of the distance from $x = 0$ to $x = \frac{a+b}{2}$ is $\frac{a+b}{3}$, and for y_3, the two-thirds point is

$$x = a + \frac{2}{3}\left(\frac{b}{2} - a\right) = \frac{a+b}{3}.$$

A similar method shows that the y-coordinate is also two-thirds of the way along the median. Thus, since the centroid lies on all three medians, we can conclude that all three medians meet at a single point, namely the centroid.

41. Let P be the COM of a system of two weights with masses m_1 and m_2 separated by a distance d. Prove Archimedes' Law of the (weightless) Lever: P is the point on a line between the two weights such that $m_1L_1 = m_2L_2$, where L_j is the distance from mass j to P.

SOLUTION Place the lever along the x-axis with mass m_1 at the origin. Then $M_y = m_2d$ and the x-coordinate of the center of mass, P, is

$$\frac{m_2d}{m_1 + m_2}.$$

Thus,

$$L_1 = \frac{m_2d}{m_1+m_2}, \quad L_2 = d - \frac{m_2d}{m_1+m_2} = \frac{m_1d}{m_1+m_2},$$

and

$$L_1m_1 = m_1\frac{m_2d}{m_1+m_2} = m_2\frac{m_1d}{m_1+m_2} = L_2m_2.$$

42. Find the COM of a system of two weights of masses m_1 and m_2 connected by a lever of length d whose mass density ρ is uniform. *Hint:* The moment of the system is the sum of the moments of the weights and the lever.

SOLUTION Let A be the cross-sectional area of the rod. Place the rod with m_1 at the origin and rod lying on the positive x-axis. The y-moment of the rod is $M_y = \frac{1}{2}\rho Ad^2$, the y-moment of the mass m_2 is $M_y = m_2d$, and the total mass of the system is $M = m_1 + m_2 + \rho Ad$. Therefore, the x-coordinate of the center of mass is

$$\frac{m_2d + \frac{1}{2}\rho Ad^2}{m_1 + m_2 + \rho Ad}.$$

43. **Symmetry Principle** Let $\mathcal{R}$ be the region under the graph of $f(x)$ over the interval $[-a, a]$, where $f(x) \geq 0$. Assume that $\mathcal{R}$ is symmetric with respect to the y-axis.

(a) Explain why $f(x)$ is even—that is, why $f(x) = f(-x)$.

(b) Show that $xf(x)$ is an *odd* function.

(c) Use (b) to prove that $M_y = 0$.

(d) Prove that the COM of $\mathcal{R}$ lies on the y-axis (a similar argument applies to symmetry with respect to the x-axis).

SOLUTION

(a) By the definition of symmetry with respect to the y-axis, $f(x) = f(-x)$, so f is even.

(b) Let $g(x) = xf(x)$ where f is even. Then

$$g(-x) = -xf(-x) = -xf(x) = -g(x),$$

and thus g is odd.

(c) $M_y = \rho \int_{-a}^{a} x f(x)\,dx = 0$ since $x f(x)$ is an odd function.

(d) By part (c), $x_{cm} = \dfrac{M_y}{M} = \dfrac{0}{M} = 0$ so the center of mass lies along the y-axis.

44. Prove directly that Eqs. (2) and (3) are equivalent in the following situation. Let $f(x)$ be a positive decreasing function on $[0, b]$ such that $f(b) = 0$. Set $d = f(0)$ and $g(y) = f^{-1}(y)$. Show that

$$\frac{1}{2}\int_0^b f(x)^2\,dx = \int_0^d y g(y)\,dy$$

Hint: First apply the substitution $y = f(x)$ to the integral on the left and observe that $dx = g'(y)\,dy$. Then apply Integration by Parts.

SOLUTION $f(x) \geq 0$ and $f'(x) < 0$ shows that f has an inverse g on $[a, b]$. Because $f(b) = 0$, $f(0) = d$, and $f^{-1}(x) = g(x)$, it follows that $g(d) = 0$ and $g(0) = b$. If we let $x = g(y)$, then $dx = g'(y)\,dy$. Thus, with $y = f(x)$,

$$\frac{1}{2}\int_0^b f(x)^2\,dx = \frac{1}{2}\int_0^b y^2\,dx = \frac{1}{2}\int_d^0 y^2 g'(y)\,dy.$$

Using Integration by Parts with $u = y^2$ and $v' = g'(y)\,dy$, we find

$$\frac{1}{2}\int_d^0 y^2 g'(y)\,dy = \frac{1}{2}\left[y^2 g(y)\Big|_d^0 - 2\int_d^0 y g(y)\,dy\right] = \frac{1}{2}\left[0 - d^2 g(d)\right] - \int_d^0 y g(y)\,dy = \int_0^d y g(y)\,dy.$$

45. Let R be a lamina of uniform density submerged in a fluid of density w (Figure 23). Prove the following law: The fluid force on one side of R is equal to the area of R times the fluid pressure on the centroid. *Hint:* Let $g(y)$ be the horizontal width of R at depth y. Express both the fluid pressure [Eq. (2) in Section 8.2] and y-coordinate of the centroid in terms of $g(y)$.

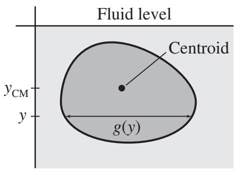

FIGURE 23

SOLUTION Let ρ denote the uniform density of the submerged lamina. Then

$$M_x = \rho\int_a^b y g(y)\,dy,$$

and the mass of the lamina is

$$M = \rho\int_a^b g(y)\,dy = \rho A,$$

where A is the area of the lamina. Thus, the y-coordinate of the centroid is

$$y_{\text{cm}} = \frac{\rho\int_a^b y g(y)\,dy}{\rho A} = \frac{\int_a^b y g(y)\,dy}{A}.$$

Now, the fluid force on the lamina is

$$F = w\int_a^b y g(y)\,dy = w\frac{\int_a^b y g(y)\,dy}{A}A = w y_{\text{cm}} A.$$

In other words, the fluid force on the lamina is equal to the fluid pressure at the centroid of the lamina times the area of the lamina.

8.4 Taylor Polynomials

Preliminary Questions

1. What is $T_3(x)$ centered at $a = 3$ for a function $f(x)$ such that $f(3) = 9$, $f'(3) = 8$, $f''(3) = 4$, and $f'''(3) = 12$?

SOLUTION In general, with $a = 3$,

$$T_3(x) = f(3) + f'(3)(x-3) + \frac{f''(3)}{2}(x-3)^2 + \frac{f'''(3)}{6}(x-3)^3.$$

Using the information provided, we find

$$T_3(x) = 9 + 8(x-3) + 2(x-3)^2 + 2(x-3)^3.$$

2. The dashed graphs in Figure 9 are Taylor polynomials for a function $f(x)$. Which of the two is a Maclaurin polynomial?

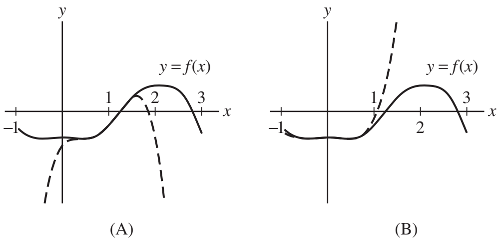

FIGURE 9

SOLUTION A Maclaurin polynomial always gives the value of $f(0)$ exactly. This is true for the Taylor polynomial sketched in (B); thus, this is the Maclaurin polynomial.

3. For which value of x does the Maclaurin polynomial $T_n(x)$ satisfy $T_n(x) = f(x)$, no matter what $f(x)$ is?

SOLUTION A Maclaurin polynomial always gives the value of $f(0)$ exactly.

4. Let $T_n(x)$ be the Maclaurin polynomial of a function $f(x)$ satisfying $|f^{(4)}(x)| \le 1$ for all x. Which of the following statements follow from the error bound?

(a) $|T_4(2) - f(2)| \le \frac{2}{3}$

(b) $|T_3(2) - f(2)| \le \frac{2}{3}$

(c) $|T_3(2) - f(2)| \le \frac{1}{3}$

SOLUTION For a function $f(x)$ satisfying $|f^{(4)}(x)| \le 1$ for all x,

$$|T_3(2) - f(2)| \le \frac{1}{24}|f^{(4)}(x)|2^4 \le \frac{16}{24} < \frac{2}{3}.$$

Thus, **(b)** is the correct answer.

Exercises

In Exercises 1–14, calculate the Taylor polynomials $T_2(x)$ and $T_3(x)$ centered at $x = a$ for the given function and value of a.

1. $f(x) = \sin x, \quad a = 0$

SOLUTION First, we calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \sin x & f(a) &= 0 \\ f'(x) &= \cos x & f'(a) &= 1 \\ f''(x) &= -\sin x & f''(a) &= 0 \\ f'''(x) &= -\cos x & f'''(a) &= -1 \end{aligned}$$

Now,

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 = 0 + 1(x-0) + \frac{0}{2}(x-0)^2 = x; \text{ and} \\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 + \frac{f'''(a)}{6}(x-a)^3 \\ &= 0 + 1(x-0) + \frac{0}{2}(x-0)^2 + \frac{-1}{6}(x-0)^3 = x - \frac{1}{6}x^3. \end{aligned}$$

2. $f(x) = \sin x, \quad a = \frac{\pi}{2}$

SOLUTION First, we calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \sin x & f(a) &= 1 \\ f'(x) &= \cos x & f'(a) &= 0 \\ f''(x) &= -\sin x & f''(a) &= -1 \\ f'''(x) &= -\cos x & f'''(a) &= 0 \end{aligned}$$

Now,

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 \\ &= 1 + 0\left(x - \frac{\pi}{2}\right) + \frac{-1}{2}\left(x - \frac{\pi}{2}\right)^2 = 1 - \frac{1}{2}\left(x - \frac{\pi}{2}\right)^2; \text{ and} \\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 + \frac{f'''(a)}{6}(x-a)^3 \\ &= 1 + 0\left(x - \frac{\pi}{2}\right) + \frac{-1}{2}\left(x - \frac{\pi}{2}\right)^2 + \frac{0}{6}\left(x - \frac{\pi}{2}\right)^3 = 1 - \frac{1}{2}\left(x - \frac{\pi}{2}\right)^2. \end{aligned}$$

3. $f(x) = \frac{1}{1+x}, \quad a = 2$

SOLUTION First, we calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \frac{1}{1+x} & f(a) &= \frac{1}{3} \\ f'(x) &= \frac{-1}{(1+x)^2} & f'(a) &= -\frac{1}{9} \\ f''(x) &= \frac{2}{(1+x)^3} & f''(a) &= \frac{2}{27} \\ f'''(x) &= \frac{-6}{(1+x)^4} & f'''(a) &= -\frac{2}{27} \end{aligned}$$

Now,

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 = \frac{1}{3} - \frac{1}{9}(x-2) + \frac{2/27}{2!}(x-2)^2 \\ &= \frac{1}{3} - \frac{1}{9}(x-2) + \frac{1}{27}(x-2)^2 \\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3 \\ &= \frac{1}{3} - \frac{1}{9}(x-2) + \frac{2/27}{2!}(x-2)^2 - \frac{2/27}{3!}(x-2)^3 = \frac{1}{3} - \frac{1}{9}(x-2) + \frac{1}{27}(x-2)^2 - \frac{1}{81}(x-2)^3 \end{aligned}$$

4. $f(x) = \frac{1}{1+x^2}, \quad a = -1$

SOLUTION First, we calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \frac{1}{1+x^2} & f(a) &= 1/2 \\ f'(x) &= \frac{-2x}{(x^2+1)^2} & f'(a) &= 1/2 \\ f''(x) &= \frac{2(3x^2-1)}{(x^2+1)^3} & f''(a) &= 1/2 \\ f'''(x) &= \frac{-24x(x^2-1)}{(x^2+1)^4} & f'''(a) &= 0 \end{aligned}$$

Now,

$$\begin{aligned}T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2\\ &= \frac{1}{2} + \frac{1}{2}(x+1) + \frac{1/2}{2}(x+1)^2 = \frac{1}{2} + \frac{1}{2}(x+1) + \frac{1}{4}(x+1)^2; \text{ and}\\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 + \frac{f'''(a)}{6}(x-a)^3\\ &= \frac{1}{2} + \frac{1}{2}(x+1) + \frac{1/2}{2}(x+1)^2 + \frac{0}{6}(x+1)^3 = \frac{1}{2} + \frac{1}{2}(x+1) + \frac{1}{4}(x+1)^2.\end{aligned}$$

5. $f(x) = x^4 - 2x, \quad a = 3$

SOLUTION First calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= x^4 - 2x & f(a) &= 75\\ f'(x) &= 4x^3 - 2 & f'(a) &= 106\\ f''(x) &= 12x^2 & f''(a) &= 108\\ f'''(x) &= 24x & f'''(a) &= 72\end{aligned}$$

Now,

$$\begin{aligned}T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 = 75 + 106(x-3) + \frac{108}{2}(x-3)^2\\ &= 75 + 106(x-3) + 54(x-3)^2\\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3\\ &= 75 + 106(x-3) + \frac{108}{2}(x-3)^2 + \frac{72}{3!}(x-3)^3\\ &= 75 + 106(x-3) + 54(x-3)^2 + 12(x-3)^3\end{aligned}$$

6. $f(x) = \dfrac{x^2+1}{x+1}, \quad a = -2$

SOLUTION First calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \frac{x^2+1}{x+1} & f(a) &= -5\\ f'(x) &= \frac{x^2+2x-1}{(x+1)^2} & f'(a) &= -1\\ f''(x) &= \frac{4}{(x+1)^3} & f''(a) &= -4\\ f'''(x) &= \frac{-12}{(x+1)^4} & f'''(a) &= -12\end{aligned}$$

Now,

$$\begin{aligned}T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 = -5 - (x+2) + \frac{-4}{2}(x+2)^2\\ &= -5 - (x+2) - 2(x+2)^2\\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3\\ &= -5 - (x+2) + \frac{-4}{2}(x+2)^2 + \frac{-12}{3!}(x+2)^3\\ &= -5 - (x+2) - 2(x+2)^2 - 2(x+2)^3\end{aligned}$$

7. $f(x) = \tan x, \quad a = 0$

SOLUTION First, we calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \tan x & f(a) &= 0 \\ f'(x) &= \sec^2 x & f'(a) &= 1 \\ f''(x) &= 2\sec^2 x \tan x & f''(a) &= 0 \\ f'''(x) &= 2\sec^4 x + 4\sec^2 x \tan^2 x & f'''(a) &= 2 \end{aligned}$$

Now,

$$T_2(x) = f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 = 0 + 1(x-0) + \frac{0}{2}(x-0)^2 = x; \text{ and}$$

$$\begin{aligned} T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 + \frac{f'''(a)}{6}(x-a)^3 \\ &= 0 + 1(x-0) + \frac{0}{2}(x-0)^2 + \frac{2}{6}(x-0)^3 = x + \frac{1}{3}x^3. \end{aligned}$$

8. $f(x) = \tan x, \quad a = \frac{\pi}{4}$

SOLUTION First, we calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \tan x & f(a) &= 1 \\ f'(x) &= \sec^2 x & f'(a) &= 2 \\ f''(x) &= 2\sec^2 x \tan x & f''(a) &= 4 \\ f'''(x) &= 2\sec^4 x + 4\sec^2 x \tan^2 x & f'''(a) &= 16 \end{aligned}$$

Now,

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 = 1 + 2\left(x - \frac{\pi}{4}\right) + \frac{4}{2}\left(x - \frac{\pi}{4}\right)^2 \\ &= 1 + 2\left(x - \frac{\pi}{4}\right) + 2\left(x - \frac{\pi}{4}\right)^2; \text{ and} \\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 + \frac{f'''(a)}{6}(x-a)^3 \\ &= 1 + 2\left(x - \frac{\pi}{4}\right) + \frac{4}{2}\left(x - \frac{\pi}{4}\right)^2 + \frac{16}{6}\left(x - \frac{\pi}{4}\right)^3 = 1 + 2\left(x - \frac{\pi}{4}\right) + 2\left(x - \frac{\pi}{4}\right)^2 + \frac{8}{3}\left(x - \frac{\pi}{4}\right)^3. \end{aligned}$$

9. $f(x) = e^{-x} + e^{-2x}, \quad a = 0$

SOLUTION First, we calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= e^{-x} + e^{-2x} & f(a) &= 2 \\ f'(x) &= -e^{-x} - 2e^{-2x} & f'(a) &= -3 \\ f''(x) &= e^{-x} + 4e^{-2x} & f''(a) &= 5 \\ f'''(x) &= -e^{-x} - 8e^{-2x} & f'''(a) &= -9 \end{aligned}$$

Now,

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 \\ &= 2 + (-3)(x-0) + \frac{5}{2}(x-0)^2 = 2 - 3x + \frac{5}{2}x^2; \text{ and} \\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 + \frac{f'''(a)}{6}(x-a)^3 \\ &= 2 + (-3)(x-0) + \frac{5}{2}(x-0)^2 + \frac{-9}{6}(x-0)^3 = 2 - 3x + \frac{5}{2}x^2 - \frac{3}{2}x^3. \end{aligned}$$

10. $f(x) = e^{2x}, \quad a = \ln 2$

SOLUTION First calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= e^{2x} & f(a) &= 4 \\ f'(x) &= 2e^{2x} & f'(a) &= 8 \\ f''(x) &= 4e^{2x} & f''(a) &= 16 \\ f'''(x) &= 8e^{2x} & f'''(a) &= 32 \end{aligned}$$

Now

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 = 4 + 8(x - \ln 2) + \frac{16}{2!}(x - \ln 2)^2 \\ &= 4 + 8(x - \ln 2) + 8(x - \ln 2)^2 \\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3 \\ &= 4 + 8(x - \ln 2) + \frac{16}{2!}(x - \ln 2)^2 + \frac{32}{6}(x - \ln 2)^3 \\ &= 4 + 8(x - \ln 2) + 8(x - \ln 2)^2 + \frac{16}{3}(x - \ln 2)^3 \end{aligned}$$

11. $f(x) = x^2e^{-x}, \quad a = 1$

SOLUTION First, we calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= x^2e^{-x} & f(a) &= 1/e \\ f'(x) &= (2x - x^2)e^{-x} & f'(a) &= 1/e \\ f''(x) &= (x^2 - 4x + 2)e^{-x} & f''(a) &= -1/e \\ f'''(x) &= (-x^2 + 6x - 6)e^{-x} & f'''(a) &= -1/e \end{aligned}$$

Now,

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 \\ &= \frac{1}{e} + \frac{1}{e}(x-1) + \frac{-1/e}{2}(x-1)^2 = \frac{1}{e} + \frac{1}{e}(x-1) - \frac{1}{2e}(x-1)^2; \text{ and} \\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 + \frac{f'''(a)}{6}(x-a)^3 \\ &= \frac{1}{e} + \frac{1}{e}(x-1) + \frac{-1/e}{2}(x-1)^2 + \left(\frac{-1/e}{6}\right)(x-1)^3 \\ &= \frac{1}{e} + \frac{1}{e}(x-1) - \frac{1}{2e}(x-1)^2 - \frac{1}{6e}(x-1)^3. \end{aligned}$$

12. $f(x) = \cosh 2x, \quad a = 0$

SOLUTION First calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \cosh 2x & f(a) &= 1 \\ f'(x) &= 2\sinh 2x & f'(a) &= 0 \\ f''(x) &= 4\cosh 2x & f''(a) &= 4 \\ f'''(x) &= 8\sinh 2x & f'''(a) &= 0 \end{aligned}$$

so that

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 = 1 + 0(x-0) + \frac{4}{2!}(x-0)^2 \\ &= 1 + 2x^2 \end{aligned}$$

$$\begin{aligned} T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3 \\ &= 1 + 0(x-0) + 2(x-0)^2 + \frac{0}{3!}(x-0)^3 \\ &= 1 + 2x^2 \end{aligned}$$

13. $f(x) = \dfrac{\ln x}{x}, \quad a = 1$

SOLUTION First calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \frac{\ln x}{x} & f(a) &= 0 \\ f'(x) &= \frac{1 - \ln x}{x^2} & f(a) &= 1 \\ f''(x) &= \frac{-3 + 2\ln x}{x^3} & f(a) &= -3 \\ f'''(x) &= \frac{11 - 6\ln x}{x^4} & f(a) &= 11 \end{aligned}$$

so that

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 = 0 + 1(x-1) + \frac{-3}{2!}(x-1)^2 \\ &= (x-1) - \frac{3}{2}(x-1)^2 \\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3 \\ &= 0 + 1(x-1) + \frac{-3}{2!}(x-1)^2 + \frac{11}{3!}(x-1)^3 \\ &= (x-1) - \frac{3}{2}(x-1)^2 + \frac{11}{6}(x-1)^3 \end{aligned}$$

14. $f(x) = \ln(x+1), \quad a = 0$

SOLUTION First, we calculate and evaluate the needed derivatives:

$$\begin{aligned} f(x) &= \ln(x+1) & f(a) &= 0 \\ f'(x) &= \frac{1}{x+1} & f'(a) &= 1 \\ f''(x) &= \frac{-1}{(x+1)^2} & f''(a) &= -1 \\ f'''(x) &= \frac{2}{(x+1)^3} & f'''(a) &= 2 \end{aligned}$$

Now,

$$\begin{aligned} T_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 = 0 + 1(x-0) + \frac{-1}{2}(x-0)^2 = x - \frac{1}{2}x^2; \text{ and} \\ T_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2}(x-a)^2 + \frac{f'''(a)}{6}(x-a)^3 \\ &= 0 + 1(x-0) + \frac{-1}{2}(x-0)^2 + \frac{2}{6}(x-0)^3 = x - \frac{1}{2}x^2 + \frac{1}{3}x^3. \end{aligned}$$

15. Show that the nth Maclaurin polynomial for e^x is

$$T_n(x) = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!}$$

SOLUTION With $f(x) = e^x$, it follows that $f^{(n)}(x) = e^x$ and $f^{(n)}(0) = 1$ for all n. Thus,

$$T_n(x) = 1 + 1(x-0) + \frac{1}{2}(x-0)^2 + \cdots + \frac{1}{n!}(x-0)^n = 1 + x + \frac{x^2}{2} + \cdots + \frac{x^n}{n!}.$$

16. Show that the nth Taylor polynomial for $\dfrac{1}{x+1}$ at $a=1$ is

$$T_n(x) = \frac{1}{2} - \frac{(x-1)}{4} + \frac{(x-1)^2}{8} + \cdots + (-1)^n \frac{(x-1)^n}{2^{n+1}}$$

SOLUTION Let $f(x) = \frac{1}{x+1}$. Then

$$\begin{aligned}
f(x) &= \frac{1}{x+1} & f(1) &= \frac{1}{2} = \frac{(-1)^0 0!}{2^{0+1}}\\
f'(x) &= \frac{-1}{(x+1)^2} & f'(1) &= -\frac{1}{4} = \frac{(-1)^1 1!}{2^{1+1}}\\
f''(x) &= \frac{2}{(x+1)^3} & f''(1) &= \frac{1}{4} = \frac{(-1)^2 2!}{2^{2+1}}\\
&\vdots & &\vdots\\
f^{(n)}(x) &= \frac{(-1)^n n!}{(x+1)^{n+1}} & f^{(n)}(1) &= \frac{(-1)^n n!}{2^{n+1}}
\end{aligned}$$

Therefore,

$$\begin{aligned}
T_n(x) &= \frac{1}{2} + \left(-\frac{1}{4}\right)(x-1) + \frac{1}{4}\frac{(x-1)^2}{2!} + \cdots + \frac{(-1)^n n!}{2^{n+1}}\frac{(x-1)^n}{n!}\\
&= \frac{1}{2} - \frac{1}{4}(x-1) + \frac{(x-1)^2}{8} + \cdots + (-1)^n \frac{(x-1)^n}{2^{n+1}}.
\end{aligned}$$

17. Show that the Maclaurin polynomials for $\sin x$ are

$$T_{2n+1}(x) = T_{2n+2}(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \cdots + (-1)^n \frac{x^{2n+1}}{(2n+1)!}$$

SOLUTION Let $f(x) = \sin x$. Then

$$\begin{aligned}
f(x) &= \sin x & f(0) &= 0\\
f'(x) &= \cos x & f'(0) &= 1\\
f''(x) &= -\sin x & f''(0) &= 0\\
f'''(x) &= -\cos x & f'''(0) &= -1\\
f^{(4)}(x) &= \sin x & f^{(4)}(0) &= 0\\
f^{(5)}(x) &= \cos x & f^{(5)}(0) &= 1\\
&\vdots & &\vdots
\end{aligned}$$

Consequently,

$$T_{2n+1}(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} + \cdots + (-1)^n \frac{x^{2n+1}}{(2n+1)!}$$

and

$$T_{2n+2}(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} + \cdots + (-1)^n \frac{x^{2n+1}}{(2n+1)!} + 0 = T_{2n+1}(x).$$

18. Show that the Maclaurin polynomials for $\ln(1+x)$ are

$$T_n(x) = x - \frac{x^2}{2} + \frac{x^3}{3} + \cdots + (-1)^{n-1}\frac{x^n}{n}$$

SOLUTION Let $f(x) = \ln(1+x)$. Then

$$\begin{aligned}
f(x) &= \ln(1+x) & f(0) &= 0\\
f'(x) &= (1+x)^{-1} & f'(0) &= 1
\end{aligned}$$

$$\begin{aligned} f''(x) &= -(1+x)^{-2} & f''(0) &= -1 \\ f'''(x) &= 2(1+x)^{-3} & f'''(0) &= 2 \\ f^{(4)}(x) &= -3!(1+x)^{-4} & f^{(4)}(0) &= -6 \\ f^{(5)}(x) &= 4!(1+x)^{-5} & f^{(5)}(0) &= 24 \end{aligned}$$

so that in general

$$f^{(n)}(x) = (-1)^{n-1}(n-1)!(1+x)^{-n} \qquad f^{(n)}(0) = (-1)^{n-1}(n-1)!$$

Thus

$$T_n(x) = x - \frac{1}{2!}x^2 + \frac{2}{3!}x^3 - \cdots + \frac{(-1)^{n-1}(n-1)!}{n!}x^n = x - \frac{x^2}{2} + \frac{x^3}{3} + \cdots + (-1)^{n-1}\frac{x^n}{n}$$

In Exercises 19–24, find $T_n(x)$ at $x = a$ for all n.

19. $f(x) = \dfrac{1}{1+x}, \quad a = 0$

SOLUTION We have

$$\frac{1}{1+x} = (\ln(1+x))'$$

so that from Exercise 18, letting $g(x) = \ln(1+x)$,

$$f^{(n)}(x) = g^{(n+1)}(x) = (-1)^n n!(x+1)^{-1-n} \quad \text{and} \quad f^{(n)}(0) = (-1)^n n!$$

Then

$$\begin{aligned} T_n(x) &= f(0) + f'(0)x + \frac{f''(0)}{2!}x^2 + \cdots + \frac{f^{(n)}(0)}{n!}x^n \\ &= 1 - x + \frac{2!}{2!}x^2 - \frac{3!}{3!}x^3 + \cdots + (-1)^n\frac{n!}{n!}x^n \\ &= 1 - x + x^2 - x^3 + \cdots + (-1)^n x^n \end{aligned}$$

20. $f(x) = \dfrac{1}{x-1}, \quad a = 4$

SOLUTION Let $f(x) = \frac{1}{x-1}$. Then

$$\begin{aligned} f(x) &= \frac{1}{x-1} & f(4) &= \frac{1}{3} = \frac{(-1)^0 0!}{3^{0+1}} \\ f'(x) &= \frac{-1}{(x-1)^2} & f'(4) &= -\frac{1}{9} = \frac{(-1)^1 1!}{3^{1+1}} \\ f''(x) &= \frac{2}{(x-1)^3} & f''(4) &= \frac{2}{27} = \frac{(-1)^2 2!}{3^{2+1}} \\ &\vdots & &\vdots \\ f^{(n)}(x) &= \frac{(-1)^n n!}{(x-1)^{n+1}} & f^{(n)}(4) &= \frac{(-1)^n n!}{3^{n+1}} \end{aligned}$$

Therefore,

$$\begin{aligned} T_n(x) &= \frac{1}{3} + \left(-\frac{1}{9}\right)(x-4) + \frac{2/27}{2}(x-4)^2 + \cdots + \frac{(-1)^n n!}{3^{n+1}}\frac{(x-4)^n}{n!} \\ &= \frac{1}{3} - \frac{1}{9}(x-4) + \frac{1}{27}(x-4)^2 + \cdots + \frac{(-1)^n}{3^{n+1}}(x-4)^n. \end{aligned}$$

21. $f(x) = e^x, \quad a = 1$

SOLUTION Let $f(x) = e^x$. Then $f^{(n)}(x) = e^x$ and $f^{(n)}(1) = e$ for all n. Therefore,

$$T_n(x) = e + e(x-1) + \frac{e}{2!}(x-1)^2 + \cdots + \frac{e}{n!}(x-1)^n.$$

22. $f(x) = x^{-2}, \quad a = 2$

SOLUTION We have

$$\begin{aligned} f(x) &= x^{-2} & f(2) &= \frac{1}{4} \\ f'(x) &= -2x^{-3} & f'(2) &= -\frac{1}{4} \\ f''(x) &= 6x^{-4} & f''(2) &= \frac{3}{8} \\ f'''(x) &= -24x^{-5} & f'''(2) &= -\frac{3}{4} \\ &\vdots & &\vdots \\ f^{(n)}(x) &= (-1)^n (n+1)! x^{-n-2} & f^{(n)}(2) &= (-1)^n \frac{(n+1)!}{2^{n+2}} \end{aligned}$$

so that

$$\begin{aligned} T_n(x) &= f(2) + f'(2)(x-2) + \frac{f''(2)}{2!}(x-2)^2 + \cdots + \frac{f^{(n)}(2)}{n!}(x-2)^n \\ &= \frac{1}{4} - \frac{1}{4}(x-2) + \frac{3}{16}(x-2)^2 + \cdots + (-1)^n \frac{n+1}{2^{n+2}}(x-2)^n \end{aligned}$$

23. $f(x) = \cos x, \quad a = \frac{\pi}{4}$

SOLUTION Let $f(x) = \cos x$. Then

$$\begin{aligned} f(x) &= \cos x & f(\pi/4) &= \frac{1}{\sqrt{2}} \\ f'(x) &= -\sin x & f'(\pi/4) &= -\frac{1}{\sqrt{2}} \\ f''(x) &= -\cos x & f''(\pi/4) &= -\frac{1}{\sqrt{2}} \\ f'''(x) &= \sin x & f'''(\pi/4) &= \frac{1}{\sqrt{2}} \end{aligned}$$

This pattern of four values repeats indefinitely. Thus,

$$f^{(n)}(\pi/4) = \begin{cases} (-1)^{(n+1)/2} \dfrac{1}{\sqrt{2}}, & n \text{ odd} \\ (-1)^{n/2} \dfrac{1}{\sqrt{2}}, & n \text{ even} \end{cases}$$

and

$$T_n(x) = \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}}\left(x - \frac{\pi}{4}\right) - \frac{1}{2\sqrt{2}}\left(x - \frac{\pi}{4}\right)^2 + \frac{1}{6\sqrt{2}}\left(x - \frac{\pi}{4}\right)^3 \cdots.$$

In general, the coefficient of $(x - \pi/4)^n$ is

$$\pm \frac{1}{(\sqrt{2})n!}$$

with the pattern of signs $+, -, -, +, +, -, -, \ldots$.

24. $f(\theta) = \sin 3\theta, \quad a = 0$

SOLUTION We have

$$\begin{aligned} f(\theta) &= \sin 3\theta & f(0) &= 0 \\ f'(\theta) &= 3\cos 3\theta & f'(0) &= 3 \\ f''(\theta) &= -9\sin 3\theta & f''(0) &= 0 \\ f'''(\theta) &= -27\cos 3\theta & f'''(0) &= -27 \\ f^{(4)}(\theta) &= 81\sin 3\theta & f^{(4)}(0) &= 0 \end{aligned}$$

and in general

$$f^{(2n)}(\theta) = (-1)^n 3^{2n} \sin 3\theta \qquad f^{(2n)}(0) = 0$$
$$f^{(2n+1)}(\theta) = (-1)^n 3^{2n+1} \cos 3\theta \qquad f^{(2n+1)}(0) = (-1)^n 3^{2n+1}$$

Thus

$$T_n(x) = 3\theta - \frac{27}{3!}\theta^3 + \frac{243}{5!}\theta^5 - \dots$$

where the coefficient of θ^{2n+1} is $(-1)^n \frac{3^{2n+1}}{(2n+1)!}$.

In Exercises 25–28, find $T_2(x)$ and use a calculator to compute the error $|f(x) - T_2(x)|$ for the given values of a and x.

25. $y = e^x, \quad a = 0, \quad x = -0.5$

SOLUTION Let $f(x) = e^x$. Then $f'(x) = e^x$, $f''(x) = e^x$, $f(a) = 1$, $f'(a) = 1$ and $f''(a) = 1$. Therefore

$$T_2(x) = 1 + 1(x-0) + \frac{1}{2}(x-0)^2 = 1 + x + \frac{1}{2}x^2,$$

and

$$T_2(-0.5) = 1 + (-0.5) + \frac{1}{2}(-0.5)^2 = 0.625.$$

Using a calculator, we find

$$f(-0.5) = \frac{1}{\sqrt{e}} = 0.606531,$$

so

$$|T_2(-0.5) - f(-0.5)| = 0.0185.$$

26. $y = \cos x, \quad a = 0, \quad x = \frac{\pi}{12}$

SOLUTION Let $f(x) = \cos x$. Then $f'(x) = -\sin x$, $f''(x) = -\cos x$, $f(a) = 1$, $f'(a) = 0$, and $f''(a) = -1$. Therefore

$$T_2(x) = 1 + 0(x-0) + \frac{-1}{2}(x-0)^2 = 1 - \frac{1}{2}x^2,$$

and

$$T_2\left(\frac{\pi}{12}\right) = 1 - \frac{1}{2}\left(\frac{\pi}{12}\right)^2 \approx 0.965731.$$

Using a calculator, we find

$$f\left(\frac{\pi}{12}\right) = 0.965926,$$

so

$$\left|T_2\left(\frac{\pi}{12}\right) - f\left(\frac{\pi}{12}\right)\right| = 0.000195.$$

27. $y = x^{-2/3}, \quad a = 1, \quad x = 1.2$

SOLUTION Let $f(x) = x^{-2/3}$. Then $f'(x) = -\frac{2}{3}x^{-5/3}$, $f''(x) = \frac{10}{9}x^{-8/3}$, $f(1) = 1$, $f'(1) = -\frac{2}{3}$, and $f''(1) = \frac{10}{9}$. Thus

$$T_2(x) = 1 - \frac{2}{3}(x-1) + \frac{10}{2\cdot 9}(x-1)^2 = 1 - \frac{2}{3}(x-1) + \frac{5}{9}(x-1)^2$$

and

$$T_2(1.2) = 1 - \frac{2}{3}(0.2) + \frac{5}{9}(0.2)^2 = \frac{8}{9} \approx 0.88889$$

Using a calculator, $f(1.2) = (1.2)^{-2/3} \approx 0.88555$ so that

$$|T_2(1.2) - f(1.2)| \approx 0.00334$$

28. $y = e^{\sin x}, \quad a = \frac{\pi}{2}, \quad x = 1.5$

SOLUTION Let $f(x) = e^{\sin x}$. Then $f'(x) = \cos x e^{\sin x}$, $f''(x) = \cos^2 x e^{\sin x} - \sin x e^{\sin x}$, $f(a) = e$, $f'(a) = 0$ and $f''(a) = -e$. Therefore

$$T_2(x) = e + 0\left(x - \frac{\pi}{2}\right) + \frac{-e}{2}\left(x - \frac{\pi}{2}\right)^2 = e - \frac{e}{2}\left(x - \frac{\pi}{2}\right)^2,$$

and

$$T_2(1.5) = e - \frac{e}{2}\left(1.5 - \frac{\pi}{2}\right)^2 \approx 2.711469651.$$

Using a calculator, we find $f(1.5) = 2.711481018$, so

$$|T_2(1.5) - f(1.5)| = 1.14 \times 10^{-5}.$$

29. GU Compute $T_3(x)$ for $f(x) = \sqrt{x}$ centered at $a = 1$. Then use a plot of the error $|f(x) - T_3(x)|$ to find a value $c > 1$ such that the error on the interval $[1, c]$ is at most 0.25.

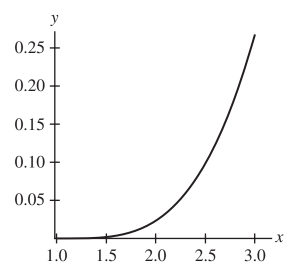
SOLUTION We have

$$\begin{aligned} f(x) &= x^{1/2} & f(1) &= 1 \\ f'(x) &= \frac{1}{2}x^{-1/2} & f'(1) &= \frac{1}{2} \\ f''(x) &= -\frac{1}{4}x^{-3/2} & f''(1) &= -\frac{1}{4} \\ f'''(x) &= \frac{3}{8}x^{-5/2} & f'''(1) &= \frac{3}{8} \end{aligned}$$

Therefore

$$T_3(x) = 1 + \frac{1}{2}(x-1) - \frac{1}{4 \cdot 2!}(x-1)^2 + \frac{3}{8 \cdot 3!}(x-1)^3 = 1 + \frac{1}{2}(x-1) - \frac{1}{8}(x-1)^2 + \frac{1}{16}(x-1)^3$$

A plot of $|f(x) - T_3(x)|$ is below.



It appears that for $x \in [1, 2.9]$ that the error does not exceed 0.25. The error at $x = 3$ appears to just exceed 0.25.

30. CAS Plot $f(x) = 1/(1+x)$ together with the Taylor polynomials $T_n(x)$ at $a = 1$ for $1 \le n \le 4$ on the interval $[-2, 8]$ (be sure to limit the upper plot range).

(a) Over which interval does $T_4(x)$ appear to approximate $f(x)$ closely?

(b) What happens for $x < -1$?

(c) Use your computer algebra system to produce and plot T_{30} together with $f(x)$ on $[-2, 8]$. Over which interval does T_{30} appear to give a close approximation?

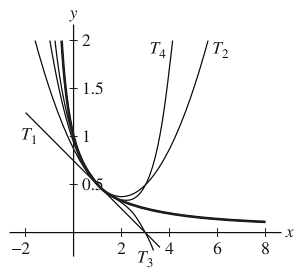
SOLUTION Let $f(x) = \frac{1}{1+x}$. Then

$$\begin{aligned} f(x) &= \frac{1}{1+x} & f(1) &= \frac{1}{2} \\ f'(x) &= -\frac{1}{(1+x)^2} & f'(1) &= -\frac{1}{4} \\ f''(x) &= \frac{2}{(1+x)^3} & f''(1) &= \frac{1}{4} \\ f'''(x) &= -\frac{6}{(1+x)^4} & f'''(1) &= -\frac{3}{8} \\ f^{(4)}(x) &= \frac{24}{(1+x)^5} & f^{(4)}(1) &= \frac{3}{4} \end{aligned}$$

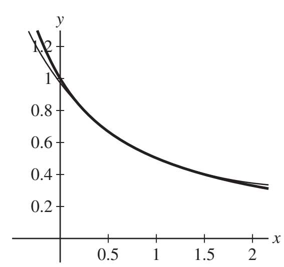
and

$$T_1(x) = \frac{1}{2} - \frac{1}{4}(x-1);$$
$$T_2(x) = \frac{1}{2} - \frac{1}{4}(x-1) + \frac{1}{8}(x-1)^2;$$
$$T_3(x) = \frac{1}{2} - \frac{1}{4}(x-1) + \frac{1}{8}(x-1)^2 - \frac{1}{16}(x-1)^3; \text{ and}$$
$$T_4(x) = \frac{1}{2} - \frac{1}{4}(x-1) + \frac{1}{8}(x-1)^2 - \frac{1}{16}(x-1)^3 + \frac{1}{32}(x-1)^4.$$

A plot of $f(x)$, $T_1(x)$, $T_2(x)$, $T_3(x)$ and $T_4(x)$ is shown below.

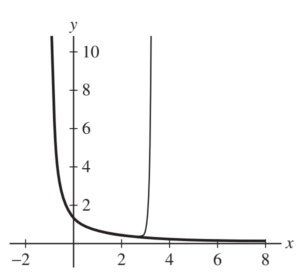


(a) The graph below displays $f(x)$ and $T_4(x)$ over the interval $[-0.5, 2.5]$. It appears that $T_4(x)$ gives a close approximation to $f(x)$ over the interval $(0.1, 2)$.



(b) For $x < -1$, $f(x)$ is negative, but the Taylor polynomials are positive; thus, the Taylor polynomials are poor approximations for $x < -1$.

(c) The graph below displays $f(x)$ and $T_{30}(x)$ over the interval $[-2, 8]$. It appears that $T_{30}(x)$ gives a close approximation to $f(x)$ over the interval $(-1, 3)$.



31. Let $T_3(x)$ be the Maclaurin polynomial of $f(x) = e^x$. Use the error bound to find the maximum possible value of $|f(1.1) - T_3(1.1)|$. Show that we can take $K = e^{1.1}$.

SOLUTION Since $f(x) = e^x$, we have $f^{(n)}(x) = e^x$ for all n; since e^x is increasing, the maximum value of e^x on the interval $[0, 1.1]$ is $K = e^{1.1}$. Then by the error bound,

$$\left|e^{1.1} - T_3(1.1)\right| \le K\frac{(1.1-0)^4}{4!} = \frac{e^{1.1}1.1^4}{24} \approx 0.183$$

32. Let $T_2(x)$ be the Taylor polynomial of $f(x) = \sqrt{x}$ at $a = 4$. Apply the error bound to find the maximum possible value of the error $|f(3.9) - T_2(3.9)|$.

SOLUTION We have $f(x) = x^{1/2}$, $f'(x) = \frac{1}{2}x^{-1/2}$, $f''(x) = -\frac{1}{4}x^{-3/2}$, and $f'''(x) = \frac{3}{8}x^{-5/2}$. This is a decreasing function of x, so its maximum value on $[3.9, 4]$ is achieved at $x = 3.9$; that value is $\frac{3}{8 \cdot 3.9^{5/2}} \approx 0.0125$, so we can take $K = 0.0125$. Then

$$|f(x) - T_2(x)| \le K\frac{|3.9-4|^3}{3!} = 0.0125\frac{0.001}{6} \approx 2.08 \times 10^{-6}$$

In Exercises 33–36, compute the Taylor polynomial indicated and use the error bound to find the maximum possible size of the error. Verify your result with a calculator.

33. $f(x) = \cos x, \quad a = 0; \quad |\cos 0.25 - T_5(0.25)|$

SOLUTION The Maclaurin series for $\cos x$ is

$$1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots$$

so that

$$T_5(x) = 1 - \frac{x^2}{2} + \frac{x^4}{24}$$
$$T_5(0.25) \approx 0.9689127604$$

In addition, $f^{(6)}(x) = -\cos x$ so that $|f^{(6)}(x)| \le 1$ and we may take $K = 1$ in the error bound formula. Then

$$|\cos 0.25 - T_5(0.25)| \le K\frac{0.25^6}{6!} = \frac{1}{2^{12} \cdot 6!} \approx 3.390842014 \cdot 10^{-7}$$

(The true value is $\cos 0.25 \approx 0.9689124217$ and the difference is in fact $\approx 3.387 \cdot 10^{-7}$.)

34. $f(x) = x^{11/2}, \quad a = 1; \quad |f(1.2) - T_4(1.2)|$

SOLUTION Let $f(x) = x^{11/2}$. Then

$$\begin{aligned} f(x) &= x^{11/2} & f(1) &= 1 \\ f'(x) &= \frac{11}{2}x^{9/2} & f'(1) &= \frac{11}{2} \\ f''(x) &= \frac{99}{4}x^{7/2} & f''(1) &= \frac{99}{4} \\ f'''(x) &= \frac{693}{8}x^{5/2} & f'''(1) &= \frac{693}{8} \\ f^{(4)}(x) &= \frac{3465}{16}x^{3/2} & f^{(4)}(1) &= \frac{3465}{16} \end{aligned}$$

and

$$T_4(x) = 1 + \frac{11}{2}(x-1) + \frac{99}{8}(x-1)^2 + \frac{231}{16}(x-1)^3 + \frac{1155}{128}(x-1)^4.$$

Using the Error Bound,

$$|f(1.2) - T_4(1.2)| \le \frac{K|1.2-1|^5}{5!} = \frac{K}{375{,}000},$$

where K is a number such that $|f^{(5)}(x)| \le K$ for x between 1 and 1.2. Now,

$$f^{(5)}(x) = \frac{10{,}395}{32}x^{1/2},$$

which is increasing for $x > 1$. Consequently, on the interval $[1, 1.2]$, $f^{(5)}(x)$ is maximized at $x = 1.2$. We can therefore take $K = \frac{10{,}395}{32}\sqrt{1.2}$, and then

$$|f(1.2) - T_4(1.2)| \le \frac{10{,}395}{(32)(375{,}000)}\sqrt{1.2} \approx 9.489 \times 10^{-4}.$$

35. $f(x) = x^{-1/2}$, $a = 4$; $|f(4.3) - T_3(4.3)|$

SOLUTION We have

$$\begin{aligned} f(x) &= x^{-1/2} & f(4) &= \frac{1}{2} \\ f'(x) &= -\frac{1}{2}x^{-3/2} & f'(4) &= -\frac{1}{16} \\ f''(x) &= \frac{3}{4}x^{-5/2} & f''(4) &= \frac{3}{128} \\ f'''(x) &= -\frac{15}{8}x^{-7/2} & f'''(4) &= -\frac{15}{1024} \\ f^{(4)}(x) &= \frac{105}{16}x^{-9/2} \end{aligned}$$

so that

$$T_3(x) = \frac{1}{2} - \frac{1}{16}(x-4) + \frac{3}{256}(x-4)^2 - \frac{5}{2048}(x-4)^3$$

Using the error bound formula,

$$|f(4.3) - T_3(4.3)| \le K\frac{|4.3-4|^4}{4!} = \frac{27K}{80{,}000}$$

where K is a number such that $|f^{(4)}(x)| \le K$ for x between 4 and 4.3. Now, $f^{(4)}(x)$ is a decreasing function for $x > 1$, so it takes its maximum value on $[4, 4.3]$ at $x = 4$; there, its value is

$$K = \frac{105}{16}4^{-9/2} = \frac{105}{8192}$$

so that

$$|f(4.3) - T_3(4.3)| \le \frac{27\frac{105}{8192}}{80{,}000} = \frac{27 \cdot 105}{8192 \cdot 80{,}000} \approx 4.3258667 \cdot 10^{-6}$$

36. $f(x) = \sqrt{1+x}$, $a = 8$; $|\sqrt{9.02} - T_3(8.02)|$

SOLUTION Let $f(x) = \sqrt{1+x}$. Then

$$\begin{aligned} f(x) &= \sqrt{1+x} & f(8) &= 3 \\ f'(x) &= \frac{1}{2}(x+1)^{-1/2} & f'(8) &= \frac{1}{6} \\ f''(x) &= \frac{-1}{4}(x+1)^{-3/2} & f''(8) &= \frac{-1}{108} \\ f'''(x) &= \frac{3}{8}(x+1)^{-5/2} & f'''(8) &= \frac{1}{648} \end{aligned}$$

and

$$T_3(x) = 3 + \frac{1}{6}(x-8) - \frac{1}{108 \cdot 2!}(x-8)^2 + \frac{1}{648 \cdot 3!}(x-8)^3 = 3 + \frac{1}{6}(x-8) - \frac{1}{216}(x-8)^2 + \frac{1}{3888}(x-8)^3.$$

Therefore

$$T_3(8.02) = 3 + \frac{1}{6}(0.02) - \frac{1}{216}(0.02)^2 + \frac{1}{3888}(0.02)^3 = 3.003331484.$$

Using the Error Bound, we have

$$|\sqrt{9.02} - T_3(8.02)| \le K\frac{|8.02-8|^4}{4!} = \frac{K}{150{,}000{,}000},$$

where K is a number such that $|f^{(4)}(x)| \le K$ for x between 8 and 8.02. Now

$$f^{(4)}(x) = -\frac{15}{16}(1+x)^{-7/2},$$

which is a decreasing function for $8 \le x \le 8.02$, so we may take

$$K = \frac{15}{16}9^{-7/2} = \frac{15}{34992}.$$

Thus,

$$|\sqrt{9.02} - T_3(8.02)| \le \frac{15/34992}{150{,}000{,}000} \approx 2.858 \times 10^{-12}.$$

37. Calculate the Maclaurin polynomial $T_3(x)$ for $f(x) = \tan^{-1} x$. Compute $T_3\left(\frac{1}{2}\right)$ and use the error bound to find a bound for the error $\left|\tan^{-1} \frac{1}{2} - T_3\left(\frac{1}{2}\right)\right|$. Refer to the graph in Figure 10 to find an acceptable value of K. Verify your result by computing $\left|\tan^{-1} \frac{1}{2} - T_3\left(\frac{1}{2}\right)\right|$ using a calculator.

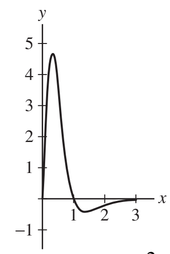


FIGURE 10 Graph of $f^{(4)}(x) = \dfrac{-24x(x^2-1)}{(x^2+1)^4}$, where $f(x) = \tan^{-1} x$.

SOLUTION Let $f(x) = \tan^{-1} x$. Then

$$\begin{aligned} f(x) &= \tan^{-1} x & f(0) &= 0 \\ f'(x) &= \frac{1}{1+x^2} & f'(0) &= 1 \\ f''(x) &= \frac{-2x}{(1+x^2)^2} & f''(0) &= 0 \\ f'''(x) &= \frac{(1+x^2)^2(-2) - (-2x)(2)(1+x^2)(2x)}{(1+x^2)^4} & f'''(0) &= -2 \end{aligned}$$

and

$$T_3(x) = 0 + 1(x-0) + \frac{0}{2}(x-0)^2 + \frac{-2}{6}(x-0)^3 = x - \frac{x^3}{3}.$$

Since $f^{(4)}(x) \le 5$ for $x \ge 0$, we may take $K = 5$ in the error bound; then,

$$\left|\tan^{-1}\left(\frac{1}{2}\right) - T_3\left(\frac{1}{2}\right)\right| \le \frac{5(1/2)^4}{4!} = \frac{5}{384}.$$

38. Let $f(x) = \ln(x^3 - x + 1)$. The third Taylor polynomial at $a = 1$ is

$$T_3(x) = 2(x-1) + (x-1)^2 - \frac{7}{3}(x-1)^3$$

Find the maximum possible value of $|f(1.1) - T_3(1.1)|$, using the graph in Figure 11 to find an acceptable value of K. Verify your result by computing $|f(1.1) - T_3(1.1)|$ using a calculator.

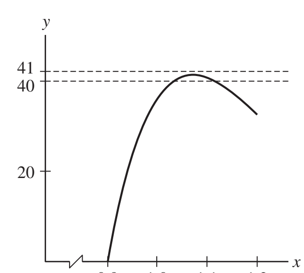

FIGURE 11 Graph of $f^{(4)}(x)$, where $f(x) = \ln(x^3 - x + 1)$.

SOLUTION The maximum value of $f^{(4)}(x)$ on $[1.0, 1.1]$ is less than 41, so we may take $K = 41$. Then

$$|f(1.1) - T_3(1.1)| \le K\frac{|1.1-1|^4}{4!} = \frac{41}{24 \cdot 10{,}000} \approx 0.00017083$$

In fact, we have

$$f(1.1) = \ln(1.1^3 - 1.1 + 1) = \ln(1.231) \approx 0.2078268472$$

$$T_3(1.1) = 2(1.1 - 1) + (1.1 - 1)^2 - \frac{7}{3}(1.1 - 1)^3 \approx 0.2076666667$$

$$|f(1.1) - T_3(1.1)| \approx 0.2078268472 - 0.2076666667 = 0.0001601805$$

which is in accordance with the error bound above.

39. $\boxed{\text{GU}}$ Calculate the $T_3(x)$ at $a = 0.5$ for $f(x) = \cos(x^2)$, and use the error bound to find the maximum possible value of $|f(0.6) - T_3(0.6)|$. Plot $f^{(4)}(x)$ to find an acceptable value of K.

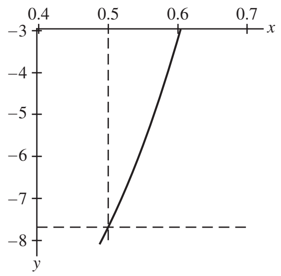
SOLUTION We have

$$\begin{aligned} f(x) &= \cos(x^2) & f(0.5) &= \cos(0.25) \approx 0.9689 \\ f'(x) &= -2x\sin(x^2) & f'(0.5) &= -\sin(0.25) \approx -0.2474039593 \\ f''(x) &= -4x^2\cos(x^2) - 2\sin(x^2) & f''(0.5) &= -\cos(0.25) - 2\sin(0.25) \approx -1.463720340 \\ f'''(x) &= 8x^3\sin(x^2) - 12x\cos(x^2) & f'''(0.5) &= \sin(0.25) - 6\cos(0.25) \approx -5.566070571 \\ f^{(4)}(x) &= 16x^4\cos(x^2) + 48x^2\sin(x^2) - 12\cos(x^2) \end{aligned}$$

so that

$$T_3(x) = 0.9689 - 0.2472039593(x - 0.5) - 0.73186017(x - 0.5)^2 - 0.92767843(x - 0.5)^3$$

and $T_3(0.6) \approx 0.9359257453$. A graph of $f^{(4)}(x)$ for x near 0.5 is below.



Clearly the maximum value of $|f^{(4)}(x)|$ on $[0.5, 0.6]$ is bounded by 8 (near $x = 0.5$), so we may take $K = 8$; then

$$|f(0.6) - T_3(0.6)| \le K\frac{|0.6 - 0.5|^4}{4!} = \frac{8}{240{,}000} \approx 0.000033333$$

40. $\boxed{\text{GU}}$ Calculate the Maclaurin polynomial $T_2(x)$ for $f(x) = \operatorname{sech} x$ and use the error bound to find the maximum possible value of $\left|f\left(\frac{1}{2}\right) - T_2\left(\frac{1}{2}\right)\right|$. Plot $f'''(x)$ to find an acceptable value of K.

SOLUTION To compute $T_2(x)$ for $f(x) = \operatorname{sech} x$, we take the first two derivatives:

$$\begin{aligned} f(x) &= \operatorname{sech} x & f(0) &= 1 \\ f'(x) &= -\operatorname{sech} x \tanh x & f'(0) &= 0 \\ f''(x) &= \operatorname{sech} x \tanh^2 x - \operatorname{sech}^3 x & f''(0) &= -1 \end{aligned}$$

From this,

$$T_2(x) = 1 - \frac{1}{2}x^2,$$

and

$$T_2\left(\frac{1}{2}\right) = 1 - \frac{1}{2}\left(\frac{1}{2}\right)^2 = 1 - \frac{1}{8} = \frac{7}{8}.$$

Using the Error Bound, we have

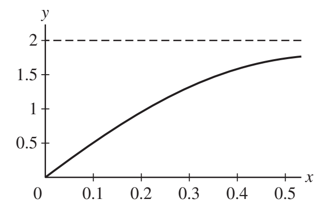
$$\left|f\left(\frac{1}{2}\right) - T_2\left(\frac{1}{2}\right)\right| \le K\frac{|1/2|^3}{6} = \frac{K}{48},$$

where K is a number such that $|f'''(x)| \le K|$ for x between 0 and $\frac{1}{2}$. Here,

$$\begin{aligned} f'''(x) &= -\operatorname{sech} x \tanh^3 x + 2\operatorname{sech}^3 x \tanh x + 3\operatorname{sech}^2 x(\operatorname{sech} x \tanh x) \\ &= 5\operatorname{sech}^2 x \tanh x - \operatorname{sech} x \tanh^3 x. \end{aligned}$$

A plot of $f'''(x)$ is given below. From the plot, we see that $|f'''(x)| \le 2$ for all x between 0 and $1/2$. Thus,

$$\left| f\left(\frac{1}{2}\right) - T_2\left(\frac{1}{2}\right) \right| \le \frac{2}{48} = \frac{1}{24}.$$



In Exercises 41–44, use the error bound to find a value of n for which the given inequality is satisfied. Then verify your result using a calculator.

41. $|\cos 0.1 - T_n(0.1)| \le 10^{-7}, \quad a = 0$

SOLUTION Using the error bound with $K = 1$ (every derivative of $f(x) = \cos x$ is $\pm \sin x$ or $\pm \cos x$, so $|f^{(n)}(x)| \le 1$ for all n), we have

$$|T_n(0.1) - \cos 0.1| \le \frac{(0.1)^{n+1}}{(n+1)!}.$$

With $n = 3$,

$$\frac{(0.1)^4}{4!} \approx 4.17 \times 10^{-6} > 10^{-7},$$

but with $n = 4$,

$$\frac{(0.1)^5}{5!} \approx 8.33 \times 10^{-8} < 10^{-7},$$

so we choose $n = 4$. Now,

$$T_4(x) = 1 - \frac{1}{2}x^2 + \frac{1}{24}x^4,$$

so

$$T_4(0.1) = 1 - \frac{1}{2}(0.1)^2 + \frac{1}{24}(0.1)^4 = 0.995004166.$$

Using a calculator, $\cos 0.1 = 0.995004165$, so

$$|T_4(0.1) - \cos 0.1| = 1.387 \times 10^{-8} < 10^{-7}.$$

42. $|\ln 1.3 - T_n(1.3)| \le 10^{-4}, \quad a = 1$

SOLUTION Let $f(x) = \ln x$. Then $f'(x) = x^{-1}$, $f''(x) = -x^{-2}$, $f'''(x) = 2x^{-3}$, $f^{(4)}(x) = -6x^{-4}$, etc. In general,

$$f^{(n)}(x) = (-1)^{n+1}(n-1)!x^{-n}.$$

Now, $|f^{(n+1)}(x)|$ is decreasing on the interval $[1, 1.3]$, so $|f^{(n+1)}(x)| \le |f^{(n+1)}(1)| = n!$ for all $x \in [1, 1.3]$. We can therefore take $K = n!$ in the error bound, and

$$|\ln 1.3 - T_n(1.3)| \le n!\frac{|1.3 - 1|^{n+1}}{(n+1)!} = \frac{(0.3)^{n+1}}{n+1}.$$

With $n = 5$,

$$\frac{(0.3)^6}{6} = 1.215 \times 10^{-4} > 10^{-4},$$

but with $n = 6$,

$$\frac{(0.3)^7}{7} = 3.124 \times 10^{-5} < 10^{-4}.$$

Therefore, the error is guaranteed to be below 10^{-4} for $n = 6$. Now,

$$T_6(x) = (x-1) - \frac{1}{2}(x-1)^2 + \frac{1}{3}(x-1)^3 - \frac{1}{4}(x-1)^4 + \frac{1}{5}(x-1)^5 - \frac{1}{6}(x-1)^6$$

and $T_6(1.3) \approx 0.2623395000$. Using a calculator, $\ln(1.3) \approx 0.2623642645$; the difference is

$$\ln(1.3) - T_6(1.3) \approx 0.0000247645 < 10^{-4}$$

43. $|\sqrt{1.3} - T_n(1.3)| \le 10^{-6}, \quad a = 1$

SOLUTION Using the Error Bound, we have

$$|\sqrt{1.3} - T_n(1.3)| \le K\frac{|1.3-1|^{n+1}}{(n+1)!} = K\frac{|0.3|^{n+1}}{(n+1)!},$$

where K is a number such that $|f^{(n+1)}(x)| \le K$ for x between 1 and 1.3. For $f(x) = \sqrt{x}$, $|f^{(n)}(x)|$ is decreasing for $x > 1$, hence the maximum value of $|f^{(n+1)}(x)|$ occurs at $x = 1$. We may therefore take

$$\begin{aligned} K = |f^{(n+1)}(1)| &= \frac{1\cdot 3\cdot 5\cdots(2n+1)}{2^{n+1}} \\ &= \frac{1\cdot 3\cdot 5\cdots(2n+1)}{2^{n+1}}\cdot\frac{2\cdot 4\cdot 6\cdots(2n+2)}{2\cdot 4\cdot 6\cdots(2n+2)} = \frac{(2n+2)!}{(n+1)!2^{2n+2}}. \end{aligned}$$

Then

$$|\sqrt{1.3} - T_n(1.3)| \le \frac{(2n+2)!}{(n+1)!2^{2n+2}}\cdot\frac{|0.3|^{n+1}}{(n+1)!} = \frac{(2n+2)!}{[(n+1)!]^2}(0.075)^{n+1}.$$

With $n = 9$

$$\frac{(20)!}{[(10)!]^2}(0.075)^{10} = 1.040 \times 10^{-6} > 10^{-6},$$

but with $n = 10$

$$\frac{(22)!}{[(11)!]^2}(0.075)^{11} = 2.979 \times 10^{-7} < 10^{-6}.$$

Hence, $n = 10$ will guarantee the desired accuracy. Using technology to compute and evaluate $T_{10}(1.3)$ gives

$$T_{10}(1.3) \approx 1.140175414, \qquad \sqrt{1.3} \approx 1.140175425$$

and

$$|\sqrt{1.3} - T_{10}(1.3)| \approx 1.1 \times 10^{-8} < 10^{-6}$$

44. $|e^{-0.1} - T_n(-0.1)| \le 10^{-6}, \quad a = 0$

SOLUTION Using the Error Bound, we have

$$|e^{-0.1} - T_n(-0.1)| \le K\frac{|-0.1-0|^{n+1}}{(n+1)!} = K\frac{1}{10^{n+1}(n+1)!}$$

where K is a number such that $|f^{(n+1)}(x)| \le K$ for x between -0.1 and 0. Since $f(x) = e^x$, $f^{(n)}(x) = e^x$ for all n; this is an increasing function, so it takes its maximum value at $x = 0$; this value is 1. So we may take $K = 1$ and then

$$|e^{-0.1} - T_n(-0.1)| \le \frac{1}{10^{n+1}(n+1)!}$$

With $n = 3$

$$\frac{1}{10^4\cdot 24} = \frac{1}{240{,}000} \approx 4.166666667 \times 10^{-6} > 10^{-6}$$

but with $n = 4$

$$\frac{1}{10^5\cdot 120} = \frac{1}{12{,}000{,}000} \approx 8.333333333 \times 10^{-8} < 10^{-6}$$

Thus $n = 4$ will guarantee the desired accuracy. Using technology to compute $T_4(x)$ and evalute,

$$T_4(-0.1) \approx 0.9048375000, \qquad e^{-0.1} \approx 0.9048374180$$

and

$$|e^{-0.1} - T_4(-0.1)| \approx 8.2 \times 10^{-8} < 10^{-6}$$

45. Let $f(x) = e^{-x}$ and $T_3(x) = 1 - x + \dfrac{x^2}{2} - \dfrac{x^3}{6}$. Use the error bound to show that for all $x \geq 0$,

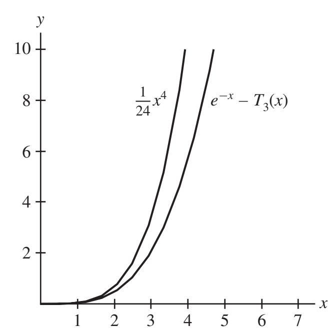
$$|f(x) - T_3(x)| \leq \frac{x^4}{24}$$

If you have a GU, illustrate this inequality by plotting $f(x) - T_3(x)$ and $x^4/24$ together over [0, 1].

SOLUTION Note that $f^{(n)}(x) = \pm e^{-x}$, so that $|f^{(n)}(x)| = f(x)$. Now, $f(x)$ is a decreasing function for $x \geq 0$, so that for any $c > 0$, $|f^{(n)}(x)|$ takes its maximum value at $x = 0$; this value is $e^0 = 1$. Thus we may take $K = 1$ in the error bound equation. Thus for any x,

$$|f(x) - T_3(x)| \leq K\frac{|x-0|^4}{4!} = \frac{x^4}{24}$$

A plot of $f(x) - T_3(x)$ and $\frac{x^4}{24}$ is shown below.



46. Use the error bound with $n = 4$ to show that

$$\left|\sin x - \left(x - \frac{x^3}{6}\right)\right| \leq \frac{|x|^5}{120} \quad \text{(for all } x\text{)}$$

SOLUTION Note that all derivatives of $\sin x$ are either $\pm\cos x$ or $\pm\sin x$ so are bounded in absolute value by 1. Thus we may take $K = 1$ in the Error Bound. Now,

$$T_4(x) = x - \frac{x^3}{3!}$$

so that

$$|\sin x - T_4(x)| = \left|\sin x - \left(x - \frac{x^3}{6}\right)\right| \leq K\frac{|x-0|^5}{5!} = \frac{|x|^5}{120}$$

47. Let $T_n(x)$ be the Taylor polynomial for $f(x) = \ln x$ at $a = 1$, and let $c > 1$. Show that

$$|\ln c - T_n(c)| \leq \frac{|c-1|^{n+1}}{n+1}$$

Then find a value of n such that $|\ln 1.5 - T_n(1.5)| \leq 10^{-2}$.

SOLUTION With $f(x) = \ln x$, we have

$$f'(x) = x^{-1},\ f''(x) = -x^{-2},\ f'''(x) = 2x^{-3},\ f^{(4)}(x) = -6x^{-4},$$

and, in general,

$$f^{(k+1)}(x) = (-1)^k k!\, x^{-k-1}.$$

Notice that $|f^{(k+1)}(x)| = k!|x|^{-k-1}$ is a decreasing function for $x > 0$. Therefore, the maximum value of $|f^{(k+1)}(x)|$ on $[1, c]$ is $|f^{(k+1)}(1)|$. Using the Error Bound, we have

$$|\ln c - T_n(c)| \leq K\frac{|c-1|^{n+1}}{(n+1)!},$$

where K is a number such that $|f^{(n+1)}(x)| \leq K$ for x between 1 and c. From part (a), we know that we may take $K = |f^{(n+1)}(1)| = n!$. Then

$$|\ln c - T_n(c)| \leq n!\frac{|c-1|^{n+1}}{(n+1)!} = \frac{|c-1|^{n+1}}{n+1}.$$

Evaluating at $c = 1.5$ gives

$$|\ln 1.5 - T_n(1.5)| \leq \frac{|1.5-1|^{n+1}}{n+1} = \frac{(0.5)^{n+1}}{n+1}.$$

With $n = 3$,

$$\frac{(0.5)^4}{4} = 0.015625 > 10^{-2}.$$

but with $n = 4$,

$$\frac{(0.5)^5}{5} = 0.00625 < 10^{-2}.$$

Hence, $n = 4$ will guarantee the desired accuracy.

48. Let $n \geq 1$. Show that if $|x|$ is small, then

$$(x+1)^{1/n} \approx 1 + \frac{x}{n} + \frac{1-n}{2n^2}x^2$$

Use this approximation with $n = 6$ to estimate $1.5^{1/6}$.

SOLUTION Let $f(x) = (x+1)^{1/n}$. Then

$$\begin{aligned} f(x) &= (x+1)^{1/n} & f(0) &= 1 \\ f'(x) &= \frac{1}{n}(x+1)^{1/n-1} & f'(0) &= \frac{1}{n} \\ f''(x) &= \frac{1}{n}\left(\frac{1}{n}-1\right)(x+1)^{1/n-2} & f''(0) &= \frac{1}{n}\left(\frac{1}{n}-1\right) \end{aligned}$$

and

$$T_2(x) = 1 + \frac{1}{n}(x) + \left(\frac{1}{n^2} - \frac{1}{n}\right)\frac{x^2}{2} = 1 + \frac{x}{n} + \left(\frac{1-n}{2n^2}\right)x^2.$$

With $n = 6$ and $x = 0.5$,

$$1.5^{1/6} \approx T_2(0.5) = \frac{307}{288} \approx 1.065972.$$

49. Verify that the third Maclaurin polynomial for $f(x) = e^x \sin x$ is equal to the product of the third Maclaurin polynomials of e^x and $\sin x$ (after discarding terms of degree greater than 3 in the product).

SOLUTION Let $f(x) = e^x \sin x$. Then

$$\begin{aligned} f(x) &= e^x \sin x & f(0) &= 0 \\ f'(x) &= e^x(\cos x + \sin x) & f'(0) &= 1 \\ f''(x) &= 2e^x \cos x & f''(0) &= 2 \\ f'''(x) &= 2e^x(\cos x - \sin x) & f'''(0) &= 2 \end{aligned}$$

and

$$T_3(x) = 0 + (1)x + \frac{2}{2!}x^2 + \frac{2}{3!}x^3 = x + x^2 + \frac{x^3}{3}.$$

Now, the third Maclaurin polynomial for e^x is $1 + x + \frac{x^2}{2} + \frac{x^3}{6}$, and the third Maclaurin polynomial for $\sin x$ is $x - \frac{x^3}{6}$. Multiplying these two polynomials, and then discarding terms of degree greater than 3, yields

$$e^x \sin x \approx x + x^2 + \frac{x^3}{3},$$

which agrees with the Maclaurin polynomial obtained from the definition.

50. Find the fourth Maclaurin polynomial for $f(x) = \sin x \cos x$ by multiplying the fourth Maclaurin polynomials for $f(x) = \sin x$ and $f(x) = \cos x$.

SOLUTION The fourth Maclaurin polynomial for $\sin x$ is $x - \frac{x^3}{6}$, and the fourth Maclaurin polynomial for $\cos x$ is $1 - \frac{x^2}{2} + \frac{x^4}{24}$. Multiplying these two polynomials, and then discarding terms of degree greater than 4, we find that the fourth Maclaurin polynomial for $f(x) = \sin x \cos x$ is

$$T_4(x) = x - \frac{2x^3}{3}.$$

51. Find the Maclaurin polynomials $T_n(x)$ for $f(x) = \cos(x^2)$. You may use the fact that $T_n(x)$ is equal to the sum of the terms up to degree n obtained by substituting x^2 for x in the nth Maclaurin polynomial of $\cos x$.

SOLUTION The Maclaurin polynomials for $\cos x$ are of the form

$$T_{2n}(x) = 1 - \frac{x^2}{2} + \frac{x^4}{4!} + \cdots + (-1)^n \frac{x^{2n}}{(2n)!}.$$

Accordingly, the Maclaurin polynomials for $\cos(x^2)$ are of the form

$$T_{4n}(x) = 1 - \frac{x^4}{2} + \frac{x^8}{4!} + \cdots + (-1)^n \frac{x^{4n}}{(2n)!}.$$

52. Find the Maclaurin polynomials of $1/(1 + x^2)$ by substituting $-x^2$ for x in the Maclaurin polynomials of $1/(1 - x)$.

SOLUTION The Maclaurin polynomials for $\frac{1}{1-x}$ are of the form

$$T_n(x) = 1 + x + x^2 + \cdots + x^n.$$

Accordingly, the Maclaurin polynomials for $\frac{1}{1+x^2}$ are of the form

$$T_{2n}(x) = 1 - x^2 + x^4 - x^6 + \cdots + (-x^2)^n.$$

53. Let $f(x) = 3x^3 + 2x^2 - x - 4$. Calculate $T_j(x)$ for $j = 1, 2, 3, 4, 5$ at both $a = 0$ and $a = 1$. Show that $T_3(x) = f(x)$ in both cases.

SOLUTION Let $f(x) = 3x^3 + 2x^2 - x - 4$. Then

$$\begin{array}{lll}
f(x) = 3x^3 + 2x^2 - x - 4 & f(0) = -4 & f(1) = 0 \\
f'(x) = 9x^2 + 4x - 1 & f'(0) = -1 & f'(1) = 12 \\
f''(x) = 18x + 4 & f''(0) = 4 & f''(1) = 22 \\
f'''(x) = 18 & f'''(0) = 18 & f'''(1) = 18 \\
f^{(4)}(x) = 0 & f^{(4)}(0) = 0 & f^{(4)}(1) = 0 \\
f^{(5)}(x) = 0 & f^{(5)}(0) = 0 & f^{(5)}(1) = 0
\end{array}$$

At $a = 0$,

$$\begin{aligned}
&T_1(x) = -4 - x; \\
&T_2(x) = -4 - x + 2x^2; \\
&T_3(x) = -4 - x + 2x^2 + 3x^3 = f(x); \\
&T_4(x) = T_3(x); \text{ and} \\
&T_5(x) = T_3(x).
\end{aligned}$$

At $a = 1$,

$$T_1(x) = 12(x-1);$$
$$T_2(x) = 12(x-1) + 11(x-1)^2;$$
$$T_3(x) = 12(x-1) + 11(x-1)^2 + 3(x-1)^3 = -4 - x + 2x^2 + 3x^3 = f(x);$$
$$T_4(x) = T_3(x); \text{ and}$$
$$T_5(x) = T_3(x).$$

54. Let $T_n(x)$ be the nth Taylor polynomial at $x = a$ for a polynomial $f(x)$ of degree n. Based on the result of Exercise 53, guess the value of $|f(x) - T_n(x)|$. Prove that your guess is correct using the error bound.

SOLUTION Based on Exercise 53, we expect $|f(x) - T_n(x)| = 0$. From the Error Bound,

$$|f(x) - T_n(x)| \le K \frac{|x-a|^{n+1}}{(n+1)!},$$

where K is a number such that $|f^{(n+1)}(u)| \le K$ for u between a and x. Since $f^{(n+1)}(x) = 0$ for an nth degree polynomial, we may take $K = 0$; the Error Bound then becomes $|f(x) - T_n(x)| = 0$.

55. Let $s(t)$ be the distance of a truck to an intersection. At time $t = 0$, the truck is 60 meters from the intersection, is traveling at a velocity of 24 m/s, and begins to slow down with an acceleration of $a = -3$ m/s^2. Determine the second Maclaurin polynomial of $s(t)$, and use it to estimate the truck's distance from the intersection after 4 s.

SOLUTION Place the origin at the intersection, so that $s(0) = 60$ (the truck is traveling away from the intersection). The second Maclaurin polynomial of $s(t)$ is

$$T_2(t) = s(0) + s'(0)t + \frac{s''(0)}{2}t^2$$

The conditions of the problem tell us that $s(0) = 60$, $s'(0) = 24$, and $s''(0) = -3$. Thus

$$T_2(t) = 60 + 24t - \frac{3}{2}t^2$$

so that after 4 seconds,

$$T_2(4) = 60 + 24 \cdot 4 - \frac{3}{2} \cdot 4^2 = 132 \text{ m}$$

The truck is 132 m past the intersection.

56. A bank owns a portfolio of bonds whose value $P(r)$ depends on the interest rate r (measured in percent; for example, $r = 5$ means a 5% interest rate). The bank's quantitative analyst determines that

$$P(5) = 100{,}000, \qquad \left.\frac{dP}{dr}\right|_{r=5} = -40{,}000, \qquad \left.\frac{d^2P}{dr^2}\right|_{r=5} = 50{,}000$$

In finance, this second derivative is called **bond convexity**. Find the second Taylor polynomial of $P(r)$ centered at $r = 5$ and use it to estimate the value of the portfolio if the interest rate moves to $r = 5.5\%$.

SOLUTION The second Taylor polynomial of $P(r)$ at $r = 5$ is

$$T_2(r) = P(5) + P'(5)(r-5) + \frac{P''(5)}{2}(r-5)^2$$

From the conditions of the problem, $P(5) = 100{,}000$, $P'(5) = -40{,}000$, and $P''(5) = 50{,}000$, so that

$$T_2(r) = 100{,}000 - 40{,}000(r-5) + 25{,}000(r-5)^2$$

If the interest rate moves to 5.5%, then the value of the portfolio can be estimated by

$$T_2(5.5) = 100{,}000 - 40{,}000(0.5) + 25{,}000(0.5)^2 = 86{,}250$$

57. A narrow, negatively charged ring of radius R exerts a force on a positively charged particle P located at distance x above the center of the ring of magnitude

$$F(x) = -\frac{kx}{(x^2+R^2)^{3/2}}$$

where $k > 0$ is a constant (Figure 12).

(a) Compute the third-degree Maclaurin polynomial for $F(x)$.

(b) Show that $F \approx -(k/R^3)x$ to second order. This shows that when x is small, $F(x)$ behaves like a restoring force similar to the force exerted by a spring.

(c) Show that $F(x) \approx -k/x^2$ when x is large by showing that

$$\lim_{x\to\infty} \frac{F(x)}{-k/x^2} = 1$$

Thus, $F(x)$ behaves like an inverse square law, and the charged ring looks like a point charge from far away.

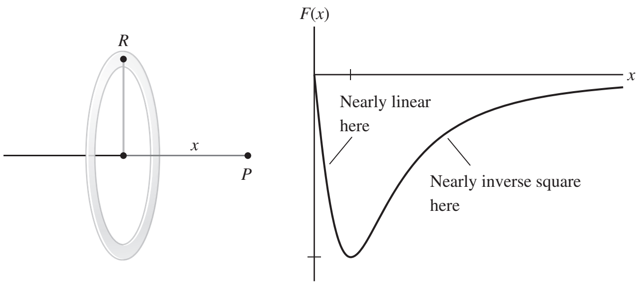


FIGURE 12

SOLUTION

(a) Start by computing and evaluating the necessary derivatives:

$$F(x) = -\frac{kx}{(x^2+R^2)^{3/2}} \qquad F(0) = 0$$

$$F'(x) = \frac{k(2x^2-R^2)}{(x^2+R^2)^{5/2}} \qquad F'(0) = -\frac{k}{R^3}$$

$$F''(x) = \frac{3kx(3R^2-2x^2)}{(x^2+R^2)^{7/2}} \qquad F''(0) = 0$$

$$F'''(x) = \frac{3k(8x^4-24x^2R^2+3R^4)}{(x^2+R^2)^{9/2}} \qquad F'''(0) = \frac{9k}{R^5}$$

so that

$$T_3(x) = F(0) + F'(0)x + \frac{F''(0)}{2!}x^2 + \frac{F'''(0)}{3!}x^3 = -\frac{k}{R^3}x + \frac{3k}{2R^5}x^3$$

(b) To degree 2, $F(x) \approx T_3(x) \approx -\frac{k}{R^3}x$ as we may ignore the x^3 term of $T_3(x)$.

(c) We have

$$\lim_{x\to\infty}\frac{F(x)}{-k/x^2} = \lim_{x\to\infty}\left(-\frac{x^2}{k}\cdot\frac{-kx}{(x^2+R^2)^{3/2}}\right) = \lim_{x\to\infty}\frac{x^3}{(x^2+R^2)^{3/2}}$$

$$= \lim_{x\to\infty}\frac{1}{x^{-3}(x^2+R^2)^{3/2}} = \lim_{x\to\infty}\frac{1}{(1+R^2/x^2)^{3/2}}$$

$$= 1$$

Thus as x grows large, $F(x)$ looks like an inverse square function.

58. A light wave of wavelength λ travels from A to B by passing through an aperture (circular region) located in a plane that is perpendicular to $\overline{AB}$ (see Figure 13 for the notation). Let $f(r) = d' + h'$; that is, $f(r)$ is the distance $AC + CB$ as a function of r.

(a) Show that $f(r) = \sqrt{d^2+r^2} + \sqrt{h^2+r^2}$, and use the Maclaurin polynomial of order 2 to show that

$$f(r) \approx d + h + \frac{1}{2}\left(\frac{1}{d}+\frac{1}{h}\right)r^2$$

(b) The **Fresnel zones**, used to determine the optical disturbance at B, are the concentric bands bounded by the circles of radius R_n such that $f(R_n) = d + h + n\lambda/2$. Show that $R_n \approx \sqrt{n\lambda L}$, where $L = (d^{-1}+h^{-1})^{-1}$.

(c) Estimate the radii R_1 and R_{100} for blue light ($\lambda = 475 \times 10^{-7}$ cm) if $d = h = 100$ cm.

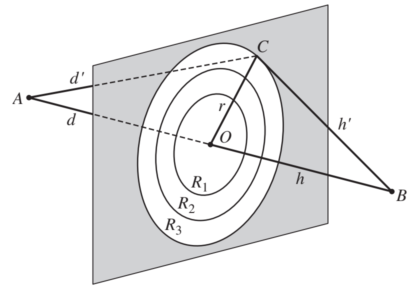

FIGURE 13 The Fresnel zones are the regions between the circles of radius R_n.

SOLUTION

(a) From the diagram, we see that $\overline{AC} = \sqrt{d^2 + r^2}$ and $\overline{CB} = \sqrt{h^2 + r^2}$. Therefore, $f(r) = \sqrt{d^2 + r^2} + \sqrt{h^2 + r^2}$. Moreover,

$$f'(r) = \frac{r}{\sqrt{d^2 + r^2}} + \frac{r}{\sqrt{h^2 + r^2}}, \quad f''(r) = \frac{d^2}{(d^2 + r^2)^{3/2}} + \frac{h^2}{(h^2 + r^2)^{3/2}},$$

$f(0) = d + h$, $f'(0) = 0$ and $f''(0) = d^{-1} + h^{-1}$. Thus,

$$f(r) \approx T_2(r) = d + h + \frac{1}{2}\left(\frac{1}{d} + \frac{1}{h}\right) r^2.$$

(b) Solving

$$f(R_n) \approx d + h + \frac{1}{2}\left(\frac{1}{d} + \frac{1}{h}\right) R_n^2 = d + h + \frac{n\lambda}{2}$$

yields

$$R_n = \sqrt{n\lambda(d^{-1} + h^{-1})^{-1}} = \sqrt{n\lambda L},$$

where $L = (d^{-1} + h^{-1})^{-1}$.

(c) With $d = h = 100$ cm, $L = 50$ cm. Taking $\lambda = 475 \times 10^{-7}$ cm, it follows that

$$R_1 \approx \sqrt{\lambda L} = 0.04873 \text{ cm; and}$$
$$R_{100} \approx \sqrt{100\lambda L} = 0.4873 \text{ cm.}$$

59. Referring to Figure 14, let a be the length of the chord $\overline{AC}$ of angle θ of the unit circle. Derive the following approximation for the excess of the arc over the chord.

$$\theta - a \approx \frac{\theta^3}{24}$$

Hint: Show that $\theta - a = \theta - 2\sin(\theta/2)$ and use the third Maclaurin polynomial as an approximation.

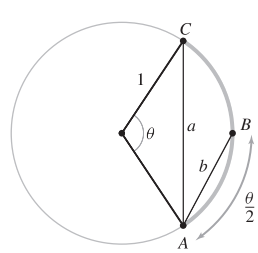

FIGURE 14 Unit circle.

SOLUTION Draw a line from the center O of the circle to B, and label the point of intersection of this line with AC as D. Then $CD = \frac{a}{2}$, and the angle COB is $\frac{\theta}{2}$. Since $CO = 1$, we have

$$\sin\frac{\theta}{2} = \frac{a}{2}$$

so that $a = 2\sin(\theta/2)$. Thus $\theta - a = \theta - 2\sin(\theta/2)$. Now, the third Maclaurin polynomial for $f(\theta) = \sin(\theta/2)$ can be computed as follows: $f(0) = 0$, $f'(x) = \frac{1}{2}\cos(\theta/2)$ so that $f'(0) = \frac{1}{2}$. $f''(x) = -\frac{1}{4}\sin(\theta/2)$ and $f''(0) = 0$. Finally, $f'''(x) = -\frac{1}{8}\cos(\theta/2)$ and $f'''(0) = -\frac{1}{8}$. Thus

$$T_3(\theta) = f(0) + f'(0)\theta + \frac{f''(0)}{2!}\theta^2 + \frac{f'''(0)}{3!}\theta^3 = \frac{1}{2}\theta - \frac{1}{48}\theta^3$$

Finally,

$$\theta - a = \theta - 2\sin\frac{\theta}{2} \approx \theta - 2T_3(\theta) = \theta - \left(\theta - \frac{1}{24}\theta^3\right) = \frac{\theta^3}{24}$$

60. To estimate the length θ of a circular arc of the unit circle, the seventeenth-century Dutch scientist Christian Huygens used the approximation $\theta \approx (8b - a)/3$, where a is the length of the chord $\overline{AC}$ of angle θ and b is length of the chord $\overline{AB}$ of angle $\theta/2$ (Figure 14).

(a) Prove that $a = 2\sin(\theta/2)$ and $b = 2\sin(\theta/4)$, and show that the Huygens approximation amounts to the approximation

$$\theta \approx \frac{16}{3}\sin\frac{\theta}{4} - \frac{2}{3}\sin\frac{\theta}{2}$$

(b) Compute the fifth Maclaurin polynomial of the function on the right.

(c) Use the error bound to show that the error in the Huygens approximation is less than $0.00022|\theta|^5$.

SOLUTION

(a) By the Law of Cosines and the identity $\sin^2(\theta/2) = (1 - \cos\theta)/2$:

$$a^2 = 1^2 + 1^2 - 2\cos\theta = 2(1 - \cos\theta) = 4\sin^2\frac{\theta}{2}$$

and so $a = 2\sin(\theta/2)$. Similarly, $b = 2\sin(\theta/4)$. Substituting these expressions for a and b into the Huygens approximation yields

$$\theta \approx \frac{8}{3}\cdot 2\sin\frac{\theta}{4} - \frac{1}{3}\cdot 2\sin\frac{\theta}{2} = \frac{16}{3}\sin\frac{\theta}{4} - \frac{2}{3}\sin\frac{\theta}{2}.$$

(b) The fifth Maclaurin polynomial for $\sin x$ is $x - \frac{x^3}{6} + \frac{x^5}{120}$; therefore, the fifth Maclaurin polynomial for $\sin(\theta/2)$ is

$$\frac{\theta}{2} - \frac{(\theta/2)^3}{6} + \frac{(\theta/2)^5}{120} = \frac{\theta}{2} - \frac{\theta^3}{48} + \frac{\theta^5}{3840},$$

and the fifth Maclaurin polynomial for $\sin(\theta/4)$ is

$$\frac{\theta}{4} - \frac{(\theta/4)^3}{6} + \frac{(\theta/4)^5}{120} = \frac{\theta}{4} - \frac{\theta^3}{384} + \frac{\theta^5}{122{,}880}.$$

Thus, the fifth Maclaurin polynomial for $f(\theta) = \frac{16}{3}\sin\frac{\theta}{4} - \frac{2}{3}\sin\frac{\theta}{2}$ is

$$\theta - \frac{1}{7680}\theta^5.$$

(c) Based on the result from part (b), the Huygens approximation for θ is equal to the fourth Maclaurin polynomial $T_4(\theta)$ for $f(\theta)$, and the error is at most $K|\theta|^5/5!$, where K is the maximum value of the absolute value of the fifth derivative $f^{(5)}(\theta)$. Because

$$f^{(5)}(\theta) = \frac{1}{192}\cos\frac{\theta}{4} - \frac{1}{48}\cos\frac{\theta}{2},$$

we may take $K = 1/48 + 1/192 = 0.0260417$, so the error is at most $|\theta|^5$ times the constant

$$\frac{0.0261}{5!} = 0.00022.$$

Further Insights and Challenges

61. Show that the nth Maclaurin polynomial of $f(x) = \arcsin x$ for n odd is

$$T_n(x) = x + \frac{1}{2}\frac{x^3}{3} + \frac{1\cdot 3}{2\cdot 4}\frac{x^5}{5} + \cdots + \frac{1\cdot 3\cdot 5\cdots(n-2)}{2\cdot 4\cdot 6\cdots(n-1)}\frac{x^n}{n}$$

SOLUTION Let $f(x) = \sin^{-1} x$. Then

$$\begin{aligned}
f(x) &= \sin^{-1} x & f(0) &= 0 \\
f'(x) &= \frac{1}{\sqrt{1-x^2}} & f'(0) &= 1 \\
f''(x) &= -\frac{1}{2}(1-x^2)^{-3/2}(-2x) & f''(0) &= 0 \\
f'''(x) &= \frac{2x^2+1}{(1-x^2)^{5/2}} & f'''(0) &= 1 \\
f^{(4)}(x) &= \frac{-3x(2x^2+3)}{(1-x^2)^{7/2}} & f^{(4)}(0) &= 0 \\
f^{(5)}(x) &= \frac{24x^4+72x^2+9}{(1-x^2)^{9/2}} & f^{(5)}(0) &= 9 \\
&\vdots & &\vdots \\
& & f^{(7)}(0) &= 225
\end{aligned}$$

and

$$T_7(x) = x + \frac{x^3}{3!} + \frac{9x^5}{5!} + \frac{225x^7}{7!} = x + \frac{1}{2}\frac{x^3}{3} + \frac{1}{2}\frac{3}{4}\frac{x^5}{5} + \frac{1}{2}\frac{3}{4}\frac{5}{6}\frac{x^7}{7}.$$

Thus, we can infer that

$$T_n(x) = x + \frac{1}{2}\cdot\frac{x^3}{3} + \frac{1}{2}\frac{3}{4}\frac{x^5}{5} + \frac{1}{2}\frac{3}{4}\frac{5}{6}\frac{x^7}{7} + \cdots + \frac{1}{2}\frac{3}{4}\cdots\frac{n-2}{n-1}\frac{x^n}{n}.$$

62. Let $x \ge 0$ and assume that $f^{(n+1)}(t) \ge 0$ for $0 \le t \le x$. Use Taylor's Theorem to show that the nth Maclaurin polynomial $T_n(x)$ satisfies

$$T_n(x) \le f(x) \quad \text{for all } x \ge 0$$

SOLUTION From Taylor's Theorem,

$$R_n(x) = f(x) - T_n(x) = \frac{1}{n!}\int_0^x (x-u)^n f^{(n+1)}(u)\,du.$$

If $f^{(n+1)}(t) \ge 0$ for all t then

$$\frac{1}{n!}\int_0^x (x-u)^n f^{(n+1)}(u)\,du \ge 0$$

since $(x-u)^n \ge 0$ for $0 \le u \le x$. Thus, $f(x) - T_n(x) \ge 0$, or $f(x) \ge T_n(x)$.

63. Use Exercise 62 to show that for $x \ge 0$ and all n,

$$e^x \ge 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!}$$

Sketch the graphs of e^x, $T_1(x)$, and $T_2(x)$ on the same coordinate axes. Does this inequality remain true for $x < 0$?

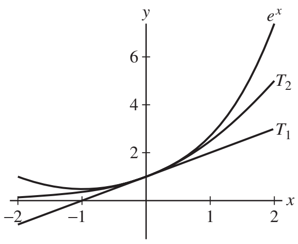
SOLUTION Let $f(x) = e^x$. Then $f^{(n)}(x) = e^x$ for all n. Because $e^x > 0$ for all x, it follows from Exercise 62 that $f(x) \ge T_n(x)$ for all $x \ge 0$ and for all n. For $f(x) = e^x$,

$$T_n(x) = 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!},$$

thus,

$$e^x \ge 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!}.$$

From the figure below, we see that the inequality does not remain true for $x < 0$, as $T_2(x) \ge e^x$ for $x < 0$.



64. This exercise is intended to reinforce the proof of Taylor's Theorem.

(a) Show that $f(x) = T_0(x) + \int_a^x f'(u)\,du$.

(b) Use Integration by Parts to prove the formula

$$\int_a^x (x-u) f^{(2)}(u)\,du = -f'(a)(x-a) + \int_a^x f'(u)\,du$$

(c) Prove the case $n = 2$ of Taylor's Theorem:

$$f(x) = T_1(x) + \int_a^x (x-u) f^{(2)}(u)\,du.$$

SOLUTION

(a)

$$T_0(x) + \int_a^x f'(u)\,du = T_0(x) + f(x) - f(a) \quad \text{(from FTC2)}$$
$$= f(a) + f(x) - f(a) = f(x).$$

(b) Using Integration by Parts with $w = x - u$ and $v' = f''(u)\,du$,

$$\int_a^x (x-u) f''(u)\,du = f'(u)(x-u)\Big|_a^x + \int_a^x f'(u)\,du$$
$$= f'(x)(x-x) - f'(a)(x-a) + \int_a^x f'(u)\,du$$
$$= -f'(a)(x-a) + \int_a^x f'(u)\,du.$$

(c)

$$T_1(x) + \int_a^x (x-u) f''(u)\,du = f(a) + f'(a)(x-a) + \big(-f'(a)(x-a)\big) + \int_a^x f'(u)\,du$$
$$= f(a) + f(x) - f(a) = f(x).$$

In Exercises 65–69, we estimate integrals using Taylor polynomials. Exercise 66 is used to estimate the error.

65. Find the fourth Maclaurin polynomial $T_4(x)$ for $f(x) = e^{-x^2}$, and calculate $I = \int_0^{1/2} T_4(x)\,dx$ as an estimate $\int_0^{1/2} e^{-x^2}\,dx$. A CAS yields the value $I \approx 0.4794255$. How large is the error in your approximation? *Hint:* $T_4(x)$ is obtained by substituting $-x^2$ in the second Maclaurin polynomial for e^x.

SOLUTION Following the hint, since the second Maclaurin polynomial for e^x is

$$1 + x + \frac{x^2}{2}$$

we substitute $-x^2$ for x to get the fourth Maclaurin polynomial for e^{x^2}:

$$T_4(x) = 1 - x^2 + \frac{x^4}{2}$$

Then

$$\int_0^{1/2} e^{-x^2}\,dx \approx \int_0^{1/2} T_4(x)\,dx = \left(x - \frac{1}{3}x^3 + \frac{1}{10}x^5\right)\Big|_0^{1/2} = \frac{443}{960} \approx 0.4614583333$$

Using a CAS, we have $\int_0^{1/2} e^{-x^2}\,dx \approx 0.4612810064$, so the error is about 1.77×10^{-4}.

66. Approximating Integrals Let $L > 0$. Show that if two functions $f(x)$ and $g(x)$ satisfy $|f(x) - g(x)| < L$ for all $x \in [a, b]$, then

$$\left| \int_a^b f(x)\,dx - \int_a^b g(x)\,dx \right| < L(b-a)$$

SOLUTION Because $f(x) - g(x) \le |f(x) - g(x)|$, it follows that

$$\left| \int_a^b f(x)\,dx - \int_a^b g(x)\,dx \right| = \left| \int_a^b (f(x) - g(x))\,dx \right| \le \int_a^b |f(x) - g(x)|\,dx$$
$$< \int_a^b L\,dx = L(b-a).$$

67. Let $T_4(x)$ be the fourth Maclaurin polynomial for $\cos x$.

(a) Show that $|\cos x - T_4(x)| \le \left(\frac{1}{2}\right)^6/6!$ for all $x \in \left[0, \frac{1}{2}\right]$. *Hint:* $T_4(x) = T_5(x)$.

(b) Evaluate $\int_0^{1/2} T_4(x)\,dx$ as an approximation to $\int_0^{1/2} \cos x\,dx$. Use Exercise 66 to find a bound for the size of the error.

SOLUTION

(a) Let $f(x) = \cos x$. Then

$$T_4(x) = 1 - \frac{x^2}{2} + \frac{x^4}{24}.$$

Moreover, with $a = 0$, $T_4(x) = T_5(x)$ and

$$|\cos x - T_4(x)| \le K\frac{|x|^6}{6!},$$

where K is a number such that $|f^{(6)}(u)| \le K$ for u between 0 and x. Now $|f^{(6)}(u)| = |\cos u| \le 1$, so we may take $K = 1$. Finally, with the restriction $x \in [0, \frac{1}{2}]$,

$$|\cos x - T_4(x)| \le \frac{(1/2)^6}{6!} \approx 0.000022.$$

(b)

$$\int_0^{1/2} \left(1 - \frac{x^2}{2} + \frac{x^4}{24}\right) dx = \frac{1841}{3840} \approx 0.479427.$$

By (a) and Exercise 66, the error associated with this approximation is less than or equal to

$$\frac{(1/2)^6}{6!}\left(\frac{1}{2} - 0\right) = \frac{1}{92{,}160} \approx 1.1 \times 10^{-5}.$$

Note that $\displaystyle\int_0^{1/2} \cos x\,dx \approx 0.4794255$, so the actual error is roughly 1.5×10^{-6}.

68. Let $Q(x) = 1 - x^2/6$. Use the error bound for $\sin x$ to show that

$$\left| \frac{\sin x}{x} - Q(x) \right| \le \frac{|x|^4}{5!}$$

Then calculate $\int_0^1 Q(x)\,dx$ as an approximation to $\int_0^1 (\sin x/x)\,dx$ and find a bound for the error.

SOLUTION The third Maclaurin polynomial for $\sin x$ is

$$T_3(x) = x - \frac{1}{3!}x^3 = x - \frac{1}{6}x^3 = xQ(x)$$

Additionally, this is also $T_4(x)$ since $(\sin x)^{(4)}(0) = 0$. All derivatives of $\sin x$ are either $\pm\sin x$ or $\pm\cos x$, which are bounded in absolute value by 1. Thus we may take $K = 1$ in the Error Bound, so

$$|\sin x - xQ(x)| = |\sin x - T_3(x)| = |\sin x - T_4(x)| \le K\frac{|x|^5}{5!} = \frac{|x|^5}{5!}$$

Divide both sides of this inequality by $|x|$ to get

$$\left|\frac{\sin x}{x} - Q(x)\right| \le \frac{|x|^4}{5!}$$

We can thus estimate $\int_0^1 (\sin x/x)\,dx$ by

$$\int_0^1 Q(x)\,dx = \int_0^1 1 - \frac{x^2}{6}\,dx = \left(x - \frac{x^3}{18}\right)\Bigg|_0^1 = \frac{17}{18} \approx 0.9444444444$$

The error in this approximation is at most

$$\frac{|1|^4}{5!} = \frac{1}{120} \approx 0.008333333333$$

The true value of the integral is approximately 0.9460830704, which is consistent with the error bound.

69. **(a)** Compute the sixth Maclaurin polynomial $T_6(x)$ for $\sin(x^2)$ by substituting x^2 in $P(x) = x - x^3/6$, the third Maclaurin polynomial for $\sin x$.

(b) Show that $|\sin(x^2) - T_6(x)| \le \dfrac{|x|^{10}}{5!}$.

Hint: Substitute x^2 for x in the error bound for $|\sin x - P(x)|$, noting that $P(x)$ is also the fourth Maclaurin polynomial for $\sin x$.

(c) Use $T_6(x)$ to approximate $\displaystyle\int_0^{1/2} \sin(x^2)\,dx$ and find a bound for the error.

SOLUTION Let $s(x) = \sin x$ and $f(x) = \sin(x^2)$. Then

(a) The third Maclaurin polynomial for $\sin x$ is

$$S_3(x) = x - \frac{x^3}{6}$$

so, substituting x^2 for x, we see that the sixth Maclaurin polynomial for $\sin(x^2)$ is

$$T_6(x) = x^2 - \frac{x^6}{6}$$

(b) Since all derivatives of $s(x)$ are either $\pm\cos x$ or $\pm\sin x$, they are bounded in magnitude by 1, so we may take $K = 1$ in the Error Bound for $\sin x$. Since the third Maclaurin polynomial $S_3(x)$ for $\sin x$ is also the fourth Maclaurin polynomial $S_4(x)$, we have

$$|\sin x - S_3(x)| = |\sin x - S_4(x)| \le K\frac{|x|^5}{5!} = \frac{|x|^5}{5!}$$

Now substitute x^2 for x in the above inequality and note from part (a) that $S_3(x^2) = T_6(x)$ to get

$$|\sin(x^2) - S_3(x^2)| = |\sin(x^2) - T_6(x)| \le \frac{|x^2|^5}{5!} = \frac{|x|^{10}}{5!}$$

(c)

$$\int_0^{1/2} \sin(x^2)\,dx \approx \int_0^{1/2} T_6(x)\,dx = \left(\frac{1}{3}x^3 - \frac{1}{42}x^7\right)\Bigg|_0^{1/2} \approx 0.04148065476$$

From part (b), the error is bounded by

$$\frac{x^{10}}{5!} = \frac{(1/2)^{10}}{120} = \frac{1}{1024 \cdot 120} \approx 8.138020833 \times 10^{-6}$$

The true value of the integral is approximately 0.04148102420, which is consistent with the computed error bound.

70. Prove by induction that for all k,

$$\frac{d^j}{dx^j}\left(\frac{(x-a)^k}{k!}\right) = \frac{k(k-1)\cdots(k-j+1)(x-a)^{k-j}}{k!}$$

$$\frac{d^j}{dx^j}\left(\frac{(x-a)^k}{k!}\right)\Bigg|_{x=a} = \begin{cases} 1 & \text{for } k = j \\ 0 & \text{for } k \ne j \end{cases}$$

Use this to prove that $T_n(x)$ agrees with $f(x)$ at $x = a$ to order n.

SOLUTION The first formula is clearly true for $j = 0$. Suppose the formula is true for an arbitrary j. Then

$$\frac{d^{j+1}}{dx^{j+1}}\left(\frac{(x-a)^k}{k!}\right) = \frac{d}{dx}\frac{d^j}{dx^j}\left(\frac{(x-a)^k}{k!}\right) = \frac{d}{dx}\left(\frac{k(k-1)\cdots(k-j+1)(x-a)^{k-j}}{k!}\right)$$
$$= \frac{k(k-1)\cdots(k-j+1)(k-(j+1)+1)(x-a)^{k-(j+1)}}{k!}$$

as desired. Note that if $k = j$, then the numerator is $k!$, the denominator is $k!$ and the value of the derivative is 1; otherwise, the value of the derivative is 0 at $x = a$. In other words,

$$\frac{d^j}{dx^j}\left(\frac{(x-a)^k}{k!}\right)\bigg|_{x=a} = \begin{cases} 1 & \text{for } k = j \\ 0 & \text{for } k \neq j \end{cases}$$

Applying this latter formula, it follows that

$$\frac{d^j}{dx^j}T_n(a)\bigg|_{x=a} = \sum_{k=0}^{n}\frac{d^j}{dx^j}\left(\frac{f^{(k)}(a)}{k!}(x-a)^k\right)\bigg|_{x=a} = f^{(j)}(a)$$

as required.

71. Let a be any number and let

$$P(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 + a_0$$

be a polynomial of degree n or less.

(a) Show that if $P^{(j)}(a) = 0$ for $j = 0, 1, \ldots, n$, then $P(x) = 0$, that is, $a_j = 0$ for all j. *Hint:* Use induction, noting that if the statement is true for degree $n-1$, then $P'(x) = 0$.

(b) Prove that $T_n(x)$ is the only polynomial of degree n or less that agrees with $f(x)$ at $x = a$ to order n. *Hint:* If $Q(x)$ is another such polynomial, apply (a) to $P(x) = T_n(x) - Q(x)$.

SOLUTION

(a) Note first that if $n = 0$, i.e. if $P(x) = a_0$ is a constant, then the statement holds: if $P^{(0)}(a) = P(a) = 0$, then $a_0 = 0$ so that $P(x) = 0$. Next, assume the statement holds for all polynomials of degree $n-1$ or less, and let $P(x)$ be a polynomial of degree at most n with $P^{(j)}(a) = 0$ for $j = 0, 1, \ldots, n$. If $P(x)$ has degree less than n, then we know $P(x) = 0$ by induction, so assume the degree of $P(x)$ is exactly n. Then

$$P(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$$

where $a_n \neq 0$; also,

$$P'(x) = na_n x^{n-1} + (n-1)a_{n-1}x^{n-2} + \cdots + a_1$$

Note that $P^{(j+1)}(a) = (P')^{(j)}(a)$ for $j = 0, 1, \ldots, n-1$. But then

$$0 = P^{(j+1)}(a) = (P')^{(j)}(a) \quad \text{for all } j = 0, 1, \ldots, n-1$$

Since $P'(x)$ has degree at most $n-1$, it follows by induction that $P'(x) = 0$. Thus $a_n = a_{n-1} = \cdots = a_1 = 0$ so that $P(x) = a_0$. But $P(a) = 0$ so that $a_0 = 0$ as well and thus $P(x) = 0$.

(b) Suppose $Q(x)$ is a polynomial of degree at most n that agrees with $f(x)$ at $x = a$ up to order n. Let $P(x) = T_n(x) - Q(x)$. Note that $P(x)$ is a polynomial of degree at most n since both $T_n(x)$ and $Q(x)$ are. Since both $T_n(x)$ and $Q(x)$ agree with $f(x)$ at $x = a$ to order n, we have

$$T_n^{(j)}(a) = f^{(j)}(a) = Q^{(j)}(a), \quad j = 0, 1, 2, \ldots, n$$

Thus

$$P^{(j)}(a) = T_n^{(j)}(a) - Q^{(j)}(a) = 0 \quad \text{for } j = 0, 1, 2, \ldots, n$$

But then by part (a), $P(x) = 0$ so that $T_n(x) = Q(x)$.

CHAPTER REVIEW EXERCISES

In Exercises 1–4, calculate the arc length over the given interval.

1. $y = \dfrac{x^5}{10} + \dfrac{x^{-3}}{6}, \quad [1, 2]$

SOLUTION Let $y = \dfrac{x^5}{10} + \dfrac{x^{-3}}{6}$. Then

$$1 + (y')^2 = 1 + \left(\frac{x^4}{2} - \frac{x^{-4}}{2}\right)^2 = 1 + \frac{x^8}{4} - \frac{1}{2} + \frac{x^{-8}}{4}$$
$$= \frac{x^8}{4} + \frac{1}{2} + \frac{x^{-8}}{4} = \left(\frac{x^4}{2} + \frac{x^{-4}}{2}\right)^2.$$

Because $\frac{1}{2}(x^4 + x^{-4}) > 0$ on $[1, 2]$, the arc length is

$$s = \int_1^2 \sqrt{1 + (y')^2}\, dx = \int_1^2 \left(\frac{x^4}{2} + \frac{x^{-4}}{2}\right) dx = \left(\frac{x^5}{10} - \frac{x^{-3}}{6}\right)\bigg|_1^2 = \frac{779}{240}.$$

2. $y = e^{x/2} + e^{-x/2}, \quad [0, 2]$

SOLUTION Let $y = e^{x/2} + e^{-x/2} = 2\cosh\frac{x}{2}$. Then, $y' = \sinh\frac{x}{2}$ and

$$\sqrt{1 + (y')^2} = \sqrt{1 + \sinh^2\frac{x}{2}} = \sqrt{\cosh^2\left(\frac{x}{2}\right)} = \cosh\frac{x}{2}.$$

Thus,

$$s = \int_0^2 \cosh\left(\frac{x}{2}\right) dx = 2\sinh\left(\frac{x}{2}\right)\bigg|_0^2 = 2\left(\sinh\left(\frac{2}{2}\right) - \sinh(0)\right) = 2\sinh(1).$$

Alternately, $y' = \frac{1}{2}(e^{x/2} - e^{-x/2})$, so

$$1 + (y')^2 = \frac{1}{4}(e^x - 2 + e^{-x}) + 1 = \frac{1}{4}(e^x + 2 + e^{-x}) = \left[\frac{1}{2}(e^{x/2} + e^{-x/2})\right]^2.$$

Because $\frac{1}{2}(e^{x/2} + e^{-x/2}) > 0$ on $[0, 2]$,

$$s = \int_0^2 \frac{1}{2}(e^{x/2} + e^{-x/2})\, dx = (e^{x/2} - e^{-x/2})\bigg|_0^2 = e - e^{-1} = 2\sinh(1).$$

3. $y = 4x - 2, \quad [-2, 2]$

SOLUTION Let $y = 4x - 2$. Then

$$\sqrt{1 + (y')^2} = \sqrt{1 + 4^2} = \sqrt{17}.$$

Hence,

$$s = \int_{-2}^2 \sqrt{17}\, dx = 4\sqrt{17}.$$

4. $y = x^{2/3}, \quad [1, 8]$

SOLUTION Let $y = x^{2/3}$. Then $y' = \frac{2}{3}x^{-1/3}$, and

$$\sqrt{1 + (y')^2} = \sqrt{1 + \frac{4}{9}x^{-2/3}} = \sqrt{\frac{4}{9}x^{-2/3}\left(\frac{9}{4}x^{2/3} + 1\right)} = \frac{2}{3}x^{-1/3}\sqrt{1 + \frac{9}{4}x^{2/3}}.$$

The arc length is

$$s = \int_1^2 \sqrt{1 + (y')^2}\, dx = \int_1^2 \frac{2}{3}x^{-1/3}\sqrt{1 + \frac{9}{4}x^{2/3}}\, dx.$$

Now, we make the substitution $u = 1 + \frac{9}{4}x^{2/3}$, $du = \frac{3}{2}x^{-1/3}\,dx$. Then

$$s = \int_{13/4}^{10} \sqrt{u} \cdot \frac{4}{9}\,du = \frac{8}{27}u^{3/2}\bigg|_{13/4}^{10} = \frac{8}{27}\left[10^{3/2} - \left(\frac{\sqrt{13}}{2}\right)^3\right]$$

$$= \frac{8}{27}\left(10\sqrt{10} - \frac{13\sqrt{13}}{8}\right) \approx 7.633705415.$$

5. Show that the arc length of $y = 2\sqrt{x}$ over $[0, a]$ is equal to $\sqrt{a(a+1)} + \ln(\sqrt{a} + \sqrt{a+1})$. *Hint:* Apply the substitution $x = \tan^2\theta$ to the arc length integral.

SOLUTION Let $y = 2\sqrt{x}$. Then $y' = \frac{1}{\sqrt{x}}$, and

$$\sqrt{1 + (y')^2} = \sqrt{1 + \frac{1}{x}} = \sqrt{\frac{x+1}{x}} = \frac{1}{\sqrt{x}}\sqrt{x+1}.$$

Thus,

$$s = \int_0^a \frac{1}{\sqrt{x}}\sqrt{1+x}\,dx.$$

We make the substitution $x = \tan^2\theta$, $dx = 2\tan\theta\sec^2\theta\,d\theta$. Then

$$s = \int_{x=0}^{x=a} \frac{1}{\tan\theta}\sec\theta \cdot 2\tan\theta\sec^2\theta\,d\theta = 2\int_{x=0}^{x=a}\sec^3\theta\,d\theta.$$

We use a reduction formula to obtain

$$s = 2\left(\frac{\tan\theta\sec\theta}{2} + \frac{1}{2}\ln|\sec\theta + \tan\theta|\right)\bigg|_{x=0}^{x=a} = (\sqrt{x}\sqrt{1+x} + \ln|\sqrt{1+x} + \sqrt{x}|)\bigg|_0^a$$

$$= \sqrt{a}\sqrt{1+a} + \ln|\sqrt{1+a} + \sqrt{a}| = \sqrt{a(a+1)} + \ln\left(\sqrt{a} + \sqrt{a+1}\right).$$

6. CAS Compute the trapezoidal approximation T_5 to the arc length s of $y = \tan x$ over $\left[0, \frac{\pi}{4}\right]$.

SOLUTION Let $y = \tan x$. With $N = 5$, the subintervals are $\left[(i-1)\frac{\pi}{20}, i\frac{\pi}{20}\right]$, $i = 1, 2, 3, 4, 5$. Now,

$$1 + (y')^2 = 1 + (\sec^2 x)^2 = 1 + \sec^4 x$$

so the arc length is approximately

$$s = \int_1^{\pi/4}\sqrt{1 + \sec^4 x}\,dx$$

$$\approx \frac{\pi}{40}\left(\sqrt{1+\sec^4 0} + 2\sqrt{1+\sec^4\frac{\pi}{20}} + 2\sqrt{1+\sec^4\frac{\pi}{10}} + 2\sqrt{1+\sec^4\frac{3\pi}{20}} + 2\sqrt{1+\sec^4\frac{\pi}{5}}\right.$$
$$\left. + \sqrt{1+\sec^4\frac{\pi}{4}}\right)$$

$$\approx \frac{\pi}{40}(1.41421356 + 2\cdot 1.43206164 + 2\cdot 1.49073513 + 2\cdot 1.60830125 + 2\cdot 1.82602534 + 2.23606797)$$

$$\approx 1.285267058$$

In Exercises 7–10, calculate the surface area of the solid obtained by rotating the curve over the given interval about the x-axis.

7. $y = x + 1$, $[0, 4]$

SOLUTION Let $y = x + 1$. Then $y' = 1$, and

$$y\sqrt{1 + y'^2} = (x+1)\sqrt{1+1} = \sqrt{2}(x+1).$$

Thus,

$$SA = 2\pi\int_0^4 \sqrt{2}(x+1)\,dx = 2\sqrt{2}\pi\left(\frac{x^2}{2} + x\right)\bigg|_0^4 = 24\sqrt{2}\pi.$$

8. $y = \frac{2}{3}x^{3/4} - \frac{2}{5}x^{5/4}$, $[0, 1]$

SOLUTION Let $y = \frac{2}{3}x^{3/4} - \frac{2}{5}x^{5/4}$. Then

$$y' = \frac{x^{-1/4}}{2} - \frac{x^{1/4}}{2},$$

and

$$1 + (y')^2 = 1 + \left(\frac{x^{-1/4}}{2} - \frac{x^{1/4}}{2}\right)^2 = \frac{x^{-1/2}}{4} + \frac{1}{2} + \frac{x^{1/2}}{4} = \left(\frac{x^{-1/4}}{2} + \frac{x^{1/4}}{2}\right)^2.$$

Because $\frac{1}{2}(x^{-1/4} + x^{1/4}) \geq 0$, the surface area is

$$\begin{aligned}2\pi \int_0^1 y\sqrt{1 + (y')^2}\, dy &= 2\pi \int_0^1 \left(\frac{2x^{3/4}}{3} - \frac{2x^{5/4}}{5}\right)\left(\frac{x^{1/4}}{2} + \frac{x^{-1/4}}{2}\right) dx \\ &= 2\pi \int_0^1 \left(-\frac{x^{3/2}}{5} - \frac{x}{5} + \frac{x}{3} + \frac{\sqrt{x}}{3}\right) dx \\ &= 2\pi \left(-\frac{2x^{5/2}}{25} + \frac{x^2}{15} + \frac{2x^{3/2}}{9}\right)\Bigg|_0^1 = \frac{94}{225}\pi.\end{aligned}$$

9. $y = \frac{2}{3}x^{3/2} - \frac{1}{2}x^{1/2}$, $[1, 2]$

SOLUTION Let $y = \frac{2}{3}x^{3/2} - \frac{1}{2}x^{1/2}$. Then

$$y' = \sqrt{x} - \frac{1}{4\sqrt{x}},$$

and

$$1 + \left(y'\right)^2 = 1 + \left(\sqrt{x} - \frac{1}{4\sqrt{x}}\right)^2 = 1 + \left(x - \frac{1}{2} + \frac{1}{16x}\right) = x + \frac{1}{2} + \frac{1}{16x} = \left(\sqrt{x} + \frac{1}{4\sqrt{x}}\right)^2.$$

Because $\sqrt{x} + \frac{1}{\sqrt{x}} \geq 0$, the surface area is

$$\begin{aligned}2\pi \int_a^b y\sqrt{1 + \left(y'\right)^2}\, dx &= 2\pi \int_1^2 \left(\frac{2}{3}x^{3/2} - \frac{\sqrt{x}}{2}\right)\left(\sqrt{x} + \frac{1}{4\sqrt{x}}\right) dx \\ &= 2\pi \int_1^2 \left(\frac{2}{3}x^2 + \frac{1}{6}x - \frac{1}{2}x - \frac{1}{8}\right) dx = 2\pi \left(\frac{2x^3}{9} - \frac{x^2}{6} - \frac{1}{8}x\right)\Bigg|_1^2 = \frac{67}{36}\pi.\end{aligned}$$

10. $y = \frac{1}{2}x^2$, $[0, 2]$

SOLUTION Let $y = \frac{1}{2}x^2$. Then $y' = x$ and

$$SA = 2\pi \int_0^2 \frac{1}{2}x^2\sqrt{1 + x^2}\, dx = \pi \int_0^2 x^2\sqrt{1 + x^2}\, dx.$$

Using the substitution $x = \tan\theta$, $dx = \sec^2\theta\, d\theta$, we find that

$$\begin{aligned}\int x^2\sqrt{1 + x^2}\, dx &= \int \sec^3\theta \tan^2\theta\, d\theta = \int \left(\sec^5\theta - \sec^3\theta\right) d\theta \\ &= \left(\frac{1}{4}\sec^3\theta\tan\theta + \frac{3}{8}\sec\theta\tan\theta + \frac{3}{8}\ln|\sec\theta + \tan\theta| - \frac{1}{2}\sec\theta\tan\theta - \frac{1}{2}\ln|\sec\theta + \tan\theta|\right) + C \\ &= \frac{x}{4}(1 + x^2)^{3/2} - \frac{x}{8}\sqrt{1 + x^2} - \frac{1}{8}\ln|\sqrt{1 + x^2} + x| + C.\end{aligned}$$

Finally,

$$\begin{aligned}SA &= \pi \left(\frac{x}{4}(1 + x^2)^{3/2} - \frac{x}{8}\sqrt{1 + x^2} - \frac{1}{8}\ln|\sqrt{1 + x^2} + x|\right)\Bigg|_0^2 \\ &= \pi \left(\frac{5\sqrt{5}}{2} - \frac{\sqrt{5}}{4} - \frac{1}{8}\ln(2 + \sqrt{5})\right) = \frac{9\sqrt{5}}{4}\pi - \frac{\pi}{8}\ln(2 + \sqrt{5}).\end{aligned}$$

11. Compute the total surface area of the coin obtained by rotating the region in Figure 1 about the x-axis. The top and bottom parts of the region are semicircles with a radius of 1 mm.

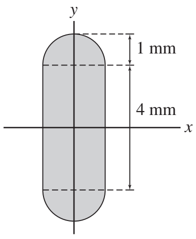


FIGURE 1

SOLUTION The generating half circle of the edge is $y = 2 + \sqrt{1 - x^2}$. Then,

$$y' = \frac{-2x}{2\sqrt{1 - x^2}} = \frac{-x}{\sqrt{1 - x^2}},$$

and

$$1 + (y')^2 = 1 + \frac{x^2}{1 - x^2} = \frac{1}{1 - x^2}.$$

The surface area of the edge of the coin is

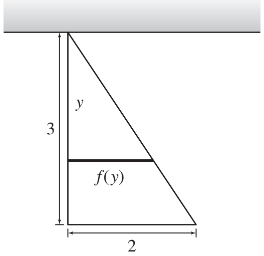
$$\begin{aligned} 2\pi \int_{-1}^{1} y\sqrt{1 + \left(y'\right)^2}\,dx &= 2\pi \int_{-1}^{1} \left(2 + \sqrt{1 - x^2}\right) \frac{1}{\sqrt{1 - x^2}}\,dx \\ &= 2\pi \left(2\int_{-1}^{1} \frac{dx}{\sqrt{1 - x^2}} + \int_{-1}^{1} \frac{\sqrt{1 - x^2}}{\sqrt{1 - x^2}}\,dx\right) \\ &= 2\pi \left(2 \arcsin x\big|_{-1}^{1} + \int_{-1}^{1} dx\right) \\ &= 2\pi(2\pi + 2) = 4\pi^2 + 4\pi. \end{aligned}$$

We now add the surface area of the two sides of the disk, which are circles of radius 2. Hence the surface area of the coin is:

$$\left(4\pi^2 + 4\pi\right) + 2\pi \cdot 2^2 = 4\pi^2 + 12\pi.$$

12. Calculate the fluid force on the side of a right triangle of height 3 m and base 2 m submerged in water vertically, with its upper vertex at the surface of the water.

SOLUTION To find the fluid force, we must find an expression for the horizontal width $f(y)$ of the triangle at depth y.



By similar triangles we have:

$$\frac{y}{f(y)} = \frac{3}{2} \qquad \text{so} \qquad f(y) = \frac{2y}{3}.$$

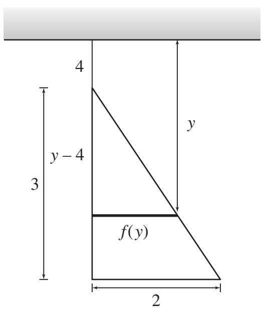
Therefore, the fluid force on the side of the triangle is

$$F = \rho g \int_0^3 y f(y)\,dy = \rho g \int_0^3 \frac{2y^2}{3}\,dy = \rho g \cdot \frac{2y^3}{9}\bigg|_0^3 = 6\rho g.$$

For water, $\rho = 10^3$; $g = 9.8$, so $F = 6 \cdot 9800 = 58{,}800$ N.

13. Calculate the fluid force on the side of a right triangle of height 3 m and base 2 m submerged in water vertically, with its upper vertex located at a depth of 4 m.

SOLUTION We need to find an expression for the horizontal width $f(y)$ at depth y.



By similar triangles we have:

$$\frac{f(y)}{y-4} = \frac{2}{3} \qquad \text{so} \qquad f(y) = \frac{2(y-4)}{3}.$$

Hence, the force on the side of the triangle is

$$F = \rho g \int_4^7 y f(y)\, dy = \frac{2\rho g}{3} \int_4^7 \left(y^2 - 4y\right)\, dy = \frac{2\rho g}{3}\left(\frac{y^3}{3} - 2y^2\right)\Big|_4^7 = 18\rho g.$$

For water, $\rho = 10^3$; $g = 9.8$, so $F = 18 \cdot 9800 = 176{,}400$ N.

14. A plate in the shape of the shaded region in Figure 2 is submerged in water. Calculate the fluid force on a side of the plate if the water surface is $y = 1$.

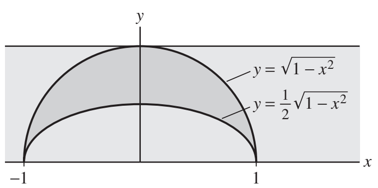


FIGURE 2

SOLUTION Here, we can proceed as follows: Calculate the force that would be exerted on the entire semicircle and then subtract the force that would be exerted on the "missing" portion of the ellipse. The force on the semicircle is

$$2w \int_0^1 (1-y)\sqrt{1-y^2}\, dy = 2w \int_0^1 \sqrt{1-y^2}\, dy - 2w \int_0^1 y\sqrt{1-y^2}\, dy.$$

The first integral can be interpreted as the area of one-quarter of a circle of radius 1. Hence,

$$\int_0^1 \sqrt{1-y^2}\, dy = \frac{\pi}{4}.$$

On the other hand,

$$\int_0^1 y\sqrt{1-y^2}\, dy = -\frac{1}{3}(1-y^2)^{3/2}\Big|_0^1 = \frac{1}{3}.$$

Thus, the force on the semicircle is

$$2w\left(\frac{\pi}{4} - \frac{1}{3}\right).$$

Now for the ellipse. The force that would be exerted on the upper half of the ellipse is

$$2w \int_0^{1/2} (1-y)\sqrt{1-4y^2}\, dy = 2w \int_0^{1/2} \sqrt{1-4y^2}\, dy - 2w \int_0^{1/2} y\sqrt{1-4y^2}\, dy.$$

Using the substitution $w = 2y$, $dw = 2\, dy$, it follows that

$$\int_0^{1/2} \sqrt{1-4y^2}\, dy = \frac{1}{2}\int_0^1 \sqrt{1-w^2}\, dw = \frac{\pi}{8},$$

and

$$\int_0^{1/2} y\sqrt{1-4y^2}\,dy = \frac{1}{4}\int_0^1 w\sqrt{1-w^2}\,dw = \frac{1}{12}.$$

Thus, the force on the "missing" ellipse is

$$2w\left(\frac{\pi}{8}-\frac{1}{12}\right).$$

Finally, the force exerted on the plate shown in Figure 2 is

$$F = 2w\left(\frac{\pi}{4}-\frac{1}{3}\right) - 2w\left(\frac{\pi}{8}-\frac{1}{12}\right) = \frac{\pi-2}{4}w.$$

15. Figure 3 shows an object whose face is an equilateral triangle with 5-m sides. The object is 2 m thick and is submerged in water with its vertex 3 m below the water surface. Calculate the fluid force on both a triangular face and a slanted rectangular edge of the object.

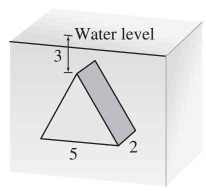

FIGURE 3

SOLUTION Start with each triangular face of the object. Place the origin at the upper vertex of the triangle, with the positive y-axis pointing downward. Note that because the equilateral triangle has sides of length 5 feet, the height of the triangle is $\frac{5\sqrt{3}}{2}$ feet. Moreover, the width of the triangle at location y is $\frac{2y}{\sqrt{3}}$. Thus,

$$F = \frac{2\rho g}{\sqrt{3}}\int_0^{5\sqrt{3}/2}(y+3)y\,dy = \frac{2\rho g}{\sqrt{3}}\left(\frac{1}{3}y^3+\frac{3}{2}y^2\right)\Big|_0^{5\sqrt{3}/2} = \frac{\rho g}{4}(125+75\sqrt{3}) \approx 624{,}514 \text{ N}.$$

Now, consider the slanted rectangular edges of the object. Each edge is a constant 2 feet wide and makes an angle of 60° with the horizontal. Therefore,

$$F = \frac{\rho g}{\sin 60^\circ}\int_0^{5\sqrt{3}/2} 2(y+3)\,dy = \frac{2\rho g}{\sqrt{3}}\left(y^2+6y\right)\Big|_0^{5\sqrt{3}/2} = \rho g\left(\frac{25\sqrt{3}}{2}+30\right) \approx 506{,}176 \text{ N}.$$

The force on the bottom face can be computed without calculus:

$$F = \left(3+\frac{5\sqrt{3}}{2}\right)(2)(5)\rho g \approx 718{,}352 \text{ N}.$$

16. The end of a horizontal oil tank is an ellipse (Figure 4) with equation $(x/4)^2+(y/3)^2=1$ (length in meters). Assume that the tank is filled with oil of density 900 kg/m^3.

(a) Calculate the total force F on the end of the tank when the tank is full.

(b) Would you expect the total force on the lower half of the tank to be greater than, less than, or equal to $\frac{1}{2}F$? Explain. Then compute the force on the lower half exactly and confirm (or refute) your expectation.

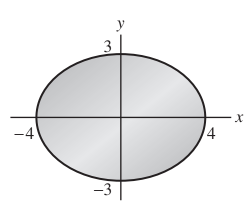

FIGURE 4

SOLUTION

(a) Solving the equation of the ellipse for x yields

$$x = \frac{4}{3}\sqrt{9-y^2}.$$

Therefore, a horizontal strip of the ellipse at height y has width $\frac{8}{3}\sqrt{9-y^2}$. This strip is at a depth of $3-y$, so the total force on the end of the tank is

$$F = \rho g \int_{-3}^{3} (3-y)\cdot\frac{8}{3}\sqrt{9-y^2}\,dy = 8\rho g \int_{-3}^{3}\sqrt{9-y^2}\,dy - \frac{8}{3}\rho g\int_{-3}^{3} y\sqrt{9-y^2}\,dy.$$

The first integral can be interpreted as the area of one-half of a circle of radius 3, so the value of this integral is $\frac{9\pi}{2}$. The second integral is zero, since the integrand is an odd function and the interval of integration is symmetric about zero. Hence,

$$F = 8\rho g\frac{9\pi}{2} - \frac{8}{3}\rho g(0) = 8\cdot 900\cdot 9.8\cdot\frac{9\pi}{2} \approx 997{,}518\text{ N}.$$

(b) The oil in the lower half of the tank is at a greater depth than the oil in the upper half, therefore we expect the total force F_l on the lower half of the tank to be greater than the total force F_u on the upper half. We compute the two forces to verify our expectation. Now,

$$F_l = \rho g \int_{-3}^{0} (3-y)\cdot\frac{8}{3}\sqrt{9-y^2}\,dy = 8\rho g \int_{-3}^{0}\sqrt{9-y^2}\,dy - \frac{8}{3}\rho g\int_{-3}^{0} y\sqrt{9-y^2}\,dy.$$

Similarly,

$$F_u = 8\rho g \int_{0}^{3}\sqrt{9-y^2}\,dy - \frac{8}{3}\rho g\int_{0}^{3} y\sqrt{9-y^2}\,dy.$$

The first integral in each expression,

$$\int_{-3}^{0}\sqrt{9-y^2}\,dy \qquad\text{and}\qquad \int_{0}^{3}\sqrt{9-y^2}\,dy,$$

can be interpreted as the area of one-quarter of a circle of radius 3, so both integrals have the value $\frac{9\pi}{4}$. Using the substitution $u = 9-y^2$, $du = -2y\,dy$ we find

$$\int_{-3}^{0} y\sqrt{9-y^2}\,dy = \int_{0}^{9}\sqrt{u}\left(-\frac{1}{2}\right)du = -\frac{1}{3}u^{3/2}\Big|_{0}^{9} = -9.$$

Moreover, since the integrand is an odd function, we have

$$\int_{0}^{3} y\sqrt{9-y^2}\,dy = -\int_{-3}^{0} y\sqrt{9-y^2}\,dy = 9.$$

Thus,

$$F_l = 8\rho g\frac{9\pi}{4} - \frac{8}{3}\rho g(-9) = (18\pi+24)\rho g;\ \text{and}$$
$$F_u = 8\rho g\frac{9\pi}{4} - \frac{8}{3}\rho g(9) = (18\pi-24)\rho g.$$

We see that $F_l > F_u$. That is, the total force on the lower half of the tank is greater than the total force on the upper half, as expected.

17. Calculate the moments and COM of the lamina occupying the region under $y = x(4-x)$ for $0 \le x \le 4$, assuming a density of $\rho = 1200\text{ kg/m}^3$.

SOLUTION Because the lamina is symmetric with respect to the vertical line $x = 2$, by the symmetry principle, we know that $x_{\rm cm} = 2$. Now,

$$M_x = \frac{\rho}{2}\int_0^4 f(x)^2\,dx = \frac{1200}{2}\int_0^4 x^2(4-x)^2\,dx = \frac{1200}{2}\left(\frac{16}{3}x^3 - 2x^4 + \frac{1}{5}x^5\right)\Big|_0^4 = 20{,}480.$$

Moreover, the mass of the lamina is

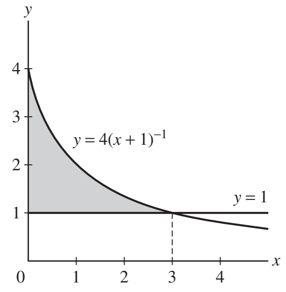
$$M = \rho\int_0^4 f(x)\,dx = 1200\int_0^4 x(4-x)\,dx = 1200\left(2x^2 - \frac{1}{3}x^3\right)\Big|_0^4 = 12{,}800.$$

Thus, the coordinates of the center of mass are

$$\left(2, \frac{20{,}480}{12{,}800}\right) = \left(2, \frac{8}{5}\right).$$

18. Sketch the region between $y = 4(x+1)^{-1}$ and $y = 1$ for $0 \le x \le 3$, and find its centroid.

SOLUTION



First, we calculate the moments:

$$M_x = \frac{1}{2}\int_0^3 \left(\frac{16}{(x+1)^2} - 1\right) dx = \frac{1}{2}\left(-\frac{16}{x+1} - x\right)\Big|_0^3 = \frac{9}{2},$$

and

$$\begin{aligned} M_y &= \int_0^3 x\left(4(x+1)^{-1} - 1\right) dx = \int_0^3 \left(\frac{4x}{x+1} - x\right) dx \\ &= \int_0^3 \left(\frac{4(x+1)-4}{x+1} - x\right) dx = \int_0^3 \left(4 - \frac{4}{x+1} - x\right) dx \\ &= \left(4x - \frac{x^2}{2} - 4\ln(x+1)\right)\Big|_0^3 = \frac{15}{2} - 4\ln 4. \end{aligned}$$

The area of the region is

$$A = \int_0^3 \left(\frac{4}{x+1} - 1\right) dx = \left(4\ln(x+1) - x\right)\big|_0^3 = 4\ln 4 - 3,$$

so the coordinates of the centroid are:

$$\left(\frac{15 - 8\ln 4}{8\ln 4 - 6}, \frac{9}{8\ln 4 - 6}\right).$$

19. Find the centroid of the region between the semicircle $y = \sqrt{1-x^2}$ and the top half of the ellipse $y = \frac{1}{2}\sqrt{1-x^2}$ (Figure 2).

SOLUTION Since the region is symmetric with respect to the y-axis, the centroid lies on the y-axis. To find $y_{\rm cm}$ we calculate

$$\begin{aligned} M_x &= \frac{1}{2}\int_{-1}^1 \left[\left(\sqrt{1-x^2}\right)^2 - \left(\frac{\sqrt{1-x^2}}{2}\right)^2\right] dx \\ &= \frac{1}{2}\int_{-1}^1 \frac{3}{4}\left(1-x^2\right) dx = \frac{3}{8}\left(x - \frac{1}{3}x^3\right)\Big|_{-1}^1 = \frac{1}{2}. \end{aligned}$$

The area of the lamina is $\frac{\pi}{2} - \frac{\pi}{4} = \frac{\pi}{4}$, so the coordinates of the centroid are

$$\left(0, \frac{1/2}{\pi/4}\right) = \left(0, \frac{2}{\pi}\right).$$

20. Find the centroid of the shaded region in Figure 5 bounded on the left by $x = 2y^2 - 2$ and on the right by a semicircle of radius 1. *Hint:* Use symmetry and additivity of moments.

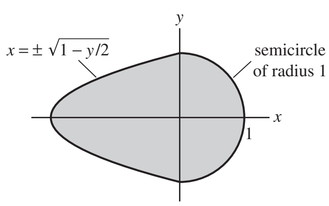


FIGURE 5

SOLUTION The region is symmetric with respect to the x-axis, hence the centroid lies on the x-axis; that is, $y_{\text{cm}} = 0$. To compute the area and the moment with respect to the y-axis, we treat the left side and the right side of the region separately. Starting with the left side, we find

$$M_y^{\text{left}} = 2\int_{-2}^{0} x\sqrt{\frac{x}{2}+1}\,dx \qquad \text{and} \qquad A^{\text{left}} = 2\int_{-2}^{0} \sqrt{\frac{x}{2}+1}\,dx.$$

In each integral we make the substitution $u = \frac{x}{2} + 1$, $du = \frac{1}{2}\,dx$, and find

$$M_y^{\text{left}} = 8\int_0^1 (u-1)u^{1/2}\,du = 8\int_0^1 \left(u^{3/2} - u^{1/2}\right)du = 8\left(\frac{2}{5}u^{5/2} - \frac{2}{3}u^{3/2}\right)\Big|_0^1 = -\frac{32}{15}$$

and

$$A^{\text{left}} = 4\int_0^1 u^{1/2}\,du = \frac{8}{3}u^{3/2}\Big|_0^1 = \frac{8}{3}.$$

On the right side of the region

$$M_y^{\text{right}} = 2\int_0^1 x\sqrt{1-x^2}\,dx = -\frac{2}{3}(1-x^2)^{3/2}\Big|_0^1 = \frac{2}{3},$$

and $A^{\text{right}} = \frac{\pi}{2}$ (because the right side of the region is one-half of a circle of radius 1). Thus,

$$M_y = M_y^{\text{left}} + M_y^{\text{right}} = -\frac{32}{15} + \frac{2}{3} = -\frac{22}{15};$$
$$A = A^{\text{left}} + A^{\text{right}} = \frac{8}{3} + \frac{\pi}{2} = \frac{16+3\pi}{6};$$

and the coordinates of the centroid are

$$\left(\frac{-22/15}{(16+3\pi)/6}, 0\right) = \left(-\frac{44}{80+15\pi}, 0\right).$$

In Exercises 21–26, find the Taylor polynomial at $x = a$ for the given function.

21. $f(x) = x^3, \quad T_3(x), \quad a = 1$

SOLUTION We start by computing the first three derivatives of $f(x) = x^3$:

$$f'(x) = 3x^2$$
$$f''(x) = 6x$$
$$f'''(x) = 6$$

Evaluating the function and its derivatives at $x = 1$, we find

$$f(1) = 1,\ f'(1) = 3,\ f''(1) = 6,\ f'''(1) = 6.$$

Therefore,

$$\begin{aligned} T_3(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-2)^2 + \frac{f'''(1)}{3!}(x-1)^3 \\ &= 1 + 3(x-1) + \frac{6}{2!}(x-2)^2 + \frac{6}{3!}(x-1)^3 \\ &= 1 + 3(x-1) + 3(x-2)^2 + (x-1)^3. \end{aligned}$$

22. $f(x) = 3(x+2)^3 - 5(x+2), \quad T_3(x), \quad a = -2$

SOLUTION $T_3(x)$ is the Taylor polynomial of f consisting of powers of $(x+2)$ up to three. Since $f(x)$ is already in this form we conclude that $T_3(x) = f(x)$.

23. $f(x) = x\ln(x), \quad T_4(x), \quad a = 1$

SOLUTION We start by computing the first four derivatives of $f(x) = x\ln x$:

$$\begin{aligned}
f'(x) &= \ln x + x \cdot \frac{1}{x} = \ln x + 1\\
f''(x) &= \frac{1}{x}\\
f'''(x) &= -\frac{1}{x^2}\\
f^{(4)}(x) &= \frac{2}{x^3}
\end{aligned}$$

Evaluating the function and its derivatives at $x = 1$, we find

$$f(1) = 0,\ f'(1) = 1,\ f''(1) = 1,\ f'''(1) = -1,\ f^{(4)}(1) = 2.$$

Therefore,

$$\begin{aligned}
T_4(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 + \frac{f'''(1)}{3!}(x-1)^3 + \frac{f^{(4)}(1)}{4!}(x-1)^4\\
&= 0 + 1(x-1) + \frac{1}{2!}(x-1)^2 - \frac{1}{3!}(x-1)^3 + \frac{2}{4!}(x-1)^4\\
&= (x-1) + \frac{1}{2}(x-1)^2 - \frac{1}{6}(x-1)^3 + \frac{1}{12}(x-1)^4.
\end{aligned}$$

24. $f(x) = (3x+2)^{1/3}, \quad T_3(x), \quad a = 2$

SOLUTION We start by computing the first three derivatives of $f(x) = (3x+2)^{1/3}$:

$$\begin{aligned}
f'(x) &= \frac{1}{3}(3x+2)^{-2/3} \cdot 3 = (3x+2)^{-2/3}\\
f''(x) &= -\frac{2}{3}(3x+2)^{-5/3} \cdot 3 = -2(3x+2)^{-5/3}\\
f'''(x) &= \frac{10}{3}(3x+2)^{-8/3} \cdot 3 = 10(3x+2)^{-8/3}
\end{aligned}$$

Evaluating the function and its derivatives at $x = 2$, we find

$$f(2) = 2,\ f'(2) = \frac{1}{4},\ f''(2) = -\frac{1}{16},\ f'''(2) = \frac{5}{128}.$$

Therefore,

$$\begin{aligned}
T_3(x) &= f(2) + f'(2)(x-2) + \frac{f''(2)}{2!}(x-2)^2 + \frac{f'''(2)}{3!}(x-2)^3\\
&= 2 + \frac{1}{4}(x-2) + \frac{-1/16}{2!}(x-2)^2 + \frac{5/128}{3!}(x-2)^3\\
&= 2 + \frac{1}{4}(x-2) - \frac{1}{32}(x-2)^2 - \frac{5}{768}(x-2)^3.
\end{aligned}$$

25. $f(x) = xe^{-x^2}, \quad T_4(x), \quad a = 0$

SOLUTION We start by computing the first four derivatives of $f(x) = xe^{-x^2}$:

$$\begin{aligned}
f'(x) &= e^{-x^2} + x \cdot (-2x)e^{-x^2} = (1-2x^2)e^{-x^2}\\
f''(x) &= -4xe^{-x^2} + (1-2x^2) \cdot (-2x)e^{-x^2} = (4x^3 - 6x)e^{-x^2}\\
f'''(x) &= (12x^2 - 6)e^{-x^2} + (4x^3 - 6x) \cdot (-2x)e^{-x^2} = (-8x^4 + 24x^2 - 6)e^{-x^2}\\
f^{(4)}(x) &= (-32x^3 + 48x)e^{-x^2} + (-8x^4 + 24x^2 - 6) \cdot (-2x)e^{-x^2} = (16x^5 - 80x^3 + 60x)e^{-x^2}
\end{aligned}$$

Evaluating the function and its derivatives at $x = 0$, we find

$$f(0) = 0,\ f'(0) = 1,\ f''(0) = 0,\ f'''(0) = -6,\ f^{(4)}(0) = 0.$$

Therefore,

$$T_4(x) = f(0) + f'(0)x + \frac{f''(0)}{2!}x^2 + \frac{f'''(0)}{3!}x^3 + \frac{f^{(4)}(0)}{4!}x^4$$
$$= 0 + x + 0 \cdot x^2 - \frac{6}{3!}x^3 + 0 \cdot x^4 = x - x^3.$$

26. $f(x) = \ln(\cos x)$, $T_3(x)$, $a = 0$

SOLUTION We start by computing the first three derivatives of $f(x) = \ln(\cos x)$:

$$f'(x) = -\frac{\sin x}{\cos x} = -\tan x$$
$$f''(x) = -\sec^2 x$$
$$f'''(x) = -2\sec^2 x \tan x$$

Evaluating the function and its derivatives at $x = 0$, we find

$$f(0) = 0,\ f'(0) = 0,\ f''(0) = -1,\ f'''(0) = 0.$$

Therefore,

$$T_3(x) = f(0) + f'(0)x + \frac{f''(0)}{2!}x^2 + \frac{f'''(0)}{3!}x^3 = 0 + \frac{0}{1!}x - \frac{1}{2!}x^2 + \frac{0}{3!}x^3 = -\frac{x^2}{2}.$$

27. Find the nth Maclaurin polynomial for $f(x) = e^{3x}$.

SOLUTION We differentiate the function $f(x) = e^{3x}$ repeatedly, looking for a pattern:

$$f'(x) = 3e^{3x} = 3^1 e^{3x}$$
$$f''(x) = 3 \cdot 3e^{3x} = 3^2 e^{3x}$$
$$f'''(x) = 3 \cdot 3^2 e^{3x} = 3^3 e^{3x}$$

Thus, for general n, $f^{(n)}(x) = 3^n e^{3x}$ and $f^{(n)}(0) = 3^n$. Substituting into the formula for the nth Taylor polynomial, we obtain:

$$T_n(x) = 1 + \frac{3x}{1!} + \frac{3^2x^2}{2!} + \frac{3^3x^3}{3!} + \frac{3^4x^4}{4!} + \cdots + \frac{3^nx^n}{n!}$$
$$= 1 + 3x + \frac{1}{2!}(3x)^2 + \frac{1}{3!}(3x)^3 + \cdots + \frac{1}{n!}(3x)^n.$$

28. Use the fifth Maclaurin polynomial of $f(x) = e^x$ to approximate $\sqrt{e}$. Use a calculator to determine the error.

SOLUTION Let $f(x) = e^x$. Then $f^{(n)}(x) = e^x$ and $f^{(n)}(0) = 1$ for all n. Hence,

$$T_5(x) = f(0) + f'(0)x + \frac{f''(0)}{2!}x^2 + \frac{f'''(0)}{3!}x^3 + \frac{f^{(4)}(0)}{4!}x^4 + \frac{f^{(5)}(0)}{5!}x^5$$
$$= 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \frac{x^5}{5!}.$$

For $x = \frac{1}{2}$ we have

$$T_5\left(\frac{1}{2}\right) = 1 + \frac{1}{2} + \frac{\left(\frac{1}{2}\right)^2}{2!} + \frac{\left(\frac{1}{2}\right)^3}{3!} + \frac{\left(\frac{1}{2}\right)^4}{4!} + \frac{\left(\frac{1}{2}\right)^5}{5!}$$
$$= 1 + \frac{1}{2} + \frac{1}{8} + \frac{1}{48} + \frac{1}{384} + \frac{1}{3840} = 1.648697917$$

Using a calculator, we find that $\sqrt{e} = 1.648721271$. The error in the Taylor polynomial approximation is

$$|1.648697917 - 1.648721271| = 2.335 \times 10^{-5}.$$

29. Use the third Taylor polynomial of $f(x) = \tan^{-1} x$ at $a = 1$ to approximate $f(1.1)$. Use a calculator to determine the error.

SOLUTION We start by computing the first three derivatives of $f(x) = \tan^{-1} x$:

$$f'(x) = \frac{1}{1+x^2}$$

$$f''(x) = -\frac{2x}{\left(1+x^2\right)^2}$$

$$f'''(x) = \frac{-2\left(1+x^2\right)^2 + 2x \cdot 2\left(1+x^2\right) \cdot 2x}{\left(1+x^2\right)^4} = \frac{2\left(3x^2-1\right)}{\left(1+x^2\right)^3}$$

Evaluating the function and its derivatives at $x = 1$, we find

$$f(1) = \frac{\pi}{4},\ f'(1) = \frac{1}{2},\ f''(1) = -\frac{1}{2},\ f'''(1) = \frac{1}{2}.$$

Therefore,

$$\begin{aligned} T_3(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 + \frac{f'''(1)}{3!}(x-1)^3 \\ &= \frac{\pi}{4} + \frac{1}{2}(x-1) - \frac{1}{4}(x-1)^2 + \frac{1}{12}(x-1)^3. \end{aligned}$$

Setting $x = 1.1$ yields:

$$T_3(1.1) = \frac{\pi}{4} + \frac{1}{2}(0.1) - \frac{1}{4}(0.1)^2 + \frac{1}{12}(0.1)^3 = 0.832981496.$$

Using a calculator, we find $\tan^{-1} 1.1 = 0.832981266$. The error in the Taylor polynomial approximation is

$$\left|T_3(1.1) - \tan^{-1} 1.1\right| = |0.832981496 - 0.832981266| = 2.301 \times 10^{-7}.$$

30. Let $T_4(x)$ be the Taylor polynomial for $f(x) = \sqrt{x}$ at $a = 16$. Use the error bound to find the maximum possible size of $|f(17) - T_4(17)|$.

SOLUTION Using the Error Bound, we have

$$|f(17) - T_4(17)| \le K\frac{(17-16)^5}{5!} = \frac{K}{5!},$$

where K is a number such that $\left|f^{(5)}(x)\right| \le K$ for all $16 \le x \le 17$. Starting from $f(x) = \sqrt{x}$ we find

$$f'(x) = \frac{1}{2}x^{-1/2},\ f''(x) = -\frac{1}{4}x^{-3/2},\ f'''(x) = \frac{3}{8}x^{-5/2},\ f^{(4)}(x) = -\frac{15}{16}x^{-7/2},$$

and

$$f^{(5)}(x) = \frac{105}{32}x^{-9/2}.$$

For $16 \le x \le 17$,

$$\left|f^{(5)}(x)\right| = \frac{105}{32x^{9/2}} \le \frac{105}{32 \cdot 16^{9/2}} = \frac{105}{8{,}388{,}608}.$$

Therefore, we may take

$$K = \frac{105}{8{,}388{,}608}.$$

Finally,

$$|f(17) - T_4(17)| \le \frac{105}{8{,}388{,}608} \cdot \frac{1}{5!} \approx 1.044 \cdot 10^{-7}.$$

31. Find n such that $|e - T_n(1)| < 10^{-8}$, where $T_n(x)$ is the nth Maclaurin polynomial for $f(x) = e^x$.

SOLUTION Using the Error Bound, we have

$$|e - T_n(1)| \le K\frac{|1-0|^{n+1}}{(n+1)!} = \frac{K}{(n+1)!}$$

where K is a number such that $\left|f^{(n+1)}(x)\right| = e^x \le K$ for all $0 \le x \le 1$. Since e^x is increasing, the maximum value on the interval $0 \le x \le 1$ is attained at the endpoint $x = 1$. Thus, for $0 \le u \le 1$, $e^u \le e^1 < 2.8$. Hence we may take $K = 2.8$ to obtain:

$$|e - T_n(1)| \le \frac{2.8}{(n+1)!}$$

We now choose n such that

$$\frac{2.8}{(n+1)!} < 10^{-8}$$
$$\frac{(n+1)!}{2.8} > 10^{8}$$
$$(n+1)! > 2.8 \times 10^{8}$$

For $n = 10$, $(n+1)! = 3.99 \times 10^7 < 2.8 \times 10^8$ and for $n = 11$, $(n+1)! = 4.79 \times 10^8 > 2.8 \times 10^8$. Hence, to make the error less than 10^{-8}, $n = 11$ is sufficient; that is,

$$|e - T_{11}(1)| < 10^{-8}.$$

32. Let $T_4(x)$ be the Taylor polynomial for $f(x) = x\ln x$ at $a = 1$ computed in Exercise 23. Use the error bound to find a bound for $|f(1.2) - T_4(1.2)|$.

SOLUTION Using the Error Bound, we have

$$|f(1.2) - T_4(1.2)| \le K\frac{(1.2-1)^5}{5!} = \frac{(0.2)^5}{120}K,$$

where K is a number such that $\left|f^{(5)}x\right| \le K$ for all $1 \le x \le 1.2$. Starting from $f(x) = x\ln x$, we find

$$f'(x) = \ln x + x\frac{1}{x} = \ln x + 1,\ f''(x) = \frac{1}{x},\ f'''(x) = -\frac{1}{x^2},\ f^{(4)}(x) = \frac{2}{x^3},$$

and

$$f^{(5)}(x) = \frac{-6}{x^4}.$$

For $1 \le x \le 1.2$,

$$\left|f^{(5)}(x)\right| = \frac{6}{x^4} \le \frac{6}{1^4} = 6.$$

Hence we may take $K = 6$ to obtain:

$$|f(1.2) - T_4(1.2)| \le \frac{(0.2)^5}{120}6 = 1.6 \times 10^{-5}.$$

33. Verify that $T_n(x) = 1 + x + x^2 + \cdots + x^n$ is the nth Maclaurin polynomial of $f(x) = 1/(1-x)$. Show using substitution that the nth Maclaurin polynomial for $f(x) = 1/(1 - x/4)$ is

$$T_n(x) = 1 + \frac{1}{4}x + \frac{1}{4^2}x^2 + \cdots + \frac{1}{4^n}x^n$$

What is the nth Maclaurin polynomial for $g(x) = \dfrac{1}{1+x}$?

SOLUTION Let $f(x) = (1-x)^{-1}$. Then, $f'(x) = (1-x)^{-2}$, $f''(x) = 2(1-x)^{-3}$, $f'''(x) = 3!(1-x)^{-4}$, and, in general, $f^{(n)}(x) = n!(1-x)^{-(n+1)}$. Therefore, $f^{(n)}(0) = n!$ and

$$T_n(x) = 1 + \frac{1!}{1!}x + \frac{2!}{2!}x^2 + \cdots + \frac{n!}{n!}x^n = 1 + x + x^2 + \cdots + x^n.$$

Upon substituting $x/4$ for x, we find that the nth Maclaurin polynomial for $f(x) = \dfrac{1}{1-x/4}$ is

$$T_n(x) = 1 + \frac{1}{4}x + \frac{1}{4^2}x^2 + \cdots + \frac{1}{4^n}x^n.$$

Substituting $-x$ for x, the nth Maclaurin polynomial for $g(x) = \dfrac{1}{1+x}$ is

$$T_n(x) = 1 - x + x^2 - x^3 + - \cdots + (-x)^n.$$

34. Let $f(x) = \dfrac{5}{4+3x-x^2}$ and let a_k be the coefficient of x^k in the Maclaurin polynomial $T_n(x)$ of for $k \le n$.

(a) Show that $f(x) = \left(\dfrac{1/4}{1-x/4} + \dfrac{1}{1+x}\right)$.

(b) Use Exercise 33 to show that $a_k = \dfrac{1}{4^{k+1}} + (-1)^k$.

(c) Compute $T_3(x)$.

SOLUTION

(a) Start by factoring the denominator and writing the form of the partial fraction decomposition:

$$f(x) = \frac{5}{4+3x-x^2} = \frac{5}{(x+1)(4-x)} = \frac{A}{x+1} + \frac{B}{4-x}.$$

Multiplying through by $(x+1)(4-x)$, we obtain:

$$5 = A(4-x) + B(x+1).$$

Substituting $x = 4$ yields $5 = A(0) + B(5)$, so $B = 1$; substituting $x = -1$ yields $5 = A(5) + B(0)$, so $A = 1$. Thus,

$$f(x) = \frac{1}{x+1} + \frac{1}{4-x} = \frac{1}{x+1} + \frac{\frac{1}{4}}{1-\frac{x}{4}}.$$

(b) The nth Maclaurin polynomial for $f(x) = \frac{\frac{1}{4}}{1-\frac{x}{4}} + \frac{1}{x+1}$ is the sum of the nth Maclaurin polynomials for the functions $g(x) = \frac{1}{4} \cdot \frac{1}{1-\frac{x}{4}}$ and $h(x) = \frac{1}{1+x}$. In Exercise 33, we found that the nth Maclaurin polynomials $P_n(x)$ and $Q_n(x)$ for g and h are

$$P_n(x) = \frac{1}{4}\left(1 + \frac{1}{4}x + \frac{1}{4^2}x^2 + \cdots + \frac{1}{4^n}x^n\right) = \frac{1}{4} + \frac{1}{4^2}x + \frac{1}{4^3}x^2 + \cdots + \frac{1}{4^{n+1}}x^n = \sum_{k=0}^{n} \frac{x^k}{4^{k+1}}$$

$$Q_n(x) = 1 - x + x^2 - x^3 + \cdots + (-1)^n x^n = \sum_{k=0}^{n} (-1)^k x^k$$

Therefore,

$$T_n(x) = P_n(x) + Q_n(x) = \sum_{k=0}^{n} \frac{x^k}{4^{k+1}} + \sum_{k=0}^{n} (-1)^k x^k = \sum_{k=0}^{n} \left[\frac{1}{4^{k+1}} + (-1)^k\right] x^k;$$

that is, the coefficient of x^k in T_n for $k \le n$ is

$$a_k = \frac{1}{4^{k+1}} + (-1)^k.$$

(c) From part (b),

$$a_0 = \frac{1}{4} + 1, \quad a_1 = \frac{1}{4^2} - 1, \quad a_2 = \frac{1}{4^3} + 1, \quad a_3 = \frac{1}{4^4} - 1$$

so that

$$T_3(x) = \frac{5}{4} - \frac{15}{16}x + \frac{65}{64}x^2 - \frac{255}{256}x^3$$

35. Let $T_n(x)$ be the nth Maclaurin polynomial for the function $f(x) = \sin x + \sinh x$.
(a) Show that $T_5(x) = T_6(x) = T_7(x) = T_8(x)$.
(b) Show that $|f^n(x)| \le 1 + \cosh x$ for all n. *Hint:* Note that $|\sinh x| \le |\cosh x|$ for all x.
(c) Show that $|T_8(x) - f(x)| \le \frac{2.6}{9!}|x|^9$ for $-1 \le x \le 1$.

SOLUTION

(a) Let $f(x) = \sin x + \sinh x$. Then

$$\begin{aligned} f'(x) &= \cos x + \cosh x \\ f''(x) &= -\sin x + \sinh x \\ f'''(x) &= -\cos x + \cosh x \\ f^{(4)}(x) &= \sin x + \sinh x. \end{aligned}$$

From this point onward, the pattern of derivatives repeats indefinitely. Thus

$$\begin{aligned} f(0) = f^{(4)}(0) = f^{(8)}(0) &= \sin 0 + \sinh 0 = 0 \\ f'(0) = f^{(5)}(0) &= \cos 0 + \cosh 0 = 2 \\ f''(0) = f^{(6)}(0) &= -\sin 0 + \sinh 0 = 0 \\ f'''(0) = f^{(7)}(0) &= -\cos 0 + \cosh 0 = 0. \end{aligned}$$

Consequently,

$$T_5(x) = f'(0)x + \frac{f^{(5)}(0)}{5!}x^5 = 2x + \frac{1}{60}x^5,$$

and, because $f^{(6)}(0) = f^{(7)}(0) = f^{(8)}(0) = 0$, it follows that

$$T_6(x) = T_7(x) = T_8(x) = T_5(x) = 2x + \frac{1}{60}x^5.$$

(b) First note that $|\sin x| \le 1$ and $|\cos x| \le 1$ for all x. Moreover,

$$|\sinh x| = \left|\frac{e^x - e^{-x}}{2}\right| \le \frac{e^x + e^{-x}}{2} = \cosh x.$$

Now, recall from part (a), that all derivatives of $f(x)$ contain two terms: the first is $\pm\sin x$ or $\pm\cos x$, while the second is either $\sinh x$ or $\cosh x$. In absolute value, the trigonometric term is always less than or equal to 1, while the hyperbolic term is always less than or equal to $\cosh x$. Thus, for all n,

$$f^{(n)}(x) \le 1 + \cosh x.$$

(c) Using the Error Bound, we have

$$|T_8(x) - f(x)| \le \frac{K|x-0|^9}{9!} = \frac{K|x|^9}{9!},$$

where K is a number such that $\left|f^{(9)}(u)\right| \le K$ for all u between 0 and x. By part (b), we know that

$$f^{(9)}(u) \le 1 + \cosh u.$$

Now, $\cosh u$ is an even function that is increasing on $(0, \infty)$. The maximum value for u between 0 and x is therefore $\cosh x$. Moreover, for $-1 \le x \le 1$, $\cosh x \le \cosh 1 \approx 1.543 < 1.6$. Hence, we may take $K = 1 + 1.6 = 2.6$, and

$$|T_8(x) - f(x)| \le \frac{2.6}{9!}|x|^9.$$

9 INTRODUCTION TO DIFFERENTIAL EQUATIONS

9.1 Solving Differential Equations

Preliminary Questions

1. Determine the order of the following differential equations:

(a) $x^5 y' = 1$

(b) $(y')^3 + x = 1$

(c) $y''' + x^4 y' = 2$

(d) $\sin(y'') + x = y$

SOLUTION

(a) The highest order derivative that appears in this equation is a first derivative, so this is a first order equation.

(b) The highest order derivative that appears in this equation is a first derivative, so this is a first order equation.

(c) The highest order derivative that appears in this equation is a third derivative, so this is a third order equation.

(d) The highest order derivative that appears in this equation is a second derivative, so this is a second order equation.

2. Is $y'' = \sin x$ a linear differential equation?

SOLUTION Yes.

3. Give an example of a nonlinear differential equation of the form $y' = f(y)$.

SOLUTION One possibility is $y' = y^2$.

4. Can a nonlinear differential equation be separable? If so, give an example.

SOLUTION Yes. An example is $y' = y^2$.

5. Give an example of a linear, nonseparable differential equation.

SOLUTION One example is $y' + y = x$.

Exercises

1. Which of the following differential equations are first-order?

(a) $y' = x^2$

(b) $y'' = y^2$

(c) $(y')^3 + yy' = \sin x$

(d) $x^2 y' - e^x y = \sin y$

(e) $y'' + 3y' = \dfrac{y}{x}$

(f) $yy' + x + y = 0$

SOLUTION

(a) The highest order derivative that appears in this equation is a first derivative, so this is a first order equation.

(b) The highest order derivative that appears in this equation is a second derivative, so this is not a first order equation.

(c) The highest order derivative that appears in this equation is a first derivative, so this is a first order equation.

(d) The highest order derivative that appears in this equation is a first derivative, so this is a first order equation.

(e) The highest order derivative that appears in this equation is a second derivative, so this is not a first order equation.

(f) The highest order derivative that appears in this equation is a first derivative, so this is a first order equation.

2. Which of the equations in Exercise 1 are linear?

SOLUTION

(a) Linear; $(1)y' - x^2 = 0$.

(b) Not linear; y^2 is not a linear function of y.

(c) Not linear; $(y')^3$ is not a linear function of y'.

(d) Not linear; $\sin y$ is not a linear function of y.

(e) Linear; $(1)y'' + (3)y' - \frac{1}{x}y = 0$.

(f) Not linear. yy' cannot be expressed as $a(x)y^{(n)}$.

In Exercises 3–8, verify that the given function is a solution of the differential equation.

3. $y' - 8x = 0, \quad y = 4x^2$

SOLUTION Let $y = 4x^2$. Then $y' = 8x$ and

$$y' - 8x = 8x - 8x = 0.$$

4. $yy' + 4x = 0, \quad y = \sqrt{12 - 4x^2}$

SOLUTION Let $y = \sqrt{12 - 4x^2}$. Then

$$y' = \frac{-4x}{\sqrt{12 - 4x^2}},$$

and

$$yy' + 4x = \sqrt{12 - 4x^2}\,\frac{-4x}{\sqrt{12 - 4x^2}} + 4x = -4x + 4x = 0.$$

5. $y' + 4xy = 0, \quad y = 25e^{-2x^2}$

SOLUTION Let $y = 25e^{-2x^2}$. Then $y' = -100xe^{-2x^2}$, and

$$y' + 4xy = -100xe^{-2x^2} + 4x(25e^{-2x^2}) = 0.$$

6. $(x^2 - 1)y' + xy = 0, \quad y = 4(x^2 - 1)^{-1/2}$

SOLUTION Let $y = 4(x^2 - 1)^{-1/2}$. Then $y' = -4x(x^2 - 1)^{-3/2}$, and

$$\begin{aligned}(x^2 - 1)y' + xy &= (x^2 - 1)(-4x)(x^2 - 1)^{-3/2} + 4x(x^2 - 1)^{-1/2}\\ &= -4x(x^2 - 1)^{-1/2} + 4x(x^2 - 1)^{-1/2} = 0.\end{aligned}$$

7. $y'' - 2xy' + 8y = 0, \quad y = 4x^4 - 12x^2 + 3$

SOLUTION Let $y = 4x^4 - 12x^2 + 3$. Then $y' = 16x^3 - 24x$, $y'' = 48x^2 - 24$, and

$$\begin{aligned}y'' - 2xy' + 8y &= (48x^2 - 24) - 2x(16x^3 - 24x) + 8(4x^4 - 12x^2 + 3)\\ &= 48x^2 - 24 - 32x^4 + 48x^2 + 32x^4 - 96x^2 + 24 = 0.\end{aligned}$$

8. $y'' - 2y' + 5y = 0, \quad y = e^x \sin 2x$

SOLUTION Let $y = e^x \sin 2x$. Then

$$\begin{aligned}y' &= 2e^x \cos 2x + e^x \sin 2x,\\ y'' &= -4e^x \sin 2x + 2e^x \cos 2x + 2e^x \cos 2x + e^x \sin 2x = -3e^x \sin 2x + 4e^x \cos 2x,\end{aligned}$$

and

$$\begin{aligned}y'' - 2y' + 5y &= -3e^x \sin 2x + 4e^x \cos 2x - 4e^x \cos 2x - 2e^x \sin 2x + 5e^x \sin 2x\\ &= (-3e^x - 2e^x + 5e^x)\sin 2x + (4e^x - 4e^x)\cos 2x = 0.\end{aligned}$$

9. Which of the following equations are separable? Write those that are separable in the form $y' = f(x)g(y)$ (but do not solve).

(a) $xy' - 9y^2 = 0$

(b) $\sqrt{4 - x^2}\,y' = e^{3y} \sin x$

(c) $y' = x^2 + y^2$

(d) $y' = 9 - y^2$

SOLUTION

(a) $xy' - 9y^2 = 0$ is separable:

$$\begin{aligned}xy' - 9y^2 &= 0\\ xy' &= 9y^2\\ y' &= \frac{9}{x}y^2\end{aligned}$$

(b) $\sqrt{4-x^2}y' = e^{3y}\sin x$ is separable:

$$\sqrt{4-x^2}y' = e^{3y}\sin x$$
$$y' = e^{3y}\frac{\sin x}{\sqrt{4-x^2}}.$$

(c) $y' = x^2 + y^2$ is not separable; y' is already isolated, but is not equal to a product $f(x)g(y)$.
(d) $y' = 9 - y^2$ is separable: $y' = (1)(9-y^2)$.

10. The following differential equations appear similar but have very different solutions.

$$\frac{dy}{dx} = x, \qquad \frac{dy}{dx} = y$$

Solve both subject to the initial condition $y(1) = 2$.

SOLUTION For the first differential equation, we have $y' = x$ so that, integrating,

$$y = \frac{x^2}{2} + C$$

Since $y(1) = 2$, $C = \frac{3}{2}$, so that

$$y = \frac{x^2+3}{2}$$

The second equation is separable: $y^{-1}\,dy = 1\,dx$, so that $\ln|y| = x + C$ and $y = Ce^x$. Since $y(1) = 2$, we have $2 = Ce$ or $C = 2e^{-1}$. Thus $y = 2e^{x-1}$.

11. Consider the differential equation $y^3y' - 9x^2 = 0$.
(a) Write it as $y^3\,dy = 9x^2\,dx$.
(b) Integrate both sides to obtain $\frac{1}{4}y^4 = 3x^3 + C$.
(c) Verify that $y = (12x^3 + C)^{1/4}$ is the general solution.
(d) Find the particular solution satisfying $y(1) = 2$.

SOLUTION Solving $y^3y' - 9x^2 = 0$ for y' gives $y' = 9x^2y^{-3}$.
(a) Separating variables in the equation above yields

$$y^3\,dy = 9x^2\,dx$$

(b) Integrating both sides gives

$$\frac{y^4}{4} = 3x^3 + C$$

(c) Simplify the equation above to get $y^4 = 12x^3 + C$, or $y = (12x^3 + C)^{1/4}$.
(d) Solve $2 = (12\cdot 1^3 + C)^{1/4}$ to get $16 = 12 + C$, or $C = 4$. Thus the particular solution is $y = (12x^3 + 4)^{1/4}$.

12. Verify that $x^2y' + e^{-y} = 0$ is separable.
(a) Write it as $e^y\,dy = -x^{-2}\,dx$.
(b) Integrate both sides to obtain $e^y = x^{-1} + C$.
(c) Verify that $y = \ln(x^{-1} + C)$ is the general solution.
(d) Find the particular solution satisfying $y(2) = 4$.

SOLUTION Solving $x^2y' + e^{-y} = 0$ for y' yields

$$y' = -x^{-2}e^{-y}.$$

(a) Separating variables in the last equation yields

$$e^y dy = -x^{-2}dx.$$

(b) Integrating both sides of the result of part (a), we find

$$\int e^y dy = -\int x^{-2}dx$$
$$e^y + C_1 = x^{-1} + C_2$$
$$e^y = x^{-1} + C$$

(c) Solving the last expression from part (b) for y, we find

$$y = \ln\left|x^{-1} + C\right|$$

(d) $y(2) = 4$ yields $4 = \ln\left|\frac{1}{2} + C\right|$, or $e^4 = C + \frac{1}{2}$. Thus the particular solution is

$$y = \ln\left|\frac{1}{x} - \frac{1}{2} + e^4\right|$$

In Exercises 13–28, use separation of variables to find the general solution.

13. $y' + 4xy^2 = 0$

SOLUTION Rewrite

$$y' + 4xy^2 = 0 \quad \text{as} \quad \frac{dy}{dx} = -4xy^2 \quad \text{and then as} \quad y^{-2}\,dy = -4x\,dx$$

Integrating both sides of this equation gives

$$\int y^{-2}\,dy = -4\int x\,dx$$
$$-y^{-1} = -2x^2 + C$$
$$y^{-1} = 2x^2 + C$$

Solving for y gives

$$y = \frac{1}{2x^2 + C}$$

where C is an arbitrary constant.

14. $y' + x^2y = 0$

SOLUTION Rewrite

$$y' + x^2y = 0 \quad \text{as} \quad \frac{dy}{dx} = -x^2y \quad \text{and then as} \quad y^{-1}\,dy = -x^2\,dx$$

Integrating both sides of this equation gives

$$\int y^{-1}\,dy = -\int x^2\,dx$$
$$\ln|y| = -\frac{x^3}{3} + C_1$$

Solve for y to get

$$y = \pm e^{-x^3/3 + C_1} = Ce^{-x^3/3}$$

where $C = \pm e^{C_1}$ is an arbitrary constant.

15. $\frac{dy}{dt} - 20t^4e^{-y} = 0$

SOLUTION Rewrite

$$\frac{dy}{dt} - 20t^4e^{-y} = 0 \quad \text{as} \quad \frac{dy}{dt} = 20t^4e^{-y} \quad \text{and then as} \quad e^y\,dy = 20t^4\,dt$$

Integrating both sides of this equation gives

$$\int e^y\,dy = \int 20t^4\,dt$$
$$e^y = 4t^5 + C$$

Solve for y to get $y = \ln(4t^5 + C)$, where C is an arbitrary constant.

16. $t^3y' + 4y^2 = 0$

SOLUTION Rewrite

$$t^3y' + 4y^2 = 0 \quad \text{as} \quad \frac{dy}{dt} = -4y^2t^{-3} \quad \text{and then as} \quad y^{-2}\,dy = -4t^{-3}\,dt$$

Integrating both sides of this equation gives

$$\int y^{-2}\,dy = -4\int t^{-3}\,dt$$
$$-y^{-1} = 2t^{-2} + C$$

Solve for y to get

$$y = \frac{-1}{2t^{-2} + C} = \frac{-t^2}{2 + Ct^2}$$

where C is an arbitrary constant.

17. $2y' + 5y = 4$

SOLUTION Rewrite

$$2y' + 5y = 4 \quad \text{as} \quad y' = 2 - \frac{5}{2}y \quad \text{and then as} \quad (4 - 5y)^{-1}\,dy = \frac{1}{2}\,dx$$

Integrating both sides and solving for y gives

$$\begin{aligned} \int \frac{dy}{4 - 5y} &= \frac{1}{2}\int 1\,dx \\ -\frac{1}{5}\ln|4 - 5y| &= \frac{1}{2}x + C_1 \\ \ln|4 - 5y| &= C_2 - \frac{5}{2}x \\ 4 - 5y &= C_3 e^{-5x/2} \\ 5y &= 4 - C_3 e^{-5x/2} \\ y &= Ce^{-5x/2} + \frac{4}{5} \end{aligned}$$

where C is an arbitrary constant.

18. $\dfrac{dy}{dt} = 8\sqrt{y}$

SOLUTION Rewrite

$$\frac{dy}{dt} = 8\sqrt{y} \qquad \text{as} \qquad \frac{dy}{\sqrt{y}} = 8\,dt.$$

Integrating both sides of this equation yields

$$\begin{aligned} \int \frac{dy}{\sqrt{y}} &= 8\int dt \\ 2\sqrt{y} &= 8t + C. \end{aligned}$$

Solving for y, we find

$$\begin{aligned} \sqrt{y} &= 4t + C \\ y &= (4t + C)^2, \end{aligned}$$

where C is an arbitrary constant.

19. $\sqrt{1 - x^2}\,y' = xy$

SOLUTION Rewrite

$$\sqrt{1 - x^2}\,\frac{dy}{dx} = xy \qquad \text{as} \qquad \frac{dy}{y} = \frac{x}{\sqrt{1 - x^2}}\,dx.$$

Integrating both sides of this equation yields

$$\begin{aligned} \int \frac{dy}{y} &= \int \frac{x}{\sqrt{1 - x^2}}\,dx \\ \ln|y| &= -\sqrt{1 - x^2} + C. \end{aligned}$$

Solving for y, we find

$$\begin{aligned} |y| &= e^{-\sqrt{1-x^2}+C} = e^C e^{-\sqrt{1-x^2}} \\ y &= \pm e^C e^{-\sqrt{1-x^2}} = Ae^{-\sqrt{1-x^2}}, \end{aligned}$$

where A is an arbitrary constant.

20. $y' = y^2(1 - x^2)$

SOLUTION Rewrite

$$\frac{dy}{dx} = y^2(1 - x^2) \qquad \text{as} \qquad \frac{dy}{y^2} = (1 - x^2)\,dx.$$

Integrating both sides of this equation yields

$$\int \frac{dy}{y^2} = \int (1 - x^2)\,dx$$
$$-y^{-1} = x - \frac{1}{3}x^3 + C.$$

Solving for y, we find

$$y^{-1} = \frac{1}{3}x^3 - x + C$$
$$y = \frac{1}{\frac{1}{3}x^3 - x + C},$$

where C is an arbitrary constant.

21. $yy' = x$

SOLUTION Rewrite

$$y\frac{dy}{dx} = x \qquad \text{as} \qquad y\,dy = x\,dx.$$

Integrating both sides of this equation yields

$$\int y\,dy = \int x\,dx$$
$$\frac{1}{2}y^2 = \frac{1}{2}x^2 + C.$$

Solving for y, we find

$$y^2 = x^2 + 2C$$
$$y = \pm\sqrt{x^2 + A},$$

where $A = 2C$ is an arbitrary constant.

22. $(\ln y)y' - ty = 0$

SOLUTION Rewrite

$$(\ln y)y' - ty = 0 \quad \text{as} \quad (\ln y)\frac{dy}{dt} = ty \quad \text{and then as} \quad \frac{\ln y}{y}\,dy = t\,dt$$

Integrating both sides of this equation gives

$$\int \frac{\ln y}{y}\,dy = \int t\,dt$$
$$\frac{1}{2}\ln^2 y = \frac{1}{2}t^2 + C_1$$
$$\ln^2 y = t^2 + C$$
$$\ln y = \pm\sqrt{t^2 + C}$$
$$y = e^{\pm\sqrt{t^2+C}}$$

23. $\dfrac{dx}{dt} = (t + 1)(x^2 + 1)$

SOLUTION Rewrite

$$\frac{dx}{dt} = (t + 1)(x^2 + 1) \qquad \text{as} \qquad \frac{1}{x^2 + 1}\,dx = (t + 1)\,dt.$$

Integrating both sides of this equation yields

$$\int \frac{1}{x^2+1}\,dx = \int (t+1)\,dt$$
$$\tan^{-1} x = \frac{1}{2}t^2 + t + C.$$

Solving for x, we find

$$x = \tan\left(\frac{1}{2}t^2 + t + C\right).$$

where $A = \tan C$ is an arbitrary constant.

24. $(1+x^2)y' = x^3y$

SOLUTION Rewrite

$$(1+x^2)\frac{dy}{dx} = x^3y \qquad \text{as} \qquad \frac{1}{y}\,dy = \frac{x^3}{1+x^2}\,dx.$$

Integrating both sides of this equation yields

$$\int \frac{1}{y}\,dy = \int \frac{x^3}{1+x^2}\,dx.$$

To integrate $\frac{x^3}{1+x^2}$, note

$$\frac{x^3}{1+x^2} = \frac{(x^3+x)-x}{1+x^2} = x - \frac{x}{1+x^2}.$$

Thus,

$$\ln|y| = \frac{1}{2}x^2 - \frac{1}{2}\ln|x^2+1| + C$$
$$|y| = e^C\frac{e^{x^2/2}}{\sqrt{x^2+1}}$$
$$y = \pm e^C\frac{e^{x^2/2}}{\sqrt{x^2+1}} = A\frac{e^{x^2/2}}{\sqrt{x^2+1}},$$

where $A = \pm e^C$ is an arbitrary constant.

25. $y' = x\sec y$

SOLUTION Rewrite

$$\frac{dy}{dx} = x\sec y \qquad \text{as} \qquad \cos y\,dy = x\,dx.$$

Integrating both sides of this equation yields

$$\int \cos y\,dy = \int x\,dx$$
$$\sin y = \frac{1}{2}x^2 + C.$$

Solving for y, we find

$$y = \sin^{-1}\left(\frac{1}{2}x^2 + C\right),$$

where C is an arbitrary constant.

26. $\dfrac{dy}{d\theta} = \tan y$

SOLUTION Rewrite

$$\frac{dy}{d\theta} = \tan y \qquad \text{as} \qquad \cot y\,dy = d\theta.$$

Integrating both sides of this equation yields

$$\int \frac{\cos y}{\sin y}\,dy = \int d\theta$$
$$\ln|\sin y| = \theta + C.$$

Solving for y, we have

$$|\sin y| = e^{\theta+C} = e^C e^\theta$$
$$\sin y = \pm e^C e^\theta$$
$$y = \sin^{-1}\left(Ae^\theta\right),$$

where $A = \pm e^C$ is an arbitrary constant.

27. $\dfrac{dy}{dt} = y\tan t$

SOLUTION Rewrite

$$\frac{dy}{dt} = y\tan t \qquad \text{as} \qquad \frac{1}{y}\,dy = \tan t\,dt.$$

Integrating both sides of this equation yields

$$\int \frac{1}{y}\,dy = \int \tan t\,dt$$
$$\ln|y| = \ln|\sec t| + C.$$

Solving for y, we find

$$|y| = e^{\ln|\sec t|+C} = e^C\,|\sec t|$$
$$y = \pm e^C \sec t = A\sec t,$$

where $A = \pm e^C$ is an arbitrary constant.

28. $\dfrac{dx}{dt} = t\tan x$

SOLUTION Rewrite

$$\frac{dx}{dt} = t\tan x \qquad \text{as} \qquad \cot x\,dx = t\,dt.$$

Integrating both sides of this equation yields

$$\int \cot x\,dx = \int t\,dt$$
$$\ln|\sin x| = \frac{1}{2}t^2 + C.$$

Solving for y, we find

$$|\sin x| = e^{\frac{1}{2}t^2+C} = e^C e^{\frac{1}{2}t^2}$$
$$\sin x = \pm e^C e^{\frac{1}{2}t^2}$$
$$x = \sin^{-1}\left(Ae^{\frac{1}{2}t^2}\right),$$

where $A = \pm e^C$ is an arbitrary constant.

In Exercises 29–42, solve the initial value problem.

29. $y' + 2y = 0, \quad y(\ln 5) = 3$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dx} + 2y = 0 \qquad \text{as} \qquad \frac{1}{y}\,dy = -2\,dx,$$

and then integrate to obtain

$$\ln|y| = -2x + C.$$

Thus,

$$y = Ae^{-2x},$$

where $A = \pm e^C$ is an arbitrary constant. The initial condition $y(\ln 5) = 3$ allows us to determine the value of A.

$$3 = Ae^{-2(\ln 5)}; \quad 3 = A\frac{1}{25}; \quad \text{so} \quad 75 = A.$$

Finally,

$$y = 75e^{-2x}.$$

30. $y' - 3y + 12 = 0, \quad y(2) = 1$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dx} - 3y + 12 = 0 \qquad \text{as} \qquad \frac{1}{3y-12}\,dy = 1\,dx,$$

and then integrate to obtain

$$\frac{1}{3}\ln|3y - 12| = x + C.$$

Thus,

$$y = Ae^{3x} + 4,$$

where $A = \pm\frac{1}{3}e^{3C}$ is an arbitrary constant. The initial condition $y(2) = 1$ allows us to determine the value of A.

$$1 = Ae^6 + 4; \quad -3 = Ae^6; \quad \text{so} \quad -3e^{-6} = A.$$

Finally,

$$y = -3e^{-6}e^{3x} + 4 = -3e^{3x-6} + 4$$

31. $yy' = xe^{-y^2}, \quad y(0) = -2$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$y\frac{dy}{dx} = xe^{-y^2} \qquad \text{as} \qquad ye^{y^2}\,dy = x\,dx,$$

and then integrate to obtain

$$\frac{1}{2}e^{y^2} = \frac{1}{2}x^2 + C.$$

Thus,

$$y = \pm\sqrt{\ln(x^2 + A)},$$

where $A = 2C$ is an arbitrary constant. The initial condition $y(0) = -2$ allows us to determine the value of A. Since $y(0) < 0$, we have $y = -\sqrt{\ln(x^2 + A)}$, and

$$-2 = -\sqrt{\ln(A)}; \quad 4 = \ln(A); \quad \text{so} \quad e^4 = A.$$

Finally,

$$y = -\sqrt{\ln(x^2 + e^4)}.$$

32. $y^2\frac{dy}{dx} = x^{-3}, \quad y(1) = 0$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$y^2\frac{dy}{dx} = x^{-3} \qquad \text{as} \qquad y^2\,dy = x^{-3}\,dx,$$

and then integrate to obtain

$$\frac{1}{3}y^3 = -\frac{1}{2}x^{-2} + C.$$

Thus,

$$y = \left(A - \frac{3}{2}x^{-2}\right)^{1/3},$$

where $A = 3C$ is an arbitrary constant. The initial condition $y(1) = 0$ allows us to determine the value of A.

$$0 = \left(A - \frac{3}{2}1^{-2}\right)^{1/3}; \quad 0 = \left(A - \frac{3}{2}\right)^{1/3}; \quad \text{so} \quad A = \frac{3}{2}.$$

Finally,

$$y = \left(\frac{3}{2} - \frac{3}{2}x^{-2}\right)^{1/3}.$$

33. $y' = (x-1)(y-2), \quad y(2) = 4$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dx} = (x-1)(y-2) \qquad \text{as} \qquad \frac{1}{y-2}\,dy = (x-1)\,dx,$$

and then integrate to obtain

$$\ln|y-2| = \frac{1}{2}x^2 - x + C.$$

Thus,

$$y = Ae^{(1/2)x^2 - x} + 2,$$

where $A = \pm e^C$ is an arbitrary constant. The initial condition $y(2) = 4$ allows us to determine the value of A.

$$4 = Ae^0 + 2 \quad \text{so} \quad A = 2.$$

Finally,

$$y = 2e^{(1/2)x^2 - x} + 2.$$

34. $y' = (x-1)(y-2), \quad y(2) = 2$

SOLUTION First (as in the previous problem), we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dx} = (x-1)(y-2) \qquad \text{as} \qquad \frac{1}{y-2}\,dy = (x-1)\,dx,$$

and then integrate to obtain

$$\ln|y-2| = \frac{1}{2}x^2 - x + C.$$

Thus,

$$y = Ae^{(1/2)x^2 - x} + 2,$$

where $A = \pm e^C$ is an arbitrary constant. The initial condition $y(2) = 2$ allows us to determine the value of A.

$$2 = Ae^0 + 2 \quad \text{so} \quad A = 0.$$

Finally,

$$y = 2.$$

35. $y' = x(y^2 + 1), \quad y(0) = 0$

SOLUTION First, find the general solution of the differential equation. Rewrite

$$\frac{dy}{dx} = x(y^2 + 1) \qquad \text{as} \qquad \frac{1}{y^2 + 1}\,dy = x\,dx$$

and integrate to obtain

$$\tan^{-1} y = \frac{1}{2}x^2 + C$$

so that

$$y = \tan\left(\frac{1}{2}x^2 + C\right)$$

where C is an arbitrary constant. The initial condition $y(0) = 0$ allows us to determine the value of C: $0 = \tan(C)$, so $C = 0$. Finally,

$$y = \tan\left(\frac{1}{2}x^2\right)$$

36. $(1-t)\dfrac{dy}{dt} - y = 0, \quad y(2) = -4$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$(1-t)\frac{dy}{dt} = y \qquad \text{as} \qquad \frac{1}{y}\,dy = \frac{-1}{t-1}\,dt,$$

and then integrate to obtain

$$\ln|y| = -\ln|t-1| + C.$$

Thus,

$$y = \frac{A}{t-1},$$

where $A = \pm e^C$ is an arbitrary constant. The initial condition $y(2) = -4$ allows us to determine the value of A.

$$-4 = \frac{A}{2-1} = A.$$

Finally,

$$y = \frac{-4}{t-1}.$$

37. $\dfrac{dy}{dt} = ye^{-t}, \quad y(0) = 1$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dt} = ye^{-t} \qquad \text{as} \qquad \frac{1}{y}\,dy = e^{-t}\,dt,$$

and then integrate to obtain

$$\ln|y| = -e^{-t} + C.$$

Thus,

$$y = Ae^{-e^{-t}},$$

where $A = \pm e^C$ is an arbitrary constant. The initial condition $y(0) = 1$ allows us to determine the value of A.

$$1 = Ae^{-1} \quad \text{so} \quad A = e.$$

Finally,

$$y = (e)e^{-e^{-t}} = e^{1-e^{-t}}.$$

38. $\dfrac{dy}{dt} = te^{-y}, \quad y(1) = 0$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dt} = te^{-y} \qquad \text{as} \qquad e^y\,dy = t\,dt,$$

and then integrate to obtain

$$e^y = \frac{1}{2}t^2 + C.$$

Thus,

$$y = \ln\left(\frac{1}{2}t^2 + C\right),$$

where C is an arbitrary constant. The initial condition $y(1) = 0$ allows us to determine the value of C.

$$0 = \ln\left(\frac{1}{2} + C\right); \quad 1 = \frac{1}{2} + C; \quad \text{so} \quad C = \frac{1}{2}.$$

Finally,

$$y = \ln\left(\frac{1}{2}t^2 + \frac{1}{2}\right).$$

39. $t^2\dfrac{dy}{dt} - t = 1 + y + ty, \quad y(1) = 0$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$t^2\frac{dy}{dt} = 1 + t + y + ty = (1+t)(1+y)$$

as

$$\frac{1}{1+y}\,dy = \frac{1+t}{t^2}\,dt,$$

and then integrate to obtain

$$\ln|1+y| = -t^{-1} + \ln|t| + C.$$

Thus,

$$y = A\frac{t}{e^{1/t}} - 1,$$

where $A = \pm e^C$ is an arbitrary constant. The initial condition $y(1) = 0$ allows us to determine the value of A.

$$0 = A\left(\frac{1}{e}\right) - 1 \quad \text{so} \quad A = e.$$

Finally,

$$y = \frac{et}{e^{1/t}} - 1.$$

40. $\sqrt{1-x^2}\,y' = y^2 + 1, \quad y(0) = 0$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\sqrt{1-x^2}\,\frac{dy}{dx} = y^2 + 1 \qquad \text{as} \qquad \frac{1}{y^2+1}\,dy = \frac{1}{\sqrt{1-x^2}}\,dx,$$

and then integrate to obtain

$$\tan^{-1} y = \sin^{-1} x + C.$$

Thus,

$$y = \tan(\sin^{-1} x + C),$$

where C is an arbitrary constant. The initial condition $y(0) = 0$ allows us to determine the value of C.

$$0 = \tan\left(\sin^{-1} 0 + C\right) = \tan C \quad \text{so} \quad 0 = C.$$

Finally,

$$y = \tan\left(\sin^{-1} x\right).$$

41. $y' = \tan y, \quad y(\ln 2) = \dfrac{\pi}{2}$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dx} = \tan y \qquad \text{as} \qquad \frac{dy}{\tan y} = dx,$$

and then integrate to obtain

$$\ln|\sin y| = x + C.$$

Thus,

$$y = \sin^{-1}(Ae^x),$$

where $A = \pm e^C$ is an arbitrary constant. The initial condition $y(\ln 2) = \frac{\pi}{2}$ allows us to determine the value of A.

$$\frac{\pi}{2} = \sin^{-1}(2A); \quad 1 = 2A \quad \text{so} \quad A = \frac{1}{2}.$$

Finally,

$$y = \sin^{-1}\left(\frac{1}{2}e^x\right).$$

42. $y' = y^2 \sin x, \quad y(\pi) = 2$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dx} = y^2 \sin x \qquad \text{as} \qquad y^{-2}\,dy = \sin x\,dx,$$

and then integrate to obtain

$$-y^{-1} = -\cos x + C.$$

Thus,

$$y = \frac{1}{A + \cos x},$$

where $A = -C$ is an arbitrary constant. The initial condition $y(\pi) = 2$ allows us to determine the value of A.

$$2 = \frac{1}{A-1}; \quad A - 1 = \frac{1}{2} \quad \text{so} \quad A = \frac{1}{2} + 1 = \frac{3}{2}.$$

Finally,

$$y = \frac{1}{\cos x + (3/2)} = \frac{2}{3 + 2\cos x}.$$

43. Find all values of a such that $y = x^a$ is a solution of

$$y'' - 12x^{-2}y = 0$$

SOLUTION Let $y = x^a$. Then

$$y' = ax^{a-1} \quad \text{and} \quad y'' = a(a-1)x^{a-2}.$$

Substituting into the differential equation, we find

$$y'' - 12x^{-2}y = a(a-1)x^{a-2} - 12x^{a-2} = x^{a-2}(a^2 - a - 12).$$

Thus, $y'' - 12x^{-2}y = 0$ if and only if

$$a^2 - a - 12 = (a-4)(a+3) = 0.$$

Hence, $y = x^a$ is a solution of the differential equation $y'' - 12x^{-2}y = 0$ provided $a = 4$ or $a = -3$.

44. Find all values of a such that $y = e^{ax}$ is a solution of

$$y'' + 4y' - 12y = 0$$

SOLUTION Let $y = e^{ax}$. Then

$$y' = ae^{ax} \quad \text{and} \quad y'' = a^2e^{ax}.$$

Substituting into the differential equation, we find

$$y'' + 4y' - 12y = e^{ax}(a^2 + 4a - 12).$$

Because e^{ax} is never zero, $y'' + 4y' - 12y = 0$ if only if $a^2 + 4a - 12 = (a+6)(a-2) = 0$. Hence, $y = e^{ax}$ is a solution of the differential equation $y'' + 4y' - 12y = 0$ provided $a = -6$ or $a = 2$.

In Exercises 45 and 46, let $y(t)$ *be a solution of* $(\cos y + 1)\dfrac{dy}{dt} = 2t$ *such that* $y(2) = 0$.

45. Show that $\sin y + y = t^2 + C$. We cannot solve for y as a function of t, but, assuming that $y(2) = 0$, find the values of t at which $y(t) = \pi$.

SOLUTION Rewrite

$$(\cos y + 1)\frac{dy}{dt} = 2t \quad \text{as} \quad (\cos y + 1)\,dy = 2t\,dt$$

and integrate to obtain

$$\sin y + y = t^2 + C$$

where C is an arbitrary constant. Since $y(2) = 0$, we have $\sin 0 + 0 = 4 + C$ so that $C = -4$ and the particular solution we seek is $\sin y + y = t^2 - 4$. To find values of t at which $y(t) = \pi$, we must solve $\sin \pi + \pi = t^2 - 4$, or $t^2 - 4 = \pi$; thus $t = \pm\sqrt{\pi + 4}$.

46. Assuming that $y(6) = \pi/3$, find an equation of the tangent line to the graph of $y(t)$ at $(6, \pi/3)$.

SOLUTION At $(6, \pi/3)$, we have

$$\left(\cos\frac{\pi}{3} + 1\right)\frac{dy}{dt} = 2(6) = 12 \quad \Rightarrow \quad \frac{3}{2}y' = 12$$

and hence $y' = 8$. The tangent line has equation

$$(y - \pi/3) = 8(x - 6)$$

In Exercises 47–52, use Eq. (4) and Torricelli's Law [Eq. (5)].

47. Water leaks through a hole of area 0.002 m^2 at the bottom of a cylindrical tank that is filled with water and has height 3 m and a base of area 10 m^2. How long does it take (a) for half of the water to leak out and (b) for the tank to empty?

SOLUTION Because the tank has a constant cross-sectional area of 10 m^2 and the hole has an area of 0.002 m^2, the differential equation for the height of the water in the tank is

$$\frac{dy}{dt} = \frac{0.002v}{10} = 0.0002v.$$

By Torricelli's Law,

$$v = -\sqrt{2gy} = -\sqrt{19.6y},$$

using $g = 9.8\ \text{m/s}^2$. Thus,

$$\frac{dy}{dt} = -0.0002\sqrt{19.6y} = -0.0002\sqrt{19.6}\cdot\sqrt{y}.$$

Separating variables and then integrating yields

$$\begin{aligned} y^{-1/2}\,dy &= -0.0002\sqrt{19.6}\,dt \\ 2y^{1/2} &= -0.0002\sqrt{19.6}t + C \end{aligned}$$

Solving for y, we find

$$y(t) = \left(C - 0.0001\sqrt{19.6}t\right)^2.$$

Since the tank is originally full, we have the initial condition $y(0) = 10$, whence $\sqrt{10} = C$. Therefore,

$$y(t) = \left(\sqrt{10} - 0.0001\sqrt{19.6}t\right)^2.$$

When half of the water is out of the tank, $y = 1.5$, so we solve:

$$1.5 = \left(\sqrt{10} - 0.0001\sqrt{19.6}t\right)^2$$

for t, finding

$$t = \frac{1}{0.0002\sqrt{19.6}}(2\sqrt{10} - \sqrt{6}) \approx 4376.44 \text{ sec.}$$

When all of the water is out of the tank, $y = 0$, so

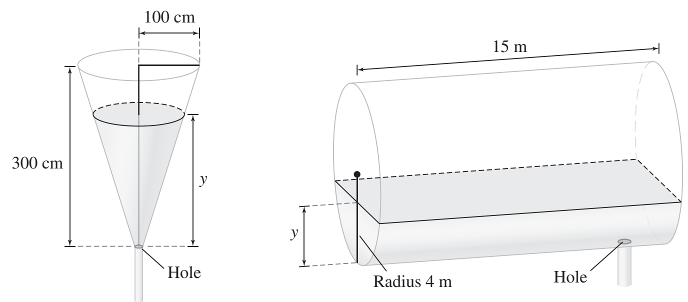
$$\sqrt{10} - 0.0001\sqrt{19.6}t = 0 \quad \text{and} \quad t = \frac{\sqrt{10}}{0.0001\sqrt{19.6}} \approx 7142.86 \text{ sec.}$$

48. At $t = 0$, a conical tank of height 300 cm and top radius 100 cm [Figure 7(A)] is filled with water. Water leaks through a hole in the bottom of area 3 cm^2. Let $y(t)$ be the water level at time t.

(a) Show that the tank's cross-sectional area at height y is $A(y) = \frac{\pi}{9}y^2$.

(b) Find and solve the differential equation satisfied by $y(t)$

(c) How long does it take for the tank to empty?



(A) Conical tank (B) Horizontal tank

FIGURE 7

SOLUTION

(a) By similar triangles, the radius r at height y satisfies

$$\frac{r}{y} = \frac{100}{300} = \frac{1}{3},$$

so $r = y/3$ and

$$A(y) = \pi r^2 = \frac{\pi}{9}y^2.$$

(b) The area of the hole is $B = 3$ cm^2, so the differential equation for the height of the water in the tank becomes:

$$\frac{dy}{dt} = -\frac{3\sqrt{19.6}\sqrt{y}}{A(y)} = -\frac{27\sqrt{19.6}}{\pi}y^{-3/2}.$$

Separating variables and integrating then yields

$$y^{3/2}\,dy = -\frac{27\sqrt{19.6}}{\pi}\,dt$$

$$\frac{2}{5}y^{5/2} = C - \frac{27\sqrt{19.6}}{\pi}t$$

When $t = 0$, $y = 300$, so we find $C = \frac{2}{5}(300)^{5/2}$. Therefore,

$$y(t) = \left(300^{5/2} - \frac{135\sqrt{19.6}}{2\pi}t\right)^{2/5}.$$

(c) The tank is empty when $y = 0$. Using the result from part (b), $y = 0$ when

$$t = \frac{4000\pi\sqrt{300}}{3\sqrt{19.6}} \approx 16{,}387.82 \text{ seconds.}$$

Thus, it takes roughly 4 hours, 33 minutes for the tank to empty.

49. The tank in Figure 7(B) is a cylinder of radius 4 m and height 15 m. Assume that the tank is half-filled with water and that water leaks through a hole in the bottom of area $B = 0.001$ m^2. Determine the water level $y(t)$ and the time t_e when the tank is empty.

SOLUTION When the water is at height y over the bottom, the top cross section is a rectangle with length 15 m, and with width x satisfying the equation:

$$(x/2)^2 + (y-4)^2 = 16.$$

Thus, $x = 2\sqrt{8y - y^2}$, and

$$A(y) = 15x = 30\sqrt{8y - y^2}.$$

With $B = 0.001$ m^2 and $v = -\sqrt{2gy} = -\sqrt{19.6}\sqrt{y}$, it follows that

$$\frac{dy}{dt} = -\frac{0.001\sqrt{19.6}\sqrt{y}}{30\sqrt{8y-y^2}} = -\frac{0.001\sqrt{19.6}}{30\sqrt{8-y}}.$$

Separating variables and integrating then yields:

$$\sqrt{8-y}\,dy = -\frac{0.001\sqrt{19.6}}{30}\,dt = -\frac{0.0001\sqrt{19.6}}{3}\,dt$$
$$-\frac{2}{3}(8-y)^{3/2} = -\frac{0.0001\sqrt{19.6}}{3}t + C$$

When $t = 0$, $y = 4$, so $C = -\frac{2}{3}4^{3/2} = -\frac{16}{3}$, and

$$-\frac{2}{3}(8-y)^{3/2} = -\frac{0.0001\sqrt{19.6}}{3}t - \frac{16}{3}$$
$$y(t) = 8 - \left(\frac{0.0001\sqrt{19.6}}{2}t + 8\right)^{2/3}.$$

The tank is empty when $y = 0$. Thus, t_e satisfies the equation

$$8 - \left(\frac{0.0001\sqrt{19.6}}{2}t + 8\right)^{2/3} = 0.$$

It follows that

$$t_e = \frac{2(8^{3/2} - 8)}{0.0001\sqrt{19.6}} \approx 66{,}079.9 \text{ seconds.}$$

50. A tank has the shape of the parabola $y = x^2$, revolved around the y-axis. Water leaks from a hole of area $B = 0.0005$ m^2 at the bottom of the tank. Let $y(t)$ be the water level at time t. How long does it take for the tank to empty if it is initially filled to height $y_0 = 1$ m.

SOLUTION When the water is at height y, the surface of the water is a circle with radius $\sqrt{y}$, so the cross-sectional area is $A(y) = \pi y$. With $B = 0.0005$ m and $v = -\sqrt{2gy} = -\sqrt{19.6}\sqrt{y}$, it follows that

$$\frac{dy}{dt} = -\frac{0.0005\sqrt{19.6}\sqrt{y}}{A(y)} = -\frac{0.0005\sqrt{19.6}\sqrt{y}}{\pi y} = -\frac{0.0005\sqrt{19.6}}{\pi\sqrt{y}}$$

Separating variables and integrating yields

$$\pi y^{1/2}\,dy = -0.0005\sqrt{19.6}\,dt$$
$$\frac{2}{3}\pi y^{3/2} = -0.0005\sqrt{19.6}t + C$$
$$y^{3/2} = -\frac{0.00075\sqrt{19.6}}{\pi}t + C$$

Since $y(0) = 1$, we have $C = 1$, so that

$$y = \left(1 - \frac{0.00075\sqrt{19.6}}{\pi}t\right)^{2/3}$$

The tank is empty when $y = 0$, so when $1 - \frac{0.00075\sqrt{19.6}}{\pi}t = 0$ and thus

$$t = \frac{\pi}{0.00075\sqrt{19.6}} \approx 946.15 \text{ s}$$

51. A tank has the shape of the parabola $y = ax^2$ (where a is a constant) revolved around the y-axis. Water drains from a hole of area B m^2 at the bottom of the tank.

(a) Show that the water level at time t is

$$y(t) = \left(y_0^{3/2} - \frac{3aB\sqrt{2g}}{2\pi}t\right)^{2/3}$$

where y_0 is the water level at time $t = 0$.

(b) Show that if the total volume of water in the tank has volume V at time $t = 0$, then $y_0 = \sqrt{2aV/\pi}$. *Hint:* Compute the volume of the tank as a volume of rotation.

(c) Show that the tank is empty at time

$$t_e = \left(\frac{2}{3B\sqrt{g}}\right)\left(\frac{2\pi V^3}{a}\right)^{1/4}$$

We see that for fixed initial water volume V, the time t_e is proportional to $a^{-1/4}$. A large value of a corresponds to a tall thin tank. Such a tank drains more quickly than a short wide tank of the same initial volume.

SOLUTION

(a) When the water is at height y, the surface of the water is a circle of radius $\sqrt{y/a}$, so that the cross-sectional area is $A(y) = \pi y/a$. With $v = -\sqrt{2gy} = -\sqrt{2g}\sqrt{y}$, we have

$$\frac{dy}{dt} = -\frac{B\sqrt{2g}\sqrt{y}}{A} = -\frac{aB\sqrt{2g}\sqrt{y}}{\pi y} = -\frac{aB\sqrt{2g}}{\pi}y^{-1/2}$$

Separating variables and integrating gives

$$\sqrt{y}\,dy = -\frac{aB\sqrt{2g}}{\pi}\,dt$$

$$\frac{2}{3}y^{3/2} = -\frac{aB\sqrt{2g}}{\pi}t + C_1$$

$$y^{3/2} = -\frac{3aB\sqrt{2g}}{2\pi}t + C$$

Since $y(0) = y_0$, we have $C = y_0^{3/2}$; solving for y gives

$$y = \left(y_0^{3/2} - \frac{3aB\sqrt{2g}}{2\pi}t\right)^{2/3}$$

(b) The volume of the tank can be computed as a volume of rotation. Using the disk method and applying it to the function $x = \sqrt{y/a}$, we have

$$V = \int_0^{y_0} \pi\sqrt{\frac{y}{a}}^2\,dy = \frac{\pi}{a}\int_0^{y_0} y\,dy = \frac{\pi}{2a}y^2\Big|_0^{y_0} = \frac{\pi}{2a}y_0^2$$

Solving for y_0 gives

$$y_0 = \sqrt{2aV/\pi}$$

(c) The tank is empty when $y = 0$; this occurs when

$$y_0^{3/2} - \frac{3aB\sqrt{2g}}{2\pi}t = 0$$

From part (b), we have

$$y_0^{3/2} = \sqrt{2aV/\pi}^{3/2} = ((2aV/\pi)^{1/2})^{3/2} = (2aV/\pi)^{3/4}$$

so that

$$t_e = \frac{2\pi y_0^{3/2}}{3aB\sqrt{2g}} = \frac{2\pi\sqrt[4]{8a^3V^3}}{3\pi^{3/4}B\sqrt[4]{a^4}\sqrt[4]{4}\sqrt{g}} = \frac{2\pi^{1/4}\sqrt[4]{2V^3a^{-1}}}{3B\sqrt{g}} = \left(\frac{2}{3B\sqrt{g}}\right)\left(\frac{2\pi V^3}{a}\right)^{1/4}$$

52. A cylindrical tank filled with water has height h and a base of area A. Water leaks through a hole in the bottom of area B.

(a) Show that the time required for the tank to empty is proportional to $A\sqrt{h}/B$.
(b) Show that the emptying time is proportional to $Vh^{-1/2}$, where V is the volume of the tank.
(c) Two tanks have the same volume and a hole of the same size, but they have different heights and bases. Which tank empties first: the taller or the shorter tank?

SOLUTION Torricelli's law gives the differential equation for the height of the water in the tank as

$$\frac{dy}{dt} = -\sqrt{2g}\frac{B\sqrt{y}}{A}$$

Separating variables and integrating then yields:

$$y^{-1/2}\,dy = -\sqrt{2g}\frac{B}{A}\,dt$$

$$2y^{1/2} = -\sqrt{2g}\frac{Bt}{A} + C$$

$$y^{1/2} = -\sqrt{g/2}\frac{Bt}{A} + C$$

When $t = 0$, $y = h$, so $C = h^{1/2}$ and

$$y^{1/2} = \sqrt{h} - \sqrt{g/2}\frac{Bt}{A}.$$

(a) When the tank is empty, $y = 0$. Thus, the time required for the tank to empty, t_e, satisfies the equation

$$0 = \sqrt{h} - \sqrt{g/2}\frac{Bt_e}{A}.$$

It follows that

$$t_e = \frac{A}{B}\sqrt{2h/g} = \sqrt{2/g}\left(\frac{A\sqrt{h}}{B}\right);$$

that is, the time required for the tank to empty is proportional to $A\sqrt{h}/B$.
(b) The volume of the tank is $V = Ah$; therefore

$$\frac{A\sqrt{h}}{B} = \frac{1}{B}\frac{V}{\sqrt{h}},$$

and

$$t_e = \sqrt{2/g}\left(\frac{A\sqrt{h}}{B}\right) = \frac{\sqrt{2/g}}{B}\left(\frac{V}{\sqrt{h}}\right);$$

that is, the time required for the tank to empty is proportional to $Vh^{-1/2}$.
(c) By part (b), with V and B held constant, the emptying time decreases with height. The taller tank therefore empties first.

53. Figure 8 shows a circuit consisting of a resistor of R ohms, a capacitor of C farads, and a battery of voltage V. When the circuit is completed, the amount of charge $q(t)$ (in coulombs) on the plates of the capacitor varies according to the differential equation (t in seconds)

$$R\frac{dq}{dt} + \frac{1}{C}q = V$$

where R, C, and V are constants.

(a) Solve for $q(t)$, assuming that $q(0) = 0$.
(b) Show that $\lim_{t\to\infty} q(t) = CV$.
(c) Show that the capacitor charges to approximately 63% of its final value CV after a time period of length $\tau = RC$ (τ is called the time constant of the capacitor).

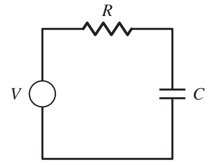


FIGURE 8 An RC circuit.

SOLUTION

(a) Upon rearranging the terms of the differential equation, we have

$$\frac{dq}{dt} = -\frac{q - CV}{RC}.$$

Separating the variables and integrating both sides, we obtain

$$\frac{dq}{q - CV} = -\frac{dt}{RC}$$

$$\int \frac{dq}{q - CV} = -\int \frac{dt}{RC}$$

and

$$\ln|q - CV| = -\frac{t}{RC} + k,$$

where k is an arbitrary constant. Solving for $q(t)$ yields

$$q(t) = CV + Ke^{-\frac{1}{RC}t},$$

where $K = \pm e^k$. We use the initial condition $q(0) = 0$ to solve for K:

$$0 = CV + K \quad \Rightarrow \quad K = -CV$$

so that the particular solution is

$$q(t) = CV(1 - e^{-\frac{1}{RC}t})$$

(b) Using the result from part (a), we calculate

$$\lim_{t\to\infty} q(t) = \lim_{t\to\infty} CV(1 - e^{-\frac{1}{RC}t}) = CV(1 - \lim_{t\to\infty} 1 - e^{-\frac{1}{RC}t}) = CV.$$

(c) We have

$$q(\tau) = q(RC) = CV(1 - e^{-\frac{1}{RC}RC}) = CV(1 - e^{-1}) \approx 0.632CV.$$

54. Assume in the circuit of Figure 8 that $R = 200\ \Omega$, $C = 0.02$ F, and $V = 12$ V. How many seconds does it take for the charge on the capacitor plates to reach half of its limiting value?

SOLUTION From Exercise 53, we know that

$$q(t) = CV\left(1 - e^{-t/(RC)}\right) = 0.24(1 - e^{-t/4}),$$

and the limiting value of $q(t)$ is $CV = 0.24$. If the charge on the capacitor plates has reached half its limiting value, then

$$\begin{aligned} \frac{0.24}{2} &= 0.24(1 - e^{-t/4}) \\ 1 - e^{-t/4} &= 1/2 \\ e^{-t/4} &= 1/2 \\ t &= 4\ln 2 \end{aligned}$$

Therefore, the charge on the capacitor plates reaches half of its limiting value after $4\ln 2 \approx 2.773$ seconds.

55. According to one hypothesis, the growth rate dV/dt of a cell's volume V is proportional to its surface area A. Since V has cubic units such as cm^3 and A has square units such as cm^2, we may assume roughly that $A \propto V^{2/3}$, and hence $dV/dt = kV^{2/3}$ for some constant k. If this hypothesis is correct, which dependence of volume on time would we expect to see (again, roughly speaking) in the laboratory?

(a) Linear **(b)** Quadratic **(c)** Cubic

SOLUTION Rewrite

$$\frac{dV}{dt} = kV^{2/3} \qquad \text{as} \qquad V^{-2/3}\,dv = k\,dt,$$

and then integrate both sides to obtain

$$3V^{1/3} = kt + C$$
$$V = (kt/3 + C)^3.$$

Thus, we expect to see V increasing roughly like the cube of time.

56. We might also guess that the volume V of a melting snowball decreases at a rate proportional to its surface area. Argue as in Exercise 55 to find a differential equation satisfied by V. Suppose the snowball has volume 1000 cm^3 and that it loses half of its volume after 5 min. According to this model, when will the snowball disappear?

SOLUTION Since the volume is decreasing, we write (as in Exercise 55) $V' = -kV^{2/3}$ where k is positive, so $V(t) = (C - kt/3)^3$. $V(0) = 1000$ implies that $C = 10$ so $V(t) = (10 - kt/3)^3$. Since it loses half of its volume after 5 minutes, we have $V(5) = \frac{1}{2}V(0)$, so that

$$(10 - 5k/3)^3 = 500 \qquad \text{so that} \quad k = 6 - 3 \cdot 2^{2/3} \approx 1.2378$$

and finally the equation is

$$V(t) = \left(10 - \frac{1.2378t}{3}\right)^3$$

The snowball is melted when its volume is zero, so when

$$10 - \frac{1.2378t}{3} = 0 \quad \Rightarrow \quad t = \frac{30}{1.2378} \approx 24.24 \text{ minutes}$$

57. In general, $(fg)'$ is not equal to $f'g'$, but let $f(x) = e^{3x}$ and find a function $g(x)$ such that $(fg)' = f'g'$. Do the same for $f(x) = x$.

SOLUTION If $(fg)' = f'g'$, we have

$$f'(x)g(x) + g'(x)f(x) = f'(x)g'(x)$$
$$g'(x)(f(x) - f'(x)) = -g(x)f'(x)$$
$$\frac{g'(x)}{g(x)} = \frac{f'(x)}{f'(x) - f(x)}$$

Now, let $f(x) = e^{3x}$. Then $f'(x) = 3e^{3x}$ and

$$\frac{g'(x)}{g(x)} = \frac{3e^{3x}}{3e^{3x} - e^{3x}} = \frac{3}{2}.$$

Integrating and solving for $g(x)$, we find

$$\frac{dg}{g} = \frac{3}{2}\,dx$$
$$\ln|g| = \frac{3}{2}x + C$$
$$g(x) = Ae^{(3/2)x},$$

where $A = \pm e^C$ is an arbitrary constant.

If $f(x) = x$, then $f'(x) = 1$, and

$$\frac{g'(x)}{g(x)} = \frac{1}{1-x}.$$

Thus,

$$\frac{dg}{g} = \frac{1}{1-x}\,dx$$
$$\ln|g| = -\ln|1-x| + C$$
$$g(x) = \frac{A}{1-x},$$

where $A = \pm e^C$ is an arbitrary constant.

58. A boy standing at point B on a dock holds a rope of length ℓ attached to a boat at point A [Figure 9(A)]. As the boy walks along the dock, holding the rope taut, the boat moves along a curve called a **tractrix** (from the Latin *tractus*, meaning "to pull"). The segment from a point P on the curve to the x-axis along the tangent line has constant length ℓ. Let $y = f(x)$ be the equation of the tractrix.

(a) Show that $y^2 + (y/y')^2 = \ell^2$ and conclude $y' = -\frac{y}{\sqrt{\ell^2 - y^2}}$. Why must we choose the negative square root?

(b) Prove that the tractrix is the graph of

$$x = \ell \ln\left(\frac{\ell + \sqrt{\ell^2 - y^2}}{y}\right) - \sqrt{\ell^2 - y^2}$$

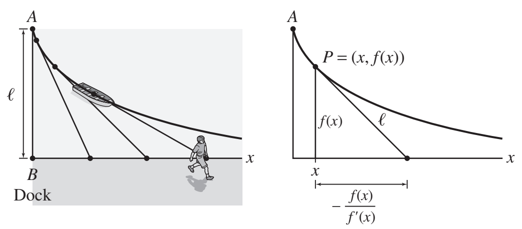

FIGURE 9

SOLUTION

(a) From the diagram on the right in Figure 9, we see that

$$f(x)^2 + \left(-\frac{f(x)}{f'(x)}\right)^2 = \ell^2.$$

If we let $y = f(x)$, this last equation reduces to $y^2 + (y/y')^2 = \ell^2$. Solving for y', we find

$$y' = -\frac{y}{\sqrt{\ell^2 - y^2}},$$

where we must choose the negative sign because y is a decreasing function of x.

(b) Rewrite

$$\frac{dy}{dx} = -\frac{y}{\sqrt{\ell^2 - y^2}} \qquad \text{as} \qquad \frac{\sqrt{\ell^2 - y^2}}{y}\, dy = -dx,$$

and then integrate both sides to obtain

$$-x + C = \int \frac{\sqrt{\ell^2 - y^2}}{y}\, dy.$$

For the remaining integral, we use the trigonometric substitution $y = \ell \sin\theta$, $dy = \ell \cos\theta\, d\theta$. Then

$$\int \frac{\sqrt{\ell^2 - y^2}}{y}\, dy = \ell \int \frac{\cos^2\theta}{\sin\theta}\, d\theta = \ell \int \frac{1 - \sin^2\theta}{\sin\theta}\, d\theta = \ell \int (\csc\theta - \sin\theta)\, d\theta$$

$$= \ell\,[\ln|\csc\theta - \cot\theta| + \cos\theta] + C = \ell \ln\left(\frac{\ell}{y} - \frac{\sqrt{\ell^2 - y^2}}{y}\right) + \sqrt{\ell^2 - y^2} + C$$

Therefore,

$$x = -\ell \ln\left(\frac{\ell - \sqrt{\ell^2 - y^2}}{y}\right) - \sqrt{\ell^2 - y^2} + C = \ell \ln\left(\frac{y}{\ell - \sqrt{\ell^2 - y^2}}\right) - \sqrt{\ell^2 - y^2} + C$$

$$= \ell \ln\left(\frac{\ell + \sqrt{\ell^2 - y^2}}{y}\right) - \sqrt{\ell^2 - y^2} + C$$

Now, when $x = 0$, $y = \ell$, so we find $C = 0$. Finally, the equation for the tractrix is

$$x = \ell \ln\left(\frac{\ell + \sqrt{\ell^2 - y^2}}{y}\right) - \sqrt{\ell^2 - y^2}.$$

59. Show that the differential equations $y' = 3y/x$ and $y' = -x/3y$ define **orthogonal families** of curves; that is, the graphs of solutions to the first equation intersect the graphs of the solutions to the second equation in right angles (Figure 10). Find these curves explicitly.

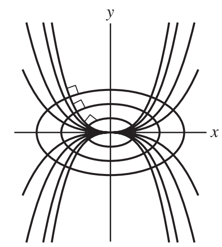

FIGURE 10 Two orthogonal families of curves.

SOLUTION Let y_1 be a solution to $y' = \frac{3y}{x}$ and let y_2 be a solution to $y' = -\frac{x}{3y}$. Suppose these two curves intersect at a point (x_0, y_0). The line tangent to the curve $y_1(x)$ at (x_0, y_0) has a slope of $\frac{3y_0}{x_0}$ and the line tangent to the curve $y_2(x)$ has a slope of $-\frac{x_0}{3y_0}$. The slopes are negative reciprocals of one another; hence the tangent lines are perpendicular.

Separation of variables and integration applied to $y' = \frac{3y}{x}$ gives

$$\frac{dy}{y} = 3\frac{dx}{x}$$
$$\ln|y| = 3\ln|x| + C$$
$$y = Ax^3$$

On the other hand, separation of variables and integration applied to $y' = -\frac{x}{3y}$ gives

$$3y\,dy = -x\,dx$$
$$3y^2/2 = -x^2/2 + C$$
$$y = \pm\sqrt{C - x^2/3}$$

60. Find the family of curves satisfying $y' = x/y$ and sketch several members of the family. Then find the differential equation for the orthogonal family (see Exercise 59), find its general solution, and add some members of this orthogonal family to your plot.

SOLUTION Separation of variables and integration applied to $y' = x/y$ gives

$$y\,dy = x\,dx$$
$$\frac{1}{2}y^2 = \frac{1}{2}x^2 + C$$
$$y = \pm\sqrt{x^2 + C}$$

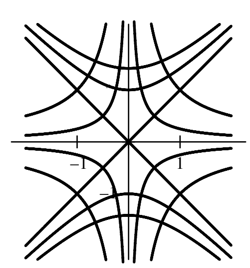
If $y(x)$ is a curve of the family orthogonal to these, it must have tangent lines of slope $-y/x$ at every point (x, y). This gives

$$y' = -y/x$$

Separation of variables and integration give

$$\frac{dy}{y} = -\frac{dx}{x}$$
$$\ln|y| = -\ln|x| + C$$
$$y = \frac{A}{x}$$

Several solution curves of both differential equations appear below:



61. A 50-kg model rocket lifts off by expelling fuel at a rate of $k = 4.75$ kg/s for 10 s. The fuel leaves the end of the rocket with an exhaust velocity of $b = -100$ m/s. Let $m(t)$ be the mass of the rocket at time t. From the law of conservation of momentum, we find the following differential equation for the rocket's velocity $v(t)$ (in meters per second):

$$m(t)v'(t) = -9.8m(t) + b\frac{dm}{dt}$$

(a) Show that $m(t) = 50 - 4.75t$ kg.
(b) Solve for $v(t)$ and compute the rocket's velocity at rocket burnout (after 10 s).

SOLUTION

(a) For $0 \le t \le 10$, the rocket is expelling fuel at a constant rate of 4.75 kg/s, giving $m'(t) = -4.75$. Hence, $m(t) = -4.75t + C$. Initially, the rocket has a mass of 50 kg, so $C = 50$. Therefore, $m(t) = 50 - 4.75t$.

(b) With $m(t) = 50 - 4.75t$ and $\dfrac{dm}{dt} = -4.75$, the equation for v becomes

$$\frac{dv}{dt} = -9.8 + \frac{b\frac{dm}{dt}}{50 - 4.75t} = -9.8 + \frac{(100)(-4.75)}{50 - 4.75t}$$

and therefore

$$v(t) = -9.8t + 100\int \frac{4.75\,dt}{50 - 4.75t} = -9.8t - 100\ln(50 - 4.75t) + C$$

Because $v(0) = 0$, we find $C = 100\ln 50$ and

$$v(t) = -9.8t - 100\ln(50 - 4.75t) + 100\ln(50).$$

After 10 seconds the velocity is:

$$v(10) = -98 - 100\ln(2.5) + 100\ln(50) \approx 201.573 \text{ m/s}.$$

62. Let $v(t)$ be the velocity of an object of mass m in free fall near the earth's surface. If we assume that air resistance is proportional to v^2, then v satisfies the differential equation $m\frac{dv}{dt} = -g + kv^2$ for some constant $k > 0$.

(a) Set $\alpha = (g/k)^{1/2}$ and rewrite the differential equation as

$$\frac{dv}{dt} = -\frac{k}{m}(\alpha^2 - v^2)$$

Then solve using separation of variables with initial condition $v(0) = 0$.
(b) Show that the terminal velocity $\lim_{t\to\infty} v(t)$ is equal to $-\alpha$.

SOLUTION

(a) Let $\alpha = (g/k)^{1/2}$. Then

$$\frac{dv}{dt} = -\frac{g}{m} + \frac{k}{m}v^2 = -\frac{k}{m}\left(\frac{g}{k} - v^2\right) = -\frac{k}{m}\left(\alpha^2 - v^2\right)$$

Separating variables and integrating yields

$$\int \frac{dv}{\alpha^2 - v^2} = -\frac{k}{m}\int dt = -\frac{k}{m}t + C$$

We now use partial fraction decomposition for the remaining integral to obtain

$$\int \frac{dv}{\alpha^2 - v^2} = \frac{1}{2\alpha}\int \left(\frac{1}{\alpha + v} + \frac{1}{\alpha - v}\right)dv = \frac{1}{2\alpha}\ln\left|\frac{\alpha + v}{\alpha - v}\right|$$

Therefore,

$$\frac{1}{2\alpha}\ln\left|\frac{\alpha + v}{\alpha - v}\right| = -\frac{k}{m}t + C.$$

The initial condition $v(0) = 0$ allows us to determine the value of C:

$$\frac{1}{2\alpha}\ln\left|\frac{\alpha + 0}{\alpha - 0}\right| = -\frac{k}{m}(0) + C$$

$$C = \frac{1}{2\alpha}\ln 1 = 0.$$

Finally, solving for v, we find

$$v(t) = -\alpha\left(\frac{1 - e^{-2(\sqrt{gk}/m)t}}{1 + e^{-2(\sqrt{gk}/m)t}}\right).$$

(b) As $t \to \infty$, $e^{-2(\sqrt{gk}/m)t} \to 0$, so

$$v(t) \to -\alpha\left(\frac{1-0}{1+0}\right) = -\alpha.$$

63. If a bucket of water spins about a vertical axis with constant angular velocity ω (in radians per second), the water climbs up the side of the bucket until it reaches an equilibrium position (Figure 11). Two forces act on a particle located at a distance x from the vertical axis: the gravitational force $-mg$ acting downward and the force of the bucket on the particle (transmitted indirectly through the liquid) in the direction perpendicular to the surface of the water. These two forces must combine to supply a centripetal force $m\omega^2 x$, and this occurs if the diagonal of the rectangle in Figure 11 is normal to the water's surface (that is, perpendicular to the tangent line). Prove that if $y = f(x)$ is the equation of the curve obtained by taking a vertical cross section through the axis, then $-1/y' = -g/(\omega^2 x)$. Show that $y = f(x)$ is a parabola.

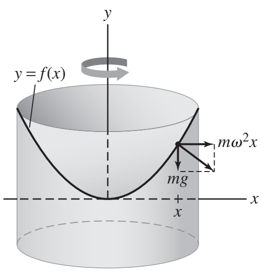


FIGURE 11

SOLUTION At any point along the surface of the water, the slope of the tangent line is given by the value of y' at that point; hence, the slope of the line perpendicular to the surface of the water is given by $-1/y'$. The slope of the resultant force generated by the gravitational force and the centrifugal force is

$$\frac{-mg}{m\omega^2 x} = -\frac{g}{\omega^2 x}.$$

Therefore, the curve obtained by taking a vertical cross-section of the water surface is determined by the equation

$$-\frac{1}{y'} = -\frac{g}{\omega^2 x} \qquad \text{or} \qquad y' = \frac{\omega^2}{g}x.$$

Performing one integration yields

$$y = f(x) = \frac{\omega^2}{2g}x^2 + C,$$

where C is a constant of integration. Thus, $y = f(x)$ is a parabola.

Further Insights and Challenges

64. In Section 6.2, we computed the volume V of a solid as the integral of cross-sectional area. Explain this formula in terms of differential equations. Let $V(y)$ be the volume of the solid up to height y, and let $A(y)$ be the cross-sectional area at height y as in Figure 12.

(a) Explain the following approximation for small Δy:

$$V(y + \Delta y) - V(y) \approx A(y)\,\Delta y \tag{8}$$

(b) Use Eq. (8) to justify the differential equation $dV/dy = A(y)$. Then derive the formula

$$V = \int_a^b A(y)\,dy$$

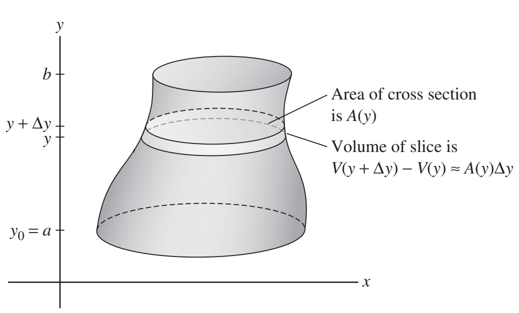

FIGURE 12

SOLUTION

(a) If Δy is very small, then the slice between y and $y + \Delta y$ is very similar to the *prism* formed by thickening the cross-sectional area $A(y)$ by a thickness of Δy. A prism with cross-sectional area A and height Δy has volume $A\Delta y$. This gives

$$V(y + \Delta y) - V(y) \approx A(y)\Delta y.$$

(b) Dividing Eq. (8) by Δy, we obtain

$$\frac{V(y + \Delta y) - V(y)}{\Delta y} \approx A(y).$$

In the limit as $\Delta y \to 0$, this becomes

$$\frac{dV}{dy} = A(y).$$

Integrating this last equation yields

$$V = \int_a^b A(y)\,dy.$$

65. A basic theorem states that a *linear* differential equation of order n has a general solution that depends on n arbitrary constants. There are, however, nonlinear exceptions.

(a) Show that $(y')^2 + y^2 = 0$ is a first-order equation with only one solution $y = 0$.

(b) Show that $(y')^2 + y^2 + 1 = 0$ is a first-order equation with no solutions.

SOLUTION

(a) $(y')^2 + y^2 \geq 0$ and equals zero if and only if $y' = 0$ and $y = 0$

(b) $(y')^2 + y^2 + 1 \geq 1 > 0$ for all y' and y, so $(y')^2 + y^2 + 1 = 0$ has no solution

66. Show that $y = Ce^{rx}$ is a solution of $y'' + ay' + by = 0$ if and only if r is a root of $P(r) = r^2 + ar + b$. Then verify directly that $y = C_1e^{3x} + C_2e^{-x}$ is a solution of $y'' - 2y' - 3y = 0$ for any constants C_1, C_2.

SOLUTION

(a) Let $y(x) = Ce^{rx}$. Then $y' = rCe^{rx}$, and $y'' = r^2Ce^{rx}$. Thus

$$y'' + ay' + by = r^2Ce^{rx} + arCe^{rx} + bCe^{rx} = Ce^{rx}\left(r^2 + ar + b\right) = Ce^{rx}P(r).$$

Hence, Ce^{rx} is a solution of the differential equation $y'' + ay' + by = 0$ if and only if $P(r) = 0$.

(b) Let $y(x) = C_1e^{3x} + C_2e^{-x}$. Then

$$y'(x) = 3C_1e^{3x} - C_2e^{-x}$$
$$y''(x) = 9C_1e^{3x} + C_2e^{-x}$$

and

$$\begin{aligned} y'' - 2y' - 3y &= 9C_1e^{3x} + C_2e^{-x} - 6C_1e^{3x} + 2C_2e^{-x} - 3C_1e^{3x} - 3C_2e^{-x} \\ &= (9 - 6 - 3)\,C_1e^{3x} + (1 + 2 - 3)\,C_2e^{-x} = 0. \end{aligned}$$

67. A spherical tank of radius R is half-filled with water. Suppose that water leaks through a hole in the bottom of area B. Let $y(t)$ be the water level at time t (seconds).

(a) Show that $\dfrac{dy}{dt} = \dfrac{-\sqrt{2g}B\sqrt{y}}{\pi(2Ry - y^2)}$.

(b) Show that for some constant C,

$$\frac{2\pi}{15B\sqrt{2g}}\left(10Ry^{3/2} - 3y^{5/2}\right) = C - t$$

(c) Use the initial condition $y(0) = R$ to compute C, and show that $C = t_e$, the time at which the tank is empty.

(d) Show that t_e is proportional to $R^{5/2}$ and inversely proportional to B.

SOLUTION

(a) At height y above the bottom of the tank, the cross section is a circle of radius

$$r = \sqrt{R^2 - (R - y)^2} = \sqrt{2Ry - y^2}.$$

The cross-sectional area function is then $A(y) = \pi(2Ry - y^2)$. The differential equation for the height of the water in the tank is then

$$\frac{dy}{dt} = -\frac{\sqrt{2g}B\sqrt{y}}{\pi(2Ry - y^2)}$$

by Torricelli's law.

(b) Rewrite the differential equation as

$$\frac{\pi}{\sqrt{2g}B}\left(2Ry^{1/2} - y^{3/2}\right)dy = -dt,$$

and then integrate both sides to obtain

$$\frac{2\pi}{\sqrt{2g}B}\left(\frac{2}{3}Ry^{3/2} - \frac{1}{5}y^{5/2}\right) = C - t,$$

where C is an arbitrary constant. Simplifying gives

$$\frac{2\pi}{15B\sqrt{2g}}(10Ry^{3/2} - 3y^{5/2}) = C - t \qquad (*)$$

(c) From Equation (*) we see that $y = 0$ when $t = C$. It follows that $C = t_e$, the time at which the tank is empty. Moreover, the initial condition $y(0) = R$ allows us to determine the value of C:

$$\frac{2\pi}{15B\sqrt{2g}}(10R^{5/2} - 3R^{5/2}) = \frac{14\pi}{15B\sqrt{2g}}R^{5/2} = C$$

(d) From part (c),

$$t_e = \frac{14\pi}{15\sqrt{2g}} \cdot \frac{R^{5/2}}{B},$$

from which it is clear that t_e is proportional to $R^{5/2}$ and inversely proportional to B.

9.2 Models Involving $y' = k(y - b)$

Preliminary Questions

1. Write down a solution to $y' = 4(y - 5)$ that tends to $-\infty$ as $t \to \infty$.

SOLUTION The general solution is $y(t) = 5 + Ce^{4t}$ for any constant C; thus the solution tends to $-\infty$ as $t \to \infty$ whenever $C < 0$. One specific example is $y(t) = 5 - e^{4t}$.

2. Does $y' = -4(y - 5)$ have a solution that tends to ∞ as $t \to \infty$?

SOLUTION The general solution is $y(t) = 5 + Ce^{-4t}$ for any constant C. As $t \to \infty$, $y(t) \to 5$. Thus, there is no solution of $y' = -4(y - 5)$ that tends to ∞ as $t \to \infty$.

3. True or false? If $k > 0$, then all solutions of $y' = -k(y - b)$ approach the same limit as $t \to \infty$.

SOLUTION True. The general solution of $y' = -k(y - b)$ is $y(t) = b + Ce^{-kt}$ for any constant C. If $k > 0$, then $y(t) \to b$ as $t \to \infty$.

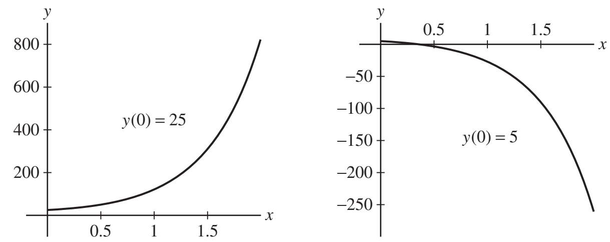
4. As an object cools, its rate of cooling slows. Explain how this follows from Newton's Law of Cooling.

SOLUTION Newton's Law of Cooling states that $y' = -k(y - T_0)$ where $y(t)$ is the temperature and T_0 is the ambient temperature. Thus as $y(t)$ gets closer to T_0, $y'(t)$, the rate of cooling, gets smaller and the rate of cooling slows.

Exercises

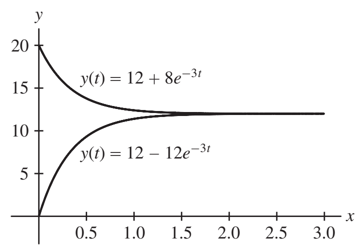
1. Find the general solution of $y' = 2(y - 10)$. Then find the two solutions satisfying $y(0) = 25$ and $y(0) = 5$, and sketch their graphs.

SOLUTION The general solution of $y' = 2(y - 10)$ is $y(t) = 10 + Ce^{2t}$ for any constant C. If $y(0) = 25$, then $10 + C = 25$, or $C = 15$; therefore, $y(t) = 10 + 15e^{2t}$. On the other hand, if $y(0) = 5$, then $10 + C = 5$, or $C = -5$; therefore, $y(t) = 10 - 5e^{2t}$. Graphs of these two functions are given below.



2. Verify directly that $y = 12 + Ce^{-3t}$ satisfies $y' = -3(y - 12)$ for all C. Then find the two solutions satisfying $y(0) = 20$ and $y(0) = 0$, and sketch their graphs.

SOLUTION The general solution of $y' = -3(y - 12)$ is $y(t) = 12 + Ce^{-3t}$ for any constant C. If $y(0) = 20$, then $12 + C = 20$, or $C = 8$; therefore, $y(t) = 12 + 8e^{-3t}$. On the other hand, if $y(0) = 0$, then $12 + C = 0$, or $C = -12$; therefore, $y(t) = 12 - 12e^{-3t}$. Graphs of these two functions are given below.



3. Solve $y' = 4y + 24$ subject to $y(0) = 5$.

SOLUTION Rewrite

$$y' = 4y + 24 \quad \text{as} \quad \frac{1}{4y + 24}\,dy = 1\,dt$$

Integrating gives

$$\begin{aligned} \frac{1}{4}\ln|4y + 24| &= t + C \\ \ln|4y + 24| &= 4t + C \\ 4y + 24 &= \pm e^{4t+C} \\ y &= Ae^{4t} - 6 \end{aligned}$$

where $A = \pm e^{C}/4$ is any constant. Since $y(0) = 5$ we have $5 = A - 6$ so that $A = 11$, and the solution is $y = 11e^{4t} - 6$.

4. Solve $y' + 6y = 12$ subject to $y(2) = 10$.

SOLUTION Rewrite

$$y' + 6y = 12 \quad \text{as} \quad \frac{dy}{dt} = 12 - 6y \quad \text{and then as} \quad \frac{1}{12 - 6y}\,dy = 1\,dt$$

Integrate both sides:

$$\begin{aligned} -\frac{1}{6}\ln|12 - 6y| &= t + C \\ \ln|12 - 6y| &= -6t + C \\ 12 - 6y &= \pm e^{-6t+C} \\ y &= Ae^{-6t} + 2 \end{aligned}$$

where $A = \pm e^{C}/6$ is any constant. Since $y(2) = 10$ we have $10 = Ae^{-12} + 2$ so that $A = 8e^{12}$, and the solution is $y = 8e^{12-6t} + 2$.

In Exercises 5–12, use Newton's Law of Cooling.

5. A hot anvil with cooling constant $k = 0.02\ \text{s}^{-1}$ is submerged in a large pool of water whose temperature is 10°C. Let $y(t)$ be the anvil's temperature t seconds later.

(a) What is the differential equation satisfied by $y(t)$?
(b) Find a formula for $y(t)$, assuming the object's initial temperature is 100°C.
(c) How long does it take the object to cool down to 20°?

SOLUTION

(a) By Newton's Law of Cooling, the differential equation is

$$y' = -0.02(y - 10)$$

(b) Separating variables gives

$$\frac{1}{y - 10}\,dy = -0.02\,dt$$

Integrate to get

$$\ln|y - 10| = -0.02t + C$$
$$y - 10 = \pm e^{-0.02t+C}$$
$$y = 10 + Ae^{-0.02t}$$

where $A = \pm e^C$ is a constant. Since the initial temperature is 100°C, we have $y(0) = 100 = 10 + A$ so that $A = 90$, and $y = 10 + 90e^{-0.02t}$.

(c) We must find the value of t such that $y(t) = 20$, so we need to solve $20 = 10 + 90e^{-0.02t}$. Thus

$$10 = 90e^{-0.02t} \quad \Rightarrow \quad \frac{1}{9} = e^{-0.02t} \quad \Rightarrow \quad -\ln 9 = -0.02t \quad \Rightarrow \quad t = 50\ln 9 \approx 109.86 \text{ s}$$

6. Frank's automobile engine runs at 100°C. On a day when the outside temperature is 21°C, he turns off the ignition and notes that five minutes later, the engine has cooled to 70°C.

(a) Determine the engine's cooling constant k.

(b) What is the formula for $y(t)$?

(c) When will the engine cool to 40°C?

SOLUTION

(a) The differential equation is

$$y' = -k(y - 21)$$

Rewriting gives $\frac{1}{y - 21}\,dy = -k\,dt$. Integrate to get

$$\ln|y - 21| = -kt + C$$
$$y - 21 = \pm e^{C-kt}$$
$$y = 21 + Ae^{-kt}$$

where $A = \pm e^C$ is a constant. The initial temperature is 100°C, so $y(0) = 100$. Thus $100 = 21 + A$ and $A = 79$, so that $y = 21 + 79e^{-kt}$. The second piece of information tells us that $y(5) = 70 = 21 + 79e^{-5k}$. Solving for k gives

$$k = -\frac{1}{5}\ln\frac{49}{79} \approx 0.0955$$

(b) From part (b), the equation is $y = 21 + 79e^{-0.0955t}$.

(c) The engine has cooled to 40°C when $y(t) = 40$; solving gives

$$40 = 21 + 79e^{-0.0955t} \quad \Rightarrow \quad e^{-0.0955t} = \frac{19}{79} \quad \Rightarrow \quad t = -\frac{1}{0.0955}\ln\frac{19}{79} \approx 14.92 \text{ m}$$

7. At 10:30 AM, detectives discover a dead body in a room and measure its temperature at 26°C. One hour later, the body's temperature had dropped to 24.8°C. Determine the time of death (when the body temperature was a normal 37°C), assuming that the temperature in the room was held constant at 20°C.

SOLUTION Let $t = 0$ be the time when the person died, and let t_0 denote 10:30AM. The differential equation satisfied by the body temperature, $y(t)$, is

$$y' = -k(y - 20)$$

by Newton's Law of Cooling. Separating variables gives $\frac{1}{y-20}\,dy = -k\,dt$. Integrate to get

$$\ln|y-20| = -kt + C$$
$$y - 20 = \pm e^{-kt+C}$$
$$y = 20 + Ae^{-kt}$$

where $A = \pm e^C$ is a constant. Since normal body temperature is 37°C, we have $y(0) = 37 = 20 + A$ so that $A = 17$. To determine k, note that

$$26 = 20 + 17e^{-kt_0} \qquad \text{and} \qquad 24.8 = 20 + 17e^{-k(t_0+1)}$$
$$kt_0 = -\ln\frac{6}{17} \qquad\qquad kt_0 + k = -\ln\frac{4.8}{17}$$

Subtracting these equations gives

$$k = \ln\frac{6}{17} - \ln\frac{4.8}{17} = \ln\frac{6}{4.8} \approx 0.223$$

We thus have

$$y = 20 + 17e^{-0.223t}$$

as the equation for the body temperature at time t. Since $y(t_0) = 26$, we have

$$26 = 20 + 17e^{-0.223t} \quad \Rightarrow \quad e^{-0.223t} = \frac{6}{17} \quad \Rightarrow \quad t = -\frac{1}{0.223}\ln\frac{6}{17} \approx 4.667 \text{ h}$$

so that the time of death was approximately 4 hours and 40 minutes ago.

8. A cup of coffee with cooling constant $k = 0.09$ min^{-1} is placed in a room at temperature 20°C.

(a) How fast is the coffee cooling (in degrees per minute) when its temperature is $T = 80$°C?

(b) Use the Linear Approximation to estimate the change in temperature over the next 6 s when $T = 80$°C.

(c) If the coffee is served at 90°C, how long will it take to reach an optimal drinking temperature of 65°C?

SOLUTION

(a) According to Newton's Law of Cooling, the coffee will cool at the rate $k(T - T_0)$, where k is the cooling constant of the coffee, T is the current temperature of the coffee and T_0 is the temperature of the surroundings. With $k = 0.09$ min^{-1}, $T = 80$°C and $T_0 = 20$°C, the coffee is cooling at the rate

$$0.09(80 - 20) = 5.4°\text{C/min}.$$

(b) Using the result from part (a) and the Linear Approximation, we estimate that the coffee will cool

$$(5.4°\text{C/min})(0.1 \text{ min}) = 0.54°\text{C}$$

over the next 6 seconds.

(c) With $T_0 = 20$°C and an initial temperature of 90°C, the temperature of the coffee at any time t is $T(t) = 20 + 70e^{-0.09t}$. Solving $20 + 70e^{-0.09t} = 65$ for t yields

$$t = -\frac{1}{0.09}\ln\left(\frac{45}{70}\right) \approx 4.91 \text{ minutes.}$$

9. A cold metal bar at −30°C is submerged in a pool maintained at a temperature of 40°C. Half a minute later, the temperature of the bar is 20°C. How long will it take for the bar to attain a temperature of 30°C?

SOLUTION With $T_0 = 40$°C, the temperature of the bar is given by $F(t) = 40 + Ce^{-kt}$ for some constants C and k. From the initial condition, $F(0) = 40 + C = -30$, so $C = -70$. After 30 seconds, $F(30) = 40 - 70e^{-30k} = 20$, so

$$k = -\frac{1}{30}\ln\left(\frac{20}{70}\right) \approx 0.0418 \text{ seconds}^{-1}.$$

To attain a temperature of 30°C we must solve $40 - 70e^{-0.0418t} = 30$ for t. This yields

$$t = \frac{\ln\left(\frac{10}{70}\right)}{-0.0418} \approx 46.55 \text{ seconds.}$$

10. When a hot object is placed in a water bath whose temperature is 25°C, it cools from 100°C to 50°C in 150 s. In another bath, the same cooling occurs in 120 s. Find the temperature of the second bath.

SOLUTION With $T_0 = 25$°C, the temperature of the object is given by $F(t) = 25 + Ce^{-kt}$ for some constants C and k. From the initial condition, $F(0) = 25 + C = 100$, so $C = 75$. After 150 seconds, $F(150) = 25 + 75e^{-150k} = 50$, so

$$k = -\frac{1}{150}\ln\left(\frac{25}{75}\right) \approx 0.0073 \text{ seconds}^{-1}.$$

If we place the same object with a temperature of 100°C into a second bath whose temperature is T_0, then the temperature of the object is given by

$$F(t) = T_0 + (100 - T_0)e^{-0.0073t}.$$

To cool from 100°C to 50°C in 120 seconds, T_0 must satisfy

$$T_0 + (100 - T_0)e^{-0.0073(120)} = 50.$$

Thus, $T_0 = 14.32$°C.

11. $\boxed{\text{GU}}$ Objects A and B are placed in a warm bath at temperature $T_0 = 40$°C. Object A has initial temperature −20°C and cooling constant $k = 0.004\ \text{s}^{-1}$. Object B has initial temperature 0°C and cooling constant $k = 0.002\ \text{s}^{-1}$. Plot the temperatures of A and B for $0 \le t \le 1000$. After how many seconds will the objects have the same temperature?

SOLUTION With $T_0 = 40$°C, the temperature of A and B are given by

$$A(t) = 40 + C_A e^{-0.004t} \qquad B(t) = 40 + C_B e^{-0.002t}$$

Since $A(0) = -20$ and $B(0) = 0$, we have

$$A(t) = 40 - 60e^{-0.004t} \qquad B(t) = 40 - 40e^{-0.002t}$$

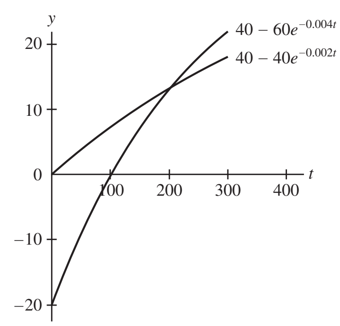
The two objects will have the same temperature whenever $A(t) = B(t)$, so we must solve

$$40 - 60e^{-0.004t} = 40 - 40e^{-0.002t} \quad \Rightarrow \quad 3e^{-0.004t} = 2e^{-0.002t}$$

Take logs to get

$$-0.004t + \ln 3 = -0.002t + \ln 2 \quad \Rightarrow \quad t = \frac{\ln 3 - \ln 2}{0.002} \approx 202.7 \text{ s}$$

or about 3 minutes 22 seconds.



12. In Newton's Law of Cooling, the constant $\tau = 1/k$ is called the "characteristic time." Show that τ is the time required for the temperature difference $(y - T_0)$ to decrease by the factor $e^{-1} \approx 0.37$. For example, if $y(0) = 100$°C and $T_0 = 0$°C, then the object cools to $100/e \approx 37$°C in time τ, to $100/e^2 \approx 13.5$°C in time 2τ, and so on.

SOLUTION If $y' = -k(y - T_0)$, then $y(t) = T_0 + Ce^{-kt}$. But then

$$\frac{y(t+\tau) - T_0}{y(t) - T_0} = \frac{Ce^{-k(t+\tau)}}{Ce^{-kt}} = e^{-k\tau} = e^{-k\cdot 1/k} = e^{-1}$$

Thus after time τ starting from any time t, the temperature difference will have decreased by a factor of e^{-1}.

In Exercises 13–16, use Eq. (3) as a model for free-fall with air resistance.

13. A 60-kg skydiver jumps out of an airplane. What is her terminal velocity, in meters per second, assuming that $k = 10$ kg/s for free-fall (no parachute)?

SOLUTION The free-fall terminal velocity is

$$\frac{-gm}{k} = \frac{-9.8(60)}{10} = -58.8 \text{ m/s.}$$

14. Find the terminal velocity of a skydiver of weight $w = 192$ lb if $k = 1.2$ lb-s/ft. How long does it take him to reach half of his terminal velocity if his initial velocity is zero? Mass and weight are related by $w = mg$, and Eq. (3) becomes $v' = -(kg/w)(v + w/k)$ with $g = 32$ ft/s^2.

SOLUTION The skydiver's velocity $v(t)$ satisfies the differential equation

$$v' = -\frac{kg}{w}\left(v + \frac{w}{k}\right),$$

where

$$\frac{kg}{w} = \frac{(1.2)(32)}{192} = 0.2 \text{ sec}^{-1} \quad \text{and} \quad \frac{w}{k} = \frac{192}{1.2} = 160 \text{ ft/sec.}$$

The general solution to this equation is $v(t) = -160 + Ce^{-0.2t}$, for some constant C. From the initial condition $v(0) = 0$, we find $0 = -160 + C$, or $C = 160$. Therefore,

$$v(t) = -160 + 160e^{-0.2t} = -160(1 - e^{-0.2t}).$$

Now, the terminal velocity of the skydiver is

$$\lim_{t\to\infty} v(t) = \lim_{t\to\infty} -160(1 - e^{-0.2t}) = -160 \text{ ft/sec.}$$

To determine how long it takes for the skydiver to reach half this terminal velocity, we must solve the equation $v(t) = -80$ for t:

$$\begin{aligned} -160(1 - e^{-0.2t}) &= -80 \\ 1 - e^{-0.2t} &= \frac{1}{2} \\ e^{-0.2t} &= \frac{1}{2} \\ t &= -\frac{1}{0.2}\ln\frac{1}{2} \approx 3.47 \text{ sec.} \end{aligned}$$

15. A 80-kg skydiver jumps out of an airplane (with zero initial velocity). Assume that $k = 12$ kg/s with a closed parachute and $k = 70$ kg/s with an open parachute. What is the skydiver's velocity at $t = 25$ s if the parachute opens after 20 s of free fall?

SOLUTION We first compute the skydiver's velocity after 20 s of free fall, then use that as the initial velocity to calculate her velocity after an additional 5 s of restrained fall. We have $m = 80$ and $g = 9.8$; for free fall, $k = 12$, so

$$\frac{k}{m} = \frac{12}{80} = 0.15, \qquad \frac{-mg}{k} = \frac{-80 \cdot 9.8}{12} \approx -65.33$$

The general solution is thus $v(t) = -65.33 + Ce^{-0.15t}$. Since $v(0) = 0$, we have $C = 65.33$, so that

$$v(t) = -65.33(1 - e^{-0.15t})$$

After 20 s of free fall, the diver's velocity is thus

$$v(20) = -65.33(1 - e^{-0.15\cdot 20}) \approx -62.08 \text{ m/s}$$

Once the parachute opens, $k = 70$, so

$$\frac{k}{m} = \frac{70}{80} = 0.875, \qquad \frac{mg}{k} = \frac{80 \cdot 9.8}{70} = 11.2$$

so that the general solution for the restrained fall model is $v_r(t) = -11.2 + Ce^{-0.875t}$. Here $v_r(0) = -62.08$, so that $C = 11.2 - 62.08 = -50.88$ and $v_r(t) = -11.20 - 50.88e^{-0.875t}$. After 5 additional seconds, the diver's velocity is therefore

$$v_r(5) = -11.20 - 50.88e^{-0.875\cdot 5} \approx -11.84 \text{ m/s}$$

16. Does a heavier or a lighter skydiver reach terminal velocity faster?

SOLUTION The velocity of a skydiver is

$$v(t) = -\frac{gm}{k} + Ce^{-kt/m}.$$

As m decreases, the fraction $-k/m$ becomes more negative and $e^{-(k/m)t}$ approaches zero more rapidly. Thus, a lighter skydiver approaches terminal velocity faster.

17. A continuous annuity with withdrawal rate $N = \$5000$/year and interest rate $r = 5\%$ is funded by an initial deposit of $P_0 = \$50{,}000$.

(a) What is the balance in the annuity after 10 years?

(b) When will the annuity run out of funds?

SOLUTION

(a) From Equation , the value of the annuity is given by

$$P(t) = \frac{5000}{0.05} + Ce^{0.05t} = 100{,}000 + Ce^{0.05t}$$

for some constant C. Since $P(0) = 50{,}000$, we have $C = -50{,}000$ and $P(t) = 100{,}000 - 50{,}000e^{0.05t}$. After ten years, then, the balance in the annuity is

$$P(10) = 100{,}000 - 50{,}000e^{0.05\cdot 10} = 100{,}000 - 50{,}000e^{0.5} \approx \$17{,}563.94$$

(b) The annuity will run out of funds when $P(t) = 0$:

$$0 = 100{,}000 - 50{,}000e^{0.05t} \quad\Rightarrow\quad e^{0.05t} = 2 \quad\Rightarrow\quad t = \frac{\ln 2}{0.05} \approx 13.86$$

The annuity will run out of funds after approximately 13 years 10 months.

18. Show that a continuous annuity with withdrawal rate $N = \$5000$/year and interest rate $r = 8\%$, funded by an initial deposit of $P_0 = \$75{,}000$, never runs out of money.

SOLUTION Let $P(t)$ denote the balance of the annuity at time t measured in years. Then

$$P(t) = \frac{N}{r} + Ce^{rt} = \frac{5000}{0.08} + Ce^{0.08t} = 62500 + Ce^{0.08t}$$

for some constant C. If $P_0 = 75{,}000$, then $75{,}000 = 62{,}500 + C$ and $C = 12{,}500$. Thus, $P(t) = 62{,}500 + 12{,}500e^{0.08t}$. As $t \to \infty$, $P(t) \to \infty$, so the annuity lives forever. Note the annuity will live forever for any $P_0 \geq \$62{,}500$.

19. Find the minimum initial deposit P_0 that will allow an annuity to pay out \$6000/year indefinitely if it earns interest at a rate of 5%.

SOLUTION Let $P(t)$ denote the balance of the annuity at time t measured in years. Then

$$P(t) = \frac{N}{r} + Ce^{rt} = \frac{6000}{0.05} + Ce^{0.05t} = 120{,}000 + Ce^{0.05t}$$

for some constant C. To fund the annuity indefinitely, we must have $C \geq 0$. If the initial deposit is P_0, then $P_0 = 120{,}000 + C$ and $C = P_0 - 120{,}000$. Thus, to fund the annuity indefinitely, we must have $P_0 \geq \$120{,}000$.

20. Find the minimum initial deposit P_0 necessary to fund an annuity for 20 years if withdrawals are made at a rate of \$10,000/year and interest is earned at a rate of 7%.

SOLUTION Let $P(t)$ denote the balance of the annuity at time t measured in years. Then

$$P(t) = \frac{N}{r} + Ce^{rt} = \frac{10{,}000}{0.07} + Ce^{0.07t} = 142{,}857.14 + Ce^{0.07t}$$

for some constant C. If the initial deposit is P_0, then $P_0 = 142{,}857.14 + C$ and $C = 142{,}857.14 - P_0$. To fund the annuity for 20 years, we need

$$P(20) = 142{,}857.14 + (P_0 - 142{,}857.14)e^{0.07(20)} \geq 0.$$

Hence,

$$P_0 \geq 142{,}857.14(1 - e^{-1.4}) = \$107{,}629.00.$$

21. An initial deposit of 100,000 euros are placed in an annuity with a French bank. What is the minimum interest rate the annuity must earn to allow withdrawals at a rate of 8000 euros/year to continue indefinitely?

SOLUTION Let $P(t)$ denote the balance of the annuity at time t measured in years. Then

$$P(t) = \frac{N}{r} + Ce^{rt} = \frac{8000}{r} + Ce^{rt}$$

for some constant C. To fund the annuity indefinitely, we need $C \geq 0$. If the initial deposit is 100,000 euros, then $100{,}000 = \frac{8000}{r} + C$ and $C = 100{,}000 - \frac{8000}{r}$. Thus, to fund the annuity indefinitely, we need $100{,}000 - \frac{8000}{r} \geq 0$, or $r \geq 0.08$. The bank must pay at least 8%.

22. Show that a continuous annuity never runs out of money if the initial balance is greater than or equal to N/r, where N is the withdrawal rate and r the interest rate.

SOLUTION With a withdrawal rate of N and an interest rate of r, the balance in the annuity is $P(t) = \frac{N}{r} + Ce^{rt}$ for some constant C. Let P_0 denote the initial balance. Then $P_0 = P(0) = \frac{N}{r} + C$ and $C = P_0 - \frac{N}{r}$. If $P_0 \geq \frac{N}{r}$, then $C \geq 0$ and the annuity lives forever.

23. Sam borrows \$10,000 from a bank at an interest rate of 9% and pays back the loan continuously at a rate of N dollars per year. Let $P(t)$ denote the amount still owed at time t.

(a) Explain why $P(t)$ satisfies the differential equation

$$y' = 0.09y - N$$

(b) How long will it take Sam to pay back the loan if $N = \$1200$?

(c) Will the loan ever be paid back if $N = \$800$?

SOLUTION

(a)

$$\begin{aligned}\text{Rate of Change of Loan} &= \text{(Amount still owed)(Interest rate)} - \text{(Payback rate)}\\ &= P(t)\cdot r - N = r\left(P - \frac{N}{r}\right).\end{aligned}$$

Therefore, if $y = P(t)$,

$$y' = r\left(y - \frac{N}{r}\right) = ry - N$$

(b) From the differential equation derived in part (a), we know that $P(t) = \frac{N}{r} + Ce^{rt} = 13{,}333.33 + Ce^{0.09t}$. Since \$10,000 was initially borrowed, $P(0) = 13{,}333.33 + C = 10{,}000$, and $C = -3333.33$. The loan is paid off when $P(t) = 13{,}333.33 - 3333.33e^{0.09t} = 0$. This yields

$$t = \frac{1}{0.09}\ln\left(\frac{13{,}333.33}{3333.33}\right) \approx 15.4 \text{ years.}$$

(c) If the annual rate of payment is \$800, then $P(t) = 800/0.09 + Ce^{0.09t} = 8888.89 + Ce^{0.09t}$. With $P(0) = 8888.89 + C = 10{,}000$, it follows that $C = 1111.11$. Since $C > 0$ and $e^{0.09t} \to \infty$ as $t \to \infty$, $P(t) \to \infty$, and the loan will never be paid back.

24. April borrows \$18,000 at an interest rate of 5% to purchase a new automobile. At what rate (in dollars per year) must she pay back the loan, if the loan must be paid off in 5 years? *Hint:* Set up the differential equation as in Exercise 23).

SOLUTION As in Exercise 23, the differential equation is

$$P(t)' = rP(t) - N = r\left(P(t) - \frac{N}{r}\right)$$

where r is the interest rate and N is the payment amount, so that here

$$P(t)' = 0.05\left(P(t) - \frac{N}{0.05}\right) \quad \Rightarrow \quad P(t) = \frac{N}{0.05} + Ce^{0.05t}$$

Since $P(0) = 18{,}000$, we have $C = 18{,}000 - \frac{N}{0.05}$, so that

$$P(t) = \frac{N}{0.05} + \left(18{,}000 - \frac{N}{0.05}\right)e^{0.05t}$$

If the loan is to be paid back in 5 years, we must have

$$P(5) = 0 = \frac{N}{0.05} + \left(18{,}000 - \frac{N}{0.05}\right)e^{0.05 \cdot 5}$$

Solving for N gives

$$N = \frac{900}{1 - e^{-0.25}} \approx 4068.73$$

so the payments must be at least \$4068.73 per year.

25. Let $N(t)$ be the fraction of the population who have heard a given piece of news t hours after its initial release. According to one model, the rate $N'(t)$ at which the news spreads is equal to k times the fraction of the population that has not yet heard the news, for some constant $k > 0$.

(a) Determine the differential equation satisfied by $N(t)$.

(b) Find the solution of this differential equation with the initial condition $N(0) = 0$ in terms of k.

(c) Suppose that half of the population is aware of an earthquake 8 hours after it occurs. Use the model to calculate k and estimate the percentage that will know about the earthquake 12 hours after it occurs.

SOLUTION

(a) $N'(t) = k(1 - N(t)) = -k(N(t) - 1)$.

(b) The general solution of the differential equation from part (a) is $N(t) = 1 + Ce^{-kt}$. The initial condition determines the value of C: $N(0) = 1 + C = 0$ so $C = -1$. Thus, $N(t) = 1 - e^{-kt}$.

(c) Knowing that $N(8) = 1 - e^{-8k} = \frac{1}{2}$, we find that

$$k = -\frac{1}{8}\ln\left(\frac{1}{2}\right) \approx 0.0866 \text{ hours}^{-1}.$$

With the value of k determined, we estimate that

$$N(12) = 1 - e^{-0.0866(12)} \approx 0.6463 = 64.63\%$$

of the population will know about the earthquake after 12 hours.

26. Current in a Circuit When the circuit in Figure 6 (which consists of a battery of V volts, a resistor of R ohms, and an inductor of L henries) is connected, the current $I(t)$ flowing in the circuit satisfies

$$L\frac{dI}{dt} + RI = V$$

with the initial condition $I(0) = 0$.

(a) Find a formula for $I(t)$ in terms of L, V, and R.

(b) Show that $\lim_{t\to\infty} I(t) = V/R$.

(c) Show that $I(t)$ reaches approximately 63% of its maximum value at the "characteristic time" $\tau = L/R$.

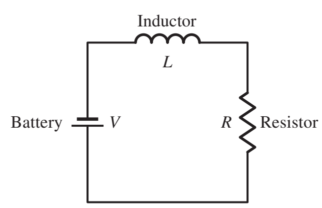


FIGURE 6 Current flow approaches the level $I_{\max} = V/R$.

SOLUTION

(a) Solve the differential equation for $\frac{dI}{dt}$:

$$\frac{dI}{dt} = -\frac{1}{L}(RI - V) = -\frac{R}{L}\left(I - \frac{V}{R}\right)$$

so that the general solution is

$$I(t) = \frac{V}{R} + Ce^{-(R/L)t}$$

The initial condition $I(0) = 0$ gives $C = -\frac{V}{R}$, so that

$$I(t) = \frac{V}{R}(1 - e^{-(R/L)t})$$

(b) As $t \to \infty$, $e^{-(R/L)t} \to 0$, so that $I(t) \to \frac{V}{R}$.
(c) When $t = \tau = L/R$,

$$I(\tau) = \frac{V}{R}(1 - e^{-(R/L)\tau}) = \frac{V}{R}(1 - e^{-(R/L)(L/R)}) = \frac{V}{R}(1 - e^{-1}) \approx 0.63\frac{V}{R}$$

which is 63% of the maximum value of V/R.

Further Insights and Challenges

27. Show that the cooling constant of an object can be determined from two temperature readings $y(t_1)$ and $y(t_2)$ at times $t_1 \neq t_2$ by the formula

$$k = \frac{1}{t_1 - t_2} \ln\left(\frac{y(t_2) - T_0}{y(t_1) - T_0}\right)$$

SOLUTION We know that $y(t_1) = T_0 + Ce^{-kt_1}$ and $y(t_2) = T_0 + Ce^{-kt_2}$. Thus, $y(t_1) - T_0 = Ce^{-kt_1}$ and $y(t_2) - T_0 = Ce^{-kt_2}$. Dividing the latter equation by the former yields

$$e^{-kt_2 + kt_1} = \frac{y(t_2) - T_0}{y(t_1) - T_0},$$

so that

$$k(t_1 - t_2) = \ln\left(\frac{y(t_2) - T_0}{y(t_1) - T_0}\right) \quad \text{and} \quad k = \frac{1}{t_1 - t_2} \ln\left(\frac{y(t_2) - T_0}{y(t_1) - T_0}\right).$$

28. Show that by Newton's Law of Cooling, the time required to cool an object from temperature A to temperature B is

$$t = \frac{1}{k} \ln\left(\frac{A - T_0}{B - T_0}\right)$$

where T_0 is the ambient temperature.

SOLUTION At any time t, the temperature of the object is $y(t) = T_0 + Ce^{-kt}$ for some constant C. Suppose the object is initially at temperature A and reaches temperature B at time t. Then $A = T_0 + C$, so $C = A - T_0$. Moreover,

$$B = T_0 + Ce^{-kt} = T_0 + (A - T_0)e^{-kt}.$$

Solving this last equation for t yields

$$t = \frac{1}{k} \ln\left(\frac{A - T_0}{B - T_0}\right).$$

29. Air Resistance A projectile of mass $m = 1$ travels straight up from ground level with initial velocity v_0. Suppose that the velocity v satisfies $v' = -g - kv$.
(a) Find a formula for $v(t)$.
(b) Show that the projectile's height $h(t)$ is given by

$$h(t) = C(1 - e^{-kt}) - \frac{g}{k}t$$

where $C = k^{-2}(g + kv_0)$.
(c) Show that the projectile reaches its maximum height at time $t_{\max} = k^{-1}\ln(1 + kv_0/g)$.
(d) In the absence of air resistance, the maximum height is reached at time $t = v_0/g$. In view of this, explain why we should expect that

$$\lim_{k \to 0} \frac{\ln(1 + \frac{kv_0}{g})}{k} = \frac{v_0}{g} \qquad \boxed{8}$$

(e) Verify Eq. (8). *Hint:* Use Theorem 2 in Section 5.8 to show that $\lim_{k \to 0}\left(1 + \frac{kv_0}{g}\right)^{1/k} = e^{v_0/g}$ or use L'Hôpital's Rule.

SOLUTION

(a) Since $v' = -g - kv = -k\left(v - \frac{-g}{k}\right)$ it follows that $v(t) = \frac{-g}{k} + Be^{-kt}$ for some constant B. The initial condition $v(0) = v_0$ determines B: $v_0 = -\frac{g}{k} + B$, so $B = v_0 + \frac{g}{k}$. Thus,

$$v(t) = -\frac{g}{k} + \left(v_0 + \frac{g}{k}\right)e^{-kt}.$$

(b) $v(t) = h'(t)$ so

$$h(t) = \int \left(-\frac{g}{k} + \left(v_0 + \frac{g}{k}\right)e^{-kt}\right) dt = -\frac{g}{k}t - \frac{1}{k}\left(v_0 + \frac{g}{k}\right)e^{-kt} + D.$$

The initial condition $h(0) = 0$ determines

$$D = \frac{1}{k}\left(v_0 + \frac{g}{k}\right) = \frac{1}{k^2}(v_0 k + g).$$

Let $C = \frac{1}{k^2}(v_0 k + g)$. Then

$$h(t) = C(1 - e^{-kt}) - \frac{g}{k}t.$$

(c) The projectile reaches its maximum height when $v(t) = 0$. This occurs when

$$-\frac{g}{k} + \left(v_0 + \frac{g}{k}\right)e^{-kt} = 0,$$

or

$$t = \frac{1}{-k}\ln\left(\frac{g}{kv_0 + g}\right) = \frac{1}{k}\ln\left(1 + \frac{kv_0}{g}\right).$$

(d) Recall that k is the proportionality constant for the force due to air resistance. Thus, as $k \to 0$, the effect of air resistance disappears. We should therefore expect that, as $k \to 0$, the time at which the maximum height is achieved from part (c) should approach v_0/g. In other words, we should expect

$$\lim_{k\to 0}\frac{1}{k}\ln\left(1 + \frac{kv_0}{g}\right) = \frac{v_0}{g}.$$

(e) Recall that

$$e^x = \lim_{n\to\infty}\left(1 + \frac{x}{n}\right)^n.$$

If we substitute $x = v_0/g$ and $k = 1/n$, we find

$$e^{v_0/g} = \lim_{k\to 0}\left(1 + \frac{v_0 k}{g}\right)^{1/k}.$$

Then

$$\lim_{k\to 0}\frac{1}{k}\ln\left(1 + \frac{kv_0}{g}\right) = \lim_{k\to 0}\ln\left(1 + \frac{v_0 k}{g}\right)^{1/k} = \ln\left(\lim_{k\to 0}\left(1 + \frac{v_0 k}{g}\right)^{1/k}\right) = \ln(e^{v_0/g}) = \frac{v_0}{g}.$$

9.3 Graphical and Numerical Methods

Preliminary Questions

1. What is the slope of the segment in the slope field for $\dot{y} = ty + 1$ at the point (2, 3)?

SOLUTION The slope of the segment in the slope field for $\dot{y} = ty + 1$ at the point (2, 3) is $(2)(3) + 1 = 7$.

2. What is the equation of the isocline of slope $c = 1$ for $\dot{y} = y^2 - t$?

SOLUTION The isocline of slope $c = 1$ has equation $y^2 - t = 1$, or $y = \pm\sqrt{1 + t}$.

3. For which of the following differential equations are the slopes at points on a vertical line $t = C$ all equal?

(a) $\dot{y} = \ln y$ **(b)** $\dot{y} = \ln t$

SOLUTION Only for the equation in part (b). The slope at a point is simply the value of $\dot{y}$ at that point, so for part (a), the slope depends on y, while for part (b), the slope depends only on t.

4. Let $y(t)$ be the solution to $\dot{y} = F(t, y)$ with $y(1) = 3$. How many iterations of Euler's Method are required to approximate $y(3)$ if the time step is $h = 0.1$?

SOLUTION The initial condition is specified at $t = 1$ and we want to obtain an approximation to the value of the solution at $t = 3$. With a time step of $h = 0.1$,

$$\frac{3 - 1}{0.1} = 20$$

iterations of Euler's method are required.

Exercises

1. Figure 8 shows the slope field for $\dot{y} = \sin y \sin t$. Sketch the graphs of the solutions with initial conditions $y(0) = 1$ and $y(0) = -1$. Show that $y(t) = 0$ is a solution and add its graph to the plot.

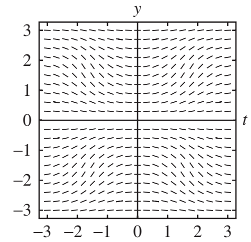

FIGURE 8 Slope field for $\dot{y} = \sin y \sin t$.

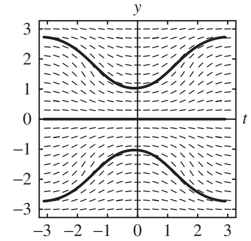
SOLUTION The sketches of the solutions appear below.



If $y(t) = 0$, then $y' = 0$; moreover, $\sin 0 \sin t = 0$. Thus, $y(t) = 0$ is a solution of $\dot{y} = \sin y \sin t$.

2. Figure 9 shows the slope field for $\dot{y} = y^2 - t^2$. Sketch the integral curve passing through the point $(0, -1)$, the curve through $(0, 0)$, and the curve through $(0, 2)$. Is $y(t) = 0$ a solution?

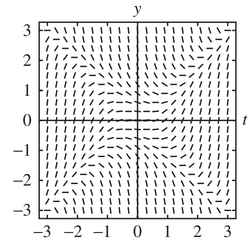


FIGURE 9 Slope field for $\dot{y} = y^2 - t^2$.

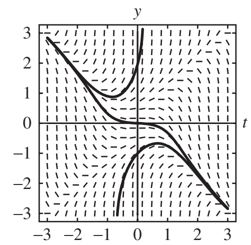
SOLUTION The sketches of the solutions appear below.



Let $y(t) = 0$. Because $\dot{y} = 0$ but $y^2 - t^2 = -t^2 \neq 0$, it follows that $y(t) = 0$ is not a solution of $\dot{y} = y^2 - t^2$.

3. Show that $f(t) = \frac{1}{2}\left(t - \frac{1}{2}\right)$ is a solution to $\dot{y} = t - 2y$. Sketch the four solutions with $y(0) = \pm 0.5, \pm 1$ on the slope field in Figure 10. The slope field suggests that every solution approaches $f(t)$ as $t \to \infty$. Confirm this by showing that $y = f(t) + Ce^{-2t}$ is the general solution.

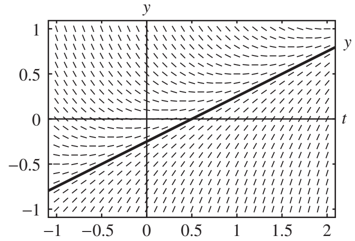


FIGURE 10 Slope field for $\dot{y} = t - 2y$.

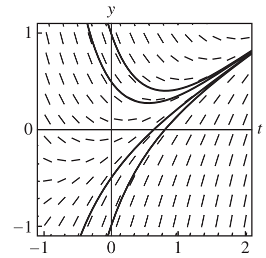
SOLUTION Let $y = f(t) = \frac{1}{2}(t - \frac{1}{2})$. Then $\dot{y} = \frac{1}{2}$ and

$$\dot{y} + 2y = \frac{1}{2} + t - \frac{1}{2} = t,$$

so $f(t) = \frac{1}{2}(t - \frac{1}{2})$ is a solution to $\dot{y} = t - 2y$. The slope field with the four required solutions is shown below.



Now, let $y = f(t) + Ce^{-2t} = \frac{1}{2}(t - \frac{1}{2}) + Ce^{-2t}$. Then

$$\dot{y} = \frac{1}{2} - 2Ce^{-2t},$$

and

$$\dot{y} + 2y = \frac{1}{2} - 2Ce^{-2t} + \left(t - \frac{1}{2}\right) + 2Ce^{-2t} = t.$$

Thus, $y = f(t) + Ce^{-2t}$ is the general solution to the equation $\dot{y} = t - 2y$.

4. One of the slope fields in Figures 11(A) and (B) is the slope field for $\dot{y} = t^2$. The other is for $\dot{y} = y^2$. Identify which is which. In each case, sketch the solutions with initial conditions $y(0) = 1$, $y(0) = 0$, and $y(0) = -1$.

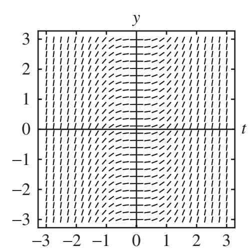


FIGURE 11(A)

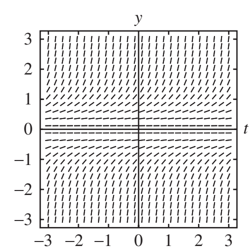

FIGURE 11(B)

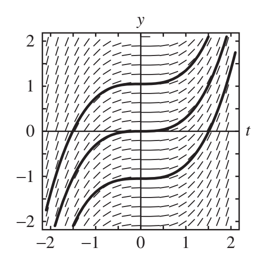
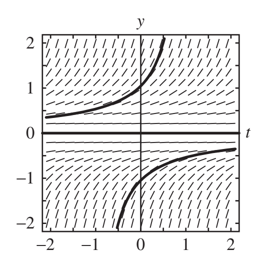
SOLUTION For $y' = t^2$, y' only depends on t. The isoclines of any slope c will be the two vertical lines $t = \pm\sqrt{c}$. This indicates that the slope field will be the one given in Figure 11(A). The solutions are sketched below:



For $y' = y^2$, y' only depends on y. The isoclines of any slope c will be the two *horizontal* lines $y = \pm\sqrt{c}$. This indicates that the slope field will be the one given in Figure 11(B). The solutions are sketched below:



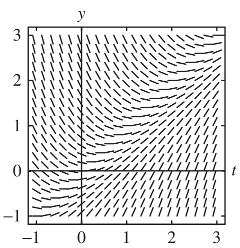
5. Consider the differential equation $\dot{y} = t - y$.

(a) Sketch the slope field of the differential equation $\dot{y} = t - y$ in the range $-1 \le t \le 3$, $-1 \le y \le 3$. As an aid, observe that the isocline of slope c is the line $t - y = c$, so the segments have slope c at points on the line $y = t - c$.

(b) Show that $y = t - 1 + Ce^{-t}$ is a solution for all C. Since $\lim_{t\to\infty} e^{-t} = 0$, these solutions approach the particular solution $y = t - 1$ as $t \to \infty$. Explain how this behavior is reflected in your slope field.

SOLUTION

(a) Here is a sketch of the slope field:



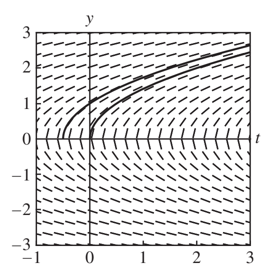
(b) Let $y = t - 1 + Ce^{-t}$. Then $\dot{y} = 1 - C^{-t}$, and

$$t - y = t - (t - 1 + Ce^{-t}) = 1 - Ce^{-t}.$$

Thus, $y = t - 1 + Ce^{-t}$ is a solution of $\dot{y} = t - y$. On the slope field, we can see that the isoclines of 1 all lie along the line $y = t - 1$. Whenever $y > t - 1$, $\dot{y} = t - y < 1$, so the solution curve will converge downward towards the line $y = t - 1$. On the other hand, if $y < t - 1$, $\dot{y} = t - y > 1$, so the solution curve will converge upward towards $y = t - 1$. In either case, the solution is approaching $t - 1$.

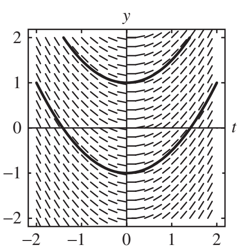
6. Show that the isoclines of $\dot{y} = 1/y$ are horizontal lines. Sketch the slope field for $-2 \le t \le 2$, $-2 \le y \le 2$ and plot the solutions with initial conditions $y(0) = 0$ and $y(0) = 1$.

SOLUTION The isocline of slope c is defined by $\frac{1}{y} = c$. This is equivalent to $y = \frac{1}{c}$, which is a horizontal line. The slope field and the solutions are shown below.



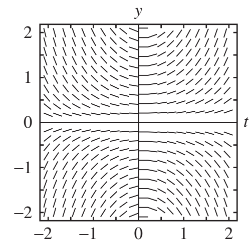
7. Show that the isoclines of $\dot{y} = t$ are vertical lines. Sketch the slope field for $-2 \le t \le 2$, $-2 \le y \le 2$ and plot the integral curves passing through $(0, -1)$ and $(0, 1)$.

SOLUTION The isocline of slope c for the differential equation $\dot{y} = t$ has equation $t = c$, which is the equation of a vertical line. The slope field and the required solution curves are shown below.



8. Sketch the slope field of $\dot{y} = ty$ for $-2 \le t \le 2$, $-2 \le y \le 2$. Based on the sketch, determine $\lim_{t\to\infty} y(t)$, where $y(t)$ is a solution with $y(0) > 0$. What is $\lim_{t\to\infty} y(t)$ if $y(0) < 0$?

SOLUTION The slope field for $\dot{y} = ty$ is shown below.



With $y(0) > 0$, the slope field indicates that y is an always increasing, always concave up function; consequently, $\lim_{t\to\infty} y = \infty$. On the other hand, when $y(0) < 0$, the slope field indicates that y is an always decreasing, always concave down function; consequently, $\lim_{t\to\infty} y = -\infty$.

9. Match each differential equation with its slope field in Figures 12(A)–(F).

(i) $\dot{y} = -1$

(ii) $\dot{y} = \dfrac{y}{t}$

(iii) $\dot{y} = t^2 y$

(iv) $\dot{y} = ty^2$

(v) $\dot{y} = t^2 + y^2$

(vi) $\dot{y} = t$

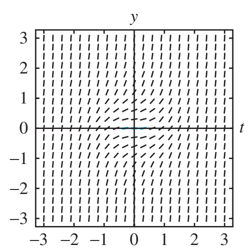


FIGURE 12(A)

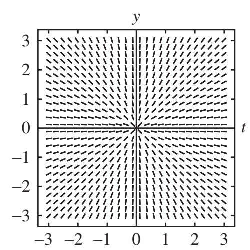

FIGURE 12(B)

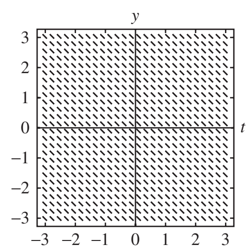

FIGURE 12(C)

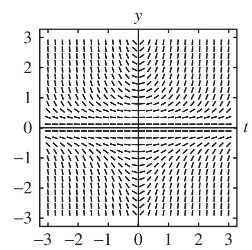

FIGURE 12(D)

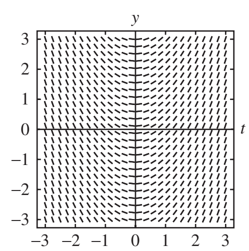

FIGURE 12(E)

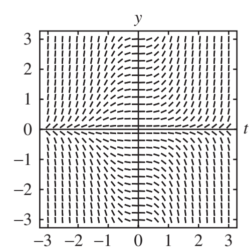

FIGURE 12(F)

SOLUTION

(i) Every segment in the slope field for $\dot{y} = -1$ will have slope -1; this matches Figure 12(C).

(ii) The segments in the slope field for $\dot{y} = \dfrac{y}{t}$ will have positive slope in the first and third quadrants and negative slopes in the second and fourth quadrant; this matches Figure 12(B).

(iii) The segments in the slope field for $\dot{y} = t^2 y$ will have positive slope in the upper half of the plane and negative slopes in the lower half of the plane; this matches Figure 12(F).
(iv) The segments in the slope field for $\dot{y} = ty^2$ will have positive slope on the right side of the plane and negative slopes on the left side of the plane; this matches Figure 12(D).
(v) Every segment in the slope field for $\dot{y} = t^2 + y^2$, except at the origin, will have positive slope; this matches Figure 12(A).
(vi) The isoclines for $\dot{y} = t$ are vertical lines; this matches Figure 12(E).

10. Sketch the solution of $\dot{y} = ty^2$ satisfying $y(0) = 1$ in the appropriate slope field of Figure 12(A)–(F). Then show, using separation of variables, that if $y(t)$ is a solution such that $y(0) > 0$, then $y(t)$ tends to infinity as $t \to \sqrt{2/y(0)}$.

SOLUTION Rewrite

$$\dot{y} = ty^2 \quad \text{as} \quad \frac{1}{y^2}\,dy = t\,dt$$

Integrate both sides:

$$\int \frac{1}{y^2}\,dy = \int t\,dt$$

$$-y^{-1} = \frac{1}{2}t^2 + C_1$$

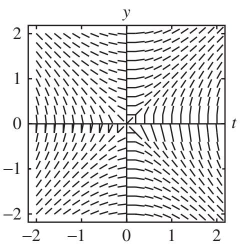
$$-y = \frac{2}{t^2 + C}$$

$$y = \frac{2}{C - t^2}$$

where $C = -C_1$ is an arbitrary constant. Then $y(0) = 2/C$ so that $C = 2/y(0)$, and then the denominator of y approaches 0 as $t \to \sqrt{2/y(0)}$, so that y tends to infinity.

11. **(a)** Sketch the slope field of $\dot{y} = t/y$ in the region $-2 \le t \le 2$, $-2 \le y \le 2$.
(b) Check that $y = \pm\sqrt{t^2 + C}$ is the general solution.
(c) Sketch the solutions on the slope field with initial conditions $y(0) = 1$ and $y(0) = -1$.

SOLUTION
(a) The slope field is shown below:



(b) Rewrite

$$\frac{dy}{dt} = \frac{t}{y} \qquad \text{as} \qquad y\,dy = t\,dt,$$

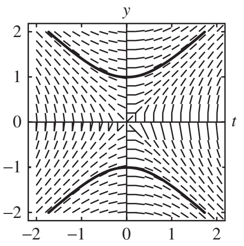
and then integrate both sides to obtain

$$\frac{1}{2}y^2 = \frac{1}{2}t^2 + C.$$

Solving for y, we find that the general solution is

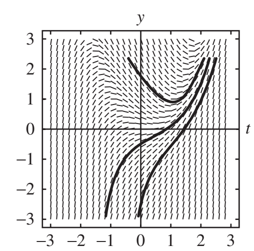
$$y = \pm\sqrt{t^2 + C}.$$

(c) The sketches of the two solutions are shown below:



12. Sketch the slope field of $\dot{y} = t^2 - y$ in the region $-3 \le t \le 3$, $-3 \le y \le 3$ and sketch the solutions satisfying $y(1) = 0$, $y(1) = 1$, and $y(1) = -1$.

SOLUTION The slope field for $\dot{y} = t^2 - y$, together with the required solution curves, is shown below.



13. Let $F(t, y) = t^2 - y$ and let $y(t)$ be the solution of $\dot{y} = F(t, y)$ satisfying $y(2) = 3$. Let $h = 0.1$ be the time step in Euler's Method, and set $y_0 = y(2) = 3$.

(a) Calculate $y_1 = y_0 + hF(2, 3)$.

(b) Calculate $y_2 = y_1 + hF(2.1, y_1)$.

(c) Calculate $y_3 = y_2 + hF(2.2, y_2)$ and continue computing y_4, y_5, and y_6.

(d) Find approximations to $y(2.2)$ and $y(2.5)$.

SOLUTION

(a) With $y_0 = 3$, $t_0 = 2$, $h = 0.1$, and $F(t, y) = t^2 - y$, we find

$$y_1 = y_0 + hF(t_0, y_0) = 3 + 0.1(1) = 3.1.$$

(b) With $y_1 = 3.1$, $t_1 = 2.1$, $h = 0.1$, and $F(t, y) = t^2 - y$, we find

$$y_2 = y_1 + hF(t_1, y_1) = 3.1 + 0.1(4.41 - 3.1) = 3.231.$$

(c) Continuing as in the previous two parts, we find

$$y_3 = y_2 + hF(t_2, y_2) = 3.3919;$$

$$y_4 = y_3 + hF(t_3, y_3) = 3.58171;$$

$$y_5 = y_4 + hF(t_4, y_4) = 3.799539;$$

$$y_6 = y_5 + hF(t_5, y_5) = 4.0445851.$$

(d) $y(2.2) \approx y_2 = 3.231$, and $y(2.5) \approx y_5 = 3.799539$.

14. Let $y(t)$ be the solution to $\dot{y} = te^{-y}$ satisfying $y(0) = 0$.

(a) Use Euler's Method with time step $h = 0.1$ to approximate $y(0.1), y(0.2), \ldots, y(0.5)$.

(b) Use separation of variables to find $y(t)$ exactly.

(c) Compute the errors in the approximations to $y(0.1)$ and $y(0.5)$.

SOLUTION

(a) With $y_0 = 0$, $t_0 = 0$, $h = 0.1$, and $F(t, y) = te^{-y}$, we compute

n	t_n	y_n
0	0	0
1	0.1	$y_0 + hF(t_0, y_0) = 0$
2	0.2	$y_1 + hF(t_1, y_1) = 0.01$
3	0.3	$y_2 + hF(t_2, y_2) = 0.029801$
4	0.4	$y_3 + hF(t_3, y_3) = 0.058920$
5	0.5	$y_4 + hF(t_4, y_4) = 0.096631$
6	0.6	$y_5 + hF(t_5, y_5) = 0.142026$
7	0.7	$y_6 + hF(t_6, y_6) = 0.194082$
8	0.8	$y_7 + hF(t_7, y_7) = 0.251733$
9	0.9	$y_8 + hF(t_8, y_8) = 0.313929$
10	1.0	$y_9 + hF(t_9, y_9) = 0.379681$

(b) Rewrite

$$\frac{dy}{dt} = te^{-y} \qquad \text{as} \qquad e^y\,dy = t\,dt,$$

and then integrate both sides to obtain

$$e^y = \frac{1}{2}t^2 + C.$$

Thus,

$$y = \ln\left|\frac{1}{2}t^2 + C\right|.$$

Applying the initial condition $y(0) = 0$ yields $0 = \ln|C|$, so $C = 1$. The exact solution to the initial value problem is then $y = \ln\left(\frac{1}{2}t^2 + 1\right)$.

(c) The two errors requested are computed here:

$$|y(0.1) - y_1| = |0.00498754 - 0| = 0.00498754;$$
$$|y(0.5) - y_5| = |0.117783 - 0.0966314| = 0.021152$$

In Exercises 15–20, use Euler's Method to approximate the given value of $y(t)$ with the time step h indicated.

15. $y(0.5);\quad \dot{y} = y + t,\quad y(0) = 1,\quad h = 0.1$

SOLUTION With $y_0 = 1$, $t_0 = 0$, $h = 0.1$, and $F(t, y) = y + t$, we compute

n	t_n	y_n
0	0	1
1	0.1	$y_0 + hF(t_0, y_0) = 1.1$
2	0.2	$y_1 + hF(t_1, y_1) = 1.22$
3	0.3	$y_2 + hF(t_2, y_2) = 1.362$
4	0.4	$y_3 + hF(t_3, y_3) = 1.5282$
5	0.5	$y_4 + hF(t_4, y_4) = 1.72102$

16. $y(0.7);\quad \dot{y} = 2y,\quad y(0) = 3,\quad h = 0.1$

SOLUTION With $y_0 = 3$, $t_0 = 0$, $h = 0.1$, and $F(t, y) = 2y$, we compute

n	t_n	y_n
0	0	3
1	0.1	$y_0 + hF(t_0, y_0) = 3.6$
2	0.2	$y_1 + hF(t_1, y_1) = 4.32$
3	0.3	$y_2 + hF(t_2, y_2) = 5.184$
4	0.4	$y_3 + hF(t_3, y_3) = 6.2208$
5	0.5	$y_4 + hF(t_4, y_4) = 7.464960$
6	0.6	$y_5 + hF(t_5, y_5) = 8.957952$
7	0.7	$y_6 + hF(t_6, y_6) = 10.749542$

17. $y(3.3)$; $\dot{y} = t^2 - y$, $y(3) = 1$, $h = 0.05$

SOLUTION With $y_0 = 1$, $t_0 = 3$, $h = 0.05$, and $F(t, y) = t^2 - y$, we compute

n	t_n	y_n
0	3	1
1	3.05	$y_0 + hF(t_0, y_0) = 1.4$
2	3.1	$y_1 + hF(t_1, y_1) = 1.795125$
3	3.15	$y_2 + hF(t_2, y_2) = 2.185869$
4	3.2	$y_3 + hF(t_3, y_3) = 2.572700$
5	3.25	$y_4 + hF(t_4, y_4) = 2.956065$
6	3.3	$y_5 + hF(t_5, y_5) = 3.336387$

18. $y(3)$; $\dot{y} = \sqrt{t + y}$, $y(2.7) = 5$, $h = 0.05$

SOLUTION With $y_0 = 5$, $t_0 = 2.7$, $h = 0.05$, and $F(t, y) = \sqrt{t + y}$, we compute

n	t_n	y_n
0	2.7	5
1	2.75	$y_0 + hF(t_0, y_0) = 5.138744$
2	2.8	$y_1 + hF(t_1, y_1) = 5.279179$
3	2.85	$y_2 + hF(t_2, y_2) = 5.421298$
4	2.9	$y_3 + hF(t_3, y_3) = 5.565098$
5	2.95	$y_4 + hF(t_4, y_4) = 5.710572$
6	3.0	$y_5 + hF(t_5, y_5) = 5.857716$

19. $y(2)$; $\dot{y} = t \sin y$, $y(1) = 2$, $h = 0.2$

SOLUTION Let $F(t, y) = t \sin y$. With $t_0 = 1$, $y_0 = 2$ and $h = 0.2$, we compute

n	t_n	y_n
0	1	2
1	1.2	$y_0 + hF(t_0, y_0) = 2.181859$
2	1.4	$y_1 + hF(t_1, y_1) = 2.378429$
3	1.6	$y_2 + hF(t_2, y_2) = 2.571968$
4	1.8	$y_3 + hF(t_3, y_3) = 2.744549$
5	2.0	$y_4 + hF(t_4, y_4) = 2.883759$

20. $y(5.2)$; $\dot{y} = t - \sec y$, $y(4) = -2$, $h = 0.2$

SOLUTION With $t_0 = 4$, $y_0 = -2$, $F(t, y) = t - \sec y$, and $h = 0.2$, we compute

n	t_n	y_n
0	4	-2
1	4.2	$y_0 + hF(t_0, y_0) = -0.7194$
2	4.4	$y_1 + hF(t_1, y_1) = -0.142587$
3	4.6	$y_2 + hF(t_2, y_2) = 0.532584$
4	4.8	$y_3 + hF(t_3, y_3) = 1.220430$
5	5.0	$y_4 + hF(t_4, y_4) = 1.597751$
6	5.2	$y_5 + hF(t_5, y_5) = 10.018619$

Note that $\sec y$ has a discontinuity at $y = \pi/2 \approx 1.57$ and at $y = 3\pi/2 \approx 4.71$, so this numerical solution should be regarded with some skepticism.

Further Insights and Challenges

21. If $f(t)$ is continuous on $[a, b]$, then the solution to $\dot{y} = f(t)$ with initial condition $y(a) = 0$ is $y(t) = \int_a^t f(u)\,du$. Show that Euler's Method with time step $h = (b-a)/N$ for N steps yields the Nth left-endpoint approximation to $y(b) = \int_a^b f(u)\,du$.

SOLUTION For a differential equation of the form $\dot{y} = f(t)$, the equation for Euler's method reduces to

$$y_k = y_{k-1} + hf(t_{k-1}).$$

With a step size of $h = (b-a)/N$, $y(b) =\approx y_N$. Starting from $y_0 = 0$, we compute

$$\begin{aligned}
y_1 &= y_0 + hf(t_0) = hf(t_0)\\
y_2 &= y_1 + hf(t_1) = h\,[f(t_0) + f(t_1)]\\
y_3 &= y_2 + hf(t_2) = h\,[f(t_0) + f(t_1) + f(t_2)]\\
&\;\;\vdots\\
y_N &= y_{N_1} + hf(t_{N-1}) = h\left[f(t_0) + f(t_1) + f(t_2) + \ldots + f(t_{N-1})\right] = h\sum_{k=0}^{N-1} f(t_k)
\end{aligned}$$

Observe this last expression is exactly the Nth left-endpoint approximation to $y(b) = \displaystyle\int_a^b f(u)\,du$.

*Exercises 22–27: **Euler's Midpoint Method** is a variation on Euler's Method that is significantly more accurate in general. For time step h and initial value $y_0 = y(t_0)$, the values y_k are defined successively by*

$$y_k = y_{k-1} + hm_{k-1}$$

where $m_{k-1} = F\left(t_{k-1} + \dfrac{h}{2}, y_{k-1} + \dfrac{h}{2}F(t_{k-1}, y_{k-1})\right)$.

22. Apply both Euler's Method and the Euler Midpoint Method with $h = 0.1$ to estimate $y(1.5)$, where $y(t)$ satisfies $\dot{y} = y$ with $y(0) = 1$. Find $y(t)$ exactly and compute the errors in these two approximations.

SOLUTION Let $F(t, y) = y$. With $t_0 = 0$, $y_0 = 1$, and $h = 0.1$, fifteen iterations of Euler's method yield

$$y(1.5) \approx y_{15} = 4.177248.$$

The Euler midpoint approximation with $F(t, y) = y$ is

$$m_{k-1} = F\left(t_{k-1} + \frac{h}{2}, y_{k-1} + \frac{h}{2}F(t_{k-1}, y_{k-1})\right) = y_{k-1} + \frac{h}{2}y_{k-1}$$

$$y_k = y_{k-1} + h\left(y_{k-1} + \frac{h}{2}y_{k-1}\right) = y_{k-1} + hy_{k-1} + \frac{h^2}{2}y_{k-1}$$

Fifteen iterations of Euler's midpoint method yield:

$$y(1.5) \approx y_{15} = 4.471304.$$

The exact solution to $y' = y$, $y(0) = 1$ is $y(t) = e^t$; therefore $y(1.5) = 4.481689$. The error from Euler's method is $|4.177248 - 4.481689| = 0.304441$, while the error from Euler's midpoint method is $|4.471304 - 4.481689| = 0.010385$.

In Exercises 23–26, use Euler's Midpoint Method with the time step indicated to approximate the given value of $y(t)$.

23. $y(0.5)$; $\dot{y} = y + t$, $y(0) = 1$, $h = 0.1$

SOLUTION With $t_0 = 0$, $y_0 = 1$, $F(t, y) = y + t$, and $h = 0.1$ we compute

n	t_n	y_n
0	0	1
1	0.1	$y_0 + hF(t_0 + h/2, y_0 + (h/2)F(t_0, y_0)) = 1.11$
2	0.2	$y_1 + hF(t_1 + h/2, y_1 + (h/2)F(t_1, y_1)) = 1.242050$
3	0.3	$y_2 + hF(t_2 + h/2, y_2 + (h/2)F(t_2, y_2)) = 1.398465$
4	0.4	$y_3 + hF(t_3 + h/2, y_3 + (h/2)F(t_3, y_3)) = 1.581804$
5	0.5	$y_4 + hF(t_4 + h/2, y_4 + (h/2)F(t_4, y_4)) = 1.794894$

24. $y(2)$; $\quad \dot{y} = t^2 - y, \quad y(1) = 3, \quad h = 0.2$

SOLUTION With $t_0 = 1$, $y_0 = 3$, $F(t, y) = t^2 - y$, and $h = 0.2$ we compute

n	t_n	y_n
0	1	3
1	1.2	$y_0 + hF(t_0 + h/2, y_0 + (h/2)F(t_0, y_0)) = 2.682$
2	1.4	$y_1 + hF(t_1 + h/2, y_1 + (h/2)F(t_1, y_1)) = 2.50844$
3	1.6	$y_2 + hF(t_2 + h/2, y_2 + (h/2)F(t_2, y_2)) = 2.467721$
4	1.8	$y_3 + hF(t_3 + h/2, y_3 + (h/2)F(t_3, y_3)) = 2.550331$
5	2.0	$y_4 + hF(t_4 + h/2, y_4 + (h/2)F(t_4, y_4)) = 2.748471$

25. $y(0.25)$; $\quad \dot{y} = \cos(y + t), \quad y(0) = 1, \quad h = 0.05$

SOLUTION With $t_0 = 0$, $y_0 = 1$, $F(t, y) = \cos(y + t)$, and $h = 0.05$ we compute

n	t_n	y_n
0	0	1
1	0.05	$y_0 + hF(t_0 + h/2, y_0 + (h/2)F(t_0, y_0)) = 1.025375$
2	0.10	$y_1 + hF(t_1 + h/2, y_1 + (h/2)F(t_1, y_1)) = 1.047507$
3	0.15	$y_2 + hF(t_2 + h/2, y_2 + (h/2)F(t_2, y_2)) = 1.066425$
4	0.20	$y_3 + hF(t_3 + h/2, y_3 + (h/2)F(t_3, y_3)) = 1.082186$
5	0.25	$y_4 + hF(t_4 + h/2, y_4 + (h/2)F(t_4, y_4)) = 1.094871$

26. $y(2.3)$; $\quad \dot{y} = y + t^2, \quad y(2) = 1, \quad h = 0.05$

SOLUTION With $t_0 = 2$, $y_0 = 1$, $F(t, y) = y + t^2$, and $h = 0.05$ we compute

n	t_n	y_n
0	2.00	1
1	2.05	$y_0 + hF(t_0 + h/2, y_0 + (h/2)F(t_0, y_0)) = 1.261281$
2	2.10	$y_1 + hF(t_1 + h/2, y_1 + (h/2)F(t_1, y_1)) = 1.546456$
3	2.15	$y_2 + hF(t_2 + h/2, y_2 + (h/2)F(t_2, y_2)) = 1.857006$
4	2.20	$y_3 + hF(t_3 + h/2, y_3 + (h/2)F(t_3, y_3)) = 2.194487$
5	2.25	$y_4 + hF(t_4 + h/2, y_4 + (h/2)F(t_4, y_4)) = 2.560536$
6	2.30	$y_5 + hF(t_5 + h/2, y_5 + (h/2)F(t_5, y_5)) = 2.956872$

27. Assume that $f(t)$ is continuous on $[a, b]$. Show that Euler's Midpoint Method applied to $\dot{y} = f(t)$ with initial condition $y(a) = 0$ and time step $h = (b - a)/N$ for N steps yields the Nth midpoint approximation to

$$y(b) = \int_a^b f(u)\, du$$

SOLUTION For a differential equation of the form $\dot{y} = f(t)$, the equations for Euler's midpoint method reduce to

$$m_{k-1} = f\left(t_{k-1} + \frac{h}{2}\right) \qquad \text{and} \qquad y_k = y_{k-1} + hf\left(t_{k-1} + \frac{h}{2}\right).$$

With a step size of $h = (b - a)/N$, $y(b) =\approx y_N$. Starting from $y_0 = 0$, we compute

$$y_1 = y_0 + hf\left(t_0 + \frac{h}{2}\right) = hf\left(t_0 + \frac{h}{2}\right)$$

$$y_2 = y_1 + hf\left(t_1 + \frac{h}{2}\right) = h\left[f\left(t_0 + \frac{h}{2}\right) + f\left(t_1 + \frac{h}{2}\right)\right]$$

$$y_3 = y_2 + hf\left(t_2 + \frac{h}{2}\right) = h\left[f\left(t_0 + \frac{h}{2}\right) + f\left(t_1 + \frac{h}{2}\right) + f\left(t_2 + \frac{h}{2}\right)\right]$$

$$\vdots$$

$$y_N = y_{N_1} + hf\left(t_{N-1} + \frac{h}{2}\right) = h\left[f\left(t_0 + \frac{h}{2}\right) + f\left(t_1 + \frac{h}{2}\right) + f\left(t_2 + \frac{h}{2}\right) + \ldots + f\left(t_{N-1} + \frac{h}{2}\right)\right]$$

$$= h\sum_{k=0}^{N-1} f\left(t_k + \frac{h}{2}\right)$$

Observe this last expression is exactly the Nth midpoint approximation to $y(b) = \int_a^b f(u)\,du$.

9.4 The Logistic Equation

Preliminary Questions

1. Which of the following differential equations is a logistic differential equation?

(a) $\dot{y} = 2y(1 - y^2)$ **(b)** $\dot{y} = 2y\left(1 - \frac{y}{3}\right)$

(c) $\dot{y} = 2y\left(1 - \frac{t}{4}\right)$ **(d)** $\dot{y} = 2y(1 - 3y)$

SOLUTION The differential equations in **(b)** and **(d)** are logistic equations. The equation in **(a)** is not a logistic equation because of the y^2 term inside the parentheses on the right-hand side; the equation in **(c)** is not a logistic equation because of the presence of the independent variable on the right-hand side.

2. Is the logistic equation a linear differential equation?

SOLUTION No, the logistic equation is not linear.

$$\dot{y} = ky\left(1 - \frac{y}{A}\right) \quad \text{can be rewritten} \quad \dot{y} = ky - \frac{k}{A}y^2$$

and we see that a term involving y^2 occurs.

3. Is the logistic equation separable?

SOLUTION Yes, the logistic equation is a separable differential equation.

Exercises

1. Find the general solution of the logistic equation

$$\dot{y} = 3y\left(1 - \frac{y}{5}\right)$$

Then find the particular solution satisfying $y(0) = 2$.

SOLUTION $\dot{y} = 3y(1 - y/5)$ is a logistic equation with $k = 3$ and $A = 5$; therefore, the general solution is

$$y = \frac{5}{1 - e^{-3t}/C}.$$

The initial condition $y(0) = 2$ allows us to determine the value of C:

$$2 = \frac{5}{1 - 1/C}; \quad 1 - \frac{1}{C} = \frac{5}{2}; \quad \text{so} \quad C = -\frac{2}{3}.$$

The particular solution is then

$$y = \frac{5}{1 + \frac{3}{2}e^{-3t}} = \frac{10}{2 + 3e^{-3t}}.$$

2. Find the solution of $\dot{y} = 2y(3 - y)$, $y(0) = 10$.

SOLUTION By rewriting

$$2y(3 - y) \qquad \text{as} \qquad 6y\left(1 - \frac{y}{3}\right),$$

we identify the given differential equation as a logistic equation with $k = 6$ and $A = 3$. The general solution is therefore

$$y = \frac{3}{1 - e^{-6t}/C}.$$

The initial condition $y(0) = 10$ allows us to determine the value of C:

$$10 = \frac{3}{1 - 1/C}; \quad 1 - \frac{1}{C} = \frac{3}{10}; \quad \text{so} \quad C = \frac{10}{7}.$$

The particular solution is then

$$y = \frac{3}{1 - \frac{7}{10}e^{-6t}} = \frac{30}{10 - 7e^{-6t}}.$$

3. Let $y(t)$ be a solution of $\dot{y} = 0.5y(1 - 0.5y)$ such that $y(0) = 4$. Determine $\lim_{t\to\infty} y(t)$ without finding $y(t)$ explicitly.

SOLUTION This is a logistic equation with $k = \frac{1}{2}$ and $A = 2$, so the carrying capacity is 2. Thus the required limit is 2.

4. Let $y(t)$ be a solution of $\dot{y} = 5y(1 - y/5)$. State whether $y(t)$ is increasing, decreasing, or constant in the following cases:

(a) $y(0) = 2$ **(b)** $y(0) = 5$ **(c)** $y(0) = 8$

SOLUTION This is a logistic equation with $k = A = 5$.

(a) $0 < y(0) < A$, so $y(t)$ is increasing and approaches A asymptotically.

(b) $y(0) = A$; this represents a stable equilibrium and $y(t)$ is constant.

(c) $y(0) > A$, so $y(t)$ is decreasing and approaches A asymptotically.

5. A population of squirrels lives in a forest with a carrying capacity of 2000. Assume logistic growth with growth constant $k = 0.6\ \text{yr}^{-1}$.

(a) Find a formula for the squirrel population $P(t)$, assuming an initial population of 500 squirrels.

(b) How long will it take for the squirrel population to double?

SOLUTION

(a) Since $k = 0.6$ and the carrying capacity is $A = 2000$, the population $P(t)$ of the squirrels satisfies the differential equation

$$P'(t) = 0.6P(t)(1 - P(t)/2000),$$

with general solution

$$P(t) = \frac{2000}{1 - e^{-0.6t}/C}.$$

The initial condition $P(0) = 500$ allows us to determine the value of C:

$$500 = \frac{2000}{1 - 1/C}; \quad 1 - \frac{1}{C} = 4; \quad \text{so} \quad C = -\frac{1}{3}.$$

The formula for the population is then

$$P(t) = \frac{2000}{1 + 3e^{-0.6t}}.$$

(b) The squirrel population will have doubled at the time t where $P(t) = 1000$. This gives

$$1000 = \frac{2000}{1 + 3e^{-0.6t}}; \quad 1 + 3e^{-0.6t} = 2; \quad \text{so} \quad t = \frac{5}{3}\ln 3 \approx 1.83.$$

It therefore takes approximately 1.83 years for the squirrel population to double.

6. The population $P(t)$ of mosquito larvae growing in a tree hole increases according to the logistic equation with growth constant $k = 0.3\ \text{day}^{-1}$ and carrying capacity $A = 500$.

(a) Find a formula for the larvae population $P(t)$, assuming an initial population of $P_0 = 50$ larvae.

(b) After how many days will the larvae population reach 200?

SOLUTION

(a) Since $k = 0.3$ and $A = 500$, the population of the larvae satisfies the differential equation

$$P'(t) = 0.3P(t)(1 - P(t)/500),$$

with general solution

$$P(t) = \frac{500}{1 - e^{-0.3t}/C}.$$

The initial condition $P(0) = 50$ allows us to determine the value of C:

$$50 = \frac{500}{1 - 1/C}; \quad 1 - \frac{1}{C} = 10; \quad \text{so} \quad C = -\frac{1}{9}.$$

The particular solution is then

$$P(t) = \frac{500}{1 + 9e^{-0.3t}}.$$

(b) The population will reach 200 after t days, where $P(t) = 200$. This gives

$$200 = \frac{500}{1 + 9e^{-0.3t}}; \quad 1 + 9e^{-0.3t} = 2.5; \quad \text{so} \quad t = \frac{10}{3}\ln 6 \approx 5.97.$$

It therefore takes approximately 5.97 days for the larvae to reach 200 in number.

7. Sunset Lake is stocked with 2000 rainbow trout, and after 1 year the population has grown to 4500. Assuming logistic growth with a carrying capacity of 20,000, find the growth constant k (specify the units) and determine when the population will increase to 10,000.

SOLUTION Since $A = 20{,}000$, the trout population $P(t)$ satisfies the logistic equation

$$P'(t) = kP(t)(1 - P(t)/20{,}000),$$

with general solution

$$P(t) = \frac{20{,}000}{1 - e^{-kt}/C}.$$

The initial condition $P(0) = 2000$ allows us to determine the value of C:

$$2000 = \frac{20{,}000}{1 - 1/C}; \quad 1 - \frac{1}{C} = 10; \quad \text{so} \quad C = -\frac{1}{9}.$$

After one year, we know the population has grown to 4500. Let's measure time in years. Then

$$\begin{aligned}
4500 &= \frac{20{,}000}{1 + 9e^{-k}} \\
1 + 9e^{-k} &= \frac{40}{9} \\
e^{-k} &= \frac{31}{81} \\
k &= \ln\frac{81}{31} \approx 0.9605 \text{ years}^{-1}.
\end{aligned}$$

The population will increase to 10,000 at time t where $P(t) = 10{,}000$. This gives

$$\begin{aligned}
10{,}000 &= \frac{20{,}000}{1 + 9e^{-0.9605t}} \\
1 + 9e^{-0.9605t} &= 2 \\
e^{-0.9605t} &= \frac{1}{9} \\
t &= \frac{1}{0.9605}\ln 9 \approx 2.29 \text{ years.}
\end{aligned}$$

8. Spread of a Rumor A rumor spreads through a small town. Let $y(t)$ be the fraction of the population that has heard the rumor at time t and assume that the rate at which the rumor spreads is proportional to the product of the fraction y of the population that has heard the rumor and the fraction $1 - y$ that has not yet heard the rumor.

(a) Write down the differential equation satisfied by y in terms of a proportionality factor k.

(b) Find k (in units of day^{-1}), assuming that 10% of the population knows the rumor at $t = 0$ and 40% knows it at $t = 2$ days.

(c) Using the assumptions of part (b), determine when 75% of the population will know the rumor.

SOLUTION

(a) $y'(t)$ is the rate at which the rumor is spreading, in percentage of the population per day. By the description given, the rate satisfies:

$$y'(t) = ky(1-y),$$

where k is a constant of proportionality.

(b) The equation in part (a) is a logistic equation with constant k and capacity 1 (no more than 100% of the population can hear the rumor). Thus, y takes the form

$$y(t) = \frac{1}{1 - e^{-kt}/C}.$$

The initial condition $y(0) = \frac{1}{10}$ allows us to determine the value of C:

$$\frac{1}{10} = \frac{1}{1 - 1/C}; \quad 1 - \frac{1}{C} = 10; \quad \text{so} \quad C = -\frac{1}{9}.$$

The condition $y(2) = \frac{2}{5}$ now allows us to determine the value of k:

$$\frac{2}{5} = \frac{1}{1 + 9e^{-2k}}; \quad 1 + 9e^{-2k} = \frac{5}{2}; \quad \text{so} \quad k = \frac{1}{2}\ln 6 \approx 0.896 \text{ days}^{-1}.$$

The particular solution of the differential equation for y is then

$$y(t) = \frac{1}{1 + 9e^{-0.896t}}.$$

(c) If 75% of the population knows the rumor at time t, we have

$$\begin{aligned}
\frac{3}{4} &= \frac{1}{1 + 9e^{-0.896t}} \\
1 + 9e^{-0.896t} &= \frac{4}{3} \\
t &= \frac{\ln 27}{0.896} \approx 3.67839
\end{aligned}$$

Thus, 75% of the population knows the rumor after approximately 3.67 days.

9. A rumor spreads through a school with 1000 students. At 8 AM, 80 students have heard the rumor, and by noon, half the school has heard it. Using the logistic model of Exercise 8, determine when 90% of the students will have heard the rumor.

SOLUTION Let $y(t)$ be the proportion of students that have heard the rumor at a time t hours after 8 AM. In the logistic model of Exercise 8, we have a capacity of $A = 1$ (100% of students) and an unknown growth factor of k. Hence,

$$y(t) = \frac{1}{1 - e^{-kt}/C}.$$

The initial condition $y(0) = 0.08$ allows us to determine the value of C:

$$\frac{2}{25} = \frac{1}{1 - 1/C}; \quad 1 - \frac{1}{C} = \frac{25}{2}; \quad \text{so} \quad C = -\frac{2}{23}.$$

so that

$$y(t) = \frac{2}{2 + 23e^{-kt}}.$$

The condition $y(4) = 0.5$ now allows us to determine the value of k:

$$\frac{1}{2} = \frac{2}{2+23e^{-4k}}; \quad 2+23e^{-4k} = 4; \quad \text{so} \quad k = \frac{1}{4}\ln\frac{23}{2} \approx 0.6106 \text{ hours}^{-1}.$$

90% of the students have heard the rumor when $y(t) = 0.9$. Thus

$$\frac{9}{10} = \frac{2}{2+23e^{-0.6106t}}$$
$$2+23e^{-0.6106t} = \frac{20}{9}$$
$$t = \frac{1}{0.6106}\ln\frac{207}{2} \approx 7.6 \text{ hours.}$$

Thus, 90% of the students have heard the rumor after 7.6 hours, or at 3:36 PM.

10. GU A simpler model for the spread of a rumor assumes that the rate at which the rumor spreads is proportional (with factor k) to the fraction of the population that has not yet heard the rumor.

(a) Compute the solutions to this model and the model of Exercise 8 with the values $k = 0.9$ and $y_0 = 0.1$.

(b) Graph the two solutions on the same axis.

(c) Which model seems more realistic? Why?

SOLUTION

(a) Let $y(t)$ denote the fraction of a population that has heard a rumor, and suppose the rumor spreads at a rate proportional to the fraction of the population that has not yet heard the rumor. Then

$$y' = k(1-y),$$

for some constant of proportionality k. Separating variables and integrating both sides yields

$$\frac{dy}{1-y} = k\,dt$$
$$-\ln|1-y| = kt + C.$$

Thus,

$$y(t) = 1 - Ae^{-kt},$$

where $A = \pm e^{-C}$ is an arbitrary constant. The initial condition $y(0) = 0.1$ allows us to determine the value of A:

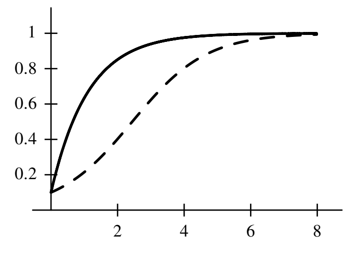
$$0.1 = 1 - A \qquad \text{so} \qquad A = 0.9.$$

With $k = 0.9$, we have $y(t) = 1 - 0.9e^{-0.9t}$.

Using the model from Exercise 8 with $k = 0.9$ and $y(0) = 0.1$, we find

$$y(t) = \frac{1}{1+9e^{-0.9t}}.$$

(b) The figure below shows the solutions from part (a): the solid curve corresponds to the model presented in this exercise while the dashed curve corresponds to the model from Exercise 8.



(c) The model from Exercise 8 seems more realistic because it predicts the rumor starts spreading slowly, picks up speed and then levels off as we near the time when the entire population has heard the rumor.

11. Let $k = 1$ and $A = 1$ in the logistic equation.

(a) Find the solutions satisfying $y_1(0) = 10$ and $y_2(0) = -1$.

(b) Find the time t when $y_1(t) = 5$.

(c) When does $y_2(t)$ become infinite?

SOLUTION The general solution of the logistic equation with $k = 1$ and $A = 1$ is

$$y(t) = \frac{1}{1 - e^{-t}/C}.$$

(a) Given $y_1(0) = 10$, we find $C = \frac{10}{9}$, and

$$y_1(t) = \frac{1}{1 - \frac{10}{9}e^{-t}} = \frac{10}{10 - 9e^{-t}}.$$

On the other hand, given $y_2(0) = -1$, we find $C = \frac{1}{2}$, and

$$y_2(t) = \frac{1}{1 - 2e^{-t}}.$$

(b) From part (a), we have

$$y_1(t) = \frac{10}{10 - 9e^{-t}}.$$

Thus, $y_1(t) = 5$ when

$$5 = \frac{10}{10 - 9e^{-t}}; \quad 10 - 9e^{-t} = 2; \quad \text{so} \quad t = \ln \frac{9}{8}.$$

(c) From part (a), we have

$$y_2(t) = \frac{1}{1 - 2e^{-t}}.$$

Thus, $y_2(t)$ becomes infinite when

$$1 - 2e^{-t} = 0 \qquad \text{or} \qquad t = \ln 2.$$

12. A tissue culture grows until it has a maximum area of M cm^2. The area $A(t)$ of the culture at time t may be modeled by the differential equation

$$\dot{A} = k\sqrt{A}\left(1 - \frac{A}{M}\right) \qquad \boxed{7}$$

where k is a growth constant.

(a) Show that if we set $A = u^2$, then

$$\dot{u} = \frac{1}{2}k\left(1 - \frac{u^2}{M}\right)$$

Then find the general solution using separation of variables.

(b) Show that the general solution to Eq. (7) is

$$A(t) = M\left(\frac{Ce^{(k/\sqrt{M})t} - 1}{Ce^{(k/\sqrt{M})t} + 1}\right)^2$$

SOLUTION

(a) Let $A = u^2$. This gives $\dot{A} = 2u\dot{u}$, so that Eq. (7) becomes:

$$2u\dot{u} = ku\left(1 - \frac{u^2}{M}\right)$$

$$\dot{u} = \frac{k}{2}\left(1 - \frac{u^2}{M}\right)$$

Now, rewrite

$$\frac{du}{dt} = \frac{k}{2}\left(1 - \frac{u^2}{M}\right) \qquad \text{as} \qquad \frac{du}{1 - u^2/M} = \frac{1}{2}k\,dt.$$

The partial fraction decomposition for the term on the left-hand side is

$$\frac{1}{1 - u^2/M} = \frac{\sqrt{M}}{2}\left(\frac{1}{\sqrt{M} + u} + \frac{1}{\sqrt{M} - u}\right),$$

so after integrating both sides, we obtain

$$\frac{\sqrt{M}}{2}\ln\left|\frac{\sqrt{M}+u}{\sqrt{M}-u}\right| = \tfrac{1}{2}kt + C.$$

Thus,

$$\frac{\sqrt{M}+u}{\sqrt{M}-u} = Ce^{(k/\sqrt{M})t}$$
$$u(Ce^{(k/\sqrt{M})t}+1) = \sqrt{M}(Ce^{(k/\sqrt{M})t}-1)$$

and

$$u = \sqrt{M}\frac{Ce^{(k/\sqrt{M})t}-1}{Ce^{(k/\sqrt{M})t}+1}.$$

(b) Recall $A = u^2$. Therefore,

$$A(t) = M\left(\frac{Ce^{(k/\sqrt{M})t}-1}{Ce^{(k/\sqrt{M})t}+1}\right)^2.$$

13. GU In the model of Exercise 12, let $A(t)$ be the area at time t (hours) of a growing tissue culture with initial size $A(0) = 1$ cm^2, assuming that the maximum area is $M = 16$ cm^2 and the growth constant is $k = 0.1$.

(a) Find a formula for $A(t)$. *Note:* The initial condition is satisfied for two values of the constant C. Choose the value of C for which $A(t)$ is increasing.

(b) Determine the area of the culture at $t = 10$ hours.

(c) GU Graph the solution using a graphing utility.

SOLUTION

(a) From the values for M and k we have

$$A(t) = 16\left(\frac{Ce^{t/40}-1}{Ce^{t/40}+1}\right)^2$$

and the initial condition then gives us

$$A(0) = 1 = 16\left(\frac{Ce^{0/40}-1}{Ce^{0/40}+1}\right)^2$$

so, simplifying,

$$1 = 16\left(\frac{C-1}{C+1}\right)^2 \quad\Rightarrow\quad C^2+2C+1 = 16C^2-32C+16 \quad\Rightarrow\quad 15C^2-34C+15 = 0$$

and thus $C = \dfrac{5}{3}$ or $C = \dfrac{3}{5}$. The derivative of $A(t)$ is

$$A'(t) = \frac{16Ce^{t/40}}{(Ce^{t/40}+1)^3}\cdot(Ce^{t/40}-1)$$

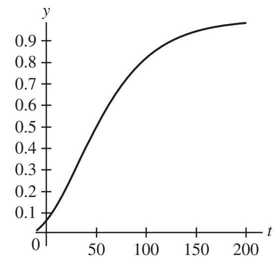
For $C = 3/5$, $A'(t)$ can be negative, while for $C = 5/3$, it is always positive. So let $C = 5/3$.

(b) From part (a), we have

$$A(t) = 16\left(\frac{\frac{5}{3}e^{t/40}-1}{\frac{5}{3}e^{t/40}+1}\right)^2$$

and $A(10) \approx 2.11$.

(c)



14. Show that if a tissue culture grows according to Eq. (7), then the growth rate reaches a maximum when $A = M/3$.

SOLUTION According to Eq. (7), the growth rate of the tissue culture is $k\sqrt{A}(1 - \frac{A}{M})$. Therefore

$$\frac{d}{dA}\left(k\sqrt{A}\left(1 - \frac{A}{M}\right)\right) = \frac{1}{2}kA^{-1/2} - \frac{3}{2}kA^{1/2}/M = \frac{1}{2}kA^{-1/2}\left(1 - \frac{3A}{M}\right) = 0$$

when $A = M/3$. Because the growth rate is zero for $A = 0$ and for $A = M$ and is positive for $0 < A < M$, it follows that the maximum growth rate occurs when $A = M/3$.

15. In 1751, Benjamin Franklin predicted that the U.S. population $P(t)$ would increase with growth constant $k = 0.028$ year^{-1}. According to the census, the U.S. population was 5 million in 1800 and 76 million in 1900. Assuming logistic growth with $k = 0.028$, find the predicted carrying capacity for the U.S. population. *Hint:* Use Eqs. (3) and (4) to show that

$$\frac{P(t)}{P(t) - A} = \frac{P_0}{P_0 - A}e^{kt}$$

SOLUTION Assuming the population grows according to the logistic equation,

$$\frac{P(t)}{P(t) - A} = Ce^{kt}.$$

But

$$C = \frac{P_0}{P_0 - A},$$

so

$$\frac{P(t)}{P(t) - A} = \frac{P_0}{P_0 - A}e^{kt}.$$

Now, let $t = 0$ correspond to the year 1800. Then the year 1900 corresponds to $t = 100$, and with $k = 0.028$, we have

$$\frac{76}{76 - A} = \frac{5}{5 - A}e^{(0.028)(100)}.$$

Solving for A, we find

$$A = \frac{5(e^{2.8} - 1)}{\frac{5}{76}e^{2.8} - 1} \approx 943.07.$$

Thus, the predicted carrying capacity for the U.S. population is approximately 943 million.

16. **Reverse Logistic Equation** Consider the following logistic equation (with $k, B > 0$):

$$\frac{dP}{dt} = -kP\left(1 - \frac{P}{B}\right) \qquad \boxed{8}$$

(a) Sketch the slope field of this equation.

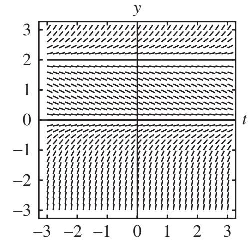
(b) The general solution is $P(t) = B/(1 - e^{kt}/C)$, where C is a nonzero constant. Show that $P(0) > B$ if $C > 1$ and $0 < P(0) < B$ if $C < 0$.

(c) Show that Eq. (8) models an "extinction–explosion" population. That is, $P(t)$ tends to zero if the initial population satisfies $0 < P(0) < B$, and it tends to ∞ after a finite amount of time if $P(0) > B$.

(d) Show that $P = 0$ is a stable equilibrium and $P = B$ an unstable equilibrium.

SOLUTION

(a) The slope field of this equation is shown below.



(b) Suppose that $C > 0$. Then $1 - \frac{1}{C} < 1$, $\left(1 - \frac{1}{C}\right)^{-1} > 1$, and

$$P(0) = \frac{B}{1 - \frac{1}{C}} > B.$$

On the other hand, if $C < 0$, then $1 - \frac{1}{C} > 1$, $0 < \left(1 - \frac{1}{C}\right)^{-1} < 1$, and

$$0 < P(0) = \frac{B}{1 - \frac{1}{C}} < B.$$

(c) From part (b), $0 < P(0) < B$ when $C < 0$. In this case, $1 - e^{kt}/C$ is never zero, but

$$1 - \frac{e^{kt}}{C} \to \infty$$

as $t \to \infty$. Thus, $P(t) \to 0$ as $t \to \infty$. On the other hand, $P(0) > B$ when $C > 0$. In this case $1 - e^{kt}/C = 0$ when $t = \frac{1}{k}\ln C$. Thus,

$$P(t) \to \infty \qquad \text{as} \qquad t \to \frac{1}{k}\ln C.$$

(d) Let

$$F(P) = -kP\left(1 - \frac{P}{B}\right).$$

Then, $F'(P) = -k + \frac{2kP}{B}$. Thus, $F'(0) = -k < 0$, and $F'(B) = -k + 2k = k > 0$, so $P = 0$ is a stable equilibrium and $P = B$ is an unstable equilibrium.

Further Insights and Challenges

In Exercises 17 and 18, let $y(t)$ be a solution of the logistic equation

$$\frac{dy}{dt} = ky\left(1 - \frac{y}{A}\right) \qquad \boxed{9}$$

where $A > 0$ and $k > 0$.

17. **(a)** Differentiate Eq. (9) with respect to t and use the Chain Rule to show that

$$\frac{d^2y}{dt^2} = k^2y\left(1 - \frac{y}{A}\right)\left(1 - \frac{2y}{A}\right)$$

(b) Show that $y(t)$ is concave up if $0 < y < A/2$ and concave down if $A/2 < y < A$.

(c) Show that if $0 < y(0) < A/2$, then $y(t)$ has a point of inflection at $y = A/2$ (Figure 6).

(d) Assume that $0 < y(0) < A/2$. Find the time t when $y(t)$ reaches the inflection point.

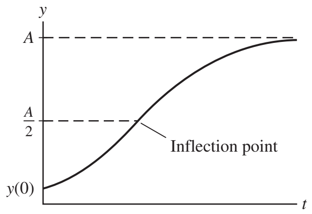


FIGURE 6 An inflection point occurs at $y = A/2$ in the logistic curve.

SOLUTION

(a) The derivative of Eq. (9) with respect to t is

$$y'' = ky' - \frac{2kyy'}{A} = ky'\left(1 - \frac{2y}{A}\right) = k\left(1 - \frac{y}{A}\right)ky\left(1 - \frac{2y}{A}\right) = k^2y\left(1 - \frac{y}{A}\right)\left(1 - \frac{2y}{A}\right).$$

(b) If $0 < y < A/2$, $1 - \frac{y}{A}$ and $1 - \frac{2y}{A}$ are both positive, so $y'' > 0$. Therefore, y is concave up. If $A/2 < y < A$, $1 - \frac{y}{A} > 0$, but $1 - \frac{2y}{A} < 0$, so $y'' < 0$, so y is concave down.

(c) If $y_0 < A$, y grows and $\lim_{t\to\infty} y(t) = A$. If $0 < y < A/2$, y is concave up at first. Once y passes $A/2$, y becomes concave down, so y has an inflection point at $y = A/2$.

(d) The general solution to Eq. (9) is

$$y = \frac{A}{1 - e^{-kt}/C};$$

thus, $y = A/2$ when

$$\frac{A}{2} = \frac{A}{1 - e^{-kt}/C}$$
$$1 - e^{-kt}/C = 2$$
$$t = -\frac{1}{k}\ln(-C)$$

Now, $C = y_0/(y_0 - A)$, so

$$t = -\frac{1}{k}\ln\frac{y_0}{A - y_0} = \frac{1}{k}\ln\frac{A - y_0}{y_0}.$$

18. Let $y = \dfrac{A}{1 - e^{-kt}/C}$ be the general nonequilibrium Eq. (9). If $y(t)$ has a vertical asymptote at $t = t_b$, that is, if $\lim_{t\to t_b-} y(t) = \pm\infty$, we say that the solution "blows up" at $t = t_b$.

(a) Show that if $0 < y(0) < A$, then y does not blow up at any time t_b.

(b) Show that if $y(0) > A$, then y blows up at a time t_b, which is negative (and hence does not correspond to a real time).

(c) Show that y blows up at some positive time t_b if and only if $y(0) < 0$ (and hence does not correspond to a real population).

SOLUTION

(a) Let $y(0) = y_0$. From the general solution, we find

$$y_0 = \frac{A}{1 - 1/C}; \quad 1 - \frac{1}{C} = \frac{A}{y_0}; \quad \text{so} \quad C = \frac{y_0}{y_0 - A}.$$

If $y_0 < A$, then $C < 0$, and the denominator in the general solution, $1 - e^{-kt}/C$, is always positive. Thus, when $0 < y(0) < A$, y does not blow up at any time.

(b) $1 - e^{-kt}/C = 0$ when $C = e^{-kt}$. Solving for t we find

$$t = -\frac{1}{k}\ln C.$$

Because $C = \frac{y_0}{y_0 - A}$ and $y_0 > A$, it follows that $C > 1$, and thus, $\ln C > 0$. Therefore, y blows up at a time which is negative.

(c) Suppose that y blows up at some $t_b > 0$. From part (b), we know that

$$t_b = -\frac{1}{k}\ln C.$$

Thus, in order for t_b to be positive, we must have $\ln C < 0$, which requires $C < 1$. Now,

$$C = \frac{y_0}{y_0 - A},$$

so $t_b > 0$ if and only if

$$\frac{y_0}{y_0 - A} < 1 \qquad \text{or equivalently} \qquad \frac{y_0 - A}{y_0} = 1 - \frac{A}{y_0} > 1.$$

This last inequality holds if and only if $y_0 = y(0) < 0$.

9.5 First-Order Linear Equations

Preliminary Questions

1. Which of the following are first-order linear equations?

(a) $y' + x^2 y = 1$ **(b)** $y' + xy^2 = 1$

(c) $x^5 y' + y = e^x$ **(d)** $x^5 y' + y = e^y$

SOLUTION The equations in **(a)** and **(c)** are first-order linear differential equations. The equation in **(b)** is not linear because of the y^2 factor in the second term on the left-hand side of the equation; the equation in **(d)** is not linear because of the e^y term on the right-hand side of the equation.

2. If $\alpha(x)$ is an integrating factor for $y' + A(x)y = B(x)$, then $\alpha'(x)$ is equal to (choose the correct answer):

(a) $B(x)$ **(b)** $\alpha(x)A(x)$

(c) $\alpha(x)A'(x)$ **(d)** $\alpha(x)B(x)$

SOLUTION The correct answer is **(b)**: $\alpha(x)A(x)$.

Exercises

1. Consider $y' + x^{-1}y = x^3$.

(a) Verify that $\alpha(x) = x$ is an integrating factor.

(b) Show that when multiplied by $\alpha(x)$, the differential equation can be written $(xy)' = x^4$.

(c) Conclude that xy is an antiderivative of x^4 and use this information to find the general solution.

(d) Find the particular solution satisfying $y(1) = 0$.

SOLUTION

(a) The equation is of the form

$$y' + A(x)y = B(x)$$

for $A(x) = x^{-1}$ and $B(x) = x^3$. By Theorem 1, $\alpha(x)$ is defined by

$$\alpha(x) = e^{\int A(x)\,dx} = e^{\ln x} = x.$$

(b) When multiplied by $\alpha(x)$, the equation becomes:

$$xy' + y = x^4.$$

Now, $xy' + y = xy' + (x)'y = (xy)'$, so

$$(xy)' = x^4.$$

(c) Since $(xy)' = x^4$, $(xy) = \frac{x^5}{5} + C$ and

$$y = \frac{x^4}{5} + \frac{C}{x}$$

(d) If $y(1) = 0$, we find

$$0 = \frac{1}{5} + C \quad \text{so} \quad -\frac{1}{5} = C.$$

The solution, therefore, is

$$y = \frac{x^4}{5} - \frac{1}{5x}.$$

2. Consider $\dfrac{dy}{dt} + 2y = e^{-3t}$.

(a) Verify that $\alpha(t) = e^{2t}$ is an integrating factor.

(b) Use Eq. (4) to find the general solution.

(c) Find the particular solution with initial condition $y(0) = 1$.

SOLUTION

(a) The equation is of the form

$$y' + A(t)y = B(t)$$

for $A(t) = 2$ and $B(t) = e^{-3t}$. Thus,

$$\alpha(t) = e^{\int A(t)\,dt} = e^{2t}.$$

(b) According to Eq. (4),

$$y(t) = \frac{1}{\alpha(t)}\left(\int \alpha(t)B(t)\,dt + C\right).$$

With $\alpha(t) = e^{2t}$ and $B(t) = e^{-3t}$, this yields

$$y(t) = e^{-2t}\left(\int e^{-t}\,dt + C\right) = e^{-2t}\left(C - e^{-t}\right) = Ce^{-2t} - e^{-3t}.$$

(c) Using the initial condition $y(0) = 1$, we find

$$1 = -1 + C \quad \text{so} \quad 2 = C.$$

The particular solution is therefore

$$y = -e^{-3t} + 2e^{-2t}.$$

3. Let $\alpha(x) = e^{x^2}$. Verify the identity

$$(\alpha(x)y)' = \alpha(x)(y' + 2xy)$$

and explain how it is used to find the general solution of

$$y' + 2xy = x$$

SOLUTION Let $\alpha(x) = e^{x^2}$. Then

$$(\alpha(x)y)' = (e^{x^2}y)' = 2xe^{x^2}y + e^{x^2}y' = e^{x^2}\left(2xy + y'\right) = \alpha(x)\left(y' + 2xy\right).$$

If we now multiply both sides of the differential equation $y' + 2xy = x$ by $\alpha(x)$, we obtain

$$\alpha(x)(y' + 2xy) = x\alpha(x) = xe^{x^2}.$$

But $\alpha(x)(y' + 2xy) = (\alpha(x)y)'$, so by integration we find

$$\alpha(x)y = \int xe^{x^2}\,dx = \frac{1}{2}e^{x^2} + C.$$

Finally,

$$y(x) = \frac{1}{2} + Ce^{-x^2}.$$

4. Find the solution of $y' - y = e^{2x}$, $y(0) = 1$.

SOLUTION We first find the general solution of the differential equation $y' - y = e^{2x}$. This is of the standard linear form

$$y' + A(x)y = B(x)$$

with $A(x) = -1$, $B(x) = e^{2x}$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int A(x)\,dx} = e^{-x}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$e^{-x}y' - e^{-x}y = e^x \qquad \text{or} \qquad (e^{-x}y)' = e^x.$$

Integration of both sides now yields

$$e^{-x}y = \int e^x\,dx = e^x + C.$$

Therefore,

$$y(x) = e^{2x} + Ce^x.$$

Using the initial condition $y(0) = 1$, we find

$$1 = 1 + C \quad \text{so} \quad 0 = C.$$

Therefore,

$$y = e^{2x}.$$

In Exercises 5–18, find the general solution of the first-order linear differential equation.

5. $xy' + y = x$

SOLUTION Rewrite the equation as

$$y' + \frac{1}{x}y = 1,$$

which is in standard linear form with $A(x) = \frac{1}{x}$ and $B(x) = 1$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int A(x)\,dx} = e^{\ln x} = x.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$xy' + y = x \qquad \text{or} \qquad (xy)' = x.$$

Integration of both sides now yields

$$xy = \frac{1}{2}x^2 + C.$$

Finally,

$$y(x) = \frac{1}{2}x + \frac{C}{x}.$$

6. $xy' - y = x^2 - x$

SOLUTION Rewrite the equation as

$$y' - \frac{1}{x}y = x - 1,$$

which is in standard linear form with $A(x) = -\frac{1}{x}$ and $B(x) = x - 1$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int A(x)\,dx} = e^{-\ln x} = x^{-1}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$\frac{1}{x}y' - \frac{1}{x^2}y = 1 - \frac{1}{x} \qquad \text{or} \qquad \left(\frac{y}{x}\right)' = 1 - \frac{1}{x}.$$

Integration of both sides now yields

$$\frac{y}{x} = x - \ln x + C.$$

Finally,

$$y(x) = x^2 - x\ln x + Cx.$$

7. $3xy' - y = x^{-1}$

SOLUTION Rewrite the equation as

$$y' - \frac{1}{3x}y = \frac{1}{3x^2},$$

which is in standard form with $A(x) = -\frac{1}{3}x^{-1}$ and $B(x) = \frac{1}{3}x^{-2}$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int A(x)\,dx} = e^{-(1/3)\ln x} = x^{-1/3}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$x^{-1/3}y' - \frac{1}{3}x^{-4/3} = \frac{1}{3}x^{-7/3} \qquad \text{or} \qquad (x^{-1/3}y)' = \frac{1}{3}x^{-7/3}.$$

Integration of both sides now yields

$$x^{-1/3}y = -\frac{1}{4}x^{-4/3} + C.$$

Finally,

$$y(x) = -\frac{1}{4}x^{-1} + Cx^{1/3}.$$

8. $y' + xy = x$

SOLUTION This equation is in standard form with $A(x) = x$ and $B(x) = x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int x\,dx} = e^{(1/2)x^2}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$e^{(1/2)x^2}y' + xe^{(1/2)x^2}y = xe^{(1/2)x^2} \qquad \text{or} \qquad (e^{(1/2)x^2}y)' = xe^{(1/2)x^2}.$$

Integration of both sides now yields

$$e^{(1/2)x^2}y = e^{(1/2)x^2} + C.$$

Finally,

$$y(x) = 1 + Ce^{-(1/2)x^2}.$$

9. $y' + 3x^{-1}y = x + x^{-1}$

SOLUTION This equation is in standard form with $A(x) = 3x^{-1}$ and $B(x) = x + x^{-1}$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int 3x^{-1}} = e^{3\ln x} = x^3.$$

When multiplied by the integrating factor, the original differential equation becomes

$$x^3y' + 3x^2y = x^4 + x^2 \qquad \text{or} \qquad (x^3y)' = x^4 + x^3.$$

Integration of both sides now yields

$$x^3y = \frac{1}{5}x^5 + \frac{1}{3}x^3 + C.$$

Finally,

$$y(x) = \frac{1}{5}x^2 + \frac{1}{3} + Cx^{-3}.$$

10. $y' + x^{-1}y = \cos(x^2)$

SOLUTION This equation is in standard form with $A(x) = x^{-1}$ and $B(x) = \cos(x^2)$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int x^{-1}\,dx} = e^{\ln x} = x.$$

When multiplied by the integrating factor, the original differential equation becomes

$$xy' + y = x\cos(x^2) \qquad \text{or} \qquad (xy)' = x\cos(x^2).$$

Integration of both sides now yields

$$xy = \frac{1}{2}\sin(x^2) + C.$$

Finally,

$$y(x) = \frac{1}{2}x^{-1}\sin(x^2) + Cx^{-1}.$$

11. $xy' = y - x$

SOLUTION Rewrite the equation as

$$y' - \frac{1}{x}y = -1,$$

which is in standard form with $A(x) = -\frac{1}{x}$ and $B(x) = -1$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int -(1/x)\,dx} = e^{-\ln x} = x^{-1}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$\frac{1}{x}y' - \frac{1}{x^2}y = -\frac{1}{x} \qquad \text{or} \qquad \left(\frac{1}{x}y\right)' = -\frac{1}{x}.$$

Integration on both sides now yields

$$\frac{1}{x}y = -\ln x + C.$$

Finally,

$$y(x) = -x\ln x + Cx.$$

12. $xy' = x^{-2} - \dfrac{3y}{x}$

SOLUTION Rewrite the equation is

$$y' + \frac{3}{x^2}y = \frac{1}{x^3}$$

which is in standard form with $A(x) = \frac{3}{x^2}$ and $B(x) = \frac{1}{x^3}$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int (3/x^2)\,dx} = e^{-3x^{-1}}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$e^{-3/x}y' + \frac{3}{x^2}e^{-3/x}y = \frac{1}{x^3}e^{-3/x}$$

Integration on both sides now yields

$$e^{-3/x}y = \frac{x+3}{9x}e^{-3/x} + C \qquad \text{or} \qquad y = \frac{x+3}{9x} + Ce^{3/x}$$

13. $y' + y = e^x$

SOLUTION This equation is in standard form with $A(x) = 1$ and $B(x) = e^x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int 1\,dx} = e^x.$$

When multiplied by the integrating factor, the original differential equation becomes

$$e^x y' + e^x y = e^{2x} \qquad \text{or} \qquad (e^x y)' = e^{2x}.$$

Integration on both sides now yields

$$e^x y = \frac{1}{2}e^{2x} + C.$$

Finally,

$$y(x) = \frac{1}{2}e^x + Ce^{-x}.$$

14. $y' + (\sec x)y = \cos x$

SOLUTION This equation is in standard form with $A(x) = \sec x$ and $B(x) = \cos x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int \sec x\,dx} = e^{\ln(\sec x + \tan x)} = \sec x + \tan x.$$

When multiplied by the integrating factor, the original differential equation becomes

$$(\sec x + \tan x)y' + (\sec^2 x + \sec x \tan x)y = 1 + \sin x$$

or

$$((\sec x + \tan x)y)' = 1 + \sin x.$$

Integration on both sides now yields

$$(\sec x + \tan x)y = x - \cos x + C.$$

Finally,

$$y(x) = \frac{x - \cos x + C}{\sec x + \tan x}.$$

15. $y' + (\tan x)y = \cos x$

SOLUTION This equation is in standard form with $A(x) = \tan x$ and $B(x) = \cos x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int \tan x\,dx} = e^{\ln \sec x} = \sec x.$$

When multiplied by the integrating factor, the original differential equation becomes

$$\sec x y' + \sec x \tan x y = 1 \qquad \text{or} \qquad (y \sec x)' = 1.$$

Integration on both sides now yields

$$y \sec x = x + C.$$

Finally,

$$y(x) = x \cos x + C \cos x.$$

16. $e^{2x} y' = 1 - e^x y$

SOLUTION Rewrite the equation as

$$y' + e^{-x} y = e^{-2x},$$

which is in standard form with $A(x) = e^{-x}$ and $B(x) = e^{-2x}$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int e^{-x}\,dx} = e^{-e^{-x}}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$e^{-e^{-x}} y' + e^{-x-e^{-x}} y = e^{-2x} e^{-e^{-x}} \qquad \text{or} \qquad (e^{-e^{-x}} y)' = e^{-2x} e^{-e^{-x}}.$$

Integration on both sides now yields

$$(e^{-e^{-x}} y) = \int e^{-2x} e^{-e^{-x}}\,dx.$$

To handle the remaining integral, make the substitution $u = -e^{-x}$, $du = e^{-x}\,dx$. Then

$$\int e^{-2x} e^{-e^{-x}}\,dx = -\int u e^u\,du = -ue^u + e^u + C = e^{-x} e^{-e^{-x}} + e^{-e^{-x}} + C.$$

Finally,

$$y(x) = 1 + e^{-x} + Ce^{e^{-x}}.$$

17. $y' - (\ln x)y = x^x$

SOLUTION This equation is in standard form with $A(x) = -\ln x$ and $B(x) = x^x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int -\ln x\,dx} = e^{x - x\ln x} = \frac{e^x}{x^x}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$x^{-x}e^x y' - (\ln x)x^{-x}e^x y = e^x \qquad \text{or} \qquad (x^{-x}e^x y)' = e^x.$$

Integration on both sides now yields

$$x^{-x}e^x y = e^x + C.$$

Finally,

$$y(x) = x^x + Cx^x e^{-x}.$$

18. $y' + y = \cos x$

SOLUTION This equation is in standard form with $A(x) = 1$ and $B(x) = \cos x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int 1\,dx} = e^x.$$

When multiplied by the integrating factor, the original differential equation becomes

$$e^x y' + e^x y = e^x \cos x \qquad \text{or} \qquad (e^x y)' = e^x \cos x.$$

Integration on both sides (integration by parts is needed on the right-hand side of the equation) now yields

$$e^x y = \frac{1}{2}e^x (\sin x + \cos x) + C.$$

Finally,

$$y(x) = \frac{1}{2}(\sin x + \cos x) + Ce^{-x}.$$

In Exercises 19–26, solve the initial value problem.

19. $y' + 3y = e^{2x}, \quad y(0) = -1$

SOLUTION First, we find the general solution of the differential equation. This linear equation is in standard form with $A(x) = 3$ and $B(x) = e^{2x}$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{3x}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$(e^{3x}y)' = e^{5x}.$$

Integration on both sides now yields

$$(e^{3x}y) = \frac{1}{5}e^{5x} + C;$$

hence,

$$y(x) = \frac{1}{5}e^{2x} + Ce^{-3x}.$$

The initial condition $y(0) = -1$ allows us to determine the value of C:

$$-1 = \frac{1}{5} + C \qquad \text{so} \qquad C = -\frac{6}{5}.$$

The solution to the initial value problem is therefore

$$y(x) = \frac{1}{5}e^{2x} - \frac{6}{5}e^{-3x}.$$

20. $xy' + y = e^x, \quad y(1) = 3$

SOLUTION First, we find the general solution of the differential equation. Rewrite the equation as

$$y' + \frac{1}{x}y = \frac{1}{x}e^x,$$

which is in standard form with $A(x) = x^{-1}$ and $B(x) = x^{-1}e^x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int x^{-1}\,dx} = e^{\ln x} = x.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$(xy)' = e^x.$$

Integration on both sides now yields

$$xy = e^x + C;$$

hence,

$$y(x) = \frac{1}{x}e^x + \frac{C}{x}.$$

The initial condition $y(1) = 3$ allows us to determine the value of C:

$$3 = e + \frac{C}{1} \qquad \text{so} \qquad C = 3 - e.$$

The solution to the initial value problem is therefore

$$y(x) = \frac{1}{x}e^x + \frac{3-e}{x}.$$

21. $y' + \dfrac{1}{x+1}y = x^{-2}, \quad y(1) = 2$

SOLUTION First, we find the general solution of the differential equation. This linear equation is in standard form with $A(x) = \frac{1}{x+1}$ and $B(x) = x^{-2}$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int 1/(x+1)\,dx} = e^{\ln(x+1)} = x + 1.$$

When multiplied by the integrating factor, the original differential equation becomes

$$((x+1)y)' = x^{-1} + x^{-2}.$$

Integration on both sides now yields

$$(x+1)y = \ln x - x^{-1} + C;$$

hence,

$$y(x) = \frac{1}{x+1}\left(C + \ln x - \frac{1}{x}\right).$$

The initial condition $y(1) = 2$ allows us to determine the value of C:

$$2 = \frac{1}{2}(C - 1) \qquad \text{so} \qquad C = 5.$$

The solution to the initial value problem is therefore

$$y(x) = \frac{1}{x+1}\left(5 + \ln x - \frac{1}{x}\right).$$

22. $y' + y = \sin x, \quad y(0) = 1$

SOLUTION First, we find the general solution of the differential equation. This equation is in standard form with $A(x) = 1$ and $B(x) = \sin x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int 1\,dx} = e^x.$$

When multiplied by the integrating factor, the original differential equation becomes

$$(e^x y)' = e^x \sin x.$$

Integration on both sides (integration by parts is needed on the right-hand side of the equation) now yields

$$(e^x y) = \frac{1}{2}e^x(\sin x - \cos x) + C;$$

hence,

$$y(x) = \frac{1}{2}(\sin x - \cos x) + Ce^{-x}.$$

The initial condition $y(0) = 1$ allows us to determine the value of C:

$$1 = -\frac{1}{2} + C \qquad \text{so} \qquad C = \frac{3}{2}.$$

The solution to the initial value problem is therefore

$$y(x) = \frac{1}{2}(\sin x - \cos x) + \frac{3}{2}e^{-x}.$$

23. $(\sin x)y' = (\cos x)y + 1, \quad y\left(\frac{\pi}{4}\right) = 0$

SOLUTION First, we find the general solution of the differential equation. Rewrite the equation as

$$y' - (\cot x)y = \csc x,$$

which is in standard form with $A(x) = -\cot x$ and $B(x) = \csc x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int -\cot x\, dx} = e^{-\ln \sin x} = \csc x.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$(\csc x y)' = \csc^2 x.$$

Integration on both sides now yields

$$(\csc x)y = -\cot x + C;$$

hence,

$$y(x) = -\cos x + C \sin x.$$

The initial condition $y(\pi/4) = 0$ allows us to determine the value of C:

$$0 = -\frac{\sqrt{2}}{2} + C\frac{\sqrt{2}}{2} \qquad \text{so} \qquad C = 1.$$

The solution to the initial value problem is therefore

$$y(x) = -\cos x + \sin x.$$

24. $y' + (\sec t)y = \sec t, \quad y\left(\frac{\pi}{4}\right) = 1$

SOLUTION First, we find the general solution of the differential equation. This equation is in standard form with $A(t) = \sec t$ and $B(t) = \sec t$. By Theorem 1, the integrating factor is

$$\alpha(t) = e^{\int \sec t\, dt} = e^{\ln(\sec t + \tan t)} = \sec t + \tan t.$$

When multiplied by the integrating factor, the original differential equation becomes

$$((\sec t + \tan t)y)' = \sec^2 t + \sec t \tan t.$$

Integration on both sides now yields

$$(\sec t + \tan t)y = \tan t + \sec t + C;$$

hence,

$$y(t) = 1 + \frac{C}{\sec t + \tan t}.$$

The initial condition $y(\pi/4) = 1$ allows us to determine the value of C:

$$1 = 1 + \frac{C}{\sqrt{2}+1} \qquad \text{so} \qquad C = 0.$$

The solution to the initial value problem is therefore

$$y(x) = 1.$$

25. $y' + (\tanh x)y = 1, \quad y(0) = 3$

SOLUTION First, we find the general solution of the differential equation. This equation is in standard form with $A(x) = \tanh x$ and $B(x) = 1$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int \tanh x\, dx} = e^{\ln \cosh x} = \cosh x.$$

When multiplied by the integrating factor, the original differential equation becomes

$$(\cosh xy)' = \cosh x.$$

Integration on both sides now yields

$$(\cosh xy) = \sinh x + C;$$

hence,

$$y(x) = \tanh x + C \operatorname{sech} x.$$

The initial condition $y(0) = 3$ allows us to determine the value of C:

$$3 = C.$$

The solution to the initial value problem is therefore

$$y(x) = \tanh x + 3 \operatorname{sech} x.$$

26. $y' + \dfrac{x}{1+x^2}y = \dfrac{1}{(1+x^2)^{3/2}}, \quad y(1) = 0$

SOLUTION First, we find the general solution of the differential equation. This equation is in standard form with $A(x) = \frac{x}{1+x^2}$ and $B(x) = \frac{1}{(1+x^2)^{3/2}}$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int (x/(1+x^2))\,dx} = e^{(1/2)\ln(1+x^2)} = \sqrt{1+x^2}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$\left(\sqrt{1+x^2}y\right)' = \frac{1}{1+x^2}.$$

Integration on both sides now yields

$$\sqrt{1+x^2}y = \tan^{-1} x + C;$$

hence,

$$y(x) = \frac{\tan^{-1} x}{\sqrt{1+x^2}} + \frac{C}{\sqrt{1+x^2}}.$$

The initial condition $y(1) = 0$ allows us to determine the value of C:

$$0 = \frac{1}{\sqrt{2}}\left(\frac{\pi}{4} + C\right) \qquad \text{so} \qquad C = -\frac{\pi}{4}.$$

The solution to the initial value problem is therefore

$$y(x) = \frac{1}{\sqrt{1+x^2}}\left(\tan^{-1} x - \frac{\pi}{4}\right).$$

27. Find the general solution of $y' + ny = e^{mx}$ for all m, n. *Note:* The case $m = -n$ must be treated separately.

SOLUTION For any m, n, Theorem 1 gives us the formula for $\alpha(x)$:

$$\alpha(x) = e^{\int n\,dx} = e^{nx}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$(e^{nx}y)' = e^{(m+n)x}.$$

If $m \neq -n$, integration on both sides yields

$$e^{nx}y = \frac{1}{m+n}e^{(m+n)x} + C,$$

so

$$y(x) = \frac{1}{m+n}e^{mx} + Ce^{-nx}.$$

However, if $m = -n$, then $m + n = 0$ and the equation reduces to

$$(e^{nx}y)' = 1,$$

so integration yields

$$e^{nx}y = x + C \qquad \text{or} \qquad y(x) = (x + C)e^{-nx}.$$

28. Find the general solution of $y' + ny = \cos x$ for all n.

SOLUTION This equation is in standard form with $A(x) = n$ and $B(x) = \cos x$. By Theorem 1, the integrating factor is

$$\alpha(x) = e^{\int n\,dx} = e^{nx}$$

When multiplied by the integrating factor, the differential equation becomes

$$e^{nx}y' + ne^{nx}y = e^{nx}\cos x$$

Integrating both sides gives

$$e^{nx}y = \frac{e^{nx}}{n^2+1}(\sin x + n\cos x) + C$$

(To integrate the right hand side, apply integration by parts twice with $u = e^{nx}$). Finally

$$y = Ce^{-nx} + \frac{\sin x + n\cos x}{n^2+1}$$

In Exercises 29–32, a 1000 L *tank contains* 500 L *of water with a salt concentration of* 10 g/L*. Water with a salt concentration of* 50 g/L *flows into the tank at a rate of* 80 L/min*. The fluid mixes instantaneously and is pumped out at a specified rate* R_{out}*. Let* $y(t)$ *denote the quantity of salt in the tank at time* t*.*

29. Assume that $R_{\text{out}} = 40$ L/min.

(a) Set up and solve the differential equation for $y(t)$.

(b) What is the salt concentration when the tank overflows?

SOLUTION Because water flows into the tank at the rate of 80 L/min but flows out at the rate of $R_{\text{out}} = 40$ L/min, there is a net inflow of 40 L/min. Therefore, at any time t, there are $500 + 40t$ liters of water in the tank.

(a) The net flow of salt into the tank at time t is

$$\frac{dy}{dt} = \text{salt rate in} - \text{salt rate out} = \left(80\frac{\text{L}}{\text{min}}\right)\left(50\frac{\text{g}}{\text{L}}\right) - \left(40\frac{\text{L}}{\text{min}}\right)\left(\frac{y\text{ g}}{500+40t\text{ L}}\right) = 4000 - 40\cdot\frac{y}{500+40t}$$

Rewriting this linear equation in standard form, we have

$$\frac{dy}{dt} + \frac{4}{50+4t}y = 4000,$$

so $A(t) = \frac{4}{50+4t}$ and $B(t) = 4000$. By Theorem 1, the integrating factor is

$$\alpha(t) = e^{\int 4(50+4t)^{-1}\,dt} = e^{\ln(50+4t)} = 50 + 4t.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$((50+4t)y)' = 4000(50+4t).$$

Integration on both sides now yields

$$(50+4t)y = 200{,}000t + 16{,}000t^2 + C;$$

hence,

$$y(t) = \frac{200{,}000t + 8000t^2 + C}{50+4t}.$$

The initial condition $y(0) = 10$ allows us to determine the value of C:

$$10 = \frac{C}{50} \qquad \text{so} \qquad C = 500.$$

The solution to the initial value problem is therefore

$$y(t) = \frac{200{,}000t + 8000t^2 + 500}{50+4t} = \frac{250 + 4000t^2 + 100{,}000t}{25+2t}.$$

(b) The tank overflows when $t = 25/2 = 12.5$. The amount of salt in the tank at that time is

$$y(12.5) = 37{,}505 \text{ g},$$

so the concentration of salt is

$$\frac{37{,}505 \text{ g}}{1000 \text{ L}} = 37.505 \text{ g/L}.$$

30. Find the salt concentration when the tank overflows, assuming that $R_{\text{out}} = 60$ L/min.

SOLUTION We work as in Exercise 29, but with $R_{\text{out}} = 60$. There is a net inflow of 20 L/min, so at time t, there are $500 + 20t$ liters of water in the tank. The net flow of salt into the tank at time t is

$$\frac{dy}{dt} = \text{salt rate in} - \text{salt rate out} = \left(80\frac{\text{L}}{\text{min}}\right)\left(50\frac{\text{g}}{\text{L}}\right) - \left(60\frac{\text{L}}{\text{min}}\right)\left(\frac{y \text{ g}}{500 + 20t \text{ L}}\right) = 4000 - 6 \cdot \frac{y}{50 + 2t}$$

Rewriting this linear equation in standard form, we have

$$\frac{dy}{dt} + \frac{6}{50 + 2t}y = 4000,$$

so $A(t) = \frac{6}{50+2t}$ and $B(t) = 4000$. By Theorem 1, the integrating factor is

$$\alpha(t) = e^{\int 6(50+2t)^{-1}\,dt} = e^{3\ln(50+2t)} = (50 + 2t)^3.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$((50 + 2t)^3 y)' = 4000(50 + 2t)^3.$$

Integration on both sides now yields

$$(50 + 2t)^3 y = 500(50 + 2t)^4 + C;$$

hence,

$$y(t) = 25{,}000 + 1000t + \frac{C}{(50 + 2t)^3}.$$

The initial condition $y(0) = 10$ allows us to determine the value of C:

$$10 = 25{,}000 + \frac{C}{50^3} \qquad \text{so} \qquad C = -3123.75 \times 10^6.$$

The solution to the initial value problem is therefore

$$y(t) = 25{,}000 + 1000t - \frac{390{,}468{,}750}{(25 + t)^2}.$$

The tank overflows when $t = 25$. The amount of salt in the tank at that time is

$$y(25) = 46{,}876.25 \text{ g},$$

so the concentration of salt is

$$\frac{46{,}876.25 \text{ g}}{1000 \text{ L}} \approx 46.876 \text{ g/L}.$$

31. Find the limiting salt concentration as $t \to \infty$ assuming that $R_{\text{out}} = 80$ L/min.

SOLUTION The total volume of water is now constant at 500 liters, so the net flow of salt at time t is

$$\frac{dy}{dt} = \text{salt rate in} - \text{salt rate out} = \left(80\frac{\text{L}}{\text{min}}\right)\left(50\frac{\text{g}}{\text{L}}\right) - \left(80\frac{\text{L}}{\text{min}}\right)\left(\frac{y \text{ g}}{500 \text{ L}}\right) = 4000 - \frac{8}{50}y$$

Rewriting this equation in standard form gives

$$\frac{dy}{dt} + \frac{8}{50}y = 4000$$

so that the integrating factor is

$$e^{\int (8/50)\,dt} = e^{0.16t}$$

Multiplying both sides by the integrating factor gives

$$(e^{0.16t}y)' = 4000e^{0.16t}$$

Integrate both sides to get

$$e^{0.16t}y = 25{,}000e^{0.16t} + C \quad \text{so that} \quad y = 25{,}000 + Ce^{-0.16t}$$

As $t \to \infty$, the exponential term tends to zero, so that the amount of salt tends to 25,000g, or 50 g/L. (Note that this is precisely what would be expected naïvely, since the salt concentration flowing in is also 50 g/L).

32. Assuming that $R_{\text{out}} = 120$ L/min. Find $y(t)$. Then calculate the tank volume and the salt concentration at $t = 10$ minutes.

SOLUTION We work as in Exercise 29, but with $R_{\text{out}} = 120$. There is a net outflow of 40 L/min, so at time t, there are $500 - 40t$ liters of water in the tank. Note that after ten minutes, the volume of water in the tank is 100 liters.

The net flow of salt into the tank at time t is

$$\frac{dy}{dt} = \text{salt rate in} - \text{salt rate out} = \left(80\frac{\text{L}}{\text{min}}\right)\left(50\frac{\text{g}}{\text{L}}\right) - \left(120\frac{\text{L}}{\text{min}}\right)\left(\frac{y\text{ g}}{500 - 40t\text{ L}}\right) = 4000 - 12 \cdot \frac{y}{50 - 4t}$$

Rewriting this linear equation in standard form, we have

$$\frac{dy}{dt} + \frac{6}{25 - 2t}y = 4000,$$

so $A(t) = \frac{6}{25-2t}$ and $B(t) = 4000$. By Theorem 1, the integrating factor is

$$\alpha(t) = e^{\int 6(25-2t)^{-1}\,dt} = e^{-3\ln(25-2t)} = (25 - 2t)^{-3}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$((25 - 2t)^{-3}y)' = 4000(25 - 2t)^{-3}.$$

Integration on both sides now yields

$$(25 - 2t)^{-3}y = 1000(25 - 2t)^{-2} + C;$$

hence,

$$y(t) = 25{,}000 - 2000t + C(25 - 2t)^3.$$

The initial condition $y(0) = 10$ allows us to determine the value of C:

$$10 = 25{,}000 + C \cdot 50^3 \qquad \text{so} \qquad C = -1.599.$$

The solution to the initial value problem is therefore

$$y(t) = 25{,}000 - 2000t - 1.599(25 - 2t)^3.$$

The amount of salt in the tank at time $t = 10$ is then

$$y(10) = 4800.08 \text{ g},$$

so the concentration of salt is

$$\frac{4800.08\text{ g}}{100\text{ L}} \approx 48 \text{ g/L}.$$

33. Water flows into a tank at the variable rate of $R_{\text{in}} = 20/(1 + t)$ gal/min and out at the constant rate $R_{\text{out}} = 5$ gal/min. Let $V(t)$ be the volume of water in the tank at time t.

(a) Set up a differential equation for $V(t)$ and solve it with the initial condition $V(0) = 100$.

(b) Find the maximum value of V.

(c) CAS Plot $V(t)$ and estimate the time t when the tank is empty.

SOLUTION

(a) The rate of change of the volume of water in the tank is given by

$$\frac{dV}{dt} = R_{\text{in}} - R_{\text{out}} = \frac{20}{1 + t} - 5.$$

Because the right-hand side depends only on the independent variable t, we integrate to obtain

$$V(t) = 20\ln(1+t) - 5t + C.$$

The initial condition $V(0) = 100$ allows us to determine the value of C:

$$100 = 20\ln 1 - 0 + C \qquad \text{so} \qquad C = 100.$$

Therefore

$$V(t) = 20\ln(1+t) - 5t + 100.$$

(b) Using the result from part (a),

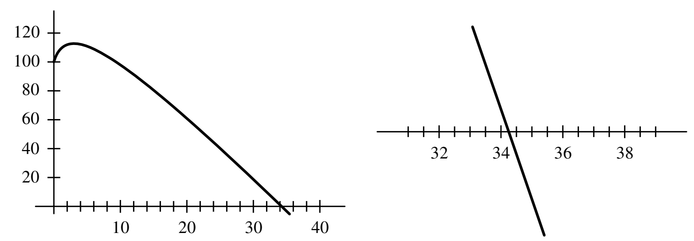
$$\frac{dV}{dt} = \frac{20}{1+t} - 5 = 0$$

when $t = 3$. Because $\frac{dV}{dt} > 0$ for $t < 3$ and $\frac{dV}{dt} < 0$ for $t > 3$, it follows that

$$V(3) = 20\ln 4 - 15 + 100 \approx 112.726 \text{ gal}$$

is the maximum volume.

(c) $V(t)$ is plotted in the figure below at the left. On the right, we zoom in near the location where the curve crosses the t-axis. From this graph, we estimate that the tank is empty after roughly 34.25 minutes.



34. A stream feeds into a lake at a rate of 1000 m^3/day. The stream is polluted with a toxin whose concentration is 5 g/m^3. Assume that the lake has volume 10^6 m^3 and that water flows out of the lake at the same rate of 1000 m^3/day.

(a) Set up a differential equation for the concentration $c(t)$ of toxin in the lake and solve for $c(t)$, assuming that $c(0) = 0$. *Hint:* Find the differential equation for the quantity of toxin $y(t)$, and observe that $c(t) = y(t)/10^6$.

(b) What is the limiting concentration for large t?

SOLUTION

(a) Let $M(t)$ denote the amount of toxin, in grams, in the lake at time t. The rate at which toxin enters the lake is given by

$$5\frac{\text{g}}{\text{m}^3} \cdot 1000\frac{\text{m}^3}{\text{day}} = 5000\frac{\text{g}}{\text{day}},$$

while the rate at which toxin exits the lake is given by

$$\frac{M(t)\ \text{g}}{10^6\ \text{m}^3} \cdot 1000\frac{\text{m}^3}{\text{day}} = \frac{M(t)}{1000}\frac{\text{g}}{\text{day}},$$

where we have assumed that any toxin in the lake is spread uniformly throughout the lake. The differential equation for $M(t)$ is then

$$\frac{dM}{dt} = 5000 - \frac{M}{1000}.$$

The concentration of the toxin in the lake is given by $c(t) = \dfrac{M(t)}{10^6}$, so $c'(t) = \frac{1}{10^6}M'(t)$, giving

$$\frac{dc}{dt} = \frac{1}{200} - \frac{1}{1000}c.$$

Rewriting this linear equation in standard form, we have

$$\frac{dc}{dt} + \frac{1}{1000}c = \frac{1}{200},$$

so $A(t) = \frac{1}{1000}$ and $B(t) = \frac{1}{200}$. By Theorem 1, the integrating factor is

$$\alpha(t) = e^{t/1000}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$(e^{t/1000}c)' = \frac{1}{200}e^{t/1000}.$$

Integration on both sides now yields

$$e^{t/1000}c = 5e^{t/1000} + A;$$

hence,

$$c(t) = 5 + Ae^{-t/1000}.$$

The initial condition $c(0) = 0$ allows us to determine the value of A:

$$0 = 5 + A \qquad \text{so} \qquad A = -5.$$

Therefore

$$c(t) = 5\left(1 - e^{-t/1000}\right) \text{ grams/m}^3.$$

(b) As $t \to \infty$, $c(t) \to 5$, so the limiting concentration of pollution is $5\ \dfrac{\text{grams}}{\text{m}^3}$.

In Exercises 35–38, consider a series circuit (Figure 4) consisting of a resistor of R ohms, an inductor of L henries, and a variable voltage source of $V(t)$ volts (time t in seconds). The current through the circuit $I(t)$ (in amperes) satisfies the differential equation

$$\frac{dI}{dt} + \frac{R}{L}I = \frac{1}{L}V(t) \qquad \boxed{10}$$

35. Find the solution to Eq. (10) with initial condition $I(0) = 0$, assuming that $R = 100\ \Omega$, $L = 5$ H, and $V(t)$ is constant with $V(t) = 10$ V.

SOLUTION If $R = 100$, $V(t) = 10$, and $L = 5$, the differential equation becomes

$$\frac{dI}{dt} + 20I = 2,$$

which is a linear equation in standard form with $A(t) = 20$ and $B(t) = 2$. The integrating factor is $\alpha(t) = e^{20t}$, and when multiplied by the integrating factor, the differential equation becomes

$$(e^{20t}I)' = 2e^{20t}.$$

Integration of both sides now yields

$$e^{20t}I = \frac{1}{10}e^{20t} + C;$$

hence,

$$I(t) = \frac{1}{10} + Ce^{-20t}.$$

The initial condition $I(0) = 0$ allows us to determine the value of C:

$$0 = \frac{1}{10} + C \qquad \text{so} \qquad C = -\frac{1}{10}.$$

Finally,

$$I(t) = \frac{1}{10}\left(1 - e^{-20t}\right).$$

36. Assume that $R = 110\ \Omega$, $L = 10$ H, and $V(t) = e^{-t}$.

(a) Solve Eq. (10) with initial condition $I(0) = 0$.

(b) Calculate t_m and $I(t_m)$, where t_m is the time at which $I(t)$ has a maximum value.

(c) GU Use a computer algebra system to sketch the graph of the solution for $0 \le t \le 3$.

SOLUTION

(a) If $R = 110$, $V(t) = e^{-t}$, and $L = 10$, the differential equation becomes

$$\frac{dI}{dt} + 11I = \frac{1}{10}e^{-t},$$

which is a linear equation in standard form with $A(t) = 11$ and $B(t) = \frac{1}{10}e^{-t}$. The integrating factor is $\alpha(t) = e^{11t}$, and when multiplied by the integrating factor, the differential equation becomes

$$(e^{11t}I)' = \frac{1}{10}e^{10t}.$$

Integration of both sides now yields

$$e^{11t}I = \frac{1}{100}e^{10t} + C;$$

hence,

$$I(t) = \frac{1}{100}e^{-t} + Ce^{-11t}.$$

The initial condition $I(0) = 0$ allows us to determine the value of C:

$$0 = \frac{1}{100} + C \qquad \text{so} \qquad C = -\frac{1}{100}.$$

Finally,

$$I(t) = \frac{1}{100}\left(e^{-t} - e^{-11t}\right).$$

(b) Using the result from part (a),

$$\frac{dI}{dt} = \frac{1}{100}\left(-e^{-t} + 11e^{-11t}\right) = 0$$

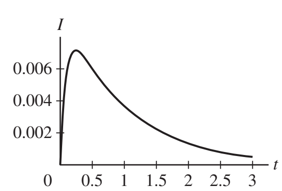
when

$$t = t_m = \frac{1}{10}\ln 11 \text{ seconds.}$$

Now,

$$I(t_m) = \frac{1}{100}\left(e^{-(1/10)\ln 11} - e^{-(11/10)\ln 11}\right) = \frac{1}{100}\left(11^{-1/10} - 11^{-11/10}\right) \approx 0.00715 \text{ amperes.}$$

(c) The graph of $I(t)$ is shown below.



37. Assume that $V(t) = V$ is constant and $I(0) = 0$.

(a) Solve for $I(t)$.

(b) Show that $\lim_{t\to\infty} I(t) = V/R$ and that $I(t)$ reaches approximately 63% of its limiting value after L/R seconds.

(c) How long does it take for $I(t)$ to reach 90% of its limiting value if $R = 500\ \Omega$, $L = 4$ H, and $V = 20$ V?

SOLUTION

(a) The equation

$$\frac{dI}{dt} + \frac{R}{L}I = \frac{1}{L}V$$

is a linear equation in standard form with $A(t) = \frac{R}{L}$ and $B(t) = \frac{1}{L}V(t)$. By Theorem 1, the integrating factor is

$$\alpha(t) = e^{\int (R/L)\,dt} = e^{(R/L)t}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$(e^{(R/L)t}I)' = e^{(R/L)t}\frac{V}{L}.$$

Integration on both sides now yields

$$(e^{(R/L)t}I) = \frac{V}{R}e^{(R/L)t} + C;$$

hence,

$$I(t) = \frac{V}{R} + Ce^{-(R/L)t}.$$

The initial condition $I(0) = 0$ allows us to determine the value of C:

$$0 = \frac{V}{R} + C \qquad \text{so} \qquad C = -\frac{V}{R}.$$

Therefore the current is given by

$$I(t) = \frac{V}{R}\left(1 - e^{-(R/L)t}\right).$$

(b) As $t \to \infty$, $e^{-(R/L)t} \to 0$, so $I(t) \to \frac{V}{R}$. Moreover, when $t = (L/R)$ seconds, we have

$$I\left(\frac{L}{R}\right) = \frac{V}{R}\left(1 - e^{-(R/L)(L/R)}\right) = \frac{V}{R}\left(1 - e^{-1}\right) \approx 0.632\frac{V}{R}.$$

(c) Using the results from part (a) and part (b), $I(t)$ reaches 90% of its limiting value when

$$\frac{9}{10} = 1 - e^{-(R/L)t},$$

or when

$$t = \frac{L}{R}\ln 10.$$

With $L = 4$ and $R = 500$, this takes approximately 0.0184 seconds.

38. Solve for $I(t)$, assuming that $R = 500\ \Omega$, $L = 4$ H, and $V = 20\cos(80t)$ volts.

SOLUTION With $R = 500$, $L = 4$, and $V = 20\cos(80t)$, Eq. (10) becomes

$$\frac{dI}{dt} + 125I = 5\cos(80t)$$

which is a linear equation in standard form with $A(t) = 125$ and $B(t) = 5\cos(80t)$. The integrating factor is e^{125t}; when multiplied by the integrating factor, the differential equation becomes

$$(e^{125t}I)' = 5e^{125t}\cos(80t)$$

To integrate the right side, apply integration by parts twice and solve the resulting formula for the desired integral, giving

$$\int 5e^{125t}\cos(80t)\,dt = \frac{1}{881}e^{125t}(25\cos(80t) + 16\sin(80t) + C$$

so that the solution is

$$e^{125t}I = \frac{1}{881}e^{125t}(25\cos(80t) + 16\sin(80t) + C$$

Multiply through by e^{-125t} to get

$$I = \frac{1}{881}(25\cos(80t) + 16\sin(80t) + Ce^{-125t}$$

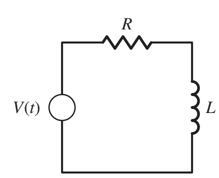


FIGURE 4 RL circuit.

39. Tank 1 in Figure 5 is filled with V_1 liters of water containing blue dye at an initial concentration of c_0 g/L. Water flows into the tank at a rate of R L/min, is mixed instantaneously with the dye solution, and flows out through the bottom at the same rate R. Let $c_1(t)$ be the dye concentration in the tank at time t.

(a) Explain why c_1 satisfies the differential equation $\dfrac{dc_1}{dt} = -\dfrac{R}{V_1}c_1$.

(b) Solve for $c_1(t)$ with $V_1 = 300$ L, $R = 50$, and $c_0 = 10$ g/L.

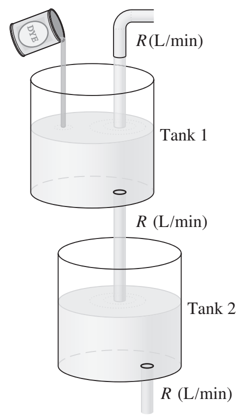

FIGURE 5

SOLUTION

(a) Let $g_1(t)$ be the number of grams of dye in the tank at time t. Then $g_1(t) = V_1c_1(t)$ and $g_1'(t) = V_1c_1'(t)$. Now,

$$g_1'(t) = \text{grams of dye in} - \text{grams of dye out} = 0 - \frac{g(t)}{V_1}\text{ g/L} \cdot R\text{ L/min} = -\frac{R}{V_1}g(t)$$

Substituting gives

$$V_1c_1'(t) = -\frac{R}{V_1}c_1(t)V_1 \quad \text{and simplifying yields} \quad c_1'(t) = -\frac{R}{V_1}c_1(t)$$

(b) In standard form, the equation is

$$c_1'(t) + \frac{R}{V_1}c_1(t) = 0$$

so that $A(t) = \dfrac{R}{V_1}$ and $B(t) = 0$. The integrating factor is $e^{(R/V_1)t}$; multiplying through gives

$$(e^{(R/V_1)t}c_1(t))' = 0 \quad \text{so, integrating,} \quad e^{(R/V_1)t}c_1(t) = C$$

and thus $c_1(t) = Ce^{-(R/V_1)t}$. With $R = 50$ and $V_1 = 300$ we have $c_1(t) = Ce^{-t/6}$; the initial condition $c_1(0) = c_0 = 10$ gives $C = 10$. Finally,

$$c_1(t) = 10e^{-t/6}$$

40. Continuing with the previous exercise, let Tank 2 be another tank filled with V_2 gal of water. Assume that the dye solution from Tank 1 empties into Tank 2 as in Figure 5, mixes instantaneously, and leaves Tank 2 at the same rate R. Let $c_2(t)$ be the dye concentration in Tank 2 at time t.

(a) Explain why c_2 satisfies the differential equation

$$\frac{dc_2}{dt} = \frac{R}{V_2}(c_1 - c_2)$$

(b) Use the solution to Exercise 39 to solve for $c_2(t)$ if $V_1 = 300$, $V_2 = 200$, $R = 50$, and $c_0 = 10$.

(c) Find the maximum concentration in Tank 2.

(d) GU Plot the solution.

SOLUTION

(a) Let $g_2(t)$ be the amount in grams of dye in Tank 2 at time t. At time t, the concentration of dye in Tank 1, and thus the concentration of dye coming into Tank 2, is $c_1(t)$. Thus

$$\begin{aligned} g_2'(t) &= \text{grams of dye in} - \text{grams of dye out} \\ &= c_1(t)\text{ g/L} \cdot R\text{ L/min} - c_2(t)\text{g/L} \cdot R\text{ L/min} = R(c_1(t) - c_2(t)) \end{aligned}$$

Since $g_2'(t) = V_2 c_2'(t)$, we get

$$c_2'(t) = \frac{R}{V_2}(c_1(t) - c_2(t))$$

(b) With $V_1 = 300$, $R = 50$, and $c_0 = 10$, part (a) tells us that

$$c_1(t) = 10e^{-t/6}$$

Since $V_2 = 200$, we have

$$c_2'(t) = \frac{1}{4}(10e^{-t/6} - c_2(t))$$

Putting this linear equation in standard form gives

$$c_2'(t) + \frac{1}{4}c_2(t) = \frac{5}{2}e^{-t/6}$$

The integrating factor is $e^{t/4}$; multiplying through gives

$$(e^{t/4}c_2(t))' = \frac{5}{2}e^{t/12}$$

Integrate to get

$$e^{t/4}c_2(t) = 30e^{t/12} + C \quad \text{so that} \quad c_2(t) = 30e^{-t/6} + Ce^{-t/4}$$

Since Tank 2 starts out filled entirely with water, we have $c_2(0) = 0$ so that $C = -30$ and

$$c_2(t) = 30(e^{-t/6} - e^{-t/4})$$

(c) The maximum concentration in Tank 2 occurs when $c_2'(t) = 0$.

$$c_2'(t) = 0 = -5e^{-t/6} + \frac{15}{2}e^{-t/4}$$

Solve this equation for t as follows:

$$\begin{aligned}
5e^{-t/6} &= \frac{15}{2}e^{-t/4} \\
2e^{-t/6} &= 3e^{-t/4} \\
-\frac{t}{6} + \ln 2 &= -\frac{t}{4} + \ln 3 \\
\frac{t}{12} &= \ln 3 - \ln 2 = \ln(3/2) \\
t &= 12\ln(3/2) \approx 4.866
\end{aligned}$$

When $t = 12\ln(3/2)$,

$$c_2(t) = 30(e^{-2\ln(3/2)} - e^{-3\ln(3/2)}) = 30\left(\frac{4}{9} - \frac{8}{27}\right) = \frac{40}{9}$$

41. Let a, b, r be constants. Show that

$$y = Ce^{-kt} + a + bk\left(\frac{k\sin rt - r\cos rt}{k^2 + r^2}\right)$$

is a general solution of

$$\frac{dy}{dt} = -k\Big(y - a - b\sin rt\Big)$$

SOLUTION This is a linear differential equation; in standard form, it is

$$\frac{dy}{dt} + ky = k(a + b\sin rt)$$

The integrating factor is then e^{kt}; multiplying through gives

$$(e^{kt}y)' = kae^{kt} + kbe^{kt}\sin rt \qquad (*)$$

The first term on the right-hand side has integral ae^{kt}. To integrate the second term, use integration by parts twice; this result in an equation of the form

$$\int kbe^{kt}\sin rt = F(t) + A\int kbe^{kt}\sin rt$$

for some function $F(t)$ and constant A. Solving for the integral gives

$$\int kbe^{kt}\sin rt = kbe^{kt}\frac{k\sin rt - r\cos rt}{k^2+r^2}$$

so that integrating equation (*) gives

$$e^{kt}y = ae^{kt} + kbe^{kt}\frac{k\sin rt - r\cos rt}{k^2+r^2} + C$$

Divide through by e^{kt} to get

$$y = a + bk\left(\frac{k\sin rt - r\cos rt}{k^2+r^2}\right) + Ce^{-kt}$$

42. Assume that the outside temperature varies as

$$T(t) = 15 + 5\sin(\pi t/12)$$

where $t = 0$ is 12 noon. A house is heated to 25°C at $t = 0$ and after that, its temperature $y(t)$ varies according to Newton's Law of Cooling (Figure 6):

$$\frac{dy}{dt} = -0.1\Big(y(t) - T(t)\Big)$$

Use Exercise 41 to solve for $y(t)$.

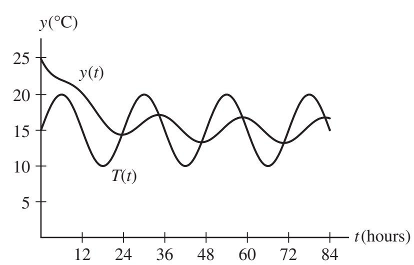

FIGURE 6 House temperature $y(t)$

SOLUTION The differential equation is

$$\frac{dy}{dt} = -0.1\Big(y(t) - 15 - 5\sin(\frac{\pi t}{12})\Big)$$

This differential equation is of the form considered in Exercise 41, with $a = 15$, $b = 5$, $r = \pi/12$, and $k = 0.1$. Thus the general solution is

$$y(t) = Ce^{-0.1t} + 15 + 0.5\left(\frac{0.1\sin(\pi t/12) - (\pi/12)\cos(\pi t/12)}{0.01 + \pi^2/144}\right)$$

Since $y(0) = 25$, we have

$$25 = C + 15 + 0.5\left(\frac{0 - \pi/12}{0.01 + \pi^2/144}\right) \approx C + 15 - 1.667$$

so that $C \approx 11.667$ and

$$y(t) = 11.667e^{-0.1t} + 15 + 0.5\left(\frac{0.1\sin(\pi t/12) - (\pi/12)\cos(\pi t/12)}{0.01 + \pi^2/144}\right)$$

Further Insights and Challenges

43. Let $\alpha(x)$ be an integrating factor for $y' + A(x)y = B(x)$. The differential equation $y' + A(x)y = 0$ is called the associated **homogeneous equation**.

(a) Show that $1/\alpha(x)$ is a solution of the associated homogeneous equation.

(b) Show that if $y = f(x)$ is a particular solution of $y' + A(x)y = B(x)$, then $f(x) + C/\alpha(x)$ is also a solution for any constant C.

SOLUTION

(a) Remember that $\alpha'(x) = A(x)\alpha(x)$. Now, let $y(x) = (\alpha(x))^{-1}$. Then

$$y' + A(x)y = -\frac{1}{(\alpha(x))^2}\alpha'(x) + \frac{A(x)}{\alpha(x)} = -\frac{1}{(\alpha(x))^2}A(x)\alpha(x) + \frac{A(x)}{\alpha(x)} = 0.$$

(b) Suppose $f(x)$ satisfies $f'(x) + A(x)f(x) = B(x)$. Now, let $y(x) = f(x) + C/\alpha(x)$, where C is an arbitrary constant. Then

$$\begin{aligned} y' + A(x)y &= f'(x) - \frac{C}{(\alpha(x))^2}\alpha'(x) + A(x)f(x) + \frac{CA(x)}{\alpha(x)} \\ &= \big(f'(x) + A(x)f(x)\big) + \frac{C}{\alpha(x)}\left(A(x) - \frac{\alpha'(x)}{\alpha(x)}\right) = B(x) + 0 = B(x). \end{aligned}$$

44. Use the Fundamental Theorem of Calculus and the Product Rule to verify directly that for any x_0, the function

$$f(x) = \alpha(x)^{-1}\int_{x_0}^{x} \alpha(t)B(t)\,dt$$

is a solution of the initial value problem

$$y' + A(x)y = B(x), \qquad y(x_0) = 0$$

where $\alpha(x)$ is an integrating factor [a solution to Eq. (3)].

SOLUTION Remember that $\alpha'(x) = A(x)\alpha(x)$. Now, let

$$y(x) = \frac{1}{\alpha(x)}\int_{x_0}^{x} \alpha(t)B(t)\,dt.$$

Then,

$$y(x_0) = \frac{1}{\alpha(x)}\int_{x_0}^{x_0} \alpha(t)B(t)\,dt = 0,$$

and

$$\begin{aligned} y' + A(x)y &= -\frac{\alpha'(x)}{(\alpha(x))^2}\int_{x_0}^{x} \alpha(t)B(t)\,dt + B(x) + \frac{A(x)}{\alpha(x)}\int_{x_0}^{x} \alpha(t)B(t)\,dt \\ &= B(x) + \left(-\frac{A(x)}{\alpha(x)} + \frac{A(x)}{\alpha(x)}\right)\int_{x_0}^{x} \alpha(t)B(t)\,dt = B(x). \end{aligned}$$

45. Transient Currents Suppose the circuit described by Eq. (10) is driven by a sinusoidal voltage source $V(t) = V\sin\omega t$ (where V and ω are constant).

(a) Show that

$$I(t) = \frac{V}{R^2 + L^2\omega^2}(R\sin\omega t - L\omega\cos\omega t) + Ce^{-(R/L)t}$$

(b) Let $Z = \sqrt{R^2 + L^2\omega^2}$. Choose θ so that $Z\cos\theta = R$ and $Z\sin\theta = L\omega$. Use the addition formula for the sine function to show that

$$I(t) = \frac{V}{Z}\sin(\omega t - \theta) + Ce^{-(R/L)t}$$

This shows that the current in the circuit varies sinusoidally apart from a DC term (called the **transient current** in electronics) that decreases exponentially.

SOLUTION
(a) With $V(t) = V \sin \omega t$, the equation

$$\frac{dI}{dt} + \frac{R}{L}I = \frac{1}{L}V(t)$$

becomes

$$\frac{dI}{dt} + \frac{R}{L}I = \frac{V}{L}\sin \omega t.$$

This is a linear equation in standard form with $A(t) = \frac{R}{L}$ and $B(t) = \frac{V}{L}\sin \omega t$. By Theorem 1, the integrating factor is

$$\alpha(t) = \int e^{\int A(t)\,dt} = e^{(R/L)\,t}.$$

When multiplied by the integrating factor, the equation becomes

$$(e^{(R/L)\,t}I)' = \frac{V}{L}e^{(R/L)\,t}\sin \omega t.$$

Integration on both sides (integration by parts is needed for the integral on the right-hand side) now yields

$$(e^{(R/L)\,t}I) = \frac{V}{R^2 + L^2\omega^2}e^{(R/L)\,t}\,(R \sin \omega t - L\omega \cos \omega t) + C;$$

hence,

$$I(t) = \frac{V}{R^2 + L^2\omega^2}\,(R \sin \omega t - L\omega \cos \omega t) + Ce^{-(R/L)\,t}.$$

(b) Let $Z = \sqrt{R^2 + L^2\omega^2}$, and choose θ so that $Z \cos \theta = R$ and $Z \sin \theta = L\omega$. Then

$$\begin{aligned}\frac{V}{R^2 + L^2\omega^2}\,(R \sin \omega t - L\omega \cos \omega t) &= \frac{V}{Z^2}\,(Z \cos \theta \sin \omega t - Z \sin \theta \cos \omega t)\\ &= \frac{V}{Z}\,(\cos \theta \sin \omega t - \sin \theta \cos \omega t) = \frac{V}{Z}\sin(\omega t - \theta).\end{aligned}$$

Thus,

$$I(t) = \frac{V}{Z}\sin(\omega t - \theta) + Ce^{-(R/L)\,t}.$$

CHAPTER REVIEW EXERCISES

1. Which of the following differential equations are linear? Determine the order of each equation.

(a) $y' = y^5 - 3x^4 y$
(b) $y' = x^5 - 3x^4 y$
(c) $y = y''' - 3x\sqrt{y}$
(d) $\sin x \cdot y'' = y - 1$

SOLUTION

(a) y^5 is a nonlinear term involving the dependent variable, so this is not a linear equation; the highest order derivative that appears in the equation is a first derivative, so this is a first-order equation.

(b) This is linear equation; the highest order derivative that appears in the equation is a first derivative, so this is a first-order equation.

(c) $\sqrt{y}$ is a nonlinear term involving the dependent variable, so this is not a linear equation; the highest order derivative that appears in the equation is a third derivative, so this is a third-order equation.

(d) This is linear equation; the highest order derivative that appears in the equation is a second derivative, so this is a second-order equation.

2. Find a value of c such that $y = x - 2 + e^{cx}$ is a solution of $2y' + y = x$.

SOLUTION Let $y = x - 2 + e^{cx}$. Then

$$y' = 1 + ce^{cx},$$

and

$$2y' + y = 2\left(1 + ce^{cx}\right) + \left(x - 2 + e^{cx}\right) = 2 + 2ce^{cx} + x - 2 + e^{cx} = (2c + 1)e^{cx} + x.$$

For this to equal x, we must have $2c + 1 = 0$, or $c = -\frac{1}{2}$ (remember that e^{cx} is never zero).

In Exercises 3–6, solve using separation of variables.

3. $\dfrac{dy}{dt} = t^2 y^{-3}$

SOLUTION Rewrite the equation as

$$y^3\,dy = t^2\,dt.$$

Upon integrating both sides of this equation, we obtain:

$$\int y^3\,dy = \int t^2\,dt$$
$$\frac{y^4}{4} = \frac{t^3}{3} + C.$$

Thus,

$$y = \pm\left(\frac{4}{3}t^3 + C\right)^{1/4},$$

where C is an arbitrary constant.

4. $xyy' = 1 - x^2$

SOLUTION Rewrite the equation

$$xy\frac{dy}{dx} = 1 - x^2 \qquad \text{as} \qquad y\,dy = \left(\frac{1}{x} - x\right)dx.$$

Upon integrating both sides of this equation, we obtain

$$\int y\,dy = \int \left(\frac{1}{x} - x\right)dx$$
$$\frac{y^2}{2} = \ln|x| - \frac{x^2}{2} + C.$$

Thus,

$$y = \pm\sqrt{\ln x^2 + A - x^2},$$

where $A = 2C$ is an arbitrary constant.

5. $x\dfrac{dy}{dx} - y = 1$

SOLUTION Rewrite the equation as

$$\frac{dy}{1+y} = \frac{dx}{x}.$$

upon integrating both sides of this equation, we obtain

$$\int \frac{dy}{1+y} = \int \frac{dx}{x}$$
$$\ln|1+y| = \ln|x| + C.$$

Thus,

$$y = -1 + Ax,$$

where $A = \pm e^C$ is an arbitrary constant.

6. $y' = \dfrac{xy^2}{x^2+1}$

SOLUTION Rewrite

$$\frac{dy}{dx} = \frac{xy^2}{x^2+1} \qquad \text{as} \qquad \frac{dy}{y^2} = \frac{x}{x^2+1}\,dx.$$

Upon integrating both sides of this equation, we obtain

$$\int \frac{dy}{y^2} = \int \frac{x}{x^2+1}\,dx$$
$$-\frac{1}{y} = \frac{1}{2}\ln\left(x^2+1\right) + C.$$

Thus,

$$y = -\frac{1}{\frac{1}{2}\ln\left(x^2+1\right)+C},$$

where C is an arbitrary constant.

In Exercises 7–10, solve the initial value problem using separation of variables.

7. $y' = \cos^2 x, \quad y(0) = \frac{\pi}{4}$

SOLUTION First, we find the general solution of the differential equation. Because the variables are already separated, we integrate both sides to obtain

$$y = \int \cos^2 x\,dx = \int \left(\frac{1}{2} + \frac{1}{2}\cos 2x\right)dx = \frac{x}{2} + \frac{\sin 2x}{4} + C.$$

The initial condition $y(0) = \frac{\pi}{4}$ allows us to determine $C = \frac{\pi}{4}$. Thus, the solution is:

$$y(x) = \frac{x}{2} + \frac{\sin 2x}{4} + \frac{\pi}{4}.$$

8. $y' = \cos^2 y, \quad y(0) = \frac{\pi}{4}$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dx} = \cos^2 y \qquad \text{as} \qquad \frac{dy}{\cos^2 y} = dx.$$

Upon integrating both sides of this equation, we find

$$\tan y = x + C;$$

thus,

$$y = \tan^{-1}(x+C).$$

The initial condition $y(0) = \frac{\pi}{4}$ allows us to determine the value of C:

$$\frac{\pi}{4} = \tan^{-1} C \qquad \text{so} \qquad C = 1.$$

Hence, the solution is $y = \tan^{-1}(x+1)$.

9. $y' = xy^2, \quad y(1) = 2$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$\frac{dy}{dx} = xy^2 \qquad \text{as} \qquad \frac{dy}{y^2} = x\,dx.$$

Upon integrating both sides of this equation, we find

$$\int \frac{dy}{y^2} = \int x\,dx$$
$$-\frac{1}{y} = \frac{1}{2}x^2 + C.$$

Thus,

$$y = -\frac{1}{\frac{1}{2}x^2 + C}.$$

The initial condition $y(1) = 2$ allows us to determine the value of C:

$$2 = -\frac{1}{\frac{1}{2}\cdot 1^2 + C} = -\frac{2}{1+2C}$$
$$1 + 2C = -1$$
$$C = -1$$

Hence, the solution to the initial value problem is

$$y = -\frac{1}{\frac{1}{2}x^2 - 1} = -\frac{2}{x^2 - 2}.$$

10. $xyy' = 1, \quad y(3) = 2$

SOLUTION First, we find the general solution of the differential equation. Rewrite

$$xy\frac{dy}{dx} = 1 \qquad \text{as} \qquad y\,dy = \frac{dx}{x}.$$

Next we integrate both sides of the equation to obtain

$$\int y\,dy = \int \frac{dx}{x}$$
$$\frac{1}{2}y^2 = \ln|x| + C.$$

Thus,

$$y = \pm\sqrt{2(\ln|x| + C)}.$$

To satisfy the initial condition $y(3) = 2$ we must choose the positive square root; moreover,

$$2 = \sqrt{2(\ln 3 + C)} \qquad \text{so} \qquad C = 2 - \ln 3.$$

Hence, the solution to the initial value problem is

$$y = \sqrt{2(\ln|x| + 2 - \ln 3)} = \sqrt{\ln\left(\frac{x^2}{9}\right) + 4}.$$

11. Figure 1 shows the slope field for $\dot{y} = \sin y + ty$. Sketch the graphs of the solutions with the initial conditions $y(0) = 1$, $y(0) = 0$, and $y(0) = -1$.

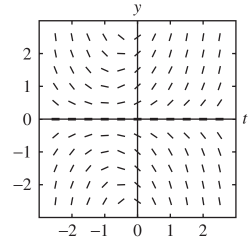

FIGURE 1

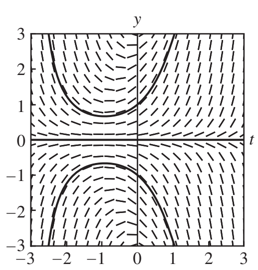
SOLUTION



12. Which of the equations (i)–(iii) corresponds to the slope field in Figure 2?

(i) $\dot{y} = 1 - y^2$
(ii) $\dot{y} = 1 + y^2$
(iii) $\dot{y} = y^2$

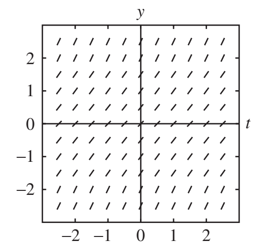


FIGURE 2

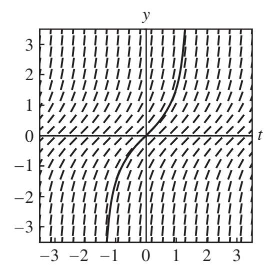
SOLUTION From the figure we see that the the slope is positive even for $y > 1$, thus, the slope field does not correspond to the equation $\dot{y} = 1 - y^2$. Moreover, the slope at $y = 0$ is positive, so the slope field also does not correspond to the equation $\dot{y} = y^2$. The slope field must therefore correspond to **(ii)**: $\dot{y} = 1 + y^2$.

13. Let $y(t)$ be the solution to the differential equation with slope field as shown in Figure 2, satisfying $y(0) = 0$. Sketch the graph of $y(t)$. Then use your answer to Exercise 12 to solve for $y(t)$.

SOLUTION As explained in the previous exercise, the slope field in Figure 2 corresponds to the equation $\dot{y} = 1 + y^2$. The graph of the solution satisfying $y(0) = 0$ is:



To solve the initial value problem $\dot{y} = 1 + y^2$, $y(0) = 0$, we first find the general solution of the differential equation. Separating variables yields:

$$\frac{dy}{1 + y^2} = dt.$$

Upon integrating both sides of this equation, we find

$$\tan^{-1} y = t + C \qquad \text{or} \qquad y = \tan(t + C).$$

The initial condition gives $C = 0$, so the solution is $y = \tan x$.

14. Let $y(t)$ be the solution of $4\dot{y} = y^2 + t$ satisfying $y(2) = 1$. Carry out Euler's Method with time step $h = 0.05$ for $n = 6$ steps.

SOLUTION Rewrite the differential equation as $\dot{y} = \frac{1}{4}(y^2 + t)$ to identify $F(t, y) = \frac{1}{4}\left(y^2 + t\right)$. With $t_0 = 2$, $y_0 = 1$, and $h = 0.05$, we calculate

$$\begin{aligned}
y_1 &= y_0 + hF(t_0, y_0) = 1.0375 \\
y_2 &= y_1 + hF(t_1, y_1) = 1.076580 \\
y_3 &= y_2 + hF(t_2, y_2) = 1.117318 \\
y_4 &= y_3 + hF(t_3, y_3) = 1.159798 \\
y_5 &= y_4 + hF(t_4, y_4) = 1.204112 \\
y_6 &= y_5 + hF(t_5, y_5) = 1.250361
\end{aligned}$$

15. Let $y(t)$ be the solution of $(x^3 + 1)\dot{y} = y$ satisfying $y(0) = 1$. Compute approximations to $y(0.1)$, $y(0.2)$, and $y(0.3)$ using Euler's Method with time step $h = 0.1$.

SOLUTION Rewriting the equation as $\dot{y} = \frac{y}{x^3+1}$ we have $F(x, y) = \frac{y}{x^3+1}$. Using Euler's Method with $x_0 = 0$, $y_0 = 1$ and $h = 0.1$, we calculate

$$\begin{aligned}
y(0.1) &\approx y_1 = y_0 + hF(x_0, y_0) = 1 + 0.1 \cdot \frac{1}{0^3 + 1} = 1.1 \\
y(0.2) &\approx y_2 = y_1 + hF(x_1, y_1) = 1.209890 \\
y(0.3) &\approx y_3 = y_2 + hF(x_2, y_2) = 1.329919
\end{aligned}$$

In Exercises 16–19, solve using the method of integrating factors.

16. $\dfrac{dy}{dt} = y + t^2, \quad y(0) = 4$

SOLUTION First, we find the general solution of the differential equation. Rewrite the equation as

$$y' - y = t^2,$$

which is in standard form with $A(t) = -1$ and $B(t) = t^2$. The integrating factor is

$$\alpha(t) = e^{\int -1\,dt} = e^{-t}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$(e^{-t}y)' = t^2 e^{-t}.$$

Integration on both sides (integration by parts is needed for the integral on the right-hand side of the equation) now yields

$$e^{-t}y = -e^{-t}(t^2 + 2t + 2) + C;$$

hence,

$$y(t) = Ce^t - t^2 - 2t - 2.$$

The initial condition $y(0) = 4$ allows us to determine the value of C:

$$4 = -2 + C \qquad \text{so} \qquad C = 6.$$

The solution to the initial value problem is then

$$y = 6e^t - t^2 - 2t - 2.$$

17. $\dfrac{dy}{dx} = \dfrac{y}{x} + x, \quad y(1) = 3$

SOLUTION First, we find the general solution of the differential equation. Rewrite the equation as

$$y' - \frac{1}{x}y = x,$$

which is in standard form with $A(x) = -\frac{1}{x}$ and $B(x) = x$. The integrating factor is

$$\alpha(x) = e^{\int -\frac{1}{x}\,dx} = e^{-\ln x} = \frac{1}{x}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$\left(\frac{1}{x}y\right)' = 1.$$

Integration on both sides now yields

$$\frac{1}{x}y = x + C;$$

hence,

$$y(x) = x^2 + Cx.$$

The initial condition $y(1) = 3$ allows us to determine the value of C:

$$3 = 1 + C \qquad \text{so} \qquad C = 2.$$

The solution to the initial value problem is then

$$y = x^2 + 2x.$$

18. $\dfrac{dy}{dt} = y - 3t, \quad y(-1) = 2$

SOLUTION First, we find the general solution of the differential equation. Rewrite the equation as

$$y' - y = -3t,$$

which is in standard form with $A(t) = -1$ and $B(t) = -3t$. The integrating factor is

$$\alpha(t) = e^{\int A(t)\,dt} = e^{\int -dt} = e^{-t}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$(e^{-t}y)' = -3te^{-t}.$$

Integration on both sides (integration by parts is needed for the integral on the right-hand side of the equation) now yields

$$e^{-t}y = (3t+3)e^{-t} + C;$$

hence,

$$y(t) = 3t + 3 + Ce^{t}.$$

The initial condition $y(-1) = 2$ allows us to determine the value of C;

$$2 = Ce^{-1} + 3(-1) + 3 \qquad \text{so} \qquad C = 2e.$$

The solution to the initial value problem is then

$$y = 2e \cdot e^{t} + 3t + 3 = 2e^{t+1} + 3t + 3.$$

19. $y' + 2y = 1 + e^{-x}, \quad y(0) = -4$

SOLUTION The equation is already in standard form with $A(x) = 2$ and $B(x) = 1 + e^{-x}$. The integrating factor is

$$\alpha(x) = e^{\int 2\,dx} = e^{2x}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$(e^{2x}y)' = e^{2x} + e^{x}.$$

Integration on both sides now yields

$$e^{2x}y = \frac{1}{2}e^{2x} + e^{x} + C;$$

hence,

$$y(x) = \frac{1}{2} + e^{-x} + Ce^{-2x}.$$

The initial condition $y(0) = -4$ allows us to determine the value of C:

$$-4 = \frac{1}{2} + 1 + C \qquad \text{so} \qquad C = -\frac{11}{2}.$$

The solution to the initial value problem is then

$$y(x) = \frac{1}{2} + e^{-x} - \frac{11}{2}e^{-2x}.$$

In Exercises 20–27, solve using the appropriate method.

20. $x^2y' = x^2 + 1, \quad y(1) = 10$

SOLUTION First, we find the general solution of the differential equation. Rewrite the equation as

$$y' = 1 + \frac{1}{x^2}.$$

Because the variables have already been separated, we integrate both sides to obtain

$$y = \int \left(1 + \frac{1}{x^2}\right) dx = x - \frac{1}{x} + C.$$

The initial condition $y(1) = 10$ allows us to determine the value of C:

$$10 = 1 - 1 + C \qquad \text{so} \qquad C = 10.$$

The solution to the initial value problem is then

$$y = x - \frac{1}{x} + 10.$$

21. $y' + (\tan x)y = \cos^2 x, \quad y(\pi) = 2$

SOLUTION First, we find the general solution of the differential equation. As this is a first order linear equation with $A(x) = \tan x$ and $B(x) = \cos^2 x$, we compute the integrating factor

$$\alpha(x) = e^{\int A(x)\,dx} = e^{\int \tan x\,dx} = e^{-\ln\cos x} = \frac{1}{\cos x}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$\left(\frac{1}{\cos x}y\right)' = \cos x.$$

Integration on both sides now yields

$$\frac{1}{\cos x}y = \sin x + C;$$

hence,

$$y(x) = \sin x\cos x + C\cos x = \frac{1}{2}\sin 2x + C\cos x.$$

The initial condition $y(\pi) = 2$ allows us to determine the value of C:

$$2 = 0 + C(-1) \qquad \text{so} \qquad C = -2.$$

The solution to the initial value problem is then

$$y = \frac{1}{2}\sin 2x - 2\cos x.$$

22. $xy' = 2y + x - 1, \quad y\left(\frac{3}{2}\right) = 9$

SOLUTION First, we find the general solution of the differential equation. This is a linear equation which can be rewritten as

$$y' - \frac{2}{x}y = 1 - \frac{1}{x}.$$

Thus, $A(x) = -\frac{2}{x}$, $B(x) = 1 - \frac{1}{x}$ and the integrating factor is

$$\alpha(x) = e^{\int A(x)\,dx} = e^{\int -\frac{2}{x}\,dx} = e^{-2\ln x} = \frac{1}{x^2}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$\left(\frac{1}{x^2}y\right)' = \frac{1}{x^2} - \frac{1}{x^3}.$$

Integration on both sides now yields

$$\frac{1}{x^2}y = -\frac{1}{x} + \frac{1}{2x^2} + C;$$

hence,

$$y(x) = -x + \frac{1}{2} + Cx^2.$$

The initial condition $y\left(\frac{3}{2}\right) = 9$ allows us to determine the value of C:

$$9 = -\frac{3}{2} + \frac{1}{2} + \frac{9}{4}C \qquad \text{so} \qquad C = \frac{40}{9}.$$

The solution to the initial value problem is then

$$y = \frac{40}{9}x^2 - x + \frac{1}{2}.$$

23. $(y-1)y' = t, \quad y(1) = -3$

SOLUTION First, we find the general solution of the differential equation. This is a separable equation that we rewrite as

$$(y-1)\,dy = t\,dt.$$

Upon integrating both sides of this equation, we find

$$\int (y-1)\,dy = \int t\,dt$$
$$\frac{y^2}{2} - y = \frac{1}{2}t^2 + C$$
$$y^2 - 2y + 1 = t^2 + C$$
$$(y-1)^2 = t^2 + C$$
$$y(t) = \pm\sqrt{t^2+C} + 1$$

To satisfy the initial condition $y(1) = -3$ we must choose the negative square root; moreover,

$$-3 = -\sqrt{1+C} + 1 \qquad \text{so} \qquad C = 15.$$

The solution to the initial value problem is then

$$y(t) = -\sqrt{t^2+15} + 1$$

24. $\left(\sqrt{y}+1\right)y' = yte^{t^2}, \quad y(0) = 1$

SOLUTION First, we find the general solution of the differential equation. This is a separable equation that we rewrite as

$$\left(\frac{1}{\sqrt{y}} + \frac{1}{y}\right) dy = te^{t^2}\,dt.$$

Upon integrating both sides of this equation, we find

$$\int \left(\frac{1}{\sqrt{y}} + \frac{1}{y}\right) dy = \int te^{t^2}\,dt$$
$$2\sqrt{y} + \ln y = \frac{1}{2}e^{t^2} + C.$$

Note that we cannot solve explicitly for $y(t)$. The initial condition $y(0) = 1$ still allows us to determine the value of C:

$$2(1) + \ln 1 = \frac{1}{2} + C \qquad \text{so} \qquad C = \frac{3}{2}.$$

Hence, the general solution is given implicitly by the equation

$$2\sqrt{y} + \ln y = \frac{1}{2}e^{x^2} + \frac{3}{2}.$$

25. $\dfrac{dw}{dx} = k\dfrac{1+w^2}{x}, \quad w(1) = 1$

SOLUTION First, we find the general solution of the differential equation. This is a separable equation that we rewrite as

$$\frac{dw}{1+w^2} = \frac{k}{x}\,dx.$$

Upon integrating both sides of this equation, we find

$$\int \frac{dw}{1+w^2} = \int \frac{k}{x}\,dx$$
$$\tan^{-1} w = k\ln x + C$$
$$w(x) = \tan(k\ln x + C).$$

Because the initial condition is specified at $x = 1$, we are interested in the solution for $x > 0$; we can therefore omit the absolute value within the natural logarithm function. The initial condition $w(1) = 1$ allows us to determine the value of C:

$$1 = \tan(k\ln 1 + C) \qquad \text{so} \qquad C = \tan^{-1} 1 = \frac{\pi}{4}.$$

The solution to the initial value problem is then

$$w = \tan\left(k \ln x + \frac{\pi}{4}\right).$$

26. $y' + \dfrac{3y-1}{t} = t + 2$

SOLUTION We rewrite this first order linear equation in standard form:

$$y' + \frac{3}{t}y = t + 2 + \frac{1}{t}.$$

Thus, $A(t) = \frac{3}{t}$, $B(t) = t + 2 + \frac{1}{t}$, and the integrating factor is

$$\alpha(t) = e^{\int A(t)\,dt} = e^{3\ln t} = t^3.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$(t^3 y)' = t^4 + 2t^3 + t^2.$$

Integration on both sides now yields

$$t^3 y = \frac{1}{5}t^5 + \frac{1}{2}t^4 + \frac{1}{3}t^3 + C;$$

hence,

$$y(t) = \frac{1}{5}t^2 + \frac{1}{2}t + \frac{1}{3} + \frac{C}{t^3}.$$

27. $y' + \dfrac{y}{x} = \sin x$

SOLUTION This is a first order linear equation with $A(x) = \frac{1}{x}$ and $B(x) = \sin x$. The integrating factor is

$$\alpha(x) = e^{\int A(x)\,dx} = e^{\ln x} = x.$$

When multiplied by the integrating factor, the original differential equation becomes

$$(xy)' = x \sin x.$$

Integration on both sides (integration by parts is needed for the integral on the right-hand side) now yields

$$xy = -x\cos x + \sin x + C;$$

hence,

$$y(x) = -\cos x + \frac{\sin x}{x} + \frac{C}{x}.$$

28. Find the solutions to $y' = 4(y - 12)$ satisfying $y(0) = 20$ and $y(0) = 0$, and sketch their graphs.

SOLUTION The general solution of the differential equation $y' = 4(y - 12)$ is

$$y(t) = 12 + Ce^{4t},$$

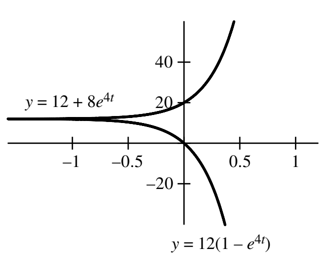
for some constant C. If $y(0) = 20$, then

$$20 = 12 + Ce^0 \quad \text{and} \quad C = 8.$$

Thus, $y(t) = 12 + 8e^{4t}$. If $y(0) = 0$, then

$$0 = 12 + Ce^0 \quad \text{and} \quad C = -12;$$

hence, $y(t) = 12(1 - e^{4t})$. The graphs of the two solutions are shown below.



29. Find the solutions to $y' = -2y + 8$ satisfying $y(0) = 3$ and $y(0) = 4$, and sketch their graphs.

SOLUTION First, rewrite the differential equation as $y' = -2(y - 4)$; from here we see that the general solution is

$$y(t) = 4 + Ce^{-2t},$$

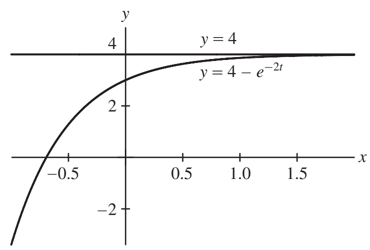
for some constant C. If $y(0) = 3$, then

$$3 = 4 + Ce^0 \quad \text{and} \quad C = -1.$$

Thus, $y(t) = 4 - e^{-2t}$. If $y(0) = 4$, then

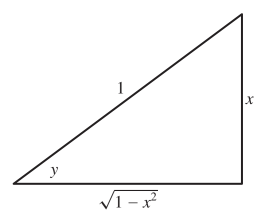
$$4 = 4 + Ce^0 \quad \text{and} \quad C = 0;$$

hence, $y(t) = 4$. The graphs of the two solutions are shown below.



30. Show that $y = \sin^{-1} x$ satisfies the differential equation $y' = \sec y$ with initial condition $y(0) = 0$.

SOLUTION Let $y = \sin^{-1} x$. Then $x = \sin y$ and we construct the right triangle shown below.



Thus,

$$\sec y = \frac{1}{\sqrt{1 - x^2}} = \frac{d}{dx} \sin^{-1} x = y'.$$

Moreover, $y(0) = \sin^{-1} 0 = 0$. Consequently, $y = \sin^{-1} x$ satisfies the differential equation $y' = \sec y$ with initial condition $y(0) = 0$.

31. What is the limit $\lim\limits_{t\to\infty} y(t)$ if $y(t)$ is a solution of:

(a) $\dfrac{dy}{dt} = -4(y - 12)$?

(b) $\dfrac{dy}{dt} = 4(y - 12)$?

(c) $\dfrac{dy}{dt} = -4y - 12$?

SOLUTION

(a) The general solution of $\dfrac{dy}{dt} = -4(y - 12)$ is $y(t) = 12 + Ce^{-4t}$, where C is an arbitrary constant. Regardless of the value of C,

$$\lim_{t\to\infty} y(t) = \lim_{t\to\infty} (12 + Ce^{-4t}) = 12.$$

(b) The general solution of $\dfrac{dy}{dt} = 4(y - 12)$ is $y(t) = 12 + Ce^{4t}$, where C is an arbitrary constant. Here, the limit depends on the value of C. Specifically,

$$\lim_{t\to\infty} y(t) = \lim_{t\to\infty} (12 + Ce^{4t}) = \begin{cases} \infty, & C > 0 \\ 12, & C = 0 \\ -\infty, & C < 0 \end{cases}$$

(c) The general solution of $\frac{dy}{dt} = -4y - 12 = -4(y+3)$ is $y(t) = -3 + Ce^{-4t}$, where C is an arbitrary constant. Regardless of the value of C,

$$\lim_{t\to\infty} y(t) = \lim_{t\to\infty} (-3 + Ce^{-4t}) = -3.$$

In Exercises 32–35, let $P(t)$ denote the balance at time t (years) of an annuity that earns 5% interest continuously compounded and pays out \$20,000*/year continuously.*

32. Find the differential equation satisfied by $P(t)$.

SOLUTION Since money is withdrawn continuously at a rate of \$20,000 a year and the growth due to interest is $0.05P$, the rate of change of the balance is

$$P'(t) = 0.05P - 20{,}000.$$

Thus, the differential equation satisfied by $P(t)$ is

$$P'(t) = 0.05(P - 400{,}000).$$

33. Determine $P(5)$ if $P(0) = \$200{,}000$.

SOLUTION In the previous exercise we concluded that $P(t)$ satisfies the equation $P' = 0.05(P - 400{,}000)$. The general solution of this differential equation is

$$P(t) = 400{,}000 + Ce^{0.05t}.$$

Given $P(0) = 200{,}000$, it follows that

$$200{,}000 = 400{,}000 + Ce^{0.05\cdot 0} = 400{,}000 + C$$

or

$$C = -200{,}000.$$

Thus,

$$P(t) = 400{,}000 - 200{,}000e^{0.05t},$$

and

$$P(5) = 400{,}000 - 200{,}000e^{0.05(5)} \approx \$143{,}194.90.$$

34. When does the annuity run out of money if $P(0) = \$300{,}000$?

SOLUTION We found that

$$P(t) = 400{,}000 + Ce^{0.05t}.$$

If $P(0) = 300{,}000$, then

$$300{,}000 = 400{,}000 + Ce^{0.05\cdot 0} = 400{,}000 + C$$

or

$$C = -100{,}000.$$

Thus,

$$P(t) = 400{,}000 - 100{,}000e^{0.05t}.$$

The annuity runs out of money when $P(t) = 0$; that is, when

$$400{,}000 - 100{,}000e^{0.05t} = 0.$$

Solving for t yields

$$t = \frac{1}{0.05}\ln 4 = 20 \ln 4 \approx 27.73.$$

The money runs out after roughly 27.73 years.

35. What is the minimum initial balance that will allow the annuity to make payments indefinitely?

SOLUTION In Exercise 33, we found that the balance at time t is

$$P(t) = 400{,}000 + Ce^{0.05t}.$$

If initial balance is P_0 then

$$P_0 = P(0) = 400{,}000 + Ce^{0.05\cdot 0} = 400{,}000 + C$$

or

$$C = P_0 - 400{,}000.$$

Thus,

$$P(t) = 400{,}000 + (P_0 - 400{,}000)\,e^{0.05t}.$$

If $P_0 \geq 400{,}000$, then $P(t)$ is always positive. Therefore, the minimum initial balance that allows the annuity to make payments indefinitely is $P_0 = \$400{,}000$.

36. State whether the differential equation can be solved using separation of variables, the method of integrating factors, both, or neither.

(a) $y' = y + x^2$

(b) $xy' = y + 1$

(c) $y' = y^2 + x^2$

(d) $xy' = y^2$

SOLUTION

(a) The equation $y' = y + x^2$ is a first order linear equation; hence, it can be solved by the method of integration factors. However, it cannot be written in the form $y' = f(x)g(y)$; therefore, separation of variables cannot be used.

(b) The equation $xy' = y + 1$ is a first order linear equation; hence, it can be solved using the method of integration factors. We can rewrite this equation as $y' = \frac{1}{x}(y+1)$; therefore, it can also be solved by separating the variables.

(c) The equation $y' = y^2 + x^2$ cannot be written in the form $y' = f(x)g(y)$; hence, separation of variables cannot be used. This equation is also not linear; hence, the method of integrating factors cannot be used.

(d) The equation $xy' = y^2$ can be rewritten as $y' = \frac{1}{x}y^2$; therefore, it can be solved by separating the variables. Since it is not a linear equation, the method of integrating factors cannot be used.

37. Let A and B be constants. Prove that if $A > 0$, then all solutions of $\frac{dy}{dt} + Ay = B$ approach the same limit as $t \to \infty$.

SOLUTION This is a linear first-order equation in standard form with integrating factor

$$\alpha(t) = e^{\int A\,dt} = e^{At}.$$

When multiplied by the integrating factor, the original differential equation becomes

$$(e^{At}y)' = Be^{At}.$$

Integration on both sides now yields

$$e^{At}y = \frac{B}{A}e^{At} + C;$$

hence,

$$y(t) = \frac{B}{A} + Ce^{-At}.$$

Because $A > 0$,

$$\lim_{t\to\infty} y(t) = \lim_{t\to\infty}\left(\frac{B}{A} + Ce^{-At}\right) = \frac{B}{A}.$$

We conclude that if $A > 0$, all solutions approach the limit $\frac{B}{A}$ as $t \to \infty$.

38. At time $t = 0$, a tank of height 5 m in the shape of an inverted pyramid whose cross section at the top is a square of side 2 m is filled with water. Water flows through a hole at the bottom of area 0.002 m^2. Use Torricelli's Law to determine the time required for the tank to empty.

SOLUTION $y(t)$, the height of the water at time t, obeys the differential equation:

$$\frac{dy}{dt} = \frac{Bv(y)}{A(y)}$$

where $v(y)$ is the velocity of the water flowing through the hole when the height of the water is y, B is the area of the hole, and $A(y)$ is the cross-sectional area of the surface of the water when it is at height y. By Torricelli's Law, $v(y) = -\sqrt{19.6}\sqrt{y} = -14\sqrt{y}/\sqrt{10}$ m/s. The area of the hole is $B = 0.002$. To determine $A(y)$, note that the ratio of the length of a side of the square forming the surface of the water to the height of the water is $2/5$ (using similar triangles). Thus when the water is at height y, the area is $A(y) = \left(\frac{2}{5}y\right)^2 = \frac{4y^2}{25}$. Thus

$$\frac{dy}{dt} = \frac{-0.002 \cdot 14\sqrt{y} \cdot 25}{4y^2\sqrt{10}} = \frac{-0.175}{\sqrt{10}}y^{-3/2}$$

Separating variables gives

$$y^{3/2}\,dy = \frac{-0.175}{\sqrt{10}}\,dt$$

Integrating both sides gives

$$\frac{2}{5}y^{5/2} = \frac{-0.175}{\sqrt{10}}t + C \quad \text{so that} \quad y = \left(\frac{-0.4375}{\sqrt{10}}t + \frac{5}{2}C\right)^{2/5}$$

At $t = 0$, $y(t) = 5$, so that

$$5 = \left(\frac{5}{2}C\right)^{2/5} \quad \text{and} \quad C \approx 22.36$$

so that

$$y(t) \approx (-0.138t + 55.9)^{2/5}$$

The tank is empty when $y(t) = 0$, so when $t = 55.9/0.138 \approx 405.07$. The tank is empty after approximately 405 seconds, or 6 minutes 45 seconds.

39. The trough in Figure 3 (dimensions in centimeters) is filled with water. At time $t = 0$ (in seconds), water begins leaking through a hole at the bottom of area 4 cm^2. Let $y(t)$ be the water height at time t. Find a differential equation for $y(t)$ and solve it to determine when the water level decreases to 60 cm.

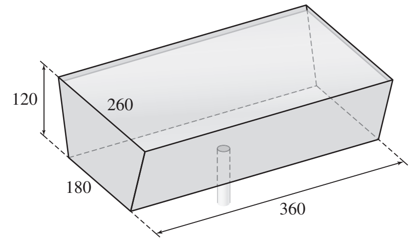


FIGURE 3

SOLUTION $y(t)$ obeys the differential equation:

$$\frac{dy}{dt} = \frac{Bv(y)}{A(y)},$$

where $v(y)$ denotes the velocity of the water flowing through the hole when the trough is filled to height y, B denotes the area of the hole and $A(y)$ denotes the area of the horizontal cross section of the trough at height y. Since measurements are all in centimeters, we will work in centimeters. We have

$$g = 9.8 \text{ m/s}^2 = 980 \text{ cm/s}^2$$

By Torricelli's Law, $v(y) = -\sqrt{2 \cdot 980}\sqrt{y} = -14\sqrt{10}\sqrt{y}$ m/s. The area of the hole is $B = 4\ \text{cm}^2$. The horizontal cross section of the trough at height y is a rectangle of length 360 and width $w(y)$. As $w(y)$ varies linearly from 180 when $y = 0$ to 260 when $y = 120$, it follows that

$$w(y) = 180 + \frac{80y}{120} = 180 + \frac{2}{3}y$$

so that the area of the horizontal cross-section at height y is

$$A(y) = 360w(y) = 64800 + 240y = 240(y + 270)$$

The differential equation for $y(t)$ then becomes

$$\frac{dy}{dt} = \frac{Bv(y)}{A(y)} = \frac{-4 \cdot 14\sqrt{10}\sqrt{y}}{240(y+270)} = \frac{-7\sqrt{10}}{30} \cdot \frac{\sqrt{y}}{y+270}$$

This equation is separable, so

$$\begin{aligned}
\frac{y+270}{\sqrt{y}}\,dy &= \frac{-7\sqrt{10}}{30}\,dt \\
(y^{1/2} + 270y^{-1/2})\,dy &= \frac{-7\sqrt{10}}{30}\,dt \\
\int (y^{1/2} + 270y^{-1/2})\,dy &= \frac{-7\sqrt{10}}{30}\int 1\,dt \\
\frac{2}{3}y^{3/2} + 540y^{1/2} &= -\frac{7\sqrt{10}}{30}t + C \\
y^{3/2} + 810y^{1/2} &= -\frac{7\sqrt{10}}{20}t + C
\end{aligned}$$

The initial condition $y(0) = 120$ allows us to determine the value of C:

$$120^{3/2} + 810 \cdot 120^{1/2} = 0 + C \quad \text{so} \quad C = 930\sqrt{120} = 1860\sqrt{30}$$

Thus the height of the water is given implicitly by the equation

$$y^{3/2} + 810y^{1/2} = -\frac{7\sqrt{10}}{20}t + 1860\sqrt{30}$$

We want to find t such that $y(t) = 60$:

$$\begin{aligned}
60^{3/2} + 810 \cdot 60^{1/2} &= -\frac{7\sqrt{10}}{20}t + 1860\sqrt{30} \\
1740\sqrt{15} &= -\frac{7\sqrt{10}}{20}t + 1860\sqrt{30} \\
t &= \frac{120}{7}\sqrt{10}(31\sqrt{30} - 29\sqrt{15}) \approx 3115.88 \text{ s}
\end{aligned}$$

The height of the water in the tank is 60 cm after approximately 3116 seconds, or 51 minutes 56 seconds.

40. Find the solution of the logistic equation $\dot{y} = 0.4y(4 - y)$ satisfying $y(0) = 8$.

SOLUTION We can write the given equation as

$$\dot{y} = 1.6y\left(1 - \frac{y}{4}\right).$$

This is a logistic equation with $k = 1.6$ and $A = 4$. Therefore,

$$y(t) = \frac{A}{1 - e^{-kt}/C} = \frac{4}{1 - e^{-1.6t}/C}.$$

The initial condition $y(0) = 8$ allows us to determine the value of C:

$$8 = \frac{4}{1 - \frac{1}{C}}; \quad 1 - \frac{1}{C} = \frac{1}{2}; \quad \text{so} \quad C = 2.$$

Thus,

$$y(t) = \frac{4}{1 - e^{-1.6t}/2} = \frac{8}{2 - e^{-1.6t}}.$$

41. Let $y(t)$ be the solution of $\dot{y} = 0.3y(2 - y)$ with $y(0) = 1$. Determine $\lim_{t\to\infty} y(t)$ without solving for y explicitly.

SOLUTION We write the given equation in the form

$$\dot{y} = 0.6y\left(1 - \frac{y}{2}\right).$$

This is a logistic equation with $A = 2$ and $k = 0.6$. Because the initial condition $y(0) = y_0 = 1$ satisfies $0 < y_0 < A$, the solution is increasing and approaches A as $t \to \infty$. That is, $\lim_{t\to\infty} y(t) = 2$.

42. Suppose that $y' = ky(1 - y/8)$ has a solution satisfying $y(0) = 12$ and $y(10) = 24$. Find k.

SOLUTION The given differential equation is a logistic equation with $A = 8$. Thus,

$$y(t) = \frac{8}{1 - e^{-kt}/C}.$$

The initial condition $y(0) = 12$ allows us to determine the value of C:

$$12 = \frac{8}{1 - \frac{1}{C}}; \quad 1 - \frac{1}{C} = \frac{2}{3}; \quad \text{so} \quad C = 3.$$

Hence,

$$y(t) = \frac{8}{1 - e^{-kt}/3} = \frac{24}{3 - e^{-kt}}.$$

Now, the condition $y(10) = 24$ allows us to determine the value of k:

$$\begin{aligned} 24 &= \frac{24}{3 - e^{-10k}} \\ 3 - e^{-10k} &= 1 \\ k &= -\frac{\ln 2}{10} \approx -0.0693. \end{aligned}$$

43. A lake has a carrying capacity of 1000 fish. Assume that the fish population grows logistically with growth constant $k = 0.2$ day^{-1}. How many days will it take for the population to reach 900 fish if the initial population is 20 fish?

SOLUTION Let $y(t)$ represent the fish population. Because the population grows logistically with $k = 0.2$ and $A = 1000$,

$$y(t) = \frac{1000}{1 - e^{-0.2t}/C}.$$

The initial condition $y(0) = 20$ allows us to determine the value of C:

$$20 = \frac{1000}{1 - \frac{1}{C}}; \quad 1 - \frac{1}{C} = 50; \quad \text{so} \quad C = -\frac{1}{49}.$$

Hence,

$$y(t) = \frac{1000}{1 + 49e^{-0.2t}}.$$

The population will reach 900 fish when

$$\frac{1000}{1 + 49e^{-0.2t}} = 900.$$

Solving for t, we find

$$t = 5 \ln 441 \approx 30.44 \text{ days}.$$

44. A rabbit population on an island increases exponentially with growth rate $k = 0.12$ months^{-1}. When the population reaches 300 rabbits (say, at time $t = 0$), wolves begin eating the rabbits at a rate of r rabbits per month.

(a) Find a differential equation satisfied by the rabbit population $P(t)$.

(b) How large can r be without the rabbit population becoming extinct?

SOLUTION

(a) The rabbit population $P(t)$ obeys the differential equation

$$\frac{dP}{dt} = 0.12P - r,$$

where the term $0.12P$ accounts for the exponential growth of the population and the term $-r$ accounts for the rate of decline in the rabbit population due to their being food for wolves.

(b) Rewrite the linear differential equation from part (a) as

$$\frac{dP}{dt} - 0.12P = -r,$$

which is in standard form with $A = -0.12$ and $B = -r$. The integrating factor is

$$\alpha(t) = e^{\int A\,dt} = e^{\int -0.12\,dt} = e^{-0.12t}.$$

When multiplied by the integrating factor, the rewritten differential equation becomes

$$(e^{-0.12t}P)' = -re^{-0.12t}.$$

Integration on both sides now yields

$$e^{-0.12t}P = \frac{r}{0.12}e^{-0.12t} + C;$$

hence,

$$P(t) = \frac{r}{0.12} + Ce^{0.12t}.$$

The initial condition $P(0) = 300$ allows us to determine the value of C:

$$300 = \frac{r}{0.12} + C \qquad \text{so} \qquad C = 300 - \frac{r}{0.12}.$$

The solution to the initial value problem is then

$$P(t) = \left(300 - \frac{r}{0.12}\right)e^{0.12t} + \frac{r}{0.12}.$$

Now, if $300 - \frac{r}{0.12} < 0$, then $\lim_{t\to\infty} P(t) = -\infty$, and the population becomes extinct. Therefore, in order for the population to survive, we must have

$$300 - \frac{r}{0.12} \ge 0 \qquad \text{or} \qquad r \le 36.$$

We conclude that the maximum rate at which the wolves can eat the rabbits without driving the rabbits to extinction is $r = 36$ rabbits per month.

45. Show that $y = \sin(\tan^{-1} x + C)$ is the general solution of $y' = \sqrt{1-y^2}/\left(1+x^2\right)$. Then use the addition formula for the sine function to show that the general solution may be written

$$y = \frac{(\cos C)x + \sin C}{\sqrt{1+x^2}}$$

SOLUTION Rewrite

$$\frac{dy}{dx} = \frac{\sqrt{1-y^2}}{1+x^2} \qquad \text{as} \qquad \frac{dy}{\sqrt{1-y^2}} = \frac{dx}{1+x^2}.$$

Upon integrating both sides of this equation, we find

$$\int \frac{dy}{\sqrt{1-y^2}} = \int \frac{dx}{1+x^2}$$
$$\sin^{-1} y = \tan^{-1} x + C$$

Thus,

$$y(x) = \sin\left(\tan^{-1} x + C\right).$$

To express the solution in the required form, we use the addition formula

$$\sin(\alpha + \beta) = \sin\alpha\cos\beta + \sin\beta\cos\alpha$$

This yields

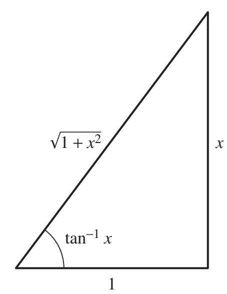
$$y(x) = \sin\left(\tan^{-1}x\right)\cos C + \sin C\cos\left(\tan^{-1}x\right).$$

Using the figure below, we see that

$$\sin\left(\tan^{-1}x\right) = \frac{x}{\sqrt{1+x^2}}; \text{ and}$$
$$\cos\left(\tan^{-1}x\right) = \frac{1}{\sqrt{1+x^2}}.$$

Finally,

$$y = \frac{x\cos C}{\sqrt{1+x^2}} + \frac{\sin C}{\sqrt{1+x^2}} = \frac{(\cos C)x + \sin C}{\sqrt{1+x^2}}.$$



46. A tank is filled with 300 liters of contaminated water containing 3 kg of toxin. Pure water is pumped in at a rate of 40 L/min, mixes instantaneously, and is then pumped out at the same rate. Let $y(t)$ be the quantity of toxin present in the tank at time t.

(a) Find a differential equation satisfied by $y(t)$.

(b) Solve for $y(t)$.

(c) Find the time at which there is 0.01 kg of toxin present.

SOLUTION

(a) The net flow of toxin into or out of the tank at time t is

$$\frac{dy}{dt} = \text{toxin rate in} - \text{toxin rate out} = \left(40\frac{\text{L}}{\text{min}}\right)\left(0\frac{\text{kg}}{\text{L}}\right) - \left(40\frac{\text{L}}{\text{min}}\right)\left(\frac{y(t)}{300}\frac{\text{kg}}{\text{L}}\right)$$
$$= -\frac{2}{15}y(t)$$

(b) This is a linear differential equation. Putting it in standard form gives

$$\frac{dy}{dt} + \frac{2}{15}y = 0$$

The integrating factor is

$$\alpha(t) = e^{\int (2/15)\,dt} = e^{2t/15}$$

When multiplied by the integrating factor, the differential equation becomes

$$(e^{2t/15}y)' = 0$$

Integrate both sides and multiply through by $e^{-2t/15}$ to get

$$y = Ce^{-2t/15}$$

Since there are initially 3 kg of toxin present, $y(0) = 3$ so that $C = 3$. Finally, we have

$$y = 3e^{-2t/15}$$

(c) We solve for t:

$$0.01 = 3e^{-2t/15} \quad \Rightarrow \quad t = -\frac{5}{2}\ln 0.01 \approx 11.51$$

There is 0.01 kg of toxin in the tank after about 11 and a half minutes.

47. At $t = 0$, a tank of volume 300 L is filled with 100 L of water containing salt at a concentration of 8 g/L. Fresh water flows in at a rate of 40 L/min, mixes instantaneously, and exits at the same rate. Let $c_1(t)$ be the salt concentration at time t.

(a) Find a differential equation satisfied by $c_1(t)$ *Hint:* Find the differential equation for the quantity of salt $y(t)$, and observe that $c_1(t) = y(t)/100$.

(b) Find the salt concentration $c_1(t)$ in the tank as a function of time.

SOLUTION

(a) Let $y(t)$ be the amount of salt in the tank at time t; then $c_1(t) = y(t)/100$. The rate of change of the amount of salt in the tank is

$$\begin{aligned}\frac{dy}{dt} &= \text{salt rate in} - \text{salt rate out} = \left(40\frac{\text{L}}{\text{min}}\right)\left(0\frac{\text{g}}{\text{L}}\right) - \left(40\frac{\text{L}}{\text{min}}\right)\left(\frac{y}{100}\cdot\frac{\text{g}}{\text{L}}\right)\\ &= -\frac{2}{5}y\end{aligned}$$

Now, $c_1'(t) = y'(t)/100$ and $c(t) = y(t)/100$, so that c_1 satisfies the same differential equation:

$$\frac{dc_1}{dt} = -\frac{2}{5}c_1$$

(b) This is a linear differential equation. Putting it in standard form gives

$$\frac{dc_1}{dt} + \frac{2}{5}c_1 = 0$$

The integrating factor is $e^{2t/5}$; multiplying both sides by the integrating factor gives

$$(e^{2t/5}c_1)' = 0$$

Integrate and multiply through by $e^{-2t/5}$ to get

$$c_1(t) = Ce^{-2t/5}$$

The initial condition tells us that $y(0) = Ce^{-2\cdot 0/5} = C = 8$, so that finally,

$$c_1(t) = 8e^{-2t/5}$$

48. The outflow of the tank in Exercise 47 is directed into a second tank containing V liters of fresh water where it mixes instantaneously and exits at the same rate of 40 L/min. Determine the salt concentration $c_2(t)$ in the second tank as a function of time in the following two cases:

(a) $V = 200$ **(b)** $V = 300$

In each case, determine the maximum concentration.

SOLUTION Let $y_2(t)$ be the amount of salt in the second tank at time t; then $y_2(t) = c_2(t)V$ and $y_2'(t) = c_2'(t)V$. The rate of change in the amount of salt in the second tank is

$$\begin{aligned}\frac{dy_2}{dt} &= \text{salt rate in} - \text{salt rate out} = \left(40\frac{\text{L}}{\text{min}}\right)\left(c_1\frac{\text{g}}{\text{L}}\right) - \left(40\frac{\text{L}}{\text{min}}\right)\left(\frac{y_2}{V}\cdot\frac{\text{g}}{\text{L}}\right)\\ &= 40c_1 - \frac{40}{V}y_2\end{aligned}$$

Substituting for $y_2(t)$ and $y_2'(t)$ gives

$$Vc_2'(t) = 40c_1(t) - \frac{40}{V}Vc_2(t) \quad \text{so} \quad c_2'(t) = \frac{40}{V}(c_1(t) - c_2(t))$$

This is a linear differential equation; in standard form, it is

$$c_2'(t) + \frac{40}{V}c_2(t) = \frac{40}{V}c_1(t)$$

From the previous problem, we know that $c_1(t) = 8e^{-2t/5}$; substituting gives

$$c_2'(t) + \frac{40}{V}c_2(t) = \frac{320}{V}e^{-2t/5}$$

The integrating factor is $e^{40t/V}$; multiplying through by this factor gives

$$(e^{40t/V}c_2)' = \frac{320}{V}e^{(40t/V)-(2t/5)} = \frac{320}{V}e^{(200-2V)t/5V}$$

Integrate both sides to get

$$e^{40t/V}c_2 = \frac{320}{V} \cdot \frac{5V}{200-2V}e^{(200-2V)t/5V} + C = \frac{800}{100-V}e^{(200-2V)t/5V} + C$$

Multiply through by $e^{-40t/V}$ to get

$$c_2(t) = \frac{800}{100-V}e^{-2t/5} + Ce^{-40t/V}$$

Since tank 2 initially contains fresh water, $c_2(0) = 0$, so that $C = -\frac{800}{100-V}$ and

$$c_2(t) = \frac{800}{100-V}(e^{-2t/5} - e^{-40t/V})$$

(a) If $V = 200$, we have

$$c_2(t) = -8(e^{-2t/5} - e^{-t/5}) = 8(e^{-t/5} - e^{-2t/5})$$

The concentration of salt is at a maximum when $c_2'(t) = 0$:

$$\begin{aligned} 0 = c_2'(t) &= \frac{16}{5}e^{-2t/5} - \frac{8}{5}e^{-t/5} \\ e^{-t/5} &= 2e^{-2t/5} \\ -\frac{t}{5} &= -\frac{2t}{5} + \ln 2 \\ t &= 5\ln 2 \approx 3.47 \end{aligned}$$

so that the concentration of salt is at a maximum after about 3 and a half minutes.
(b) If $V = 300$, we have

$$c_2(t) = -4(e^{-2t/5} - e^{-2t/15}) = 4(e^{-2t/15} - e^{-2t/5})$$

The concentration of salt is at a maximum when $c_2'(t) = 0$:

$$\begin{aligned} 0 = c_2'(t) &= \frac{8}{5}e^{-2t/5} - \frac{8}{15}e^{-2t/15} \\ e^{-2t/15} &= 3e^{-2t/5} \\ -\frac{2}{15}t &= -\frac{2}{5}t + \ln 3 \\ t &= \frac{15}{4}\ln 3 \approx 4.12 \end{aligned}$$

so that the concentration of salt is at a maximum after about 4 minutes 7 seconds.

10 INFINITE SERIES

10.1 Sequences

Preliminary Questions

1. What is a_4 for the sequence $a_n = n^2 - n$?

SOLUTION Substituting $n = 4$ in the expression for a_n gives

$$a_4 = 4^2 - 4 = 12.$$

2. Which of the following sequences converge to zero?

(a) $\dfrac{n^2}{n^2+1}$ **(b)** 2^n **(c)** $\left(\dfrac{-1}{2}\right)^n$

SOLUTION

(a) This sequence does not converge to zero:

$$\lim_{n\to\infty} \frac{n^2}{n^2+1} = \lim_{x\to\infty} \frac{x^2}{x^2+1} = \lim_{x\to\infty} \frac{1}{1+\frac{1}{x^2}} = \frac{1}{1+0} = 1.$$

(b) This sequence does not converge to zero: this is a geometric sequence with $r = 2 > 1$; hence, the sequence diverges to ∞.

(c) Recall that if $|a_n|$ converges to 0, then a_n must also converge to zero. Here,

$$\left|\left(-\frac{1}{2}\right)^n\right| = \left(\frac{1}{2}\right)^n,$$

which is a geometric sequence with $0 < r < 1$; hence, $(\frac{1}{2})^n$ converges to zero. It therefore follows that $(-\frac{1}{2})^n$ converges to zero.

3. Let a_n be the nth decimal approximation to $\sqrt{2}$. That is, $a_1 = 1$, $a_2 = 1.4$, $a_3 = 1.41$, etc. What is $\lim_{n\to\infty} a_n$?

SOLUTION $\lim_{n\to\infty} a_n = \sqrt{2}$.

4. Which of the following sequences is defined recursively?

(a) $a_n = \sqrt{4+n}$ **(b)** $b_n = \sqrt{4+b_{n-1}}$

SOLUTION

(a) a_n can be computed directly, since it depends on n only and not on preceding terms. Therefore a_n is defined explicitly and not recursively.

(b) b_n is computed in terms of the preceding term b_{n-1}, hence the sequence $\{b_n\}$ is defined recursively.

5. Theorem 5 says that every convergent sequence is bounded. Determine if the following statements are true or false and if false, give a counterexample.

(a) If $\{a_n\}$ is bounded, then it converges.

(b) If $\{a_n\}$ is not bounded, then it diverges.

(c) If $\{a_n\}$ diverges, then it is not bounded.

SOLUTION

(a) This statement is false. The sequence $a_n = \cos \pi n$ is bounded since $-1 \le \cos \pi n \le 1$ for all n, but it does not converge: since $a_n = \cos n\pi = (-1)^n$, the terms assume the two values 1 and -1 alternately, hence they do not approach one value.

(b) By Theorem 5, a converging sequence must be bounded. Therefore, if a sequence is not bounded, it certainly does not converge.

(c) The statement is false. The sequence $a_n = (-1)^n$ is bounded, but it does not approach one limit.

Exercises

1. Match each sequence with its general term:

$a_1, a_2, a_3, a_4, \ldots$	**General term**
(a) $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \ldots$	(i) $\cos \pi n$
(b) $-1, 1, -1, 1, \ldots$	(ii) $\dfrac{n!}{2^n}$
(c) $1, -1, 1, -1, \ldots$	(iii) $(-1)^{n+1}$
(d) $\frac{1}{2}, \frac{2}{4}, \frac{6}{8}, \frac{24}{16} \ldots$	(iv) $\dfrac{n}{n+1}$

SOLUTION

(a) The numerator of each term is the same as the index of the term, and the denominator is one more than the numerator; hence $a_n = \frac{n}{n+1}$, $n = 1, 2, 3, \ldots$.

(b) The terms of this sequence are alternating between -1 and 1 so that the positive terms are in the even places. Since $\cos \pi n = 1$ for even n and $\cos \pi n = -1$ for odd n, we have $a_n = \cos \pi n$, $n = 1, 2, \ldots$.

(c) The terms a_n are 1 for odd n and -1 for even n. Hence, $a_n = (-1)^{n+1}$, $n = 1, 2, \ldots$

(d) The numerator of each term is $n!$, and the denominator is 2^n; hence, $a_n = \frac{n!}{2^n}$, $n = 1, 2, 3, \ldots$.

2. Let $a_n = \dfrac{1}{2n-1}$ for $n = 1, 2, 3, \ldots$. Write out the first three terms of the following sequences.

(a) $b_n = a_{n+1}$

(b) $c_n = a_{n+3}$

(c) $d_n = a_n^2$

(d) $e_n = 2a_n - a_{n+1}$

SOLUTION

(a) The first three terms of $\{b_n\}$ are:

$$b_1 = a_2 = \frac{1}{2 \cdot 2 - 1} = \frac{1}{3}, \quad b_2 = a_3 = \frac{1}{2 \cdot 3 - 1} = \frac{1}{5}, \quad b_3 = a_4 = \frac{1}{2 \cdot 4 - 1} = \frac{1}{7}.$$

(b) The first three terms of $\{c_n\}$ are:

$$c_1 = a_4 = \frac{1}{2 \cdot 4 - 1} = \frac{1}{7}, \quad c_2 = a_5 = \frac{1}{2 \cdot 5 - 1} = \frac{1}{9}, \quad c_3 = a_6 = \frac{1}{2 \cdot 6 - 1} = \frac{1}{11}.$$

(c) Note

$$a_1 = \frac{1}{2 \cdot 1 - 1} = 1, \quad a_2 = \frac{1}{2 \cdot 2 - 1} = \frac{1}{3}, \quad a_3 = \frac{1}{2 \cdot 3 - 1} = \frac{1}{5}.$$

Thus,

$$d_1 = a_1^2 = 1^2 = 1, \quad d_2 = a_2^2 = \left(\frac{1}{3}\right)^2 = \frac{1}{9}, \quad d_3 = a_3^2 = \left(\frac{1}{5}\right)^2 = \frac{1}{25}.$$

(d) The first three terms of $\{e_n\}$ are:

$$e_1 = 2a_1 - a_2, \quad e_2 = 2a_2 - a_3, \quad e_3 = 2a_3 - a_4.$$

Thus, we must compute a_1, a_2, a_3 and a_4. We set $n = 1, 2, 3$ and 4 in the formula for a_n to obtain:

$$a_1 = \frac{1}{2 \cdot 1 - 1} = 1, \quad a_2 = \frac{1}{2 \cdot 2 - 1} = \frac{1}{3}, \quad a_3 = \frac{1}{2 \cdot 3 - 1} = \frac{1}{5}, \quad a_4 = \frac{1}{2 \cdot 4 - 1} = \frac{1}{7}.$$

Therefore,

$$e_1 = 2 \cdot 1 - \frac{1}{3} = \frac{5}{3}, \quad e_2 = 2 \cdot \frac{1}{3} - \frac{1}{5} = \frac{7}{15}, \quad e_3 = 2 \cdot \frac{1}{5} - \frac{1}{7} = \frac{9}{35}.$$

In Exercises 3–12, calculate the first four terms of the sequence, starting with $n = 1$.

3. $c_n = \dfrac{3^n}{n!}$

SOLUTION Setting $n = 1, 2, 3, 4$ in the formula for c_n gives

$$c_1 = \frac{3^1}{1!} = \frac{3}{1} = 3, \qquad c_2 = \frac{3^2}{2!} = \frac{9}{2},$$
$$c_3 = \frac{3^3}{3!} = \frac{27}{6} = \frac{9}{2}, \qquad c_4 = \frac{3^4}{4!} = \frac{81}{24} = \frac{27}{8}.$$

4. $b_n = \dfrac{(2n-1)!}{n!}$

SOLUTION Setting $n = 1, 2, 3, 4$ in the formula for b_n gives

$$b_1 = \frac{(2\cdot 1-1)!}{1!} = \frac{1}{1} = 1, \qquad b_2 = \frac{(2\cdot 2-1)}{2!} = \frac{6}{2} = 3,$$
$$b_3 = \frac{(2\cdot 3-1)!}{3!} = \frac{120}{6} = 20, \qquad b_4 = \frac{(2\cdot 4-1)}{4!} = \frac{5040}{24} = 210.$$

5. $a_1 = 2, \quad a_{n+1} = 2a_n^2 - 3$

SOLUTION For $n = 1, 2, 3$ we have:

$$a_2 = a_{1+1} = 2a_1^2 - 3 = 2\cdot 4 - 3 = 5;$$
$$a_3 = a_{2+1} = 2a_2^2 - 3 = 2\cdot 25 - 3 = 47;$$
$$a_4 = a_{3+1} = 2a_3^2 - 3 = 2\cdot 2209 - 3 = 4415.$$

The first four terms of $\{a_n\}$ are 2, 5, 47, 4415.

6. $b_1 = 1, \quad b_n = b_{n-1} + \dfrac{1}{b_{n-1}}$

SOLUTION For $n = 2, 3, 4$ we have

$$b_2 = b_1 + \frac{1}{b_1} = 1 + \frac{1}{1} = 2;$$
$$b_3 = b_2 + \frac{1}{b_2} = 2 + \frac{1}{2} = \frac{5}{2};$$
$$b_4 = b_3 + \frac{1}{b_2} = \frac{5}{2} + \frac{2}{5} = \frac{29}{10}.$$

The first four terms of $\{b_n\}$ are $1, 2, \frac{5}{2}, \frac{29}{10}$.

7. $b_n = 5 + \cos \pi n$

SOLUTION For $n = 1, 2, 3, 4$ we have

$$b_1 = 5 + \cos \pi = 4;$$
$$b_2 = 5 + \cos 2\pi = 6;$$
$$b_3 = 5 + \cos 3\pi = 4;$$
$$b_4 = 5 + \cos 4\pi = 6.$$

The first four terms of $\{b_n\}$ are 4, 6, 4, 6.

8. $c_n = (-1)^{2n+1}$

SOLUTION for $n = 1, 2, 3, 4$ we have

$$c_1 = (-1)^{2\cdot 1+1} = (-1)^3 = -1;$$
$$c_2 = (-1)^{2\cdot 2+1} = (-1)^5 = -1;$$
$$c_3 = (-1)^{2\cdot 3+1} = (-1)^7 = -1;$$
$$c_4 = (-1)^{2\cdot 4+1} = (-1)^9 = -1.$$

The first four terms of $\{c_n\}$ are $-1, -1, -1, -1$.

9. $c_n = 1 + \dfrac{1}{2} + \dfrac{1}{3} + \cdots + \dfrac{1}{n}$

SOLUTION

$$c_1 = 1;$$
$$c_2 = 1 + \frac{1}{2} = \frac{3}{2};$$
$$c_3 = 1 + \frac{1}{2} + \frac{1}{3} = \frac{3}{2} + \frac{1}{3} = \frac{11}{6};$$
$$c_4 = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} = \frac{11}{6} + \frac{1}{4} = \frac{25}{12}.$$

10. $a_n = n + (n+1) + (n+2) + \cdots + (2n)$

SOLUTION The general term a_n is the sum of $n+1$ successive numbers, where the first one is n and the last one is $2n$. Thus,

$$a_1 = 1 + 2 = 3;$$
$$a_2 = 2 + 3 + 4 = 9;$$
$$a_3 = 3 + 4 + 5 + 6 = 18;$$
$$a_4 = 4 + 5 + 6 + 7 + 8 = 30.$$

11. $b_1 = 2, \quad b_2 = 3, \quad b_n = 2b_{n-1} + b_{n-2}$

SOLUTION We need to find b_3 and b_4. Setting $n = 3$ and $n = 4$ and using the given values for b_1 and b_2 we obtain:

$$b_3 = 2b_{3-1} + b_{3-2} = 2b_2 + b_1 = 2 \cdot 3 + 2 = 8;$$
$$b_4 = 2b_{4-1} + b_{4-2} = 2b_3 + b_2 = 2 \cdot 8 + 3 = 19.$$

The first four terms of the sequence $\{b_n\}$ are 2, 3, 8, 19.

12. $c_n = n$-place decimal approximation to e

SOLUTION Using a calculator we find that $e = 2.718281828\ldots$. Thus, the four first terms of $\{c_n\}$ are

$$c_1 = 2.7; \quad c_2 = 2.72; \quad c_3 = 2.718; \quad c_4 = 2.7183.$$

13. Find a formula for the nth term of each sequence.

(a) $\frac{1}{1}, \frac{-1}{8}, \frac{1}{27}, \ldots$

(b) $\frac{2}{6}, \frac{3}{7}, \frac{4}{8}, \ldots$

SOLUTION

(a) The denominators are the third powers of the positive integers starting with $n = 1$. Also, the sign of the terms is alternating with the sign of the first term being positive. Thus,

$$a_1 = \frac{1}{1^3} = \frac{(-1)^{1+1}}{1^3}; \quad a_2 = -\frac{1}{2^3} = \frac{(-1)^{2+1}}{2^3}; \quad a_3 = \frac{1}{3^3} = \frac{(-1)^{3+1}}{3^3}.$$

This rule leads to the following formula for the nth term:

$$a_n = \frac{(-1)^{n+1}}{n^3}.$$

(b) Assuming a starting index of $n = 1$, we see that each numerator is one more than the index and the denominator is four more than the numerator. Thus, the general term a_n is

$$a_n = \frac{n+1}{n+5}.$$

14. Suppose that $\lim_{n\to\infty} a_n = 4$ and $\lim_{n\to\infty} b_n = 7$. Determine:

(a) $\lim_{n\to\infty} (a_n + b_n)$

(b) $\lim_{n\to\infty} a_n^3$

(c) $\lim_{n\to\infty} \cos(\pi b_n)$

(d) $\lim_{n\to\infty} (a_n^2 - 2a_n b_n)$

SOLUTION

(a) By the Limit Laws for Sequences, we find

$$\lim_{n\to\infty} (a_n + b_n) = \lim_{n\to\infty} a_n + \lim_{n\to\infty} b_n = 4 + 7 = 11.$$

(b) By the Limit Laws for Sequences, we find

$$\lim_{n\to\infty} a_n^3 = \lim_{n\to\infty} (a_n \cdot a_n \cdot a_n) = \left(\lim_{n\to\infty} a_n\right) \cdot \left(\lim_{n\to\infty} a_n\right) \cdot \left(\lim_{n\to\infty} a_n\right) = \left(\lim_{n\to\infty} a_n\right)^3 = 4^3 = 64.$$

(c) By Theorem 4, we can "bring the limit inside the function":

$$\lim_{n\to\infty} \cos(\pi b_n) = \cos\left(\lim_{n\to\infty} \pi b_n\right) = \cos\left(\pi \lim_{n\to\infty} b_n\right) = \cos(7\pi) = -1.$$

(d) By the Limit Laws of Sequences, we find

$$\lim_{n\to\infty}\left(a_n^2 - 2a_nb_n\right) = \lim_{n\to\infty} a_n^2 - \lim_{n\to\infty} 2a_nb_n = \left(\lim_{n\to\infty} a_n\right)^2 - 2\left(\lim_{n\to\infty} a_n\right)\left(\lim_{n\to\infty} b_n\right) = 4^2 - 2\cdot 4\cdot 7 = -40.$$

In Exercises 15–26, use Theorem 1 to determine the limit of the sequence or state that the sequence diverges.

15. $a_n = 12$

SOLUTION We have $a_n = f(n)$ where $f(x) = 12$; thus,

$$\lim_{n\to\infty} a_n = \lim_{x\to\infty} f(x) = \lim_{x\to\infty} 12 = 12.$$

16. $a_n = 20 - \dfrac{4}{n^2}$

SOLUTION We have $a_n = f(n)$ where $f(x) = 20 - \dfrac{4}{x^2}$; thus,

$$\lim_{n\to\infty}\left(20 - \frac{4}{n^2}\right) = \lim_{x\to\infty}\left(20 - \frac{4}{x^2}\right) = 20 - 0 = 20.$$

17. $b_n = \dfrac{5n-1}{12n+9}$

SOLUTION We have $b_n = f(n)$ where $f(x) = \dfrac{5x-1}{12x+9}$; thus,

$$\lim_{n\to\infty}\frac{5n-1}{12n+9} = \lim_{x\to\infty}\frac{5x-1}{12x+9} = \frac{5}{12}.$$

18. $a_n = \dfrac{4+n-3n^2}{4n^2+1}$

SOLUTION We have $a_n = f(n)$ where $f(x) = \dfrac{4+x-3x^2}{4x^2+1}$; thus,

$$\lim_{n\to\infty}\frac{4+n-3n^2}{4n^2+1} = \lim_{x\to\infty}\frac{4+x-3x^2}{4x^2+1} = -\frac{3}{4}$$

19. $c_n = -2^{-n}$

SOLUTION We have $c_n = f(n)$ where $f(x) = -2^{-x}$; thus,

$$\lim_{n\to\infty}\left(-2^{-n}\right) = \lim_{x\to\infty} -2^{-x} = \lim_{x\to\infty} -\frac{1}{2^x} = 0.$$

20. $z_n = \left(\dfrac{1}{3}\right)^n$

SOLUTION We have $z_n = f(n)$ where $f(x) = \left(\dfrac{1}{3}\right)^x$; thus,

$$\lim_{n\to\infty}\left(\frac{1}{3}\right)^n = \lim_{x\to\infty}\left(\frac{1}{3}\right)^x = 0.$$

21. $c_n = 9^n$

SOLUTION We have $c_n = f(n)$ where $f(x) = 9^x$; thus,

$$\lim_{n\to\infty} 9^n = \lim_{x\to\infty} 9^x = \infty$$

Thus, the sequence 9^n diverges.

22. $z_n = 10^{-1/n}$

SOLUTION We have $z_n = f(n)$ where $f(x) = (0.1)^{-1/x}$; thus

$$\lim_{n\to\infty}(0.1)^{-1/n} = \lim_{x\to\infty}(0.1)^{-1/x} = (0.1)^{\lim_{x\to\infty}(-1/x)} = (0.1)^0 = 1.$$

23. $a_n = \dfrac{n}{\sqrt{n^2+1}}$

SOLUTION We have $a_n = f(n)$ where $f(x) = \dfrac{x}{\sqrt{x^2+1}}$; thus,

$$\lim_{n\to\infty}\frac{n}{\sqrt{n^2+1}} = \lim_{x\to\infty}\frac{x}{\sqrt{x^2+1}} = \lim_{x\to\infty}\frac{\frac{x}{x}}{\frac{\sqrt{x^2+1}}{x}} = \lim_{x\to\infty}\frac{1}{\sqrt{\frac{x^2+1}{x^2}}} = \lim_{x\to\infty}\frac{1}{\sqrt{1+\frac{1}{x^2}}} = \frac{1}{\sqrt{1+0}} = 1.$$

24. $a_n = \dfrac{n}{\sqrt{n^3+1}}$

SOLUTION We have $a_n = f(n)$ where $f(x) = \dfrac{x}{\sqrt{x^3+1}}$; thus,

$$\lim_{n\to\infty} \frac{n}{\sqrt{n^3+1}} = \lim_{x\to\infty} \frac{x}{\sqrt{x^3+1}} = \lim_{x\to\infty} \frac{\frac{x}{x^{3/2}}}{\frac{\sqrt{x^3+1}}{x^{3/2}}} = \lim_{x\to\infty} \frac{\frac{1}{\sqrt{x}}}{\sqrt{1+\frac{1}{x^3}}} = \frac{0}{\sqrt{1+0}} = \frac{0}{1} = 0.$$

25. $a_n = \ln\left(\dfrac{12n+2}{-9+4n}\right)$

SOLUTION We have $a_n = f(n)$ where $f(x) = \ln\left(\dfrac{12x+2}{-9+4x}\right)$; thus,

$$\lim_{n\to\infty} \ln\left(\frac{12n+2}{-9+4n}\right) = \lim_{x\to\infty} \ln\left(\frac{12x+2}{-9+4x}\right) = \ln \lim_{x\to\infty}\left(\frac{12x+2}{-9+4x}\right) = \ln 3$$

26. $r_n = \ln n - \ln(n^2+1)$

SOLUTION We have $r_n = f(n)$ where $f(x) = \ln x - \ln(x^2+1)$; thus,

$$\lim_{n\to\infty} (\ln n - \ln(n^2+1)) = \lim_{x\to\infty} (\ln x - \ln(x^2+1)) = \lim_{x\to\infty} \ln \frac{x}{x^2+1}$$

But this function diverges as $x \to \infty$, so that r_n diverges as well.

In Exercises 27–30, use Theorem 4 to determine the limit of the sequence.

27. $a_n = \sqrt{4 + \dfrac{1}{n}}$

SOLUTION We have

$$\lim_{n\to\infty} 4 + \frac{1}{n} = \lim_{x\to\infty} 4 + \frac{1}{x} = 4$$

Since $\sqrt{x}$ is a continuous function for $x > 0$, Theorem 4 tells us that

$$\lim_{n\to\infty} \sqrt{4 + \frac{1}{n}} = \sqrt{\lim_{n\to\infty} 4 + \frac{1}{n}} = \sqrt{4} = 2$$

28. $a_n = e^{4n/(3n+9)}$

SOLUTION We have

$$\lim_{n\to\infty} \frac{4n}{3n+9} = \frac{4}{3}$$

Since e^x is continuous for all x, Theorem 4 tells us that

$$\lim_{n\to\infty} e^{4n/(3n+9)} = e^{\lim_{n\to\infty} 4n/(3n+9)} = e^{4/3}$$

29. $a_n = \cos^{-1}\left(\dfrac{n^3}{2n^3+1}\right)$

SOLUTION We have

$$\lim_{n\to\infty} \frac{n^3}{2n^3+1} = \frac{1}{2}$$

Since $\cos^{-1}(x)$ is continuous for all x, Theorem 4 tells us that

$$\lim_{n\to\infty} \cos^{-1}\left(\frac{n^3}{2n^3+1}\right) = \cos^{-1}\left(\lim_{n\to\infty} \frac{n^3}{2n^3+1}\right) = \cos^{-1}(1/2) = \frac{\pi}{3}$$

30. $a_n = \tan^{-1}(e^{-n})$

SOLUTION We have

$$\lim_{n\to\infty} = e^{-n} \lim_{x\to\infty} e^{-x} = 0$$

Since $\tan^{-1}(x)$ is continuous for all x, Theorem 4 tells us that

$$\lim_{n\to\infty} \tan^{-1}(e^{-n}) = \tan^{-1}\left(\lim_{n\to\infty} e^{-n}\right) = \tan^{-1}(0) = 0$$

31. Let $a_n = \dfrac{n}{n+1}$. Find a number M such that:

(a) $|a_n - 1| \le 0.001$ for $n \ge M$.

(b) $|a_n - 1| \le 0.00001$ for $n \ge M$.

Then use the limit definition to prove that $\lim_{n\to\infty} a_n = 1$.

SOLUTION

(a) We have

$$|a_n - 1| = \left|\frac{n}{n+1} - 1\right| = \left|\frac{n-(n+1)}{n+1}\right| = \left|\frac{-1}{n+1}\right| = \frac{1}{n+1}.$$

Therefore $|a_n - 1| \le 0.001$ provided $\frac{1}{n+1} \le 0.001$, that is, $n \ge 999$. It follows that we can take $M = 999$.

(b) By part (a), $|a_n - 1| \le 0.00001$ provided $\frac{1}{n+1} \le 0.00001$, that is, $n \ge 99999$. It follows that we can take $M = 99999$.

We now prove formally that $\lim_{n\to\infty} a_n = 1$. Using part (a), we know that

$$|a_n - 1| = \frac{1}{n+1} < \epsilon,$$

provided $n > \frac{1}{\epsilon} - 1$. Thus, Let $\epsilon > 0$ and take $M = \frac{1}{\epsilon} - 1$. Then, for $n > M$, we have

$$|a_n - 1| = \frac{1}{n+1} < \frac{1}{M+1} = \epsilon.$$

32. Let $b_n = \left(\frac{1}{3}\right)^n$.

(a) Find a value of M such that $|b_n| \le 10^{-5}$ for $n \ge M$.

(b) Use the limit definition to prove that $\lim_{n\to\infty} b_n = 0$.

SOLUTION

(a) Solving $\left(\frac{1}{3}\right)^n \le 10^{-5}$ for n, we find

$$n \ge 5\log_3 10 = 5\frac{\ln 10}{\ln 3} \approx 10.48.$$

It follows that we can take $M = 10.5$.

(b) We see that

$$\left|\left(\frac{1}{3}\right)^n - 0\right| = \frac{1}{3^n} < \epsilon$$

provided

$$n > \log_3 \frac{1}{\epsilon}.$$

Thus, let $\epsilon > 0$ and take $M = \log_3 \frac{1}{\epsilon}$. Then, for $n > M$, we have

$$\left|\left(\frac{1}{3}\right)^n - 0\right| = \frac{1}{3^n} < \frac{1}{3^M} = \epsilon.$$

33. Use the limit definition to prove that $\lim_{n\to\infty} n^{-2} = 0$.

SOLUTION We see that

$$|n^{-2} - 0| = \left|\frac{1}{n^2}\right| = \frac{1}{n^2} < \epsilon$$

provided

$$n > \frac{1}{\sqrt{\epsilon}}.$$

Thus, let $\epsilon > 0$ and take $M = \frac{1}{\sqrt{\epsilon}}$. Then, for $n > M$, we have

$$|n^{-2} - 0| = \left|\frac{1}{n^2}\right| = \frac{1}{n^2} < \frac{1}{M^2} = \epsilon.$$

34. Use the limit definition to prove that $\lim_{n\to\infty} \frac{n}{n+n^{-1}} = 1$.

SOLUTION Since

$$\frac{n}{n+n^{-1}} = \frac{n^2}{n(n+n^{-1})} = \frac{n^2}{n^2+1}$$

we see that

$$\left|\frac{n^2}{n^2+1} - 1\right| = \left|\frac{-1}{n^2+1}\right| = \frac{1}{n^2+1} < \epsilon$$

provided

$$n > \sqrt{\frac{1}{\epsilon} - 1}$$

So choose $\epsilon > 0$, and let $M = \sqrt{\frac{1}{\epsilon} - 1}$. Then, for $n > M$, we have

$$\left|\frac{n}{n+n^{-1}} - 1\right| = \left|\frac{-1}{n^2+1}\right| = \frac{1}{n^2+1} < \frac{1}{(\frac{1}{\epsilon} - 1) + 1} = \epsilon$$

In Exercises 35–62, use the appropriate limit laws and theorems to determine the limit of the sequence or show that it diverges.

35. $a_n = 10 + \left(-\frac{1}{9}\right)^n$

SOLUTION By the Limit Laws for Sequences we have:

$$\lim_{n\to\infty}\left(10 + \left(-\frac{1}{9}\right)^n\right) = \lim_{n\to\infty} 10 + \lim_{n\to\infty}\left(-\frac{1}{9}\right)^n = 10 + \lim_{n\to\infty}\left(-\frac{1}{9}\right)^n.$$

Now,

$$-\left(\frac{1}{9}\right)^n \le \left(-\frac{1}{9}\right)^n \le \left(\frac{1}{9}\right)^n.$$

Because

$$\lim_{n\to\infty}\left(\frac{1}{9}\right)^n = 0,$$

by the Limit Laws for Sequences,

$$\lim_{n\to\infty} -\left(\frac{1}{9}\right)^n = -\lim_{n\to\infty}\left(\frac{1}{9}\right)^n = 0.$$

Thus, we have

$$\lim_{n\to\infty}\left(-\frac{1}{9}\right)^n = 0,$$

and

$$\lim_{n\to\infty}\left(10 + \left(-\frac{1}{9}\right)^n\right) = 10 + 0 = 10.$$

36. $d_n = \sqrt{n+3} - \sqrt{n}$

SOLUTION We multiply and divide d_n by the conjugate expression $\sqrt{n+3} + \sqrt{n}$ and use the identity $(a-b)(a+b) = a^2 - b^2$ to obtain:

$$d_n = \frac{\left(\sqrt{n+3} - \sqrt{n}\right)\left(\sqrt{n+3} + \sqrt{n}\right)}{\sqrt{n+3} + \sqrt{n}} = \frac{(n+3) - n}{\sqrt{n+3} + \sqrt{n}} = \frac{3}{\sqrt{n+3} + \sqrt{n}}.$$

Thus,

$$\lim_{n\to\infty} d_n = \lim_{n\to\infty} \frac{3}{\sqrt{n+3} + \sqrt{n}} = \lim_{x\to\infty} \frac{3}{\sqrt{x+3} + \sqrt{x}} = 0.$$

37. $c_n = 1.01^n$

SOLUTION Since $c_n = f(n)$ where $f(x) = 1.01^x$, we have

$$\lim_{n\to\infty} 1.01^n = \lim_{x\to\infty} 1.01^x = \infty$$

so that the sequence diverges.

38. $b_n = e^{1-n^2}$

SOLUTION Since $b_n = f(n)$ where $f(x) = e^{1-x^2}$, we have

$$\lim_{n\to\infty} e^{1-n^2} = \lim_{x\to\infty} e^{1-x^2} = \lim_{x\to\infty} \frac{e}{e^{x^2}} = 0$$

39. $a_n = 2^{1/n}$

SOLUTION Because 2^x is a continuous function,

$$\lim_{n\to\infty} 2^{1/n} = \lim_{x\to\infty} 2^{1/x} = 2^{\lim_{x\to\infty}(1/x)} = 2^0 = 1.$$

40. $b_n = n^{1/n}$

SOLUTION Let $b_n = n^{1/n}$. Take the natural logarithm of both sides of this expression to obtain

$$\ln b_n = \ln n^{1/n} = \frac{\ln n}{n}.$$

Thus,

$$\lim_{n\to\infty} (\ln b_n) = \lim_{n\to\infty} \frac{\ln n}{n} = \lim_{x\to\infty} \frac{\ln x}{x} = \lim_{x\to\infty} \frac{1}{x} = 0.$$

Because $f(x) = e^x$ is a continuous function, it follows that

$$\lim_{n\to\infty} b_n = \lim_{n\to\infty} e^{\ln b_n} = e^{\lim_{n\to\infty}(\ln b_n)} = e^0 = 1.$$

That is,

$$\lim_{n\to\infty} n^{1/n} = 1.$$

41. $c_n = \dfrac{9^n}{n!}$

SOLUTION For $n \ge 9$, write

$$c_n = \frac{9^n}{n!} = \underbrace{\frac{9}{1} \cdot \frac{9}{2} \cdots \frac{9}{9}}_{\text{call this } C} \cdot \underbrace{\frac{9}{10} \cdot \frac{9}{11} \cdots \frac{9}{n-1} \cdot \frac{9}{n}}_{\text{Each factor is less than 1}}$$

Then clearly

$$0 \le \frac{9^n}{n!} \le C\frac{9}{n}$$

since each factor after the first nine is < 1. The squeeze theorem tells us that

$$\lim_{n\to\infty} 0 \le \lim_{n\to\infty} \frac{9^n}{n!} \le \lim_{n\to\infty} C\frac{9}{n} = C \lim_{n\to\infty} \frac{9}{n} = C \cdot 0 = 0$$

so that $\lim_{n\to\infty} c_n = 0$ as well.

42. $a_n = \dfrac{8^{2n}}{n!}$

SOLUTION Note that

$$a_n = \frac{8^{2n}}{n!} = \frac{64^n}{n!}$$

Now apply the same method as in the Exercise 41. For $n \ge 64$, write

$$c_n = \frac{64^n}{n!} = \underbrace{\frac{64}{1} \cdot \frac{64}{2} \cdots \frac{64}{64}}_{\text{call this } C} \cdot \underbrace{\frac{64}{65} \cdot \frac{64}{66} \cdots \frac{64}{n-1} \cdot \frac{64}{n}}_{\text{Each factor is less than 1}}$$

Then clearly

$$0 \le \frac{64^n}{n!} \le C\frac{64}{n}$$

since each factor after the first 64 is < 1. The squeeze theorem tells us that

$$\lim_{n\to\infty} 0 \le \lim_{n\to\infty} \frac{64^n}{n!} \le \lim_{n\to\infty} C\frac{64}{n} = C \lim_{n\to\infty} \frac{64}{n} = C \cdot 0 = 0$$

so that $\lim_{n\to\infty} a_n = 0$ as well.

43. $a_n = \dfrac{3n^2+n+2}{2n^2-3}$

SOLUTION

$$\lim_{n\to\infty} \frac{3n^2+n+2}{2n^2-3} = \lim_{x\to\infty} \frac{3x^2+x+2}{2x^2-3} = \frac{3}{2}.$$

44. $a_n = \dfrac{\sqrt{n}}{\sqrt{n}+4}$

SOLUTION

$$\lim_{n\to\infty} \frac{\sqrt{n}}{\sqrt{n}+4} = \lim_{x\to\infty} \frac{\sqrt{x}}{\sqrt{x}+4} = \lim_{x\to\infty} \frac{\frac{\sqrt{x}}{\sqrt{x}}}{\frac{\sqrt{x}}{\sqrt{x}}+\frac{4}{\sqrt{x}}} = \lim_{x\to\infty} \frac{1}{1+\frac{4}{\sqrt{x}}} = \frac{1}{1+0} = 1.$$

45. $a_n = \dfrac{\cos n}{n}$

SOLUTION Since $-1 \le \cos n \le 1$ the following holds:

$$-\frac{1}{n} \le \frac{\cos n}{n} \le \frac{1}{n}.$$

We now apply the Squeeze Theorem for Sequences and the limits

$$\lim_{n\to\infty} -\frac{1}{n} = \lim_{n\to\infty} \frac{1}{n} = 0$$

to conclude that $\lim_{n\to\infty} \frac{\cos n}{n} = 0$.

46. $c_n = \dfrac{(-1)^n}{\sqrt{n}}$

SOLUTION Clearly

$$-\frac{1}{\sqrt{n}} \le \frac{(-1)^n}{\sqrt{n}} \le \frac{1}{\sqrt{n}}$$

Since

$$\lim_{n\to\infty} \frac{-1}{\sqrt{n}} = \lim_{n\to\infty} \frac{1}{\sqrt{n}} = 0,$$

the Squeeze Theorem tells us that $\lim_{n\to\infty} \frac{(-1)^n}{\sqrt{n}} = 0$.

47. $d_n = \ln 5^n - \ln n!$

SOLUTION Note that

$$d_n = \ln \frac{5^n}{n!}$$

so that

$$e^{d_n} = \frac{5^n}{n!} \quad \text{so} \quad \lim_{n\to\infty} e^{d_n} = \lim_{n\to\infty} \frac{5^n}{n!} = 0$$

by the method of Exercise 41. If d_n converged, we could, since $f(x) = e^x$ is continuous, then write

$$\lim_{n\to\infty} e^{d_n} = e^{\lim_{n\to\infty} d_n} = 0$$

which is impossible. Thus $\{d_n\}$ diverges.

48. $d_n = \ln(n^2+4) - \ln(n^2-1)$

SOLUTION Note that

$$d_n = \ln \frac{n^2+4}{n^2-1}$$

so exponentiating both sides of this expression gives

$$e^{d_n} = \frac{n^2+4}{n^2-1} = \frac{1+(4/n^2)}{1-(1/n^2)}$$

Thus,

$$\lim_{n\to\infty} e^{d_n} = \lim_{n\to\infty} \frac{1+(4/n^2)}{1-(1/n^2)} = 1$$

Because $f(x) = \ln x$ is continuous for $x > 0$, it follows that

$$\lim_{n\to\infty} d_n = \lim_{n\to\infty} \ln(e^{d_n}) = \ln(\lim_{n\to\infty} e^{d_n}) = \ln 1 = 0$$

49. $a_n = \left(2 + \frac{4}{n^2}\right)^{1/3}$

SOLUTION Let $a_n = \left(2+\frac{4}{n^2}\right)^{1/3}$. Taking the natural logarithm of both sides of this expression yields

$$\ln a_n = \ln\left(2+\frac{4}{n^2}\right)^{1/3} = \frac{1}{3}\ln\left(2+\frac{4}{n^2}\right).$$

Thus,

$$\lim_{n\to\infty} \ln a_n = \lim_{n\to\infty} \frac{1}{3}\ln\left(2+\frac{4}{n^2}\right)^{1/3} = \frac{1}{3}\lim_{x\to\infty}\ln\left(2+\frac{4}{x^2}\right) = \frac{1}{3}\ln\left(\lim_{x\to\infty}\left(2+\frac{4}{x^2}\right)\right)$$
$$= \frac{1}{3}\ln(2+0) = \frac{1}{3}\ln 2 = \ln 2^{1/3}.$$

Because $f(x) = e^x$ is a continuous function, it follows that

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} e^{\ln a_n} = e^{\lim_{n\to\infty}(\ln a_n)} = e^{\ln 2^{1/3}} = 2^{1/3}.$$

50. $b_n = \tan^{-1}\left(1 - \frac{2}{n}\right)$

SOLUTION Because $f(x) = \tan^{-1} x$ is a continuous function, it follows that

$$\lim_{n\to\infty} a_n = \lim_{x\to\infty} \tan^{-1}\left(1-\frac{2}{x}\right) = \tan^{-1}\left(\lim_{x\to\infty}\left(1-\frac{2}{x}\right)\right) = \tan^{-1} 1 = \frac{\pi}{4}.$$

51. $c_n = \ln\left(\frac{2n+1}{3n+4}\right)$

SOLUTION Because $f(x) = \ln x$ is a continuous function, it follows that

$$\lim_{n\to\infty} c_n = \lim_{x\to\infty} \ln\left(\frac{2x+1}{3x+4}\right) = \ln\left(\lim_{x\to\infty}\frac{2x+1}{3x+4}\right) = \ln\frac{2}{3}.$$

52. $c_n = \frac{n}{n+n^{1/n}}$

SOLUTION We rewrite $\frac{n}{n+n^{1/n}}$ as follows:

$$\frac{n}{n+n^{1/n}} = \frac{\frac{n}{n}}{\frac{n}{n}+\frac{n^{1/n}}{n}} = \frac{1}{1+\frac{n^{1/n}}{n}}.$$

Now,

$$\frac{n^{1/n}}{n} = n^{\frac{1}{n}-1} = \frac{1}{n^{1-1/n}},$$

and

$$\lim_{n\to\infty}\frac{n^{1/n}}{n}=\lim_{n\to\infty}\frac{1}{n^{1-1/n}}=\lim_{x\to\infty}\frac{1}{x^{1-1/x}}=0.$$

Thus,

$$\lim_{n\to\infty}\frac{n}{n+n^{1/n}}=\lim_{x\to\infty}\frac{1}{1+\frac{x^{1/x}}{x}}=\frac{\lim_{x\to\infty}1}{\lim_{x\to\infty}\left(1+\frac{x^{1/x}}{x}\right)}=\frac{\lim_{x\to\infty}1}{\lim_{x\to\infty}1+\lim_{x\to\infty}\frac{x^{1/x}}{x}}=\frac{1}{1+0}=1.$$

53. $y_n=\dfrac{e^n}{2^n}$

SOLUTION $\frac{e^n}{2^n}=\left(\frac{e}{2}\right)^n$ and $\frac{e}{2}>1$. By the Limit of Geometric Sequences,we conclude that $\lim_{n\to\infty}\left(\frac{e}{2}\right)^n=\infty$. Thus, the given sequence diverges.

54. $a_n=\dfrac{n}{2^n}$

SOLUTION

$$\lim_{n\to\infty}\frac{n}{2^n}=\lim_{x\to\infty}\frac{x}{2^x}=\lim_{x\to\infty}\frac{\frac{d}{dx}(x)}{\frac{d}{dx}(2^x)}=\lim_{x\to\infty}\frac{1}{(\ln 2)\,2^x}=\frac{1}{\ln 2}\lim_{x\to\infty}\frac{1}{2^x}=\frac{1}{\ln 2}\cdot 0=0.$$

55. $y_n=\dfrac{e^n+(-3)^n}{5^n}$

SOLUTION

$$\lim_{n\to\infty}\frac{e^n+(-3)^n}{5^n}=\lim_{n\to\infty}\left(\frac{e}{5}\right)^n+\lim_{n\to\infty}\left(\frac{-3}{5}\right)^n$$

assuming both limits on the right-hand side exist. But by the Limit of Geometric Sequences, since

$$-1<\frac{-3}{5}<0<\frac{e}{5}<1$$

both limits on the right-hand side are 0, so that y_n converges to 0.

56. $b_n=\dfrac{(-1)^n n^3+2^{-n}}{3n^3+4^{-n}}$

SOLUTION Assuming both limits on the right-hand side exist, we have

$$\lim_{n\to\infty}\frac{(-1)^n n^3+2^{-n}}{3n^3+4^{-n}}=\lim_{n\to\infty}\frac{(-1)^n n^3}{3n^3+4^{-n}}+\lim_{n\to\infty}\frac{2^{-n}}{3n^3+4^{-n}}$$

For the first limit, let us consider instead the limit of its reciprocal:

$$\begin{aligned}\lim_{n\to\infty}(-1)^n\frac{3n^3+4^{-n}}{n^3}&=\lim_{n\to\infty}(-1)^n\frac{3n^3}{n^3}+\lim_{n\to\infty}(-1)^n\frac{4^{-n}}{n^3}\\&=\lim_{n\to\infty}(-1)^n\cdot 3+\lim_{n\to\infty}(-1)^n\frac{1}{4^n n^3}\\&=\lim_{n\to\infty}\left((-1)^n\cdot 3\right)+0\end{aligned}$$

so that one limit on the right-hand side exists and the other does not; thus the left-hand side diverges as well.

57. $a_n=n\sin\dfrac{\pi}{n}$

SOLUTION By the Theorem on Sequences Defined by a Function, we have

$$\lim_{n\to\infty}n\sin\frac{\pi}{n}=\lim_{x\to\infty}x\sin\frac{\pi}{x}.$$

Now,

$$\begin{aligned}\lim_{x\to\infty}x\sin\frac{\pi}{x}&=\lim_{x\to\infty}\frac{\sin\frac{\pi}{x}}{\frac{1}{x}}=\lim_{x\to\infty}\frac{\left(\cos\frac{\pi}{x}\right)\left(-\frac{\pi}{x^2}\right)}{-\frac{1}{x^2}}=\lim_{x\to\infty}\left(\pi\cos\frac{\pi}{x}\right)\\&=\pi\lim_{x\to\infty}\cos\frac{\pi}{x}=\pi\cos 0=\pi\cdot 1=\pi.\end{aligned}$$

Thus,

$$\lim_{n\to\infty} n \sin\frac{\pi}{n} = \pi.$$

58. $b_n = \dfrac{n!}{\pi^n}$

SOLUTION By the method of Exercise 41, we can see that $\lim_{n\to\infty} \dfrac{4^n}{n!} = 0$ so that $c_n = \dfrac{n!}{4^n}$ diverges. But $\pi < 4$ so that $c_n < b_n$ and thus b_n diverges as well.

59. $b_n = \dfrac{3-4^n}{2+7\cdot 4^n}$

SOLUTION Divide the numerator and denominator by 4^n to obtain

$$a_n = \frac{3-4^n}{2+7\cdot 4^n} = \frac{\frac{3}{4^n} - \frac{4^n}{4^n}}{\frac{2}{4^n} + \frac{7\cdot 4^n}{4^n}} = \frac{\frac{3}{4^n} - 1}{\frac{2}{4^n} + 7}.$$

Thus,

$$\lim_{n\to\infty} a_n = \lim_{x\to\infty} \frac{\frac{3}{4^x} - 1}{\frac{2}{4^x} + 7} = \frac{\lim_{x\to\infty}\left(\frac{3}{4^x} - 1\right)}{\lim_{x\to\infty}\left(\frac{2}{4^x} + 7\right)} = \frac{3\lim_{x\to\infty}\frac{1}{4^x} - \lim_{x\to\infty} 1}{2\lim_{x\to\infty}\frac{1}{4^x} - \lim_{x\to\infty} 7} = \frac{3\cdot 0 - 1}{2\cdot 0 + 7} = -\frac{1}{7}.$$

60. $a_n = \dfrac{3-4^n}{2+7\cdot 3^n}$

SOLUTION Divide the numerator and denominator by 3^n to obtain

$$a_n = \frac{3-4^n}{2+7\cdot 3^n} = \frac{\frac{3}{3^n} - \frac{4^n}{3^n}}{\frac{2}{3^n} + \frac{7\cdot 3^n}{3^n}} = \frac{\frac{3}{3^n} - \left(\frac{4}{3}\right)^n}{\frac{2}{3^n} + 7}.$$

We examine the limits of the numerator and the denominator:

$$\lim_{n\to\infty}\left(\frac{3}{3^n} - \left(\frac{4}{3}\right)^n\right) = 3\lim_{n\to\infty}\left(\frac{1}{3}\right)^n - 3\lim_{n\to\infty}\left(\frac{4}{3}\right)^n = 3\cdot 0 - \infty = -\infty,$$

whereas

$$\lim_{n\to\infty}\left(\frac{2}{3^n} + 7\right) = \lim_{n\to\infty}\frac{2}{3^n} + \lim_{n\to\infty} 7 = 2\lim_{n\to\infty}\left(\frac{1}{3}\right)^n + \lim_{n\to\infty} 7 = 2\cdot 0 + 7 = 7.$$

Thus, $\lim\limits_{n\to\infty} a_n = -\infty$; that is, the sequence diverges.

61. $a_n = \left(1 + \dfrac{1}{n}\right)^n$

SOLUTION Taking the natural logarithm of both sides of this expression yields

$$\ln a_n = \ln\left(1+\frac{1}{n}\right)^n = n\ln\left(1+\frac{1}{n}\right) = \frac{\ln\left(1+\frac{1}{n}\right)}{\frac{1}{n}}.$$

Thus,

$$\lim_{n\to\infty}(\ln a_n) = \lim_{x\to\infty}\frac{\ln\left(1+\frac{1}{x}\right)}{\frac{1}{x}} = \lim_{x\to\infty}\frac{\frac{d}{dx}\left(\ln\left(1+\frac{1}{x}\right)\right)}{\frac{d}{dx}\left(\frac{1}{x}\right)} = \lim_{x\to\infty}\frac{\frac{1}{1+\frac{1}{x}}\cdot\left(-\frac{1}{x^2}\right)}{-\frac{1}{x^2}} = \lim_{x\to\infty}\frac{1}{1+\frac{1}{x}} = \frac{1}{1+0} = 1.$$

Because $f(x) = e^x$ is a continuous function, it follows that

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} e^{\ln a_n} = e^{\lim_{n\to\infty}(\ln a_n)} = e^1 = e.$$

62. $a_n = \left(1 + \frac{1}{n^2}\right)^n$

SOLUTION Taking the natural logarithm of both sides of this expression yields

$$\ln a_n = \ln\left(1 + \frac{1}{n^2}\right)^n = n \ln\left(1 + \frac{1}{n^2}\right) = \frac{\ln\left(1 + \frac{1}{n^2}\right)}{\frac{1}{n}}.$$

Thus,

$$\lim_{n\to\infty}(\ln a_n) = \lim_{x\to\infty}\frac{\ln(1 + x^{-2})}{x^{-1}} = \lim_{x\to\infty}\frac{\frac{d}{dx}\left(\ln(1 + x^{-2})\right)}{\frac{d}{dx}(x^{-1})}$$

$$= \lim_{x\to\infty}\frac{\frac{1}{1+x^{-2}}(-2x^{-3})}{-x^{-2}} = \lim_{x\to\infty}\frac{2x^{-1}}{1 + x^{-2}} = \lim_{x\to\infty}\frac{\frac{2}{x}}{1 + \frac{1}{x^2}} = \frac{0}{1+0} = 0.$$

Because $f(x) = e^x$ is a continuous function, it follows that

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} e^{\ln a_n} = e^{\lim_{n\to\infty}(\ln a_n)} = e^0 = 1.$$

In Exercises 63–66, find the limit of the sequence using L'Hôpital's Rule.

63. $a_n = \frac{(\ln n)^2}{n}$

SOLUTION

$$\lim_{n\to\infty}\frac{(\ln n)^2}{n} = \lim_{x\to\infty}\frac{(\ln x)^2}{x} = \lim_{x\to\infty}\frac{\frac{d}{dx}(\ln x)^2}{\frac{d}{dx}x} = \lim_{x\to\infty}\frac{\frac{2\ln x}{x}}{1} = \lim_{x\to\infty}\frac{2\ln x}{x}$$

$$= \lim_{x\to\infty}\frac{\frac{d}{dx}2\ln x}{\frac{d}{dx}x} = \lim_{x\to\infty}\frac{\frac{2}{x}}{1} = \lim_{x\to\infty}\frac{2}{x} = 0$$

64. $b_n = \sqrt{n}\ln\left(1 + \frac{1}{n}\right)$

SOLUTION

$$\lim_{n\to\infty}\sqrt{n}\ln\left(1 + \frac{1}{n}\right) = \lim_{x\to\infty}\sqrt{x}\ln\left(1 + \frac{1}{x}\right) = \lim_{x\to\infty}\frac{\ln\left(1 + \frac{1}{x}\right)}{x^{-1/2}} = \lim_{x\to\infty}\frac{\frac{d}{dx}\ln\left(1 + \frac{1}{x}\right)}{\frac{d}{dx}x^{-1/2}}$$

$$= \lim_{x\to\infty}\frac{\frac{1}{1+\frac{1}{x}}\cdot\left(\frac{-1}{x^2}\right)}{\frac{-1}{2}x^{-3/2}} = \lim_{x\to\infty}\frac{2}{\sqrt{x}\left(1 + \frac{1}{x}\right)} = 0$$

65. $c_n = n\left(\sqrt{n^2+1} - n\right)$

SOLUTION

$$\lim_{n\to\infty} n\left(\sqrt{n^2+1} - n\right) = \lim_{x\to\infty} x\left(\sqrt{x^2+1} - x\right) = \lim_{x\to\infty}\frac{x\left(\sqrt{x^2+1} - x\right)\left(\sqrt{x^2+1} + x\right)}{\sqrt{x^2+1} + x}$$

$$= \lim_{x\to\infty}\frac{x}{\sqrt{x^2+1} + x} = \lim_{x\to\infty}\frac{\frac{d}{dx}x}{\frac{d}{dx}\sqrt{x^2+1} + x} = \lim_{x\to\infty}\frac{1}{1 + \frac{x}{\sqrt{x^2+1}}}$$

$$= \lim_{x\to\infty}\frac{1}{1 + \sqrt{\frac{x^2}{x^2+1}}} = \lim_{x\to\infty}\frac{1}{1 + \sqrt{\frac{1}{1+(1/x^2)}}} = \frac{1}{2}$$

66. $d_n = n^2\left(\sqrt[3]{n^3+1} - n\right)$

SOLUTION We rewrite d_n as follows:

$$d_n = n^2\left(\sqrt[3]{n^3+1} - n\right) = n^2\left(\sqrt[3]{n^3\left(1 + \frac{1}{n^3}\right)} - n\right) = n^2\left(n\sqrt[3]{1 + \frac{1}{n^3}} - n\right)$$

$$= n^3\left(\sqrt[3]{1 + \frac{1}{n^3}} - 1\right) = \frac{\left((1 + n^{-3})^{1/3} - 1\right)}{n^{-3}}.$$

Thus,

$$\lim_{n\to\infty} d_n = \lim_{x\to\infty} \frac{(1+x^{-3})^{1/3}-1}{x^{-3}} = \lim_{x\to\infty} \frac{\frac{d}{dx}\left[(1+x^{-3})^{1/3}-1\right]}{\frac{d}{dx}[x^{-3}]}$$
$$= \lim_{x\to\infty} \frac{\frac{1}{3}(1+x^{-3})^{-2/3}(-3x^{-4})}{-3x^{-4}} = \lim_{x\to\infty} \frac{1}{3}(1+x^{-3})^{-2/3} = \lim_{x\to\infty} \frac{1}{3\left(1+\frac{1}{x^3}\right)^{2/3}} = \frac{1}{3}.$$

In Exercises 67–70, use the Squeeze Theorem to evaluate $\lim_{n\to\infty} a_n$ by verifying the given inequality.

67. $a_n = \dfrac{1}{\sqrt{n^4+n^8}}, \quad \dfrac{1}{\sqrt{2n^4}} \le a_n \le \dfrac{1}{\sqrt{2n^2}}$

SOLUTION For all $n > 1$ we have $n^4 < n^8$, so the quotient $\frac{1}{\sqrt{n^4+n^8}}$ is smaller than $\frac{1}{\sqrt{n^4+n^4}}$ and larger than $\frac{1}{\sqrt{n^8+n^8}}$. That is,

$$a_n < \frac{1}{\sqrt{n^4+n^4}} = \frac{1}{\sqrt{n^4\cdot 2}} = \frac{1}{\sqrt{2n^2}}; \text{ and}$$
$$a_n > \frac{1}{\sqrt{n^8+n^8}} = \frac{1}{\sqrt{2n^8}} = \frac{1}{\sqrt{2n^4}}.$$

Now, since $\lim_{n\to\infty} \frac{1}{\sqrt{2n^4}} = \lim_{n\to\infty} \frac{1}{\sqrt{2n^2}} = 0$, the Squeeze Theorem for Sequences implies that $\lim_{n\to\infty} a_n = 0$.

68. $c_n = \dfrac{1}{\sqrt{n^2+1}} + \dfrac{1}{\sqrt{n^2+2}} + \cdots + \dfrac{1}{\sqrt{n^2+n}}$,
$\dfrac{n}{\sqrt{n^2+n}} \le c_n \le \dfrac{n}{\sqrt{n^2+1}}$

SOLUTION Since each of the n terms in the sum defining c_n is not smaller than $\frac{1}{\sqrt{n^2+n}}$ and not larger than $\frac{1}{\sqrt{n^2+1}}$ we obtain the following inequalities:

$$c_n \ge \underbrace{\frac{1}{\sqrt{n^2+n}} + \cdots + \frac{1}{\sqrt{n^2+n}}}_{n \text{ terms}} = n\cdot\frac{1}{\sqrt{n^2+n}} = \frac{n}{\sqrt{n^2+n}};$$
$$c_n \le \underbrace{\frac{1}{\sqrt{n^2+1}} + \cdots + \frac{1}{\sqrt{n^2+1}}}_{n \text{ terms}} = n\cdot\frac{1}{\sqrt{n^2+1}} = \frac{n}{\sqrt{n^2+1}}.$$

Thus,

$$\frac{n}{\sqrt{n^2+n}} \le c_n \le \frac{n}{\sqrt{n^2+1}}.$$

We now compute the limits of the two sequences:

$$\lim_{n\to\infty} \frac{n}{\sqrt{n^2+1}} = \lim_{n\to\infty} \frac{\frac{n}{n}}{\frac{\sqrt{n^2+1}}{n}} = \lim_{n\to\infty} \frac{1}{\frac{\sqrt{n^2+1}}{\sqrt{n^2}}} = \lim_{n\to\infty} \frac{1}{\sqrt{1+\frac{1}{n^2}}} = 1;$$
$$\lim_{n\to\infty} \frac{n}{\sqrt{n^2+n}} = \lim_{n\to\infty} \frac{\frac{n}{n}}{\frac{\sqrt{n^2+n}}{n}} = \lim_{n\to\infty} \frac{1}{\frac{\sqrt{n^2+n}}{\sqrt{n^2}}} = \lim_{n\to\infty} \frac{1}{\sqrt{1+\frac{1}{n}}} = 1.$$

By the Squeeze Theorem we conclude that:

$$\lim_{n\to\infty} c_n = 1.$$

69. $a_n = (2^n+3^n)^{1/n}, \quad 3 \le a_n \le (2\cdot 3^n)^{1/n} = 2^{1/n}\cdot 3$

SOLUTION Clearly $2^n + 3^n \ge 3^n$ for all $n \ge 1$. Therefore:

$$(2^n+3^n)^{1/n} \ge (3^n)^{1/n} = 3.$$

Also $2^n + 3^n \le 3^n + 3^n = 2 \cdot 3^n$, so

$$(2^n + 3^n)^{1/n} \le (2 \cdot 3^n)^{1/n} = 2^{1/n} \cdot 3.$$

Thus,

$$3 \le (2^n + 3^n)^{1/n} \le 2^{1/n} \cdot 3.$$

Because

$$\lim_{n\to\infty} 2^{1/n} \cdot 3 = 3 \lim_{n\to\infty} 2^{1/n} = 3 \cdot 1 = 3$$

and $\lim_{n\to\infty} 3 = 3$, the Squeeze Theorem for Sequences guarantees

$$\lim_{n\to\infty} (2^n + 3^n)^{1/n} = 3.$$

70. $a_n = (n + 10^n)^{1/n}, \quad 10 \le a_n \le (2 \cdot 10^n)^{1/n}$

SOLUTION Clearly

$$10^n \le n + 10^n \le 10^n + 10^n = 2 \cdot 10^n$$

for all $n \ge 0$. Thus

$$10 \le (n + 10^n)^{1/n} \le (2 \cdot 10^n)^{1/n}$$

Now,

$$\lim_{n\to\infty} (2 \cdot 10^n)^{1/n} = \lim_{n\to\infty} 2^{1/n} \cdot 10 = 10 \lim_{n\to\infty} 2^{1/n} = 10 \cdot 1 = 10$$

and $\lim_{n\to\infty} 10 = 10$, so that the Squeeze Theorem for Sequences tells us that

$$\lim_{n\to\infty} (n + 10^n)^{1/n} = 10$$

71. Which of the following statements is equivalent to the assertion $\lim\limits_{n\to\infty} a_n = L$? Explain.

(a) For every $\epsilon > 0$, the interval $(L - \epsilon, L + \epsilon)$ contains at least one element of the sequence $\{a_n\}$.

(b) For every $\epsilon > 0$, the interval $(L - \epsilon, L + \epsilon)$ contains all but at most finitely many elements of the sequence $\{a_n\}$.

SOLUTION Statement (b) is equivalent to Definition 1 of the limit, since the assertion "$|a_n - L| < \epsilon$ for all $n > M$" means that $L - \epsilon < a_n < L + \epsilon$ for all $n > M$; that is, the interval $(L - \epsilon, L + \epsilon)$ contains all the elements a_n except (maybe) the finite number of elements $a_1, a_2, \ldots, a_M$.

Statement (a) is not equivalent to the assertion $\lim\limits_{n\to\infty} a_n = L$. We show this, by considering the following sequence:

$$a_n = \begin{cases} \dfrac{1}{n} & \text{for odd } n \\ 1 + \dfrac{1}{n} & \text{for even } n \end{cases}$$

Clearly for every $\epsilon > 0$, the interval $(-\epsilon, \epsilon) = (L - \epsilon, L + \epsilon)$ for $L = 0$ contains at least one element of $\{a_n\}$, but the sequence diverges (rather than converges to $L = 0$). Since the terms in the odd places converge to 0 and the terms in the even places converge to 1. Hence, a_n does not approach one limit.

72. Show that $a_n = \dfrac{1}{2n+1}$ is decreasing.

SOLUTION Let $f(x) = \frac{1}{2x+1}$. Then

$$f'(x) = -\frac{1}{(2x+1)^2} \cdot 2 = \frac{-2}{(2x+1)^2} < 0 \qquad \text{for } x \neq -\frac{1}{2}.$$

Since $f'(x) < 0$ for $x \neq -\frac{1}{2}$, f is decreasing on the interval $x > -\frac{1}{2}$. It follows that $a_n = f(n)$ is also decreasing.

73. Show that $a_n = \dfrac{3n^2}{n^2+2}$ is increasing. Find an upper bound.

SOLUTION Let $f(x) = \frac{3x^2}{x^2+2}$. Then

$$f'(x) = \frac{6x(x^2+2) - 3x^2 \cdot 2x}{(x^2+2)^2} = \frac{12x}{(x^2+2)^2}.$$

$f'(x) > 0$ for $x > 0$, hence f is increasing on this interval. It follows that $a_n = f(n)$ is also increasing. We now show that $M = 3$ is an upper bound for a_n, by writing:

$$a_n = \frac{3n^2}{n^2+2} \le \frac{3n^2+6}{n^2+2} = \frac{3(n^2+2)}{n^2+2} = 3.$$

That is, $a_n \le 3$ for all n.

74. Show that $a_n = \sqrt[3]{n+1} - n$ is decreasing.

SOLUTION Let $f(x) = \sqrt[3]{x+1} - x$. Then

$$f'(x) = \frac{d}{dx}\left((x+1)^{1/3} - x\right) = \frac{1}{3}(x+1)^{-2/3} - 1.$$

For $x \ge 1$,

$$\frac{1}{3}(x+1)^{-2/3} - 1 \le \frac{1}{3}2^{-2/3} - 1 < 0.$$

We conclude that f is decreasing on the interval $x \ge 1$. It follows that $a_n = f(n)$ is also decreasing.

75. Give an example of a divergent sequence $\{a_n\}$ such that $\lim\limits_{n\to\infty} |a_n|$ converges.

SOLUTION Let $a_n = (-1)^n$. The sequence $\{a_n\}$ diverges because the terms alternate between $+1$ and -1; however, the sequence $\{|a_n|\}$ converges because it is a constant sequence, all of whose terms are equal to 1.

76. Give an example of *divergent* sequences $\{a_n\}$ and $\{b_n\}$ such that $\{a_n + b_n\}$ converges.

SOLUTION Let $a_n = 2^n$ and $b_n = -2^n$. Then $\{a_n\}$ and $\{b_n\}$ are divergent geometric sequences. However, since $a_n + b_n = 2^n - 2^n = 0$, the sequence $\{a_n + b_n\}$ is the constant sequence with all the terms equal zero, so it converges to zero.

77. Using the limit definition, prove that if $\{a_n\}$ converges and $\{b_n\}$ diverges, then $\{a_n + b_n\}$ diverges.

SOLUTION We will prove this result by contradiction. Suppose $\lim_{n\to\infty} a_n = L_1$ and that $\{a_n + b_n\}$ converges to a limit L_2. Now, let $\epsilon > 0$. Because $\{a_n\}$ converges to L_1 and $\{a_n + b_n\}$ converges to L_2, it follows that there exist numbers M_1 and M_2 such that:

$$|a_n - L_1| < \frac{\epsilon}{2} \qquad \text{for all } n > M_1,$$
$$|(a_n + b_n) - L_2| < \frac{\epsilon}{2} \qquad \text{for all } n > M_2.$$

Thus, for $n > M = \max\{M_1, M_2\}$,

$$|a_n - L_1| < \frac{\epsilon}{2} \quad \text{and} \quad |(a_n + b_n) - L_2| < \frac{\epsilon}{2}.$$

By the triangle inequality,

$$\begin{aligned} |b_n - (L_2 - L_1)| &= |a_n + b_n - a_n - (L_2 - L_1)| = |(-a_n + L_1) + (a_n + b_n - L_2)| \\ &\le |L_1 - a_n| + |a_n + b_n - L_2|. \end{aligned}$$

Thus, for $n > M$,

$$|b_n - (L_2 - L_1)| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon;$$

that is, $\{b_n\}$ converges to $L_2 - L_1$, in contradiction to the given data. Thus, $\{a_n + b_n\}$ must diverge.

78. Use the limit definition to prove that if $\{a_n\}$ is a convergent sequence of integers with limit L, then there exists a number M such that $a_n = L$ for all $n \geq M$.

SOLUTION Suppose $\{a_n\}$ converges to L, and let $\epsilon = \frac{1}{2}$. Then, there exists a number M such that

$$|a_n - L| < \frac{1}{2}$$

for all $n \geq M$. In other words, for all $n \geq M$,

$$L - \frac{1}{2} < a_n < L + \frac{1}{2}.$$

However, we are given that $\{a_n\}$ is a sequence of integers. Thus, it must be that $a_n = L$ for all $n \geq M$.

79. Theorem 1 states that if $\lim_{x\to\infty} f(x) = L$, then the sequence $a_n = f(n)$ converges and $\lim_{n\to\infty} a_n = L$. Show that the *converse* is false. In other words, find a function $f(x)$ such that $a_n = f(n)$ converges but $\lim_{x\to\infty} f(x)$ does not exist.

SOLUTION Let $f(x) = \sin \pi x$ and $a_n = \sin \pi n$. Then $a_n = f(n)$. Since $\sin \pi x$ is oscillating between -1 and 1 the limit $\lim_{x\to\infty} f(x)$ does not exist. However, the sequence $\{a_n\}$ is the constant sequence in which $a_n = \sin \pi n = 0$ for all n, hence it converges to zero.

80. Use the limit definition to prove that the limit does not change if a finite number of terms are added or removed from a convergent sequence.

SOLUTION Suppose that $\{a_n\}$ is a sequence such that $\lim_{n\to\infty} a_n = L$. For every $\epsilon > 0$, there is a number M such that $|a_n - L| < \epsilon$ for all $n > M$. That is, the inequality $|a_n - L| < \epsilon$ holds for all the terms of $\{a_n\}$ except possibly a finite number of terms. If we add a finite number of terms, these terms may not satisfy the inequality $|a_n - L| < \epsilon$, but there are still only a finite number of terms that do not satisfy this inequality. By removing terms from the sequence, the number of terms in the new sequence that do not satisfy $|a_n - L| < \epsilon$ are no more than in the original sequence. Hence the new sequence also converges to L.

81. Let $b_n = a_{n+1}$. Use the limit definition to prove that if $\{a_n\}$ converges, then $\{b_n\}$ also converges and $\lim_{n\to\infty} a_n = \lim_{n\to\infty} b_n$.

SOLUTION Suppose $\{a_n\}$ converges to L. Let $b_n = a_{n+1}$, and let $\epsilon > 0$. Because $\{a_n\}$ converges to L, there exists an M' such that $|a_n - L| < \epsilon$ for $n > M'$. Now, let $M = M' - 1$. Then, whenever $n > M$, $n + 1 > M + 1 = M'$. Thus, for $n > M$,

$$|b_n - L| = |a_{n+1} - L| < \epsilon.$$

Hence, $\{b_n\}$ converges to L.

82. Let $\{a_n\}$ be a sequence such that $\lim_{n\to\infty} |a_n|$ exists and is nonzero. Show that $\lim_{n\to\infty} a_n$ exists if and only if there exists an integer M such that the sign of a_n does not change for $n > M$.

SOLUTION Let $\{a_n\}$ be a sequence such that $\lim_{n\to\infty} |a_n|$ exists and is nonzero. Suppose $\lim_{n\to\infty} a_n$ exists and let $L = \lim_{n\to\infty} a_n$. Note that L cannot be zero for then $\lim_{n\to\infty} |a_n|$ would also be zero. Now, choose $\epsilon < |L|$. Then there exists an integer M such that $|a_n - L| < \epsilon$, or $L - \epsilon < a_n < L + \epsilon$, for all $n > M$. If $L < 0$, then $-2L < a_n < 0$, whereas if $L > 0$, then $0 < a_n < 2L$; that is, a_n does not change for $n > M$.

Now suppose that there exists an integer M such that a_n does not change for $n > M$. If $a_n > 0$ for $n > M$, then $a_n = |a_n|$ for $n > M$ and

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} |a_n|.$$

On the other hand, if $a_n < 0$ for $n > M$, then $a_n = -|a_n|$ for $n > M$ and

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} -|a_n| = -\lim_{n\to\infty} |a_n|.$$

In either case, $\lim_{n\to\infty} a_n$ exists. Thus, $\lim_{n\to\infty} a_n$ exists if and only if there exists an integer M such that the sign of a_n does not change for $n > M$.

83. Proceed as in Example 12 to show that the sequence $\sqrt{3}, \sqrt{3\sqrt{3}}, \sqrt{3\sqrt{3\sqrt{3}}}, \dots$ is increasing and bounded above by $M = 3$. Then prove that the limit exists and find its value.

SOLUTION This sequence is defined recursively by the formula:

$$a_{n+1} = \sqrt{3a_n}, \qquad a_1 = \sqrt{3}.$$

Consider the following inequalities:

$$a_2 = \sqrt{3a_1} = \sqrt{3\sqrt{3}} > \sqrt{3} = a_1 \quad \Rightarrow \quad a_2 > a_1;$$
$$a_3 = \sqrt{3a_2} > \sqrt{3a_1} = a_2 \quad \Rightarrow \quad a_3 > a_2;$$
$$a_4 = \sqrt{3a_3} > \sqrt{3a_2} = a_3 \quad \Rightarrow \quad a_4 > a_3.$$

In general, if we assume that $a_k > a_{k-1}$, then

$$a_{k+1} = \sqrt{3a_k} > \sqrt{3a_{k-1}} = a_k.$$

Hence, by mathematical induction, $a_{n+1} > a_n$ for all n; that is, the sequence $\{a_n\}$ is increasing.

Because $a_{n+1} = \sqrt{3a_n}$, it follows that $a_n \geq 0$ for all n. Now, $a_1 = \sqrt{3} < 3$. If $a_k \leq 3$, then

$$a_{k+1} = \sqrt{3a_k} \leq \sqrt{3 \cdot 3} = 3.$$

Thus, by mathematical induction, $a_n \leq 3$ for all n.

Since $\{a_n\}$ is increasing and bounded, it follows by the Theorem on Bounded Monotonic Sequences that this sequence is converging. Denote the limit by $L = \lim_{n\to\infty} a_n$. Using Exercise 81, it follows that

$$L = \lim_{n\to\infty} a_{n+1} = \lim_{n\to\infty} \sqrt{3a_n} = \sqrt{3 \lim_{n\to\infty} a_n} = \sqrt{3L}.$$

Thus, $L^2 = 3L$, so $L = 0$ or $L = 3$. Because the sequence is increasing, we have $a_n \geq a_1 = \sqrt{3}$ for all n. Hence, the limit also satisfies $L \geq \sqrt{3}$. We conclude that the appropriate solution is $L = 3$; that is, $\lim_{n\to\infty} a_n = 3$.

84. Let $\{a_n\}$ be the sequence defined recursively by

$$a_0 = 0, \qquad a_{n+1} = \sqrt{2 + a_n}$$

Thus, $a_1 = \sqrt{2}, \quad a_2 = \sqrt{2+\sqrt{2}}, \quad a_3 = \sqrt{2+\sqrt{2+\sqrt{2}}}, \ldots.$

(a) Show that if $a_n < 2$, then $a_{n+1} < 2$. Conclude by induction that $a_n < 2$ for all n.

(b) Show that if $a_n < 2$, then $a_n \leq a_{n+1}$. Conclude by induction that $\{a_n\}$ is increasing.

(c) Use (a) and (b) to conclude that $L = \lim_{n\to\infty} a_n$ exists. Then compute L by showing that $L = \sqrt{2 + L}$.

SOLUTION

(a) Assume $a_n < 2$. Then

$$a_{n+1} = \sqrt{2 + a_n} < \sqrt{2 + 2} = 2$$

so that $a_{n+1} < 2$. So by induction, $a_n < 2$ for all n and $\{a_n\}$ is bounded above by 2.

(b) Assume $a_n < 2$. Then

$$a_{n+1} = \sqrt{2 + a_n} > \sqrt{a_n + a_n} = \sqrt{2a_n} > \sqrt{a_n^2} = a_n$$

so that $a_n < a_{n+1}$. It follows by induction that $\{a_n\}$ is increasing.

(c) Since $\{a_n\}$ is increasing and bounded above, the Theorem on Bounded Monotone Sequences tells us that $L = \lim_{n\to\infty} a_n$ exists. We have

$$L = \lim_{n\to\infty} a_{n+1} = \lim_{n\to\infty} \sqrt{2 + a_n} = \sqrt{2 + \lim_{n\to\infty} a_n} = \sqrt{2 + L}$$

by Exercise 81. It follows that $L = \sqrt{2 + L}$, so that $L^2 - L - 2 = 0$. Thus $L = 2$ or $L = -1$. But all terms of $\{a_n\}$ are positive, so we must have $L = 2$.

Further Insights and Challenges

85. Show that $\lim_{n\to\infty} \sqrt[n]{n!} = \infty$. *Hint:* Verify that $n! \geq (n/2)^{n/2}$ by observing that half of the factors of $n!$ are greater than or equal to $n/2$.

SOLUTION We show that $n! \geq \left(\frac{n}{2}\right)^{n/2}$. For $n \geq 4$ even, we have:

$$n! = \underbrace{1 \cdot \cdots \cdot \frac{n}{2}}_{\frac{n}{2}\text{ factors}} \cdot \underbrace{\left(\frac{n}{2} + 1\right) \cdot \cdots \cdot n}_{\frac{n}{2}\text{ factors}} \geq \underbrace{\left(\frac{n}{2} + 1\right) \cdot \cdots \cdot n}_{\frac{n}{2}\text{ factors}}.$$

Since each one of the $\frac{n}{2}$ factors is greater than $\frac{n}{2}$, we have:

$$n! \geq \underbrace{\left(\frac{n}{2}+1\right)\cdot\cdots\cdot n}_{\frac{n}{2}\text{ factors}} \geq \underbrace{\frac{n}{2}\cdot\cdots\cdot\frac{n}{2}}_{\frac{n}{2}\text{ factors}} = \left(\frac{n}{2}\right)^{n/2}.$$

For $n \geq 3$ odd, we have:

$$n! = \underbrace{1\cdot\cdots\cdot\frac{n-1}{2}}_{\frac{n-1}{2}\text{ factors}}\cdot\underbrace{\frac{n+1}{2}\cdot\cdots\cdot n}_{\frac{n+1}{2}\text{ factors}} \geq \underbrace{\frac{n+1}{2}\cdot\cdots\cdot n}_{\frac{n+1}{2}\text{ factors}}.$$

Since each one of the $\frac{n+1}{2}$ factors is greater than $\frac{n}{2}$, we have:

$$n! \geq \underbrace{\frac{n+1}{2}\cdot\cdots\cdot n}_{\frac{n+1}{2}\text{ factors}} \geq \underbrace{\frac{n}{2}\cdot\cdots\cdot\frac{n}{2}}_{\frac{n+1}{2}\text{ factors}} = \left(\frac{n}{2}\right)^{(n+1)/2} = \left(\frac{n}{2}\right)^{n/2}\sqrt{\frac{n}{2}} \geq \left(\frac{n}{2}\right)^{n/2}.$$

In either case we have $n! \geq \left(\frac{n}{2}\right)^{n/2}$. Thus,

$$\sqrt[n]{n!} \geq \sqrt{\frac{n}{2}}.$$

Since $\lim_{n\to\infty}\sqrt{\frac{n}{2}} = \infty$, it follows that $\lim_{n\to\infty}\sqrt[n]{n!} = \infty$. Thus, the sequence $a_n = \sqrt[n]{n!}$ diverges.

86. Let $b_n = \dfrac{\sqrt[n]{n!}}{n}$.

(a) Show that $\ln b_n = \dfrac{1}{n}\displaystyle\sum_{k=1}^{n}\ln\frac{k}{n}$.

(b) Show that $\ln b_n$ converges to $\displaystyle\int_0^1 \ln x\,dx$, and conclude that $b_n \to e^{-1}$.

SOLUTION

(a) Let $b_n = \frac{(n!)^{1/n}}{n}$. Then

$$\ln b_n = \ln(n!)^{1/n} - \ln n = \frac{1}{n}\ln(n!) - \ln n = \frac{\ln(n!) - n\ln n}{n} = \frac{1}{n}\left[\ln(n!) - \ln n^n\right] = \frac{1}{n}\ln\frac{n!}{n^n}$$

$$= \frac{1}{n}\ln\left(\frac{1}{n}\cdot\frac{2}{n}\cdot\frac{3}{n}\cdot\cdots\cdot\frac{n}{n}\right) = \frac{1}{n}\left(\ln\frac{1}{n} + \ln\frac{2}{n} + \ln\frac{3}{n} + \cdots + \ln\frac{n}{n}\right) = \frac{1}{n}\sum_{k=1}^{n}\ln\frac{k}{n}.$$

(b) By part (a) we have,

$$\lim_{n\to\infty}(\ln b_n) = \lim_{n\to\infty}\frac{1}{n}\sum_{k=1}^{n}\ln\frac{k}{n}.$$

Notice that $\frac{1}{n}\sum_{k=1}^{n}\ln\frac{k}{n}$ is the nth right-endpoint approximation of the integral of $\ln x$ over the interval $[0, 1]$. Hence,

$$\lim_{n\to\infty}\frac{1}{n}\sum_{k=1}^{n}\ln\frac{k}{n} = \int_0^1 \ln x\,dx.$$

We compute the improper integral using integration by parts, with $u = \ln x$ and $v' = 1$. Then $u' = \frac{1}{x}$, $v = x$ and

$$\int_0^1 \ln x\,dx = x\ln x\Big|_0^1 - \int_0^1 \frac{1}{x}x\,dx = 1\cdot\ln 1 - \lim_{x\to 0+}(x\ln x) - \int_0^1 dx$$

$$= 0 - \lim_{x\to 0+}(x\ln x) - x\Big|_0^1 = -1 - \lim_{x\to 0+}(x\ln x).$$

We compute the remaining limit using L'Hôpital's Rule. This gives:

$$\lim_{x\to 0+}(x\cdot\ln x) = \lim_{x\to 0+}\frac{\ln x}{\frac{1}{x}} = \lim_{x\to 0+}\frac{\frac{1}{x}}{-\frac{1}{x^2}} = \lim_{x\to 0+}(-x) = 0.$$

Thus,

$$\lim_{n\to\infty} \ln b_n = \int_0^1 \ln x\, dx = -1,$$

and

$$\lim_{n\to\infty} b_n = e^{-1}.$$

87. Given positive numbers $a_1 < b_1$, define two sequences recursively by

$$a_{n+1} = \sqrt{a_n b_n}, \qquad b_{n+1} = \frac{a_n + b_n}{2}$$

(a) Show that $a_n \le b_n$ for all n (Figure 13).

(b) Show that $\{a_n\}$ is increasing and $\{b_n\}$ is decreasing.

(c) Show that $b_{n+1} - a_{n+1} \le \dfrac{b_n - a_n}{2}$.

(d) Prove that both $\{a_n\}$ and $\{b_n\}$ converge and have the same limit. This limit, denoted $\text{AGM}(a_1, b_1)$, is called the **arithmetic-geometric mean** of a_1 and b_1.

(e) Estimate $\text{AGM}(1, \sqrt{2})$ to three decimal places.

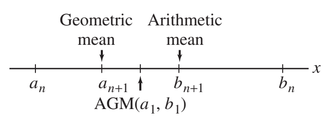


FIGURE 13

SOLUTION

(a) Examine the following:

$$b_{n+1} - a_{n+1} = \frac{a_n + b_n}{2} - \sqrt{a_n b_n} = \frac{a_n + b_n - 2\sqrt{a_n b_n}}{2} = \frac{\left(\sqrt{a_n}\right)^2 - 2\sqrt{a_n}\sqrt{b_n} + \left(\sqrt{b_n}\right)^2}{2}$$
$$= \frac{\left(\sqrt{a_n} - \sqrt{b_n}\right)^2}{2} \ge 0.$$

We conclude that $b_{n+1} \ge a_{n+1}$ for all $n > 1$. By the given information $b_1 > a_1$; hence, $b_n \ge a_n$ for all n.

(b) By part (a), $b_n \ge a_n$ for all n, so

$$a_{n+1} = \sqrt{a_n b_n} \ge \sqrt{a_n \cdot a_n} = \sqrt{a_n^2} = a_n$$

for all n. Hence, the sequence $\{a_n\}$ is increasing. Moreover, since $a_n \le b_n$ for all n,

$$b_{n+1} = \frac{a_n + b_n}{2} \le \frac{b_n + b_n}{2} = \frac{2b_n}{2} = b_n$$

for all n; that is, the sequence $\{b_n\}$ is decreasing.

(c) Since $\{a_n\}$ is increasing, $a_{n+1} \ge a_n$. Thus,

$$b_{n+1} - a_{n+1} \le b_{n+1} - a_n = \frac{a_n + b_n}{2} - a_n = \frac{a_n + b_n - 2a_n}{2} = \frac{b_n - a_n}{2}.$$

Now, by part (a), $a_n \le b_n$ for all n. By part (b), $\{b_n\}$ is decreasing. Hence $b_n \le b_1$ for all n. Combining the two inequalities we conclude that $a_n \le b_1$ for all n. That is, the sequence $\{a_n\}$ is increasing and bounded ($0 \le a_n \le b_1$). By the Theorem on Bounded Monotonic Sequences we conclude that $\{a_n\}$ converges. Similarly, since $\{a_n\}$ is increasing, $a_n \ge a_1$ for all n. We combine this inequality with $b_n \ge a_n$ to conclude that $b_n \ge a_1$ for all n. Thus, $\{b_n\}$ is decreasing and bounded ($a_1 \le b_n \le b_1$); hence this sequence converges.

To show that $\{a_n\}$ and $\{b_n\}$ converge to the same limit, note that

$$b_n - a_n \le \frac{b_{n-1} - a_{n-1}}{2} \le \frac{b_{n-2} - a_{n-2}}{2^2} \le \cdots \le \frac{b_1 - a_1}{2^{n-1}}.$$

Thus,

$$\lim_{n\to\infty} (b_n - a_n) = (b_1 - a_1) \lim_{n\to\infty} \frac{1}{2^{n-1}} = 0.$$

(d) We have

$$a_{n+1} = \sqrt{a_n b_n}, \quad a_1 = 1; \quad b_{n+1} = \frac{a_n + b_n}{2}, \quad b_1 = \sqrt{2}$$

Computing the values of a_n and b_n until the first three decimal digits are equal in successive terms, we obtain:

$$\begin{aligned}
a_2 &= \sqrt{a_1 b_1} = \sqrt{1 \cdot \sqrt{2}} = 1.1892 \\
b_2 &= \frac{a_1 + b_1}{2} = \frac{1 + \sqrt{2}}{2} = 1.2071 \\
a_3 &= \sqrt{a_2 b_2} = \sqrt{1.1892 \cdot 1.2071} = 1.1981 \\
b_3 &= \frac{a_2 + b_2}{2} = \frac{1.1892 \cdot 1.2071}{2} = 1.1981 \\
a_4 &= \sqrt{a_3 b_3} = 1.1981 \\
b_4 &= \frac{a_3 + b_3}{2} = 1.1981
\end{aligned}$$

Thus,

$$AGM\left(1, \sqrt{2}\right) \approx 1.198.$$

88. Let $c_n = \frac{1}{n} + \frac{1}{n+1} + \frac{1}{n+2} + \cdots + \frac{1}{2n}$.

(a) Calculate c_1, c_2, c_3, c_4.

(b) Use a comparison of rectangles with the area under $y = x^{-1}$ over the interval $[n, 2n]$ to prove that

$$\int_n^{2n} \frac{dx}{x} + \frac{1}{2n} \le c_n \le \int_n^{2n} \frac{dx}{x} + \frac{1}{n}$$

(c) Use the Squeeze Theorem to determine $\lim_{n\to\infty} c_n$.

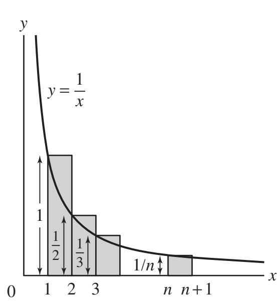
SOLUTION

(a)

$$\begin{aligned}
c_1 &= 1 + \frac{1}{2} = \frac{3}{2}; \\
c_2 &= \frac{1}{2} + \frac{1}{3} + \frac{1}{4} = \frac{13}{12}; \\
c_3 &= \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} = \frac{19}{20}; \\
c_4 &= \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7} + \frac{1}{8} = \frac{743}{840};
\end{aligned}$$

(b) We consider the left endpoint approximation to the integral of $y = \frac{1}{x}$ over the interval $[n, 2n]$. Since the function $y = \frac{1}{x}$ is decreasing, the left endpoint approximation is greater than $\int_n^{2n} \frac{dx}{x}$; that is,

$$\int_n^{2n} \frac{dx}{x} \le \frac{1}{n} \cdot 1 + \frac{1}{n+1} \cdot 1 + \frac{1}{n+2} \cdot 1 + \cdots + \frac{1}{2n-1} \cdot 1.$$

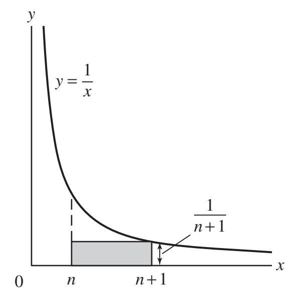


We express the right hand-side of the inequality in terms of c_n, obtaining:

$$\int_n^{2n} \frac{dx}{x} \le c_n - \frac{1}{2n}.$$

We now consider the right endpoint approximation to the integral $\int_n^{2n} \frac{dx}{x}$; that is,

$$\frac{1}{n+1} \cdot 1 + \frac{1}{n+2} \cdot 1 + \cdots + \frac{1}{2n} \cdot 1 \le \int_n^{2n} \frac{dx}{x}.$$



We express the left hand-side of the inequality in terms of c_n, obtaining:

$$c_n - \frac{1}{n} \le \int_n^{2n} \frac{dx}{x}.$$

Thus,

$$\int_n^{2n} \frac{dx}{x} + \frac{1}{2n} \le c_n \le \int_n^{2n} \frac{dx}{x} + \frac{1}{n}.$$

(c) With

$$\int_n^{2n} \frac{dx}{x} = \ln x|_n^{2n} = \ln 2n - \ln n = \ln \frac{2n}{n} = \ln 2,$$

the result from part (b) becomes

$$\ln 2 + \frac{1}{2n} \le c_n \le \ln 2 + \frac{1}{n}.$$

Because

$$\lim_{n\to\infty} \frac{1}{2n} = \lim_{n\to\infty} \frac{1}{n} = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{n\to\infty} c_n = \ln 2.$$

89. Let $a_n = H_n - \ln n$, where H_n is the nth harmonic number

$$H_n = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{n}$$

(a) Show that $a_n \ge 0$ for $n \ge 1$. *Hint:* Show that $H_n \ge \int_1^{n+1} \frac{dx}{x}$.

(b) Show that $\{a_n\}$ is decreasing by interpreting $a_n - a_{n+1}$ as an area.

(c) Prove that $\lim_{n\to\infty} a_n$ exists.

This limit, denoted γ, is known as *Euler's Constant*. It appears in many areas of mathematics, including analysis and number theory, and has been calculated to more than 100 million decimal places, but it is still not known whether γ is an irrational number. The first 10 digits are $\gamma \approx 0.5772156649$.

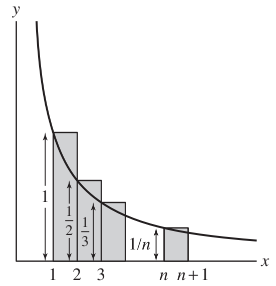
SOLUTION

(a) Since the function $y = \frac{1}{x}$ is decreasing, the left endpoint approximation to the integral $\int_1^{n+1} \frac{dx}{x}$ is greater than this integral; that is,

$$1 \cdot 1 + \frac{1}{2} \cdot 1 + \frac{1}{3} \cdot 1 + \cdots + \frac{1}{n} \cdot 1 \ge \int_1^{n+1} \frac{dx}{x}$$

or

$$H_n \ge \int_1^{n+1} \frac{dx}{x}.$$



Moreover, since the function $y = \frac{1}{x}$ is positive for $x > 0$, we have:

$$\int_1^{n+1} \frac{dx}{x} \geq \int_1^n \frac{dx}{x}.$$

Thus,

$$H_n \geq \int_1^n \frac{dx}{x} = \ln x \Big|_1^n = \ln n - \ln 1 = \ln n,$$

and

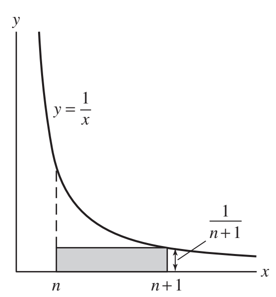
$$a_n = H_n - \ln n \geq 0 \qquad \text{for all } n \geq 1.$$

(b) To show that $\{a_n\}$ is decreasing, we consider the difference $a_n - a_{n+1}$:

$$\begin{aligned} a_n - a_{n+1} &= H_n - \ln n - \big(H_{n+1} - \ln(n+1)\big) = H_n - H_{n+1} + \ln(n+1) - \ln n \\ &= 1 + \frac{1}{2} + \cdots + \frac{1}{n} - \left(1 + \frac{1}{2} + \cdots + \frac{1}{n} + \frac{1}{n+1}\right) + \ln(n+1) - \ln n \\ &= -\frac{1}{n+1} + \ln(n+1) - \ln n. \end{aligned}$$

Now, $\ln(n+1) - \ln n = \int_n^{n+1} \frac{dx}{x}$, whereas $\frac{1}{n+1}$ is the right endpoint approximation to the integral $\int_n^{n+1} \frac{dx}{x}$. Recalling $y = \frac{1}{x}$ is decreasing, it follows that

$$\int_n^{n+1} \frac{dx}{x} \geq \frac{1}{n+1}$$



so

$$a_n - a_{n+1} \geq 0.$$

(c) By parts (a) and (b), $\{a_n\}$ is decreasing and 0 is a lower bound for this sequence. Hence $0 \leq a_n \leq a_1$ for all n. A monotonic and bounded sequence is convergent, so $\lim_{n\to\infty} a_n$ exists.

10.2 Summing an Infinite Series

Preliminary Questions

1. What role do partial sums play in defining the sum of an infinite series?

SOLUTION The sum of an infinite series is defined as the limit of the sequence of partial sums. If the limit of this sequence does not exist, the series is said to diverge.

2. What is the sum of the following infinite series?

$$\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+\frac{1}{32}+\frac{1}{64}+\cdots$$

SOLUTION This is a geometric series with $c=\frac{1}{4}$ and $r=\frac{1}{2}$. The sum of the series is therefore

$$\frac{\frac{1}{4}}{1-\frac{1}{2}}=\frac{\frac{1}{4}}{\frac{1}{2}}=\frac{1}{2}.$$

3. What happens if you apply the formula for the sum of a geometric series to the following series? Is the formula valid?

$$1+3+3^2+3^3+3^4+\cdots$$

SOLUTION This is a geometric series with $c=1$ and $r=3$. Applying the formula for the sum of a geometric series then gives

$$\sum_{n=0}^{\infty}3^n=\frac{1}{1-3}=-\frac{1}{2}.$$

Clearly, this is not valid: a series with all positive terms cannot have a negative sum. The formula is not valid in this case because a geometric series with $r=3$ diverges.

4. Arvind asserts that $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n^2}=0$ because $\dfrac{1}{n^2}$ tends to zero. Is this valid reasoning?

SOLUTION Arvind's reasoning is not valid. Though the terms in the series do tend to zero, the general term in the sequence of partial sums,

$$S_n=1+\frac{1}{2^2}+\frac{1}{3^2}+\cdots+\frac{1}{n^2},$$

is clearly larger than 1. The sum of the series therefore cannot be zero.

5. Colleen claims that $\displaystyle\sum_{n=1}^{\infty}\frac{1}{\sqrt{n}}$ converges because

$$\lim_{n\to\infty}\frac{1}{\sqrt{n}}=0$$

Is this valid reasoning?

SOLUTION Colleen's reasoning is not valid. Although the general term of a convergent series must tend to zero, a series whose general term tends to zero need not converge. In the case of $\displaystyle\sum_{n=1}^{\infty}\frac{1}{\sqrt{n}}$, the series diverges even though its general term tends to zero.

6. Find an N such that $S_N>25$ for the series $\displaystyle\sum_{n=1}^{\infty}2$.

SOLUTION The Nth partial sum of the series is:

$$S_N=\sum_{n=1}^{N}2=\underbrace{2+\cdots+2}_{N}=2N.$$

7. Does there exist an N such that $S_N>25$ for the series $\displaystyle\sum_{n=1}^{\infty}2^{-n}$? Explain.

SOLUTION The series $\displaystyle\sum_{n=1}^{\infty}2^{-n}$ is a convergent geometric series with the common ratio $r=\dfrac{1}{2}$. The sum of the series is:

$$S=\frac{\frac{1}{2}}{1-\frac{1}{2}}=1.$$

Notice that the sequence of partial sums $\{S_N\}$ is increasing and converges to 1; therefore $S_N\le 1$ for all N. Thus, there does not exist an N such that $S_N>25$.

8. Give an example of a divergent infinite series whose general term tends to zero.

SOLUTION Consider the series $\sum_{n=1}^{\infty} \frac{1}{n^{\frac{9}{10}}}$. The general term tends to zero, since $\lim_{n\to\infty} \frac{1}{n^{\frac{9}{10}}} = 0$. However, the Nth partial sum satisfies the following inequality:

$$S_N = \frac{1}{1^{\frac{9}{10}}} + \frac{1}{2^{\frac{9}{10}}} + \cdots + \frac{1}{N^{\frac{9}{10}}} \geq \frac{N}{N^{\frac{9}{10}}} = N^{1-\frac{9}{10}} = N^{\frac{1}{10}}.$$

That is, $S_N \geq N^{\frac{1}{10}}$ for all N. Since $\lim_{N\to\infty} N^{\frac{1}{10}} = \infty$, the sequence of partial sums S_n diverges; hence, the series $\sum_{n=1}^{\infty} \frac{1}{n^{\frac{9}{10}}}$ diverges.

Exercises

1. Find a formula for the general term a_n (not the partial sum) of the infinite series.

(a) $\frac{1}{3} + \frac{1}{9} + \frac{1}{27} + \frac{1}{81} + \cdots$

(b) $\frac{1}{1} + \frac{5}{2} + \frac{25}{4} + \frac{125}{8} + \cdots$

(c) $\frac{1}{1} - \frac{2^2}{2\cdot 1} + \frac{3^3}{3\cdot 2\cdot 1} - \frac{4^4}{4\cdot 3\cdot 2\cdot 1} + \cdots$

(d) $\frac{2}{1^2+1} + \frac{1}{2^2+1} + \frac{2}{3^2+1} + \frac{1}{4^2+1} + \cdots$

SOLUTION

(a) The denominators of the terms are powers of 3, starting with the first power. Hence, the general term is:

$$a_n = \frac{1}{3^n}.$$

(b) The numerators are powers of 5, and the denominators are the same powers of 2. The first term is $a_1 = 1$ so,

$$a_n = \left(\frac{5}{2}\right)^{n-1}.$$

(c) The general term of this series is,

$$a_n = (-1)^{n+1}\frac{n^n}{n!}.$$

(d) Notice that the numerators of a_n equal 2 for odd values of n and 1 for even values of n. Thus,

$$a_n = \begin{cases} \dfrac{2}{n^2+1} & \text{odd } n \\ \dfrac{1}{n^2+1} & \text{even } n \end{cases}$$

The formula can also be rewritten as follows:

$$a_n = \frac{1 + \frac{(-1)^{n+1}+1}{2}}{n^2+1}.$$

2. Write in summation notation:

(a) $1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \cdots$

(b) $\frac{1}{9} + \frac{1}{16} + \frac{1}{25} + \frac{1}{36} + \cdots$

(c) $1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots$

(d) $\frac{125}{9} + \frac{625}{16} + \frac{3125}{25} + \frac{15{,}625}{36} + \cdots$

SOLUTION

(a) The general term is $a_n = \frac{1}{n^2}$, $n = 1, 2, 3, \ldots$; hence, the series is $\sum_{n=1}^{\infty} \frac{1}{n^2}$.

(b) The general term is $a_n = \dfrac{1}{n^2}$, $n = 3, 4, 5, \ldots$ or $a_n = \dfrac{1}{(n+2)^2}$, $n = 1, 2, 3, \ldots$; hence, the series is $\displaystyle\sum_{n=3}^{\infty} \frac{1}{n^2} = \sum_{n=1}^{\infty} \frac{1}{(n+2)^2}$.

(c) The general term is $a_n = \dfrac{(-1)^{n+1}}{2n-1}$, $n = 1, 2, 3, \ldots$; hence, the series is $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{2n-1}$.

(d) The general term is $a_n = \dfrac{5^n}{n^2}$, $n = 3, 4, 5, \ldots$ or $a_n = \dfrac{5^{n+2}}{(n+2)^2}$, $n = 1, 2, 3, \ldots$; hence, the series is $\displaystyle\sum_{n=3}^{\infty} \frac{5^n}{n^2} = \sum_{n=1}^{\infty} \frac{5^{n+2}}{(n+2)^2}$.

In Exercises 3–6, compute the partial sums S_2, S_4, and S_6.

3. $1 + \dfrac{1}{2^2} + \dfrac{1}{3^2} + \dfrac{1}{4^2} + \cdots$

SOLUTION

$$S_2 = 1 + \frac{1}{2^2} = \frac{5}{4};$$
$$S_4 = 1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} = \frac{205}{144};$$
$$S_6 = 1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \frac{1}{6^2} = \frac{5369}{3600}.$$

4. $\displaystyle\sum_{k=1}^{\infty} (-1)^k k^{-1}$

SOLUTION

$$S_2 = (-1)^1 \cdot 1^{-1} + (-1)^2 \cdot 2^{-1} = -1 + \frac{1}{2} = -\frac{1}{2};$$
$$S_4 = (-1)^1 \cdot 1^{-1} + (-1)^2 \cdot 2^{-1} + (-1)^3 \cdot 3^{-1} + (-1)^4 \cdot 4^{-1} = S_2 - \frac{1}{3} + \frac{1}{4} = -\frac{1}{2} - \frac{1}{3} + \frac{1}{4} = -\frac{7}{12};$$
$$S_6 = -\frac{7}{12} + (-1)^5 \cdot 5^{-1} + (-1)^6 \cdot 6^{-1} = -\frac{7}{12} - \frac{1}{5} + \frac{1}{6} = -\frac{37}{60}.$$

5. $\dfrac{1}{1 \cdot 2} + \dfrac{1}{2 \cdot 3} + \dfrac{1}{3 \cdot 4} + \cdots$

SOLUTION

$$S_2 = \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} = \frac{1}{2} + \frac{1}{6} = \frac{4}{6} = \frac{2}{3};$$
$$S_4 = S_2 + a_3 + a_4 = \frac{2}{3} + \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} = \frac{2}{3} + \frac{1}{12} + \frac{1}{20} = \frac{4}{5};$$
$$S_6 = S_4 + a_5 + a_6 = \frac{4}{5} + \frac{1}{5 \cdot 6} + \frac{1}{6 \cdot 7} = \frac{4}{5} + \frac{1}{30} + \frac{1}{42} = \frac{6}{7}.$$

6. $\displaystyle\sum_{j=1}^{\infty} \frac{1}{j!}$

SOLUTION

$$S_2 = \frac{1}{1!} + \frac{1}{2!} = 1 + \frac{1}{2} = \frac{3}{2};$$
$$S_4 = S_2 + \frac{1}{3!} + \frac{1}{4!} = \frac{3}{2} + \frac{1}{6} + \frac{1}{24} = \frac{41}{24};$$
$$S_6 = S_4 + \frac{1}{5!} + \frac{1}{6!} = \frac{41}{24} + \frac{1}{120} + \frac{1}{720} = \frac{1237}{720}.$$

7. The series $S = 1 + \left(\frac{1}{5}\right) + \left(\frac{1}{5}\right)^2 + \left(\frac{1}{5}\right)^3 + \cdots$ converges to $\frac{5}{4}$. Calculate S_N for $N = 1, 2, \ldots$ until you find an S_N that approximates $\frac{5}{4}$ with an error less than 0.0001.

SOLUTION

$$S_1 = 1$$

$$S_2 = 1 + \frac{1}{5} = \frac{6}{5} = 1.2$$

$$S_3 = 1 + \frac{1}{5} + \frac{1}{25} = \frac{31}{25} = 1.24$$

$$S_3 = 1 + \frac{1}{5} + \frac{1}{25} + \frac{1}{125} = \frac{156}{125} = 1.248$$

$$S_4 = 1 + \frac{1}{5} + \frac{1}{25} + \frac{1}{125} + \frac{1}{625} = \frac{781}{625} = 1.2496$$

$$S_5 = 1 + \frac{1}{5} + \frac{1}{25} + \frac{1}{125} + \frac{1}{625} + \frac{1}{3125} = \frac{3906}{3125} = 1.24992$$

Note that

$$1.25 - S_5 = 1.25 - 1.24992 = 0.00008 < 0.0001$$

8. The series $S = \frac{1}{0!} - \frac{1}{1!} + \frac{1}{2!} - \frac{1}{3!} + \cdots$ is known to converge to e^{-1} (recall that $0! = 1$). Calculate S_N for $N = 1, 2, \ldots$ until you find an S_N that approximates e^{-1} with an error less than 0.001.

SOLUTION The general term of the series is

$$a_n = \frac{(-1)^{n-1}}{(n-1)!};$$

thus, the Nth partial sum of the series is

$$S_N = \sum_{n=1}^{N} a_n = \sum_{n=1}^{N} \frac{(-1)^{n-1}}{(n-1)!} = \frac{1}{0!} - \frac{1}{1!} + \frac{1}{2!} - \cdots + \frac{(-1)^{N-1}}{(N-1)!}.$$

Using a calculator we find $e^{-1} = 0.367879$. Working sequentially, we find

$$S_1 = \frac{1}{0!} = 1$$

$$S_2 = S_1 + a_2 = 1 - \frac{1}{1!} = 0$$

$$S_3 = S_2 + a_3 = 0 + \frac{1}{2!} = \frac{1}{2} = 0.5$$

$$S_4 = S_3 + a_4 = 0.5 - \frac{1}{3!} = 0.333333$$

$$S_5 = S_4 + a_5 = 0.333333 + \frac{1}{4!} = 0.375$$

$$S_6 = S_5 + a_6 = 0.375 - \frac{1}{5!} = 0.366667$$

$$S_7 = S_6 + a_7 = 0.366667 + \frac{1}{6!} = 0.368056$$

Note that

$$|S_7 - e^{-1}| = 1.76 \times 10^{-4} < 10^{-3}.$$

In Exercises 9 and 10, use a computer algebra system to compute S_{10}, S_{100}, S_{500}, and S_{1000} for the series. Do these values suggest convergence to the given value?

9. CAS

$$\frac{\pi - 3}{4} = \frac{1}{2 \cdot 3 \cdot 4} - \frac{1}{4 \cdot 5 \cdot 6} + \frac{1}{6 \cdot 7 \cdot 8} - \frac{1}{8 \cdot 9 \cdot 10} + \cdots$$

SOLUTION Write

$$a_n = \frac{(-1)^{n+1}}{2n \cdot (2n+1) \cdot (2n+2)}$$

Then

$$S_N = \sum_{i=1}^{N} a_n$$

Computing, we find

$$\begin{aligned}
\frac{\pi - 3}{4} &\approx 0.0353981635 \\
S_{10} &\approx 0.03535167962 \\
S_{100} &\approx 0.03539810274 \\
S_{500} &\approx 0.03539816290 \\
S_{1000} &\approx 0.03539816334
\end{aligned}$$

It appears that $S_N \to \frac{\pi-3}{4}$.

10. CAS

$$\frac{\pi^4}{90} = 1 + \frac{1}{2^4} + \frac{1}{3^4} + \frac{1}{4^4} + \cdots$$

SOLUTION Write

$$S_N = \sum_{i=1}^{N} \frac{1}{i^4}$$

Computing, we find

$$\begin{aligned}
\frac{\pi^4}{90} &\approx 1.082323234 \\
S(10) &\approx 1.082036583 \\
S(100) &\approx 1.082322905 \\
S(500) &\approx 1.082323231 \\
S(1000) &\approx 1.082323233
\end{aligned}$$

It appears that $S_N \to \frac{\pi^4}{90}$.

11. Calculate S_3, S_4, and S_5 and then find the sum of the telescoping series

$$S = \sum_{n=1}^{\infty} \left(\frac{1}{n+1} - \frac{1}{n+2} \right)$$

SOLUTION

$$\begin{aligned}
S_3 &= \left(\frac{1}{2} - \frac{1}{3}\right) + \left(\frac{1}{3} - \frac{1}{4}\right) + \left(\frac{1}{4} - \frac{1}{5}\right) = \frac{1}{2} - \frac{1}{5} = \frac{3}{10}; \\
S_4 &= S_3 + \left(\frac{1}{5} - \frac{1}{6}\right) = \frac{1}{2} - \frac{1}{6} = \frac{1}{3}; \\
S_5 &= S_4 + \left(\frac{1}{6} - \frac{1}{7}\right) = \frac{1}{2} - \frac{1}{7} = \frac{5}{14}.
\end{aligned}$$

The general term in the sequence of partial sums is

$$S_N = \left(\frac{1}{2} - \frac{1}{3}\right) + \left(\frac{1}{3} - \frac{1}{4}\right) + \left(\frac{1}{4} - \frac{1}{5}\right) + \cdots + \left(\frac{1}{N+1} - \frac{1}{N+2}\right) = \frac{1}{2} - \frac{1}{N+2};$$

thus,

$$S = \lim_{N\to\infty} S_N = \lim_{N\to\infty} \left(\frac{1}{2} - \frac{1}{N+2}\right) = \frac{1}{2}.$$

The sum of the telescoping series is therefore $\frac{1}{2}$.

12. Write $\displaystyle\sum_{n=3}^{\infty} \frac{1}{n(n-1)}$ as a telescoping series and find its sum.

SOLUTION By partial fraction decomposition

$$\frac{1}{n(n-1)} = \frac{1}{n-1} - \frac{1}{n},$$

so

$$\sum_{n=3}^{\infty} \frac{1}{n(n-1)} = \sum_{n=3}^{\infty} \left(\frac{1}{n-1} - \frac{1}{n}\right).$$

The general term in the sequence of partial sums for this series is

$$S_N = \left(\frac{1}{2} - \frac{1}{3}\right) + \left(\frac{1}{3} - \frac{1}{4}\right) + \left(\frac{1}{4} - \frac{1}{5}\right) + \cdots + \left(\frac{1}{N-1} - \frac{1}{N}\right) = \frac{1}{2} - \frac{1}{N};$$

thus,

$$S = \lim_{N\to\infty} S_N = \lim_{N\to\infty} \left(\frac{1}{2} - \frac{1}{N}\right) = \frac{1}{2}.$$

13. Calculate S_3, S_4, and S_5 and then find the sum $S = \displaystyle\sum_{n=1}^{\infty} \frac{1}{4n^2-1}$ using the identity

$$\frac{1}{4n^2-1} = \frac{1}{2}\left(\frac{1}{2n-1} - \frac{1}{2n+1}\right)$$

SOLUTION

$$S_3 = \frac{1}{2}\left(\frac{1}{1} - \frac{1}{3}\right) + \frac{1}{2}\left(\frac{1}{3} - \frac{1}{5}\right) + \frac{1}{2}\left(\frac{1}{5} - \frac{1}{7}\right) = \frac{1}{2}\left(1 - \frac{1}{7}\right) = \frac{3}{7};$$

$$S_4 = S_3 + \frac{1}{2}\left(\frac{1}{7} - \frac{1}{9}\right) = \frac{1}{2}\left(1 - \frac{1}{9}\right) = \frac{4}{9};$$

$$S_5 = S_4 + \frac{1}{2}\left(\frac{1}{9} - \frac{1}{11}\right) = \frac{1}{2}\left(1 - \frac{1}{11}\right) = \frac{5}{11}.$$

The general term in the sequence of partial sums is

$$S_N = \frac{1}{2}\left(\frac{1}{1} - \frac{1}{3}\right) + \frac{1}{2}\left(\frac{1}{3} - \frac{1}{5}\right) + \frac{1}{2}\left(\frac{1}{5} - \frac{1}{7}\right) + \cdots + \frac{1}{2}\left(\frac{1}{2N-1} - \frac{1}{2N+1}\right) = \frac{1}{2}\left(1 - \frac{1}{2N+1}\right);$$

thus,

$$S = \lim_{N\to\infty} S_N = \lim_{N\to\infty} \frac{1}{2}\left(1 - \frac{1}{2N+1}\right) = \frac{1}{2}.$$

14. Use partial fractions to rewrite $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n(n+3)}$ as a telescoping series and find its sum.

SOLUTION By partial fraction decomposition

$$\frac{1}{n\,(n+3)} = \frac{A}{n} + \frac{B}{n+3};$$

clearing denominators gives

$$1 = A\,(n+3) + Bn.$$

Setting $n = 0$ yields $A = \frac{1}{3}$, while setting $n = -3$ yields $B = -\frac{1}{3}$. Thus,

$$\frac{1}{n(n+3)} = \frac{1}{3}\left(\frac{1}{n} - \frac{1}{n+3}\right),$$

and

$$\sum_{n=1}^{\infty} \frac{1}{n(n+3)} = \sum_{n=1}^{\infty} \frac{1}{3}\left(\frac{1}{n} - \frac{1}{n+3}\right).$$

The general term in the sequence of partial sums for the series on the right-hand side is

$$\begin{aligned} S_N &= \frac{1}{3}\left(1-\frac{1}{4}\right) + \frac{1}{3}\left(\frac{1}{2}-\frac{1}{5}\right) + \frac{1}{3}\left(\frac{1}{3}-\frac{1}{6}\right) + \frac{1}{3}\left(\frac{1}{4}-\frac{1}{7}\right) + \frac{1}{3}\left(\frac{1}{5}-\frac{1}{8}\right) + \frac{1}{3}\left(\frac{1}{6}-\frac{1}{9}\right) \\ &\quad + \cdots + \frac{1}{3}\left(\frac{1}{N-2}-\frac{1}{N+1}\right) + \frac{1}{3}\left(\frac{1}{N-1}-\frac{1}{N+2}\right) + \frac{1}{3}\left(\frac{1}{N}-\frac{1}{N+3}\right) \\ &= \frac{1}{3}\left(1+\frac{1}{2}+\frac{1}{3}\right) - \frac{1}{3}\left(\frac{1}{N+1}+\frac{1}{N+2}+\frac{1}{N+3}\right) = \frac{11}{18} - \frac{1}{3}\left(\frac{1}{N+1}+\frac{1}{N+2}+\frac{1}{N+3}\right). \end{aligned}$$

Thus,

$$\lim_{N\to\infty} S_N = \lim_{N\to\infty}\left[\frac{11}{18} - \frac{1}{3}\left(\frac{1}{N+1}+\frac{1}{N+2}+\frac{1}{N+3}\right)\right] = \frac{11}{18},$$

and

$$\sum_{n=1}^{\infty} \frac{1}{n(n+3)} = \frac{11}{18}.$$

15. Find the sum of $\frac{1}{1\cdot 3} + \frac{1}{3\cdot 5} + \frac{1}{5\cdot 7} + \cdots$.

SOLUTION We may write this sum as

$$\sum_{n=1}^{\infty} \frac{1}{(2n-1)(2n+1)} = \sum_{n=1}^{\infty} \frac{1}{2}\left(\frac{1}{2n-1} - \frac{1}{2n+1}\right).$$

The general term in the sequence of partial sums is

$$S_N = \frac{1}{2}\left(\frac{1}{1}-\frac{1}{3}\right) + \frac{1}{2}\left(\frac{1}{3}-\frac{1}{5}\right) + \frac{1}{2}\left(\frac{1}{5}-\frac{1}{7}\right) + \cdots + \frac{1}{2}\left(\frac{1}{2N-1}-\frac{1}{2N+1}\right) = \frac{1}{2}\left(1-\frac{1}{2N+1}\right);$$

thus,

$$\lim_{N\to\infty} S_N = \lim_{N\to\infty} \frac{1}{2}\left(1-\frac{1}{2N+1}\right) = \frac{1}{2},$$

and

$$\sum_{n=1}^{\infty} \frac{1}{(2n-1)(2n+1)} = \frac{1}{2}.$$

16. Find a formula for the partial sum S_N of $\sum_{n=1}^{\infty} (-1)^{n-1}$ and show that the series diverges.

SOLUTION The partial sums of the series are:

$$\begin{aligned} S_1 &= (-1)^{1-1} = 1; \\ S_2 &= (-1)^0 + (-1)^1 = 1 - 1 = 0; \\ S_3 &= (-1)^0 + (-1)^1 + (-1)^2 = 1; \\ S_4 &= (-1)^0 + (-1)^1 + (-1)^2 + (-1)^3 = 0; \cdots \end{aligned}$$

In general,

$$S_N = \begin{cases} 1 & \text{if } N \text{ odd} \\ 0 & \text{if } N \text{ even} \end{cases}$$

Because the values of S_N alternate between 0 and 1, the sequence of partial sums diverges; this, in turn, implies that the series $\sum_{n=1}^{\infty} (-1)^{n-1}$ diverges.

In Exercises 17–22, use Theorem 3 to prove that the following series diverge.

17. $\displaystyle\sum_{n=1}^{\infty} \frac{n}{10n+12}$

SOLUTION The general term, $\dfrac{n}{10n+12}$, has limit

$$\lim_{n\to\infty} \frac{n}{10n+12} = \lim_{n\to\infty} \frac{1}{10+(12/n)} = \frac{1}{10}$$

Since the general term does not tend to zero, the series diverges.

18. $\displaystyle\sum_{n=1}^{\infty} \frac{n}{\sqrt{n^2+1}}$

SOLUTION The general term, $\dfrac{n}{\sqrt{n^2+1}}$, has limit

$$\lim_{n\to\infty} \frac{n}{\sqrt{n^2+1}} = \lim_{n\to\infty} \sqrt{\frac{n^2}{n^2+1}} = \lim_{n\to\infty} \sqrt{\frac{1}{1+(1/n^2)}} = 1$$

Since the general term does not tend to zero, the series diverges.

19. $\dfrac{0}{1} - \dfrac{1}{2} + \dfrac{2}{3} - \dfrac{3}{4} + \cdots$

SOLUTION The general term $a_n = (-1)^{n-1}\frac{n-1}{n}$ does not tend to zero. In fact, because $\lim_{n\to\infty} \frac{n-1}{n} = 1$, $\lim_{n\to\infty} a_n$ does not exist. By Theorem 3, we conclude that the given series diverges.

20. $\displaystyle\sum_{n=1}^{\infty} (-1)^n n^2$

SOLUTION The general term $a_n = (-1)^n n^2$ does not tend to zero. In fact, because $\lim_{n\to\infty} n^2 = \infty$, $\lim_{n\to\infty} a_n$ does not exist. By Theorem 3, we conclude that the given series diverges.

21. $\cos\dfrac{1}{2} + \cos\dfrac{1}{3} + \cos\dfrac{1}{4} + \cdots$

SOLUTION The general term $a_n = \cos\frac{1}{n+1}$ tends to 1, not zero. By Theorem 3, we conclude that the given series diverges.

22. $\displaystyle\sum_{n=0}^{\infty} \left(\sqrt{4n^2+1} - n\right)$

SOLUTION The general term of the series satisfies

$$\sqrt{4n^2+1} - n > \sqrt{4n^2} - n = n$$

Thus the general term tends to infinity. The series diverges by Theorem 2.

In Exercises 23–36, use the formula for the sum of a geometric series to find the sum or state that the series diverges.

23. $\dfrac{1}{1} + \dfrac{1}{8} + \dfrac{1}{8^2} + \cdots$

SOLUTION This is a geometric series with $c = 1$ and $r = \frac{1}{8}$, so its sum is

$$\frac{1}{1-\frac{1}{8}} = \frac{1}{7/8} = \frac{8}{7}$$

24. $\dfrac{4^3}{5^3} + \dfrac{4^4}{5^4} + \dfrac{4^5}{5^5} + \cdots$

SOLUTION This is a geometric series with

$$c = \frac{4^3}{5^3} \quad \text{and} \quad r = \frac{4}{5}$$

so its sum is

$$\frac{c}{1-r} = \frac{4^3/5^3}{1-\frac{4}{5}} = \frac{4^3}{5^3 - 4\cdot 5^2} = \frac{64}{25}$$

25. $\displaystyle\sum_{n=3}^{\infty}\left(\frac{3}{11}\right)^{-n}$

SOLUTION Rewrite this series as

$$\sum_{n=3}^{\infty}\left(\frac{11}{3}\right)^{n}$$

This is a geometric series with $r = \dfrac{11}{3} > 1$, so it is divergent.

26. $\displaystyle\sum_{n=2}^{\infty}\frac{7\cdot(-3)^n}{5^n}$

SOLUTION This is a geometric series with $c = 7$ and $r = -\dfrac{3}{5}$, starting at $n = 2$. Its sum is thus

$$\frac{cr^2}{1-r} = \frac{7\cdot(9/25)}{1-\frac{3}{5}} = \frac{63}{25}\cdot\frac{5}{8} = \frac{63}{40}$$

27. $\displaystyle\sum_{n=-4}^{\infty}\left(-\frac{4}{9}\right)^{n}$

SOLUTION This is a geometric series with $c = 1$ and $r = -\dfrac{4}{9}$, starting at $n = -4$. Its sum is thus

$$\frac{cr^{-4}}{1-r} = \frac{c}{r^4-r^5} = \frac{1}{\frac{4^4}{9^4}+\frac{4^5}{9^5}} = \frac{9^5}{9\cdot 4^4+4^5} = \frac{59{,}049}{3328}$$

28. $\displaystyle\sum_{n=0}^{\infty}\left(\frac{\pi}{e}\right)^{n}$

SOLUTION Since $\pi > e$, this is a geometric series with $r > 1$, so it diverges.

29. $\displaystyle\sum_{n=1}^{\infty}e^{-n}$

SOLUTION Rewrite the series as

$$\sum_{n=1}^{\infty}\left(\frac{1}{e}\right)^{n}$$

to recognize it as a geometric series with $c = \frac{1}{e}$ and $r = \frac{1}{e}$. Thus,

$$\sum_{n=1}^{\infty}e^{-n} = \frac{\frac{1}{e}}{1-\frac{1}{e}} = \frac{1}{e-1}.$$

30. $\displaystyle\sum_{n=2}^{\infty}e^{3-2n}$

SOLUTION Rewrite the series as

$$\sum_{n=2}^{\infty}e^3e^{-2n} = \sum_{n=2}^{\infty}e^3\left(\frac{1}{e^2}\right)^{n}$$

to recognize it as a geometric series with $c = e^3\left(\frac{1}{e^2}\right)^2 = \frac{1}{e}$ and $r = \frac{1}{e^2}$. Thus,

$$\sum_{n=2}^{\infty}e^{3-2n} = \frac{\frac{1}{e}}{1-\frac{1}{e^2}} = \frac{e}{e^2-1}.$$

31. $\displaystyle\sum_{n=0}^{\infty}\frac{8+2^n}{5^n}$

SOLUTION Rewrite the series as

$$\sum_{n=0}^{\infty}\frac{8}{5^n}+\sum_{n=0}^{\infty}\frac{2^n}{5^n} = \sum_{n=0}^{\infty}8\cdot\left(\frac{1}{5}\right)^{n}+\sum_{n=0}^{\infty}\left(\frac{2}{5}\right)^{n},$$

which is a sum of two geometric series. The first series has $c = 8\left(\frac{1}{5}\right)^0 = 8$ and $r = \frac{1}{5}$; the second has $c = \left(\frac{2}{5}\right)^0 = 1$ and $r = \frac{2}{5}$. Thus,

$$\sum_{n=0}^{\infty} 8 \cdot \left(\frac{1}{5}\right)^n = \frac{8}{1-\frac{1}{5}} = \frac{8}{\frac{4}{5}} = 10,$$

$$\sum_{n=0}^{\infty} \left(\frac{2}{5}\right)^n = \frac{1}{1-\frac{2}{5}} = \frac{1}{\frac{3}{5}} = \frac{5}{3},$$

and

$$\sum_{n=0}^{\infty} \frac{8+2^n}{5^n} = 10 + \frac{5}{3} = \frac{35}{3}.$$

32. $\displaystyle\sum_{n=0}^{\infty} \frac{3(-2)^n - 5^n}{8^n}$

SOLUTION Rewrite the series as

$$\sum_{n=0}^{\infty} \frac{3(-2)^n - 5^n}{8^n} = \sum_{n=0}^{\infty} \frac{3(-2)^n}{8^n} - \sum_{n=0}^{\infty} \frac{5^n}{8^n}$$

which is a difference of two geometric series. The first has $c = 3$ and $r = -\frac{1}{4}$; the second has $c = 1$ and $r = \frac{5}{8}$. Thus

$$\sum_{n=0}^{\infty} \frac{3(-2)^n}{8^n} = \frac{3}{1+\frac{1}{4}} = \frac{12}{5}$$

$$\sum_{n=0}^{\infty} \frac{5^n}{8^n} = \frac{1}{1-\frac{5}{8}} = \frac{8}{3}$$

so that

$$\sum_{n=0}^{\infty} \frac{3(-2)^n - 5^n}{8^n} = \frac{12}{5} - \frac{8}{3} = -\frac{4}{15}$$

33. $5 - \frac{5}{4} + \frac{5}{4^2} - \frac{5}{4^3} + \cdots$

SOLUTION This is a geometric series with $c = 5$ and $r = -\frac{1}{4}$. Thus,

$$\sum_{n=0}^{\infty} 5 \cdot \left(-\frac{1}{4}\right)^n = \frac{5}{1-\left(-\frac{1}{4}\right)} = \frac{5}{1+\frac{1}{4}} = \frac{5}{\frac{5}{4}} = 4.$$

34. $\frac{2^3}{7} + \frac{2^4}{7^2} + \frac{2^5}{7^3} + \frac{2^6}{7^4} + \cdots$

SOLUTION This is a geometric series with $c = \frac{8}{7}$ and $r = \frac{2}{7}$. Thus,

$$\sum_{n=0}^{\infty} \frac{8}{7} \cdot \left(\frac{2}{7}\right)^n = \frac{\frac{8}{7}}{1-\frac{2}{7}} = \frac{\frac{8}{7}}{\frac{5}{7}} = \frac{8}{5}.$$

35. $\frac{7}{8} - \frac{49}{64} + \frac{343}{512} - \frac{2401}{4096} + \cdots$

SOLUTION This is a geometric series with $c = \frac{7}{8}$ and $r = -\frac{7}{8}$. Thus,

$$\sum_{n=0}^{\infty} \frac{7}{8} \cdot \left(-\frac{7}{8}\right)^n = \frac{\frac{7}{8}}{1-\left(-\frac{7}{8}\right)} = \frac{\frac{7}{8}}{\frac{15}{8}} = \frac{7}{15}.$$

36. $\frac{25}{9}+\frac{5}{3}+1+\frac{3}{5}+\frac{9}{25}+\frac{27}{125}+\cdots$

SOLUTION This appears to be a geometric series with

$$c=\frac{25}{9}\quad\text{and}\quad r=\frac{3}{5}$$

so its sum is

$$\frac{c}{1-r}=\frac{25/9}{1-\frac{3}{5}}=\frac{25}{9}\cdot\frac{5}{2}=\frac{125}{18}$$

37. Which of the following are *not* geometric series?

(a) $\sum_{n=0}^{\infty}\frac{7^n}{29^n}$

(b) $\sum_{n=3}^{\infty}\frac{1}{n^4}$

(c) $\sum_{n=0}^{\infty}\frac{n^2}{2^n}$

(d) $\sum_{n=5}^{\infty}\pi^{-n}$

SOLUTION

(a) $\sum_{n=0}^{\infty}\frac{7^n}{29^n}=\sum_{n=0}^{\infty}\left(\frac{7}{29}\right)^n$: this is a geometric series with common ratio $r=\frac{7}{29}$.

(b) The ratio between two successive terms is

$$\frac{a_{n+1}}{a_n}=\frac{\frac{1}{(n+1)^4}}{\frac{1}{n^4}}=\frac{n^4}{(n+1)^4}=\left(\frac{n}{n+1}\right)^4.$$

This ratio is not constant since it depends on n. Hence, the series $\sum_{n=3}^{\infty}\frac{1}{n^4}$ is not a geometric series.

(c) The ratio between two successive terms is

$$\frac{a_{n+1}}{a_n}=\frac{\frac{(n+1)^2}{2^{n+1}}}{\frac{n^2}{2^n}}=\frac{(n+1)^2}{n^2}\cdot\frac{2^n}{2^{n+1}}=\left(1+\frac{1}{n}\right)^2\cdot\frac{1}{2}.$$

This ratio is not constant since it depends on n. Hence, the series $\sum_{n=0}^{\infty}\frac{n^2}{2^n}$ is not a geometric series.

(d) $\sum_{n=5}^{\infty}\pi^{-n}=\sum_{n=5}^{\infty}\left(\frac{1}{\pi}\right)^n$: this is a geometric series with common ratio $r=\frac{1}{\pi}$.

38. Use the method of Example 8 to show that $\sum_{k=1}^{\infty}\frac{1}{k^{1/3}}$ diverges.

SOLUTION Each term in the Nth partial sum is greater than or equal to $\frac{1}{N^{\frac{1}{3}}}$, hence:

$$S_N=\frac{1}{1^{1/3}}+\frac{1}{2^{1/3}}+\frac{3}{3^{1/3}}+\cdots+\frac{1}{N^{1/3}}\geq\frac{1}{N^{1/3}}+\frac{1}{N^{1/3}}+\frac{1}{N^{1/3}}+\cdots+\frac{1}{N^{1/3}}=N\cdot\frac{1}{N^{1/3}}=N^{2/3}.$$

Since $\lim_{N\to\infty}N^{2/3}=\infty$, it follows that

$$\lim_{N\to\infty}S_N=\infty.$$

Thus, the series $\sum_{k=1}^{\infty}\frac{1}{k^{1/3}}$ diverges.

39. Prove that if $\sum_{n=1}^{\infty}a_n$ converges and $\sum_{n=1}^{\infty}b_n$ diverges, then $\sum_{n=1}^{\infty}(a_n+b_n)$ diverges. *Hint:* If not, derive a contradiction by writing

$$\sum_{n=1}^{\infty}b_n=\sum_{n=1}^{\infty}(a_n+b_n)-\sum_{n=1}^{\infty}a_n$$

SOLUTION Suppose to the contrary that $\sum_{n=1}^{\infty} a_n$ converges, $\sum_{n=1}^{\infty} b_n$ diverges, but $\sum_{n=1}^{\infty}(a_n + b_n)$ converges. Then by the Linearity of Infinite Series, we have

$$\sum_{n=1}^{\infty} b_n = \sum_{n=1}^{\infty}(a_n + b_n) - \sum_{n=1}^{\infty} a_n$$

so that $\sum_{n=1}^{\infty} b_n$ converges, a contradiction.

40. Prove the divergence of $\displaystyle\sum_{n=0}^{\infty} \frac{9^n + 2^n}{5^n}$.

SOLUTION Note that this is the sum of two infinite series:

$$\sum_{n=0}^{\infty} \frac{9^n + 2^n}{5^n} = \sum_{n=0}^{\infty} \frac{9^n}{5^n} + \sum_{n=0}^{\infty} \frac{2^n}{5^n}$$

The first of these is a geometric series with $r = \frac{9}{5} > 1$, so diverges, while the second is a geometric series with $r = \frac{2}{5} < 1$, so converges. By the previous exercise, the sum of the two also diverges.

41. Give a counterexample to show that each of the following statements is false.

(a) If the general term a_n tends to zero, then $\displaystyle\sum_{n=1}^{\infty} a_n = 0$.

(b) The Nth partial sum of the infinite series defined by $\{a_n\}$ is a_N.

(c) If a_n tends to zero, then $\displaystyle\sum_{n=1}^{\infty} a_n$ converges.

(d) If a_n tends to L, then $\displaystyle\sum_{n=1}^{\infty} a_n = L$.

SOLUTION

(a) Let $a_n = 2^{-n}$. Then $\lim_{n\to\infty} a_n = 0$, but a_n is a geometric series with $c = 2^0 = 1$ and $r = 1/2$, so its sum is $\dfrac{1}{1 - (1/2)} = 2$.

(b) Let $a_n = 1$. Then the n^{th} partial sum is $a_1 + a_2 + \cdots + a_n = n$ while $a_n = 1$.

(c) Let $a_n = \dfrac{1}{\sqrt{n}}$. An example in the text shows that while a_n tends to zero, the sum $\sum_{n=1}^{\infty} a_n$ does not converge.

(d) Let $a_n = 1$. Then clearly a_n tends to $L = 1$, while the series $\sum_{n=1}^{\infty} a_n$ obviously diverges.

42. Suppose that $S = \displaystyle\sum_{n=1}^{\infty} a_n$ is an infinite series with partial sum $S_N = 5 - \dfrac{2}{N^2}$.

(a) What are the values of $\displaystyle\sum_{n=1}^{10} a_n$ and $\displaystyle\sum_{n=5}^{16} a_n$?

(b) What is the value of a_3?

(c) Find a general formula for a_n.

(d) Find the sum $\displaystyle\sum_{n=1}^{\infty} a_n$.

SOLUTION

(a)

$$\sum_{n=1}^{10} a_n = S_{10} = 5 - \frac{2}{10^2} = \frac{249}{50};$$

$$\sum_{n=5}^{16} a_n = (a_1 + \cdots + a_{16}) - (a_1 + a_2 + a_3 + a_4) = S_{16} - S_4 = \left(5 - \frac{2}{16^2}\right) - \left(5 - \frac{2}{4^2}\right) = \frac{2}{16} - \frac{2}{256} = \frac{15}{128}.$$

(b)

$$a_3 = (a_1 + a_2 + a_3) - (a_1 + a_2) = S_3 - S_2 = \left(5 - \frac{2}{3^2}\right) - \left(5 - \frac{2}{2^2}\right) = \frac{1}{2} - \frac{2}{9} = \frac{5}{18}.$$

(c) Since $a_n = S_n - S_{n-1}$, we have:

$$a_n = S_n - S_{n-1} = \left(5 - \frac{2}{n^2}\right) - \left(5 - \frac{2}{(n-1)^2}\right) = \frac{2}{(n-1)^2} - \frac{2}{n^2}$$
$$= \frac{2\left(n^2 - (n-1)^2\right)}{(n(n-1))^2} = \frac{2\left(n^2 - n^2 + 2n - 1\right)}{(n(n-1))^2} = \frac{2(2n-1)}{n^2(n-1)^2}.$$

(d) The sum $\sum_{n=1}^{\infty} a_n$ is the limit of the sequence of partial sums $\{S_N\}$. Hence:

$$\sum_{n=1}^{\infty} a_n = \lim_{N\to\infty} S_N = \lim_{N\to\infty}\left(5 - \frac{2}{N^2}\right) = 5.$$

43. Compute the total area of the (infinitely many) triangles in Figure 4.

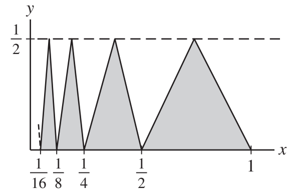


FIGURE 4

SOLUTION The area of a triangle with base B and height H is $A = \frac{1}{2}BH$. Because all of the triangles in Figure 4 have height $\frac{1}{2}$, the area of each triangle equals one-quarter of the base. Now, for $n \geq 0$, the nth triangle has a base which extends from $x = \frac{1}{2^{n+1}}$ to $x = \frac{1}{2^n}$. Thus,

$$B = \frac{1}{2^n} - \frac{1}{2^{n+1}} = \frac{1}{2^{n+1}} \quad \text{and} \quad A = \frac{1}{4}B = \frac{1}{2^{n+3}}.$$

The total area of the triangles is then given by the geometric series

$$\sum_{n=0}^{\infty} \frac{1}{2^{n+3}} = \sum_{n=0}^{\infty} \frac{1}{8}\left(\frac{1}{2}\right)^n = \frac{\frac{1}{8}}{1 - \frac{1}{2}} = \frac{1}{4}.$$

44. The winner of a lottery receives m dollars at the end of each year for N years. The present value (PV) of this prize in today's dollars is $\text{PV} = \sum_{i=1}^{N} m(1+r)^{-i}$, where r is the interest rate. Calculate PV if $m = \$50{,}000$, $r = 0.06$, and $N = 20$. What is PV if $N = \infty$?

SOLUTION For the given values r, m and N, we have

$$PV = \sum_{i=1}^{20} 50{,}000(1+0.06)^{-i} = \sum_{i=1}^{20} 50{,}000\left(\frac{50}{53}\right)^i = 50{,}000\frac{1 - \left(\frac{50}{53}\right)^{21}}{1 - \frac{50}{53}} = \$623{,}496.06.$$

If we extend the payments forever, then $N = \infty$ and

$$PV = \sum_{i=1}^{\infty} 50{,}000(1+0.06)^{-i} = \sum_{i=1}^{\infty} 50{,}000\left(\frac{50}{53}\right)^i = \frac{50{,}000\left(\frac{50}{53}\right)}{1 - \frac{50}{53}} = \$833{,}333.33.$$

45. Find the total length of the infinite zigzag path in Figure 5 (each zag occurs at an angle of $\frac{\pi}{4}$).

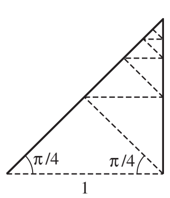

FIGURE 5

SOLUTION Because the angle at the lower left in Figure 5 has measure $\frac{\pi}{4}$ and each zag in the path occurs at an angle of $\frac{\pi}{4}$, every triangle in the figure is an isosceles right triangle. Accordingly, the length of each new segment in the path is $\frac{1}{\sqrt{2}}$ times the length of the previous segment. Since the first segment has length 1, the total length of the path is

$$\sum_{n=0}^{\infty}\left(\frac{1}{\sqrt{2}}\right)^n = \frac{1}{1-\frac{1}{\sqrt{2}}} = \frac{\sqrt{2}}{\sqrt{2}-1} = 2+\sqrt{2}.$$

46. Evaluate $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n(n+1)(n+2)}$. *Hint:* Find constants A, B, and C such that

$$\frac{1}{n(n+1)(n+2)} = \frac{A}{n} + \frac{B}{n+1} + \frac{C}{n+2}$$

SOLUTION By partial fraction decomposition

$$\frac{1}{n(n+1)(n+2)} = \frac{A}{n} + \frac{B}{n+1} + \frac{C}{n+2};$$

clearing denominators then gives

$$1 = A\,(n+1)\,(n+2) + Bn\,(n+2) + Cn\,(n+1)\,.$$

Setting $n=0$ now yields $A=\frac{1}{2}$, while setting $n=-1$ yields $B=-1$ and setting $n=-2$ yields $C=\frac{1}{2}$. Thus,

$$\frac{1}{n\,(n+1)\,(n+2)} = \frac{\frac{1}{2}}{n} - \frac{1}{n+1} + \frac{\frac{1}{2}}{n+2} = \frac{1}{2}\left(\frac{1}{n} - \frac{2}{n+1} + \frac{1}{n+2}\right),$$

and

$$\sum_{n=1}^{\infty}\frac{1}{n(n+1)(n+2)} = \sum_{n=1}^{\infty}\frac{1}{2}\left(\frac{1}{n} - \frac{2}{n+1} + \frac{1}{n+2}\right).$$

The general term of the sequence of partial sums for the series on the right-hand side is

$$\begin{aligned} S_N &= \frac{1}{2}\left(1-\frac{2}{2}+\frac{1}{3}\right) + \frac{1}{2}\left(\frac{1}{2}-\frac{2}{3}+\frac{1}{4}\right) + \frac{1}{2}\left(\frac{1}{3}-\frac{2}{4}+\frac{1}{5}\right) + \frac{1}{2}\left(\frac{1}{4}+\frac{2}{5}+\frac{1}{6}\right) + \frac{1}{2}\left(\frac{1}{5}-\frac{2}{6}+\frac{1}{7}\right) \\ &\quad + \cdots + \frac{1}{2}\left(\frac{1}{N-2}-\frac{2}{N-1}+\frac{1}{N}\right) + \frac{1}{2}\left(\frac{1}{N-1}-\frac{2}{N}+\frac{1}{N+1}\right) + \frac{1}{2}\left(\frac{1}{N}-\frac{2}{N+1}+\frac{1}{N+2}\right) \\ &= \frac{1}{2}\left(\frac{1}{2}-\frac{1}{N+1}+\frac{1}{N+2}\right). \end{aligned}$$

Thus,

$$\sum_{n=1}^{\infty}\frac{1}{n(n+1)(n+2)} = \lim_{N\to\infty} S_N = \lim_{N\to\infty}\frac{1}{2}\left(\frac{1}{2}-\frac{1}{N+1}+\frac{1}{N+2}\right) = \frac{1}{4}.$$

47. Show that if a is a positive integer, then

$$\sum_{n=1}^{\infty}\frac{1}{n(n+a)} = \frac{1}{a}\left(1+\frac{1}{2}+\cdots+\frac{1}{a}\right)$$

SOLUTION By partial fraction decomposition

$$\frac{1}{n\,(n+a)} = \frac{A}{n} + \frac{B}{n+a};$$

clearing the denominators gives

$$1 = A(n+a) + Bn.$$

Setting $n=0$ then yields $A=\frac{1}{a}$, while setting $n=-a$ yields $B=-\frac{1}{a}$. Thus,

$$\frac{1}{n\,(n+a)} = \frac{\frac{1}{a}}{n} - \frac{\frac{1}{a}}{n+a} = \frac{1}{a}\left(\frac{1}{n}-\frac{1}{n+a}\right),$$

and

$$\sum_{n=1}^{\infty} \frac{1}{n(n+a)} = \sum_{n=1}^{\infty} \frac{1}{a}\left(\frac{1}{n} - \frac{1}{n+a}\right).$$

For $N > a$, the Nth partial sum is

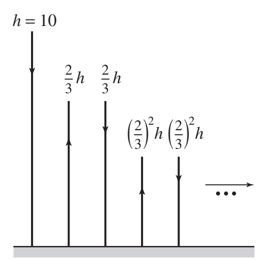
$$S_N = \frac{1}{a}\left(1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{a}\right) - \frac{1}{a}\left(\frac{1}{N+1} + \frac{1}{N+2} + \frac{1}{N+3} + \cdots + \frac{1}{N+a}\right).$$

Thus,

$$\sum_{n=1}^{\infty} \frac{1}{n(n+a)} = \lim_{N\to\infty} S_N = \frac{1}{a}\left(1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{a}\right).$$

48. A ball dropped from a height of 10 ft begins to bounce. Each time it strikes the ground, it returns to two-thirds of its previous height. What is the total distance traveled by the ball if it bounces infinitely many times?

SOLUTION The distance traveled by the ball is shown in the accompanying figure:



The total distance d traveled by the ball is given by the following infinite sum:

$$d = h + 2\cdot\frac{2}{3}h + 2\cdot\left(\frac{2}{3}\right)^2 h + 2\cdot\left(\frac{2}{3}\right)^3 h + \cdots = h + 2h\left(\frac{2}{3} + \left(\frac{2}{3}\right)^2 + \left(\frac{2}{3}\right)^3 + \cdots\right) = h + 2h\sum_{n=1}^{\infty}\left(\frac{2}{3}\right)^n.$$

We use the formula for the sum of a geometric series to compute the sum of the resulting series:

$$d = h + 2h \cdot \frac{\left(\frac{2}{3}\right)^1}{1 - \frac{2}{3}} = h + 2h(2) = 5h.$$

With $h = 10$ feet, it follows that the total distance traveled by the ball is 50 feet.

49. Let $\{b_n\}$ be a sequence and let $a_n = b_n - b_{n-1}$. Show that $\sum_{n=1}^{\infty} a_n$ converges if and only if $\lim_{n\to\infty} b_n$ exists.

SOLUTION Let $a_n = b_n - b_{n-1}$. The general term in the sequence of partial sums for the series $\sum_{n=1}^{\infty} a_n$ is then

$$S_N = (b_1 - b_0) + (b_2 - b_1) + (b_3 - b_2) + \cdots + (b_N - b_{N-1}) = b_N - b_0.$$

Now, if $\lim_{N\to\infty} b_N$ exists, then so does $\lim_{N\to\infty} S_N$ and $\sum_{n=1}^{\infty} a_n$ converges. On the other hand, if $\sum_{n=1}^{\infty} a_n$ converges, then $\lim_{N\to\infty} S_N$ exists, which implies that $\lim_{N\to\infty} b_N$ also exists. Thus, $\sum_{n=1}^{\infty} a_n$ converges if and only if $\lim_{n\to\infty} b_n$ exists.

50. Assumptions Matter Show, by giving counterexamples, that the assertions of Theorem 1 are not valid if the series $\sum_{n=0}^{\infty} a_n$ and $\sum_{n=0}^{\infty} b_n$ are not convergent.

SOLUTION Let $a_n = 2^{-n} - 2^n$ and $b_n = 2^n$. Then, both

$$\sum_{n=0}^{\infty} a_n \quad \text{and} \quad \sum_{n=0}^{\infty} b_n$$

diverge, so the sum

$$\sum_{n=0}^{\infty} a_n + \sum_{n=0}^{\infty} b_n$$

is not defined. However,

$$\sum_{n=0}^{\infty}(a_n + b_n) = \sum_{n=0}^{\infty}((2^{-n} - 2^n) + 2^n) = \sum_{n=0}^{\infty} 2^{-n} = 1.$$

Further Insights and Challenges

Exercises 51–53 use the formula

$$1 + r + r^2 + \cdots + r^{N-1} = \frac{1 - r^N}{1 - r} \qquad \boxed{7}$$

51. Professor George Andrews of Pennsylvania State University observed that we can use Eq. (7) to calculate the derivative of $f(x) = x^N$ (for $N \geq 0$). Assume that $a \neq 0$ and let $x = ra$. Show that

$$f'(a) = \lim_{x \to a} \frac{x^N - a^N}{x - a} = a^{N-1} \lim_{r \to 1} \frac{r^N - 1}{r - 1}$$

and evaluate the limit.

SOLUTION According to the definition of derivative of $f(x)$ at $x = a$

$$f'(a) = \lim_{x \to a} \frac{x^N - a^N}{x - a}.$$

Now, let $x = ra$. Then $x \to a$ if and only if $r \to 1$, and

$$f'(a) = \lim_{x \to a} \frac{x^N - a^N}{x - a} = \lim_{r \to 1} \frac{(ra)^N - a^N}{ra - a} = \lim_{r \to 1} \frac{a^N\left(r^N - 1\right)}{a(r - 1)} = a^{N-1} \lim_{r \to 1} \frac{r^N - 1}{r - 1}.$$

By Eq. (7) for a geometric sum,

$$\frac{1 - r^N}{1 - r} = \frac{r^N - 1}{r - 1} = 1 + r + r^2 + \cdots + r^{N-1},$$

so

$$\lim_{r \to 1} \frac{r^N - 1}{r - 1} = \lim_{r \to 1}\left(1 + r + r^2 + \cdots + r^{N-1}\right) = 1 + 1 + 1^2 + \cdots + 1^{N-1} = N.$$

Therefore, $f'(a) = a^{N-1} \cdot N = Na^{N-1}$

52. Pierre de Fermat used geometric series to compute the area under the graph of $f(x) = x^N$ over $[0, A]$. For $0 < r < 1$, let $F(r)$ be the sum of the areas of the infinitely many right-endpoint rectangles with endpoints Ar^n, as in Figure 6. As r tends to 1, the rectangles become narrower and $F(r)$ tends to the area under the graph.

(a) Show that $F(r) = A^{N+1}\dfrac{1 - r}{1 - r^{N+1}}$.

(b) Use Eq. (7) to evaluate $\displaystyle\int_0^A x^N\,dx = \lim_{r \to 1} F(r)$.

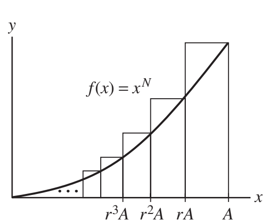


FIGURE 6

SOLUTION

(a) The area of the rectangle whose base extends from $x = r^n A$ to $x = r^{n-1}A$ is

$$(r^{n-1}A)^N(r^{n-1}A - r^n A).$$

Hence, $F(r)$ is the sum

$$F(r) = \sum_{n=1}^{\infty} \left(r^{n-1}A\right)^N \left(r^{n-1}A - r^n A\right) = \sum_{n=1}^{\infty} r^{(n-1)N} r^{n-1}(1-r)A^{N+1} = A^{N+1}(1-r)\sum_{n=1}^{\infty} r^{nN-N+n-1}$$

$$= \frac{A^{N+1}(1-r)}{r^{N+1}} \sum_{n=1}^{\infty} \left(r^{N+1}\right)^n = \frac{A^{N+1}(1-r)}{r^{N+1}} \cdot \frac{r^{N+1}}{1-r^{N+1}} = A^{N+1}\frac{1-r}{1-r^{N+1}}.$$

(b) Using the result from part (a) and Eq. (7) from Exercise 51,

$$\int_0^A x^N\,dx = \lim_{r\to 1} F(r) = A^{N+1} \lim_{r\to 1} \frac{1-r}{1-r^{N+1}} = A^{N+1} \lim_{r\to 1} \frac{1}{1+r+r^2+\cdots+r^N} = A^{N+1}\cdot\frac{1}{N+1} = \frac{A^{N+1}}{N+1}.$$

53. Verify the Gregory–Leibniz formula as follows.

(a) Set $r = -x^2$ in Eq. (7) and rearrange to show that

$$\frac{1}{1+x^2} = 1 - x^2 + x^4 - \cdots + (-1)^{N-1}x^{2N-2} + \frac{(-1)^N x^{2N}}{1+x^2}$$

(b) Show, by integrating over [0, 1], that

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots + \frac{(-1)^{N-1}}{2N-1} + (-1)^N \int_0^1 \frac{x^{2N}\,dx}{1+x^2}$$

(c) Use the Comparison Theorem for integrals to prove that

$$0 \le \int_0^1 \frac{x^{2N}\,dx}{1+x^2} \le \frac{1}{2N+1}$$

Hint: Observe that the integrand is $\le x^{2N}$.

(d) Prove that

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \cdots$$

Hint: Use (b) and (c) to show that the partial sums S_N of satisfy $\left|S_N - \frac{\pi}{4}\right| \le \frac{1}{2N+1}$, and thereby conclude that $\lim_{N\to\infty} S_N = \frac{\pi}{4}$.

SOLUTION

(a) Start with Eq. (7), and substitute $-x^2$ for r:

$$1 + r + r^2 + \cdots + r^{N-1} = \frac{1-r^N}{1-r}$$

$$1 - x^2 + x^4 + \cdots + (-1)^{N-1}x^{2N-2} = \frac{1-(-1)^N x^{2N}}{1-(-x^2)}$$

$$1 - x^2 + x^4 + \cdots + (-1)^{N-1}x^{2N-2} = \frac{1}{1+x^2} - \frac{(-1)^N x^{2N}}{1+x^2}$$

$$\frac{1}{1+x^2} = 1 - x^2 + x^4 + \cdots + (-1)^{N-1}x^{2N-2} + \frac{(-1)^N x^{2N}}{1+x^2}$$

(b) The integrals of both sides must be equal. Now,

$$\int_0^1 \frac{1}{1+x^2}\,dx = \tan^{-1} x\Big|_0^1 = \tan^{-1} 1 - \tan^{-1} 0 = \frac{\pi}{4}$$

while

$$\int_0^1 \left(1 - x^2 + x^4 + \cdots + (-1)^{N-1}x^{2N-2} + \frac{(-1)^N x^{2N}}{1+x^2}\right) dx$$

$$= \left(x - \frac{1}{3}x^3 + \frac{1}{5}x^5 + \cdots + (-1)^{N-1}\frac{1}{2N-1}x^{2N-1}\right) + (-1)^N \int_0^1 \frac{x^{2N}\,dx}{1+x^2}$$

$$= 1 - \frac{1}{3} + \frac{1}{5} + \cdots + (-1)^{N-1}\frac{1}{2N-1} + (-1)^N \int_0^1 \frac{x^{2N}\,dx}{1+x^2}$$

(c) Note that for $x \in [0, 1]$, we have $1 + x^2 \geq 1$, so that

$$0 \leq \frac{x^{2N}}{1+x^2} \leq x^{2N}$$

By the Comparison Theorem for integrals, we then see that

$$0 \leq \int_0^1 \frac{x^{2N}\,dx}{1+x^2} \leq \int_0^1 x^{2N}\,dx = \frac{1}{2N+1}x^{2N+1}\Big|_0^1 = \frac{1}{2N+1}$$

(d) Write

$$a_n = (-1)^n \frac{1}{2n-1}, \quad n \geq 1$$

and let S_N be the partial sums. Then

$$\left|S_N - \frac{\pi}{4}\right| = \left|(-1)^N \int_0^1 \frac{x^{2N}\,dx}{1+x^2}\right| = \int_0^1 \frac{x^{2N}\,dx}{1+x^2} \leq \frac{1}{2N+1}$$

Thus $\lim_{N\to\infty} S_N = \frac{\pi}{4}$ so that

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \dots$$

54. Cantor's Disappearing Table (following Larry Knop of Hamilton College) Take a table of length L (Figure 7). At stage 1, remove the section of length $L/4$ centered at the midpoint. Two sections remain, each with length less than $L/2$. At stage 2, remove sections of length $L/4^2$ from each of these two sections (this stage removes $L/8$ of the table). Now four sections remain, each of length less than $L/4$. At stage 3, remove the four central sections of length $L/4^3$, etc.

(a) Show that at the Nth stage, each remaining section has length less than $L/2^N$ and that the total amount of table removed is

$$L\left(\frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \cdots + \frac{1}{2^{N+1}}\right)$$

(b) Show that in the limit as $N \to \infty$, precisely one-half of the table remains.

This result is curious, because there are no nonzero intervals of table left (at each stage, the remaining sections have a length less than $L/2^N$). So the table has "disappeared." However, we can place any object longer than $L/4$ on the table. It will not fall through because it will not fit through any of the removed sections.

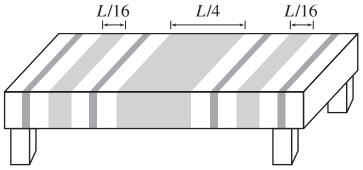

FIGURE 7

SOLUTION

(a) After the Nth stage, the total amount of table that has been removed is

$$\frac{L}{4} + \frac{2L}{4^2} + \frac{4L}{4^3} + \cdots + \frac{2^{N-1}L}{4^N} = L\left(\frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \cdots + \frac{2^{N-1}}{2^{2N}}\right) = L\left(\frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \cdots + \frac{1}{2^{N+1}}\right)$$

At the first stage ($N = 1$), there are two remaining sections each of length

$$\frac{L - \frac{L}{4}}{2} = \frac{3L}{8} < \frac{L}{2}.$$

Suppose that at the Kth stage, each of the 2^K remaining sections has length less than $\frac{L}{2^K}$. The $(K+1)$st stage is obtained by removing the section of length $\frac{L}{4^{K+1}}$ centered at the midpoint of each segment in the Kth stage. Let a_k and a_{K+1}, respectively, denote the length of each segment in the Kth and $(K+1)$st stage. Then,

$$a_{K+1} = \frac{a_K - \frac{L}{4^{K+1}}}{2} < \frac{\frac{L}{2^K} - \frac{L}{4^{K+1}}}{2} = \frac{L}{2^K}\left(\frac{1 - \frac{1}{2^{K+2}}}{2}\right) < \frac{L}{2^K}\cdot\frac{1}{2} = \frac{L}{2^{K+1}}.$$

Thus, by mathematical induction, each remaining section at the Nth stage has length less than $\frac{L}{2^N}$.

(b) From part (a), we know that after N stages, the amount of the table that has been removed is

$$L\left(\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+\cdots+\frac{1}{2^{N+1}}\right)=\sum_{n=1}^{N}\frac{1}{2^{n+1}}.$$

As $N\to\infty$, the amount of the table that has been removed becomes a geometric series whose sum is

$$L\sum_{n=1}^{\infty}\frac{1}{2}\left(\frac{1}{2}\right)^n=L\frac{\frac{1}{4}}{1-\frac{1}{2}}=\frac{1}{2}L.$$

Thus, the amount of table that remains is $L-\frac{1}{2}L=\frac{1}{2}L$.

55. The **Koch snowflake** (described in 1904 by Swedish mathematician Helge von Koch) is an infinitely jagged "fractal" curve obtained as a limit of polygonal curves (it is continuous but has no tangent line at any point). Begin with an equilateral triangle (stage 0) and produce stage 1 by replacing each edge with four edges of one-third the length, arranged as in Figure 8. Continue the process: At the nth stage, replace each edge with four edges of one-third the length.

(a) Show that the perimeter P_n of the polygon at the nth stage satisfies $P_n=\frac{4}{3}P_{n-1}$. Prove that $\lim_{n\to\infty}P_n=\infty$. The snowflake has infinite length.

(b) Let A_0 be the area of the original equilateral triangle. Show that $(3)4^{n-1}$ new triangles are added at the nth stage, each with area $A_0/9^n$ (for $n\geq 1$). Show that the total area of the Koch snowflake is $\frac{8}{5}A_0$.

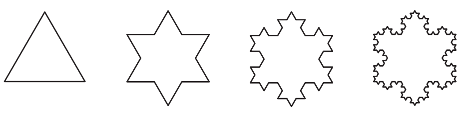

FIGURE 8

SOLUTION

(a) Each edge of the polygon at the $(n-1)$st stage is replaced by four edges of one-third the length; hence the perimeter of the polygon at the nth stage is $\frac{4}{3}$ times the perimeter of the polygon at the $(n-1)$th stage. That is, $P_n=\frac{4}{3}P_{n-1}$. Thus,

$$P_1=\frac{4}{3}P_0;\quad P_2=\frac{4}{3}P_1=\left(\frac{4}{3}\right)^2P_0,\quad P_3=\frac{4}{3}P_2=\left(\frac{4}{3}\right)^3P_0,$$

and, in general, $P_n=\left(\frac{4}{3}\right)^nP_0$. As $n\to\infty$, it follows that

$$\lim_{n\to\infty}P_n=P_0\lim_{n\to\infty}\left(\frac{4}{3}\right)^n=\infty.$$

(b) When each edge is replaced by four edges of one-third the length, one new triangle is created. At the $(n-1)$st stage, there are $3\cdot 4^{n-1}$ edges in the snowflake, so $3\cdot 4^{n-1}$ new triangles are generated at the nth stage. Because the area of an equilateral triangle is proportional to the square of its side length and the side length for each new triangle is one-third the side length of triangles from the previous stage, it follows that the area of the triangles added at each stage is reduced by a factor of $\frac{1}{9}$ from the area of the triangles added at the previous stage. Thus, each triangle added at the nth stage has an area of $A_0/9^n$. This means that the nth stage contributes

$$3\cdot 4^{n-1}\cdot\frac{A_0}{9^n}=\frac{3}{4}A_0\left(\frac{4}{9}\right)^n$$

to the area of the snowflake. The total area is therefore

$$A=A_0+\frac{3}{4}A_0\sum_{n=1}^{\infty}\left(\frac{4}{9}\right)^n=A_0+\frac{3}{4}A_0\frac{\frac{4}{9}}{1-\frac{4}{9}}=A_0+\frac{3}{4}A_0\cdot\frac{4}{5}=\frac{8}{5}A_0.$$

10.3 Convergence of Series with Positive Terms

Preliminary Questions

1. Let $S=\sum_{n=1}^{\infty}a_n$. If the partial sums S_N are increasing, then (choose the correct conclusion):

(a) $\{a_n\}$ is an increasing sequence.

(b) $\{a_n\}$ is a positive sequence.

SOLUTION The correct response is **(b)**. Recall that $S_N = a_1 + a_2 + a_3 + \cdots + a_N$; thus, $S_N - S_{N-1} = a_N$. If S_N is increasing, then $S_N - S_{N-1} \ge 0$. It then follows that $a_N \ge 0$; that is, $\{a_n\}$ is a positive sequence.

2. What are the hypotheses of the Integral Test?

SOLUTION The hypotheses for the Integral Test are: A function $f(x)$ such that $a_n = f(n)$ must be positive, decreasing, and continuous for $x \ge 1$.

3. Which test would you use to determine whether $\sum_{n=1}^{\infty} n^{-3.2}$ converges?

SOLUTION Because $n^{-3.2} = \frac{1}{n^{3.2}}$, we see that the indicated series is a p-series with $p = 3.2 > 1$. Therefore, the series converges.

4. Which test would you use to determine whether $\sum_{n=1}^{\infty} \frac{1}{2^n + \sqrt{n}}$ converges?

SOLUTION Because

$$\frac{1}{2^n + \sqrt{n}} < \frac{1}{2^n} = \left(\frac{1}{2}\right)^n,$$

and

$$\sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^n$$

is a convergent geometric series, the comparison test would be an appropriate choice to establish that the given series converges.

5. Ralph hopes to investigate the convergence of $\sum_{n=1}^{\infty} \frac{e^{-n}}{n}$ by comparing it with $\sum_{n=1}^{\infty} \frac{1}{n}$. Is Ralph on the right track?

SOLUTION No, Ralph is not on the right track. For $n \ge 1$,

$$\frac{e^{-n}}{n} < \frac{1}{n};$$

however, $\sum_{n=1}^{\infty} \frac{1}{n}$ is a divergent series. The Comparison Test therefore does not allow us to draw a conclusion about the convergence or divergence of the series $\sum_{n=1}^{\infty} \frac{e^{-n}}{n}$.

Exercises

In Exercises 1–14, use the Integral Test to determine whether the infinite series is convergent.

1. $\sum_{n=1}^{\infty} \frac{1}{n^4}$

SOLUTION Let $f(x) = \frac{1}{x^4}$. This function is continuous, positive and decreasing on the interval $x \ge 1$, so the Integral Test applies. Moreover,

$$\int_1^{\infty} \frac{dx}{x^4} = \lim_{R\to\infty} \int_1^R x^{-4}\,dx = -\frac{1}{3} \lim_{R\to\infty} \left(\frac{1}{R^3} - 1\right) = \frac{1}{3}.$$

The integral converges; hence, the series $\sum_{n=1}^{\infty} \frac{1}{n^4}$ also converges.

2. $\sum_{n=1}^{\infty} \frac{1}{n+3}$

SOLUTION Let $f(x) = \frac{1}{x+3}$. This function is continuous, positive and decreasing on the interval $x \ge 1$, so the Integral Test applies. Moreover,

$$\int_1^{\infty} \frac{dx}{x+3} = \lim_{R\to\infty} \int_1^R \frac{dx}{x+3} = \lim_{R\to\infty} (\ln(R+3) - \ln 4) = \infty.$$

The integral diverges; hence, the series $\sum_{n=1}^{\infty} \frac{1}{n+3}$ also diverges.

3. $\displaystyle\sum_{n=1}^{\infty} n^{-1/3}$

SOLUTION Let $f(x) = x^{-\frac{1}{3}} = \dfrac{1}{\sqrt[3]{x}}$. This function is continuous, positive and decreasing on the interval $x \ge 1$, so the Integral Test applies. Moreover,

$$\int_1^{\infty} x^{-1/3}\,dx = \lim_{R\to\infty}\int_1^R x^{-1/3}\,dx = \frac{3}{2}\lim_{R\to\infty}\left(R^{2/3}-1\right) = \infty.$$

The integral diverges; hence, the series $\displaystyle\sum_{n=1}^{\infty} n^{-1/3}$ also diverges.

4. $\displaystyle\sum_{n=5}^{\infty} \frac{1}{\sqrt{n-4}}$

SOLUTION Let $f(x) = \dfrac{1}{\sqrt{x-4}}$. This function is continuous, positive and decreasing on the interval $x \ge 5$, so the Integral Test applies. Moreover,

$$\int_5^{\infty} \frac{dx}{\sqrt{x-4}} = \lim_{R\to\infty}\int_5^R \frac{dx}{\sqrt{x-4}} = 2\lim_{R\to\infty}\left(\sqrt{R-4}-1\right) = \infty.$$

The integral diverges; hence, the series $\displaystyle\sum_{n=5}^{\infty} \frac{1}{\sqrt{n-4}}$ also diverges.

5. $\displaystyle\sum_{n=25}^{\infty} \frac{n^2}{(n^3+9)^{5/2}}$

SOLUTION Let $f(x) = \dfrac{x^2}{\left(x^3+9\right)^{5/2}}$. This function is positive and continuous for $x \ge 25$. Moreover, because

$$f'(x) = \frac{2x(x^3+9)^{5/2} - x^2\cdot\frac{5}{2}(x^3+9)^{3/2}\cdot 3x^2}{(x^3+9)^5} = \frac{x(36-11x^3)}{2(x^3+9)^{7/2}},$$

we see that $f'(x) < 0$ for $x \ge 25$, so f is decreasing on the interval $x \ge 25$. The Integral Test therefore applies. To evaluate the improper integral, we use the substitution $u = x^3+9$, $du = 3x^2dx$. We then find

$$\int_{25}^{\infty} \frac{x^2}{(x^3+9)^{5/2}}\,dx = \lim_{R\to\infty}\int_{25}^R \frac{x^2}{(x^3+9)^{5/2}}\,dx = \frac{1}{3}\lim_{R\to\infty}\int_{15634}^{R^3+9}\frac{du}{u^{5/2}}$$
$$= -\frac{2}{9}\lim_{R\to\infty}\left(\frac{1}{(R^3+9)^{3/2}} - \frac{1}{15634^{3/2}}\right) = \frac{2}{9\cdot 15634^{3/2}}.$$

The integral converges; hence, the series $\displaystyle\sum_{n=25}^{\infty} \frac{n^2}{\left(n^3+9\right)^{5/2}}$ also converges.

6. $\displaystyle\sum_{n=1}^{\infty} \frac{n}{(n^2+1)^{3/5}}$

SOLUTION Let $f(x) = \dfrac{x}{(x^2+1)^{3/5}}$. Because

$$f'(x) = \frac{(x^2+1)^{3/5} - x\cdot\frac{6}{5}x(x^2+1)^{-2/5}}{(x^2+1)^{6/5}} = \frac{1-\frac{1}{5}x^2}{(x^2+1)^{8/5}},$$

we see that $f'(x) < 0$ for $x > \sqrt{5} \approx 2.236$. We conclude that f is decreasing on the interval $x \ge 3$. Since f is also positive and continuous on this interval, the Integral Test can be applied. To evaluate the improper integral, we make the substitution $u = x^2+1$, $du = 2x\,dx$. This gives

$$\int_3^{\infty} \frac{x}{(x^2+1)^{3/5}}\,dx = \lim_{R\to\infty}\int_3^R \frac{x}{(x^2+1)^{3/5}}\,dx = \frac{1}{2}\lim_{R\to\infty}\int_{10}^{R^2+1}\frac{du}{u^{3/5}} = \frac{5}{4}\lim_{R\to\infty}\left((R^2+1)^{2/5} - 10^{2/5}\right) = \infty.$$

The integral diverges; therefore, the series $\sum_{n=3}^{\infty} \frac{n}{(n^2+1)^{3/5}}$ also diverges. Since the divergence of the series is not affected by adding the finite sum $\sum_{n=1}^{2} \frac{n}{(n^2+1)^{3/5}}$, the series $\sum_{n=1}^{\infty} \frac{n}{(n^2+1)^{3/5}}$ also diverges.

7. $\sum_{n=1}^{\infty} \frac{1}{n^2+1}$

SOLUTION Let $f(x) = \frac{1}{x^2+1}$. This function is positive, decreasing and continuous on the interval $x \geq 1$, hence the Integral Test applies. Moreover,

$$\int_1^{\infty} \frac{dx}{x^2+1} = \lim_{R\to\infty} \int_1^R \frac{dx}{x^2+1} = \lim_{R\to\infty} \left(\tan^{-1} R - \frac{\pi}{4}\right) = \frac{\pi}{2} - \frac{\pi}{4} = \frac{\pi}{4}.$$

The integral converges; hence, the series $\sum_{n=1}^{\infty} \frac{1}{n^2+1}$ also converges.

8. $\sum_{n=4}^{\infty} \frac{1}{n^2-1}$

SOLUTION Let $f(x) = \frac{1}{x^2-1}$.This function is continuous, positive and decreasing on the interval $x \geq 4$; therefore, the Integral Test applies. We compute the improper integral using partial fractions:

$$\int_4^{\infty} \frac{dx}{x^2-1} = \lim_{R\to\infty} \int_4^R \left(\frac{\frac{1}{2}}{x-1} - \frac{\frac{1}{2}}{x+1}\right) dx = \frac{1}{2} \lim_{R\to\infty} \ln \frac{x-1}{x+1}\bigg|_4^R = \frac{1}{2} \lim_{R\to\infty} \left(\ln \frac{R-1}{R+1} - \ln \frac{3}{5}\right)$$

$$= \frac{1}{2}\left(\ln 1 - \ln \frac{3}{5}\right) = -\frac{1}{2} \ln \frac{3}{5}.$$

The integral converges; hence, the series $\sum_{n=4}^{\infty} \frac{1}{n^2-1}$ also converges.

9. $\sum_{n=1}^{\infty} \frac{1}{n(n+1)}$

SOLUTION Let $f(x) = \frac{1}{x(x+1)}$. This function is positive, continuous and decreasing on the interval $x \geq 1$, so the Integral Test applies. We compute the improper integral using partial fractions:

$$\int_1^{\infty} \frac{dx}{x(x+1)} = \lim_{R\to\infty} \int_1^R \left(\frac{1}{x} - \frac{1}{x+1}\right) dx = \lim_{R\to\infty} \ln \frac{x}{x+1}\bigg|_1^R = \lim_{R\to\infty} \left(\ln \frac{R}{R+1} - \ln \frac{1}{2}\right) = \ln 1 - \ln \frac{1}{2} = \ln 2.$$

The integral converges; hence, the series $\sum_{n=1}^{\infty} \frac{1}{n(n+1)}$ converges.

10. $\sum_{n=1}^{\infty} ne^{-n^2}$

SOLUTION Let $f(x) = xe^{-x^2}$. This function is continuous and positive on the interval $x \geq 1$. Moreover, because

$$f'(x) = 1 \cdot e^{-x^2} + x \cdot e^{-x^2} \cdot (-2x) = e^{-x^2}\left(1 - 2x^2\right),$$

we see that $f'(x) < 0$ for $x \geq 1$, so f is decreasing on this interval. To compute the improper integral we make the substitution $u = x^2$, $du = 2x\,dx$. Then, we find

$$\int_1^{\infty} xe^{-x^2}\,dx = \lim_{R\to\infty} \int_1^R xe^{-x^2}\,dx = \frac{1}{2}\int_1^{R^2} e^{-u}\,du = -\frac{1}{2} \lim_{R\to\infty} \left(e^{-R^2} - e^{-1}\right) = \frac{1}{2e}.$$

The integral converges; hence, the series $\sum_{n=1}^{\infty} ne^{-n^2}$ also converges.

11. $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^2}$

SOLUTION Let $f(x) = \dfrac{1}{x(\ln x)^2}$. This function is positive and continuous for $x \geq 2$. Moreover,

$$f'(x) = -\frac{1}{x^2(\ln x)^4}\left(1 \cdot (\ln x)^2 + x \cdot 2(\ln x) \cdot \frac{1}{x}\right) = -\frac{1}{x^2(\ln x)^4}\left((\ln x)^2 + 2\ln x\right).$$

Since $\ln x > 0$ for $x > 1$, $f'(x)$ is negative for $x > 1$; hence, f is decreasing for $x \geq 2$. To compute the improper integral, we make the substitution $u = \ln x$, $du = \frac{1}{x}\,dx$. We obtain:

$$\int_2^{\infty} \frac{1}{x(\ln x)^2}\,dx = \lim_{R\to\infty} \int_2^R \frac{1}{x(\ln x)^2}\,dx = \lim_{R\to\infty} \int_{\ln 2}^{\ln R} \frac{du}{u^2}$$
$$= -\lim_{R\to\infty}\left(\frac{1}{\ln R} - \frac{1}{\ln 2}\right) = \frac{1}{\ln 2}.$$

The integral converges; hence, the series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^2}$ also converges.

12. $\displaystyle\sum_{n=1}^{\infty} \frac{\ln n}{n^2}$

SOLUTION Let $f(x) = \dfrac{\ln x}{x^2}$. Because

$$f'(x) = \frac{\frac{1}{x} \cdot x^2 - 2x\ln x}{x^4} = \frac{x(1 - 2\ln x)}{x^4} = \frac{1 - 2\ln x}{x^3},$$

we see that $f'(x) < 0$ for $x > \sqrt{e} \approx 1.65$. We conclude that f is decreasing on the interval $x \geq 2$. Since f is also positive and continuous on this interval, the Integral Test can be applied. By Integration by Parts, we find

$$\int \frac{\ln x}{x^2}\,dx = -\frac{\ln x}{x} + \int x^{-2}\,dx = -\frac{\ln x}{x} - \frac{1}{x} + C;$$

therefore,

$$\int_2^{\infty} \frac{\ln x}{x^2}\,dx = \lim_{R\to\infty} \int_2^R \frac{\ln x}{x^2}\,dx = \lim_{R\to\infty}\left(\frac{1}{2} + \frac{\ln 2}{2} - \frac{1}{R} - \frac{\ln R}{R}\right) = \frac{1 + \ln 2}{2} - \lim_{R\to\infty} \frac{\ln R}{R}.$$

We compute the resulting limit using L'Hôpital's Rule:

$$\lim_{R\to\infty} \frac{\ln R}{R} = \lim_{R\to\infty} \frac{1/R}{1} = 0.$$

Hence,

$$\int_2^{\infty} \frac{\ln x}{x^2}\,dx = \frac{1 + \ln 2}{2}.$$

The integral converges; therefore, the series $\displaystyle\sum_{n=2}^{\infty} \frac{\ln n}{n^2}$ also converges. Since the convergence of the series is not affected by adding the finite sum $\displaystyle\sum_{n=1}^{1} \frac{\ln n}{n^2}$, the series $\displaystyle\sum_{n=1}^{\infty} \frac{\ln n}{n^2}$ also converges.

13. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{2^{\ln n}}$

SOLUTION Note that

$$2^{\ln n} = (e^{\ln 2})^{\ln n} = (e^{\ln n})^{\ln 2} = n^{\ln 2}.$$

Thus,

$$\sum_{n=1}^{\infty} \frac{1}{2^{\ln n}} = \sum_{n=1}^{\infty} \frac{1}{n^{\ln 2}}.$$

Now, let $f(x) = \dfrac{1}{x^{\ln 2}}$. This function is positive, continuous and decreasing on the interval $x \geq 1$; therefore, the Integral Test applies. Moreover,

$$\int_1^\infty \frac{dx}{x^{\ln 2}} = \lim_{R\to\infty} \int_1^R \frac{dx}{x^{\ln 2}} = \frac{1}{1-\ln 2} \lim_{R\to\infty} (R^{1-\ln 2} - 1) = \infty,$$

because $1 - \ln 2 > 0$. The integral diverges; hence, the series $\sum_{n=1}^{\infty} \dfrac{1}{2^{\ln n}}$ also diverges.

14. $\sum_{n=1}^{\infty} \dfrac{1}{3^{\ln n}}$

SOLUTION Note that

$$3^{\ln n} = (e^{\ln 3})^{\ln n} = (e^{\ln n})^{\ln 3} = n^{\ln 3}.$$

Thus,

$$\sum_{n=1}^{\infty} \frac{1}{3^{\ln n}} = \sum_{n=1}^{\infty} \frac{1}{n^{\ln 3}}.$$

Now, let $f(x) = \dfrac{1}{x^{\ln 3}}$. This function is positive, continuous and decreasing on the interval $x \geq 1$; therefore, the Integral Test applies. Moreover,

$$\int_1^\infty \frac{dx}{x^{\ln 3}} = \lim_{R\to\infty} \int_1^R \frac{dx}{x^{\ln 3}} = \frac{1}{1-\ln 3} \lim_{R\to\infty} (R^{1-\ln 3} - 1) = -\frac{1}{1-\ln 3},$$

because $1 - \ln 3 < 0$. The integral converges; hence, the series $\sum_{n=1}^{\infty} \dfrac{1}{3^{\ln n}}$ also converges.

15. Show that $\sum_{n=1}^{\infty} \dfrac{1}{n^3 + 8n}$ converges by using the Comparison Test with $\sum_{n=1}^{\infty} n^{-3}$.

SOLUTION We compare the series with the p-series $\sum_{n=1}^{\infty} n^{-3}$. For $n \geq 1$,

$$\frac{1}{n^3 + 8n} \leq \frac{1}{n^3}.$$

Since $\sum_{n=1}^{\infty} \dfrac{1}{n^3}$ converges (it is a p-series with $p = 3 > 1$), the series $\sum_{n=1}^{\infty} \dfrac{1}{n^3 + 8n}$ also converges by the Comparison Test.

16. Show that $\sum_{n=2}^{\infty} \dfrac{1}{\sqrt{n^2 - 3}}$ diverges by comparing with $\sum_{n=2}^{\infty} n^{-1}$.

SOLUTION For $n \geq 2$,

$$\frac{1}{\sqrt{n^2 - 3}} \geq \frac{1}{\sqrt{n^2}} = \frac{1}{n}.$$

The harmonic series $\sum_{n=1}^{\infty} \dfrac{1}{n}$ diverges, and it still diverges if we drop the first term. Thus, the series $\sum_{n=2}^{\infty} \dfrac{1}{n}$ also diverges. The Comparison Test now lets us conclude that the larger series $\sum_{n=2}^{\infty} \dfrac{1}{\sqrt{n^2 - 3}}$ also diverges.

17. Let $S = \sum_{n=1}^{\infty} \dfrac{1}{n + \sqrt{n}}$. Verify that for $n \geq 1$,

$$\frac{1}{n + \sqrt{n}} \leq \frac{1}{n}, \qquad \frac{1}{n + \sqrt{n}} \leq \frac{1}{\sqrt{n}}$$

Can either inequality be used to show that S diverges? Show that $\dfrac{1}{n + \sqrt{n}} \geq \dfrac{1}{2n}$ and conclude that S diverges.

SOLUTION For $n \ge 1$, $n + \sqrt{n} \ge n$ and $n + \sqrt{n} \ge \sqrt{n}$. Taking the reciprocal of each of these inequalities yields

$$\frac{1}{n+\sqrt{n}} \le \frac{1}{n} \quad \text{and} \quad \frac{1}{n+\sqrt{n}} \le \frac{1}{\sqrt{n}}.$$

These inequalities indicate that the series $\sum_{n=1}^{\infty} \frac{1}{n+\sqrt{n}}$ is smaller than both $\sum_{n=1}^{\infty} \frac{1}{n}$ and $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$; however, $\sum_{n=1}^{\infty} \frac{1}{n}$ and $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ both diverge so neither inequality allows us to show that S diverges.

On the other hand, for $n \ge 1$, $n \ge \sqrt{n}$, so $2n \ge n + \sqrt{n}$ and

$$\frac{1}{n+\sqrt{n}} \ge \frac{1}{2n}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{2n} = 2\sum_{n=1}^{\infty} \frac{1}{n}$ diverges, since the harmonic series diverges. The Comparison Test then lets us conclude that the larger series $\sum_{n=1}^{\infty} \frac{1}{n+\sqrt{n}}$ also diverges.

18. Which of the following inequalities can be used to study the convergence of $\sum_{n=2}^{\infty} \frac{1}{n^2+\sqrt{n}}$? Explain.

$$\frac{1}{n^2+\sqrt{n}} \le \frac{1}{\sqrt{n}}, \qquad \frac{1}{n^2+\sqrt{n}} \le \frac{1}{n^2}$$

SOLUTION The series $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ is a divergent p-series, hence the series $\sum_{n=2}^{\infty} \frac{1}{\sqrt{n}}$ also diverges. The first inequality given above therefore establishes that $\sum_{n=2}^{\infty} \frac{1}{n^2+\sqrt{n}}$ is smaller than a divergent series, which does not allow us to conclude whether $\sum_{n=2}^{\infty} \frac{1}{n^2+\sqrt{n}}$ converges or diverges.

However, the second inequality given above establishes that $\sum_{n=2}^{\infty} \frac{1}{n^2+\sqrt{n}}$ is smaller than the convergent p-series $\sum_{n=2}^{\infty} \frac{1}{n^2}$. By the Comparison Test, we therefore conclude that $\sum_{n=2}^{\infty} \frac{1}{n^2+\sqrt{n}}$ also converges.

In Exercises 19–30, use the Comparison Test to determine whether the infinite series is convergent.

19. $\sum_{n=1}^{\infty} \frac{1}{n2^n}$

SOLUTION We compare with the geometric series $\sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^n$. For $n \ge 1$,

$$\frac{1}{n2^n} \le \frac{1}{2^n} = \left(\frac{1}{2}\right)^n.$$

Since $\sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^n$ converges (it is a geometric series with $r = \frac{1}{2}$), we conclude by the Comparison Test that $\sum_{n=1}^{\infty} \frac{1}{n2^n}$ also converges.

20. $\sum_{n=1}^{\infty} \frac{n^3}{n^5+4n+1}$

SOLUTION For $n \ge 1$,

$$\frac{n^3}{n^5+4n+1} \le \frac{n^3}{n^5} = \frac{1}{n^2}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a p-series with $p = 2 > 1$, so it converges. By the Comparison Test we can therefore conclude that the series $\sum_{n=1}^{\infty} \frac{n^3}{n^5 + 4n + 1}$ also converges.

21. $\sum_{n=1}^{\infty} \frac{1}{n^{1/3} + 2^n}$

SOLUTION For $n \geq 1$,

$$\frac{1}{n^{1/3} + 2^n} \leq \frac{1}{2^n}$$

The series $\sum_{n=1}^{\infty} \frac{1}{2^n}$ is a geometric series with $r = \frac{1}{2}$, so it converges. By the Comparison test, so does $\sum_{n=1}^{\infty} \frac{1}{n^{1/3} + 2^n}$.

22. $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n^3 + 2n - 1}}$

SOLUTION For $n \geq 1$, we have $2n - 1 \geq 0$ so that

$$\frac{1}{\sqrt{n^3 + 2n - 1}} \leq \frac{1}{\sqrt{n^3}} = \frac{1}{n^{3/2}}.$$

This latter series is a p-series with $p = \frac{3}{2} > 1$, so it converges. By the Comparison Test, so does $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n^3 + 2n - 1}}$.

23. $\sum_{m=1}^{\infty} \frac{4}{m! + 4^m}$

SOLUTION For $m \geq 1$,

$$\frac{4}{m! + 4^m} \leq \frac{4}{4^m} = \left(\frac{1}{4}\right)^{m-1}.$$

The series $\sum_{m=1}^{\infty} \left(\frac{1}{4}\right)^{m-1}$ is a geometric series with $r = \frac{1}{4}$, so it converges. By the Comparison Test we can therefore conclude that the series $\sum_{m=1}^{\infty} \frac{4}{m! + 4^m}$ also converges.

24. $\sum_{n=4}^{\infty} \frac{\sqrt{n}}{n - 3}$

SOLUTION For $n \geq 4$,

$$\frac{\sqrt{n}}{n - 3} \geq \frac{\sqrt{n}}{n} = \frac{1}{n^{1/2}}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^{1/2}}$ is a p-series with $p = \frac{1}{2} < 1$, so it diverges, and it continues to diverge if we drop the terms $n = 1, 2, 3$; that is, $\sum_{n=4}^{\infty} \frac{1}{n^{1/2}}$ also diverges. By the Comparison Test we can therefore conclude that series $\sum_{n=4}^{\infty} \frac{\sqrt{n}}{n - 3}$ diverges.

25. $\sum_{k=1}^{\infty} \frac{\sin^2 k}{k^2}$

SOLUTION For $k \geq 1$, $0 \leq \sin^2 k \leq 1$, so

$$0 \leq \frac{\sin^2 k}{k^2} \leq \frac{1}{k^2}.$$

The series $\sum_{k=1}^{\infty} \frac{1}{k^2}$ is a p-series with $p = 2 > 1$, so it converges. By the Comparison Test we can therefore conclude that the series $\sum_{k=1}^{\infty} \frac{\sin^2 k}{k^2}$ also converges.

26. $\displaystyle\sum_{k=2}^{\infty} \frac{k^{1/3}}{k^{5/4} - k}$

SOLUTION For $k \geq 2$, $k^{5/4} - k < k^{5/4}$ so that

$$\frac{k^{1/3}}{k^{5/4} - k} \geq \frac{k^{1/3}}{k^{5/4}} = \frac{1}{k^{11/12}}$$

The series $\sum_{k=2}^{\infty} \frac{1}{k^{11/12}}$ is a p-series with $p = \frac{11}{12} < 1$, so it diverges. By the Comparison Test, so does $\displaystyle\sum_{k=2}^{\infty} \frac{k^{1/3}}{k^{5/4} - k}$.

27. $\displaystyle\sum_{n=1}^{\infty} \frac{2}{3^n + 3^{-n}}$

SOLUTION Since $3^{-n} > 0$ for all n,

$$\frac{2}{3^n + 3^{-n}} \leq \frac{2}{3^n} = 2\left(\frac{1}{3}\right)^n.$$

The series $\displaystyle\sum_{n=1}^{\infty} 2\left(\frac{1}{3}\right)^n$ is a geometric series with $r = \frac{1}{3}$, so it converges. By the Comparison Theorem we can therefore conclude that the series $\displaystyle\sum_{n=1}^{\infty} \frac{2}{3^n + 3^{-n}}$ also converges.

28. $\displaystyle\sum_{k=1}^{\infty} 2^{-k^2}$

SOLUTION For $k \geq 1$, $k^2 \geq k$ and

$$\frac{1}{2^{k^2}} \leq \frac{1}{2^k} = \left(\frac{1}{2}\right)^k.$$

The series $\displaystyle\sum_{k=1}^{\infty} \left(\frac{1}{2}\right)^k$ is a geometric series with $r = \frac{1}{2}$, so it converges. By the Comparison Test we can therefore conclude that the series $\displaystyle\sum_{k=1}^{\infty} \frac{1}{2^{k^2}} = \sum_{k=1}^{\infty} 2^{-k^2}$ also converges.

29. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{(n+1)!}$

SOLUTION Note that for $n \geq 2$,

$$(n+1)! = 1 \cdot \underbrace{2 \cdot 3 \cdots n \cdot (n+1)}_{n \text{ factors}} \leq 2^n$$

so that

$$\sum_{n=1}^{\infty} \frac{1}{(n+1)!} = 1 + \sum_{n=2}^{\infty} \frac{1}{(n+1)!} \leq 1 + \sum_{n=2}^{\infty} \frac{1}{2^n}$$

But $\sum_{n=2}^{\infty} \frac{1}{2^n}$ is a geometric series with ratio $r = \frac{1}{2}$, so it converges. By the comparison test, $\displaystyle\sum_{n=1}^{\infty} \frac{1}{(n+1)!}$ converges as well.

30. $\displaystyle\sum_{n=1}^{\infty} \frac{n!}{n^3}$

SOLUTION Note that for $n \geq 4$, we have $(n-1)(n-2) > n$ [to see this, solve the equation $(n-1)(n-2) = n$ for n; the positive root is $2 + \sqrt{2} \approx 3.4$]. Thus

$$\sum_{n=4}^{\infty} \frac{n!}{n^3} = \sum_{n=4}^{\infty} \frac{n(n-1)(n-2)(n-3)!}{n^3} \geq \sum_{n=4}^{\infty} \frac{(n-3)!}{n} \geq \sum_{n=4}^{\infty} \frac{1}{n}$$

But $\sum_{n=4}^{\infty} \frac{1}{n}$ is the harmonic series, which diverges, so that $\sum_{n=4}^{\infty} \frac{n!}{n^3}$ also diverges. Adding back in the terms for $n = 1$, 2, and 3 does not affect this result. Thus the original series diverges.

Exercise 31–36: For all $a > 0$ and $b > 1$, the inequalities

$$\ln n \le n^a, \qquad n^a < b^n$$

are true for n sufficiently large (this can be proved using L'Hopital's Rule). Use this, together with the Comparison Theorem, to determine whether the series converges or diverges.

31. $\displaystyle\sum_{n=1}^{\infty} \frac{\ln n}{n^3}$

SOLUTION For n sufficiently large (say $n = k$, although in this case $n = 1$ suffices), we have $\ln n \le n$, so that

$$\sum_{n=k}^{\infty} \frac{\ln n}{n^3} \le \sum_{n=k}^{\infty} \frac{n}{n^3} = \sum_{n=k}^{\infty} \frac{1}{n^2}$$

This is a p-series with $p = 2 > 1$, so it converges. Thus $\sum_{n=k}^{\infty} \frac{\ln n}{n^3}$ also converges; adding back in the finite number of terms for $1 \le n \le k$ does not affect this result.

32. $\displaystyle\sum_{m=2}^{\infty} \frac{1}{\ln m}$

SOLUTION For $m > 1$ sufficiently large (say $m = k$, although in this case $m = 2$ suffices), we have $\ln m \le m$, so that

$$\sum_{m=k}^{\infty} \frac{1}{\ln m} \ge \sum_{m=k}^{\infty} \frac{1}{m}$$

This is the harmonic series, which diverges (the absence of the finite number of terms for $m = 1, \dots, k-1$ does not affect convergence). By the comparison theorem, $\displaystyle\sum_{m=2}^{\infty} \frac{1}{\ln m}$ also diverges (again, ignoring the finite number of terms for $m = 1, \dots, k-1$ does not affect convergence).

33. $\displaystyle\sum_{n=1}^{\infty} \frac{(\ln n)^{100}}{n^{1.1}}$

SOLUTION Choose N so that $\ln n \le n^{0.0005}$ for $n \ge N$. Then also for $n > N$, $(\ln n)^{100} \le (n^{0.0005})^{100} = n^{0.05}$. Then

$$\sum_{n=N}^{\infty} \frac{(\ln n)^{100}}{n^{1.1}} \le \sum_{n=N}^{\infty} \frac{n^{0.05}}{n^{1.1}} = \sum_{n=N}^{\infty} \frac{1}{n^{1.05}}$$

But $\displaystyle\sum_{n=N}^{\infty} \frac{1}{n^{1.05}}$ is a p-series with $p = 1.05 > 1$, so is convergent. It follows that $\sum_{n=N}^{\infty} \frac{(\ln n)^100}{n^{1.1}}$ is also convergent; adding back in the finite number of terms for $n = 1, 2, \dots, N-1$ shows that $\displaystyle\sum_{n=1}^{\infty} \frac{(\ln n)^{100}}{n^{1.1}}$ converges as well.

34. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{(\ln n)^{10}}$

SOLUTION Choose N such that $\ln n \le n^{0.1}$ for $n \ge N$; then also $(\ln n)^{10} \le n$ for $n \ge N$. So we have

$$\sum_{n=N}^{\infty} \frac{1}{(\ln n)^{10}} \ge \sum_{n=N}^{\infty} \frac{1}{n}$$

The latter sum is the harmonic series, which diverges, so the series on the left diverges as well. Adding back in the finite number of terms for $n < N$ shows that $\displaystyle\sum_{n=1}^{\infty} \frac{1}{(\ln n)^{10}}$ diverges.

35. $\displaystyle\sum_{n=1}^{\infty} \frac{n}{3^n}$

SOLUTION Choose N such that $n \le 2^n$ for $n \ge N$. Then

$$\sum_{n=N}^{\infty} \frac{n}{3^n} \le \sum_{n=N}^{\infty} \left(\frac{2}{3}\right)^n$$

The latter sum is a geometric series with $r = \frac{2}{3} < 1$, so it converges. Thus the series on the left converges as well. Adding back in the finite number of terms for $n < N$ shows that $\sum_{n=1}^{\infty} \frac{n}{3^n}$ converges.

36. $\sum_{n=1}^{\infty} \frac{n^5}{2^n}$

SOLUTION Choose N such that $n^5 \le 1.5^n$ for $n \ge N$. Then

$$\sum_{n=N}^{\infty} \frac{n^5}{2^n} \le \sum_{n=N}^{\infty} \left(\frac{1.5}{2}\right)^n$$

The latter sum is a geometric series with $r = \frac{1.5}{2} < 1$, so it converges. Thus the series on the left converges as well. Adding back in the finite number of terms for $n < N$ shows that $\sum_{n=1}^{\infty} \frac{n^5}{2^n}$ converges.

37. Show that $\sum_{n=1}^{\infty} \sin \frac{1}{n^2}$ converges. *Hint:* Use the inequality $\sin x \le x$ for $x \ge 0$.

SOLUTION For $n \ge 1$,

$$0 \le \frac{1}{n^2} \le 1 < \pi;$$

therefore, $\sin \frac{1}{n^2} > 0$ for $n \ge 1$. Moreover, for $n \ge 1$,

$$\sin \frac{1}{n^2} \le \frac{1}{n^2}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a p-series with $p = 2 > 1$, so it converges. By the Comparison Test we can therefore conclude that the series $\sum_{n=1}^{\infty} \sin \frac{1}{n^2}$ also converges.

38. Does $\sum_{n=2}^{\infty} \frac{\sin(1/n)}{\ln n}$ converge?

SOLUTION No, it diverges. Either the Comparison Theorem or the Limit Comparison Theorem may be used. Using the Comparison Theorem, recall that

$$\frac{\sin x}{x} > \cos x \quad \text{for } x > 0$$

so that $\sin x > x \cos x$. Substituting $1/n$ for x gives

$$\sin\left(\frac{1}{n}\right) > \frac{1}{n} \cos\left(\frac{1}{n}\right) = \frac{\cos(1/n)}{n} \ge \frac{1}{2n}$$

since $\cos\left(\frac{1}{n}\right) \ge \frac{1}{2}$ for $n \ge 2$. Thus

$$\sum_{n=1}^{\infty} \frac{\sin(1/n)}{\ln n} > \sum_{n=1}^{\infty} \frac{1}{2n \ln n}$$

Apply the Integral Test to the latter expression, making the substitution $u = \ln x$:

$$\int_1^{\infty} \frac{1}{2x \ln x}\, dx = \frac{1}{2} \int_0^{\infty} \frac{1}{u}\, du = \frac{1}{2} \ln u\Big|_0^{\infty}$$

and the integral diverges. Thus

$$\sum_{n=1}^{\infty} \frac{1}{2n \ln n} \quad \text{diverges, and thus} \quad \sum_{n=1}^{\infty} \frac{\sin(1/n)}{\ln n} \quad \text{diverges as well.}$$

Applying the Limit Comparison Test is similar but perhaps simpler: Recall that

$$\lim_{x\to\infty}\frac{\sin(1/x)}{1/x}=\lim_{x\to 0}\frac{\sin x}{x}=1$$

so apply the Limit Comparison Test with $b_n=\dfrac{1/x}{\ln x}$:

$$L=\lim_{x\to\infty}\frac{\sin(1/x)}{\ln x}\cdot\frac{\ln x}{1/x}=\lim_{x\to\infty}\frac{\sin(1/x)}{1/x}=1$$

so that either both series converge or both diverge. But by the Integral Test as above,

$$\sum_{n=1}^{\infty}\frac{(1/x)}{\ln x}=\sum_{n=1}^{\infty}\frac{1}{x\ln x}$$

diverges.

In Exercises 39–48, use the Limit Comparison Test to prove convergence or divergence of the infinite series.

39. $\displaystyle\sum_{n=2}^{\infty}\frac{n^2}{n^4-1}$

SOLUTION Let $a_n=\dfrac{n^2}{n^4-1}$. For large n, $\dfrac{n^2}{n^4-1}\approx\dfrac{n^2}{n^4}=\dfrac{1}{n^2}$, so we apply the Limit Comparison Test with $b_n=\dfrac{1}{n^2}$. We find

$$L=\lim_{n\to\infty}\frac{a_n}{b_n}=\lim_{n\to\infty}\frac{\frac{n^2}{n^4-1}}{\frac{1}{n^2}}=\lim_{n\to\infty}\frac{n^4}{n^4-1}=1.$$

The series $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n^2}$ is a p-series with $p=2>1$, so it converges; hence, $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n^2}$ also converges. Because L exists, by the Limit Comparison Test we can conclude that the series $\displaystyle\sum_{n=2}^{\infty}\frac{n^2}{n^4-1}$ converges.

40. $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n^2-\sqrt{n}}$

SOLUTION Let $a_n=\dfrac{1}{n^2-\sqrt{n}}$. For large n, $\dfrac{1}{n^2-\sqrt{n}}\approx\dfrac{1}{n^2}$, so we apply the Limit Comparison Test with $b_n=\dfrac{1}{n^2}$. We find

$$L=\lim_{n\to\infty}\frac{a_n}{b_n}=\lim_{n\to\infty}\frac{\frac{1}{n^2-\sqrt{n}}}{\frac{1}{n^2}}=\lim_{n\to\infty}\frac{n^2}{n^2-\sqrt{n}}=1.$$

The series $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n^2}$ is a p-series with $p=2>1$, so it converges; hence, the series $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n^2}$ also converges. Because L exists, by the Limit Comparison Test we can conclude that the series $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n^2-\sqrt{n}}$ converges.

41. $\displaystyle\sum_{n=2}^{\infty}\frac{n}{\sqrt{n^3+1}}$

SOLUTION Let $a_n=\dfrac{n}{\sqrt{n^3+1}}$. For large n, $\dfrac{n}{\sqrt{n^3+1}}\approx\dfrac{n}{\sqrt{n^3}}=\dfrac{1}{\sqrt{n}}$, so we apply the Limit Comparison test with $b_n=\dfrac{1}{\sqrt{n}}$. We find

$$L=\lim_{n\to\infty}\frac{a_n}{b_n}=\lim_{n\to\infty}\frac{\frac{n}{\sqrt{n^3+1}}}{\frac{1}{\sqrt{n}}}=\lim_{n\to\infty}\frac{\sqrt{n^3}}{\sqrt{n^3+1}}=1.$$

The series $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ is a p-series with $p = \frac{1}{2} < 1$, so it diverges; hence, $\sum_{n=2}^{\infty} \frac{1}{\sqrt{n}}$ also diverges. Because $L > 0$, by the Limit Comparison Test we can conclude that the series $\sum_{n=2}^{\infty} \frac{n}{\sqrt{n^3+1}}$ diverges.

42. $\sum_{n=2}^{\infty} \frac{n^3}{\sqrt{n^7 + 2n^2 + 1}}$

SOLUTION Let a_n be the general term of our series. Observe that

$$a_n = \frac{n^3}{\sqrt{n^7+2n^2+1}} = \frac{n^{-3} \cdot n^3}{n^{-3} \cdot \sqrt{n^7+2n^2+1}} = \frac{1}{\sqrt{n+2n^{-4}+n^{-6}}}$$

This suggests that we apply the Limit Comparison Test, comparing our series with

$$\sum_{n=2}^{\infty} b_n = \sum_{n=2}^{\infty} \frac{1}{n^{1/2}}$$

The ratio of the terms is

$$\frac{a_n}{b_n} = \frac{1}{\sqrt{n+2n^{-4}+n^{-6}}} \cdot \frac{\sqrt{n}}{1} = \frac{1}{\sqrt{1+2n^{-5}+n^{-7}}}$$

Hence

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{1}{\sqrt{1+2n^{-5}+n^{-7}}} = 1$$

The p-series $\sum_{n=2}^{\infty} \frac{1}{n^{1/2}}$ diverges since $p = 1/2 < 1$. Therefore, our original series diverges.

43. $\sum_{n=3}^{\infty} \frac{3n+5}{n(n-1)(n-2)}$

SOLUTION Let $a_n = \frac{3n+5}{n(n-1)(n-2)}$. For large n, $\frac{3n+5}{n(n-1)(n-2)} \approx \frac{3n}{n^3} = \frac{3}{n^2}$, so we apply the Limit Comparison Test with $b_n = \frac{1}{n^2}$. We find

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{3n+5}{n(n+1)(n+2)}}{\frac{1}{n^2}} = \lim_{n\to\infty} \frac{3n^3+5n^2}{n(n+1)(n+2)} = 3.$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a p-series with $p = 2 > 1$, so it converges; hence, the series $\sum_{n=3}^{\infty} \frac{1}{n^2}$ also converges. Because L exists, by the Limit Comparison Test we can conclude that the series $\sum_{n=3}^{\infty} \frac{3n+5}{n(n-1)(n-2)}$ converges.

44. $\sum_{n=1}^{\infty} \frac{e^n+n}{e^{2n}-n^2}$

SOLUTION Let

$$a_n = \frac{e^n+n}{e^{2n}-n^2} = \frac{e^n+n}{(e^n-n)(e^n+n)} = \frac{1}{e^n-n}.$$

For large n,

$$\frac{1}{e^n-n} \approx \frac{1}{e^n} = e^{-n},$$

so we apply the Limit Comparison Test with $b_n = e^{-n}$. We find

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{1}{e^n-n}}{e^{-n}} = \lim_{n\to\infty} \frac{e^n}{e^n-n} = 1.$$

The series $\sum_{n=1}^{\infty} e^{-n} = \sum_{n=1}^{\infty} \left(\frac{1}{e}\right)^n$ is a geometric series with $r = \frac{1}{e} < 1$, so it converges. Because L exists, by the Limit Comparison Test we can conclude that the series $\sum_{n=1}^{\infty} \frac{e^n + n}{e^{2n} - n^2}$ also converges.

45. $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n} + \ln n}$

SOLUTION Let

$$a_n = \frac{1}{\sqrt{n} + \ln n}$$

For large n, $\sqrt{n} + \ln n \approx \sqrt{n}$, so apply the Comparison Test with $b_n = \frac{1}{\sqrt{n}}$. We find

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{1}{\sqrt{n} + \ln n} \cdot \frac{\sqrt{n}}{1} = \lim_{n\to\infty} \frac{1}{1 + \frac{\ln n}{\sqrt{n}}} = 1$$

The series $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ is a p-series with $p = \frac{1}{2} < 1$, so it diverges. Because L exists, the Limit Comparison Test tells us the the original series also diverges.

46. $\sum_{n=1}^{\infty} \frac{\ln(n+4)}{n^{5/2}}$

SOLUTION Let

$$a_n = \frac{\ln(n+4)}{n^{5/2}}$$

For large n, $a_n \approx \frac{\ln n}{n^{5/2}}$, so apply the Comparison Test with $b_n = \frac{\ln n}{n^{5/2}}$. We find

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\ln(n+4)}{n^{5/2}} \cdot \frac{n^{5/2}}{\ln n} = \lim_{n\to\infty} \frac{\ln(n+4)}{\ln n}$$

Applying L'Hôpital's rule gives

$$L = \lim_{n\to\infty} \frac{\ln(n+4)}{\ln n} = \lim_{n\to\infty} \frac{1/(n+4)}{1/n} = \lim_{n\to\infty} \frac{n}{n+4} = \lim_{n\to\infty} \frac{1}{1+4/n} = 1$$

To see that $\sum_{n=1}^{\infty} b_n$ converges, choose N so that $\ln n < n$ for $n \geq N$; then

$$\sum_{n=N}^{\infty} \frac{\ln n}{n^{5/2}} \leq \sum_{n=N}^{\infty} \frac{n}{n^{5/2}} = \sum_{n=N}^{\infty} \frac{1}{n^{3/2}}$$

which is a p-series with $p = \frac{3}{2} > 1$, so it converges. Adding back in the finite number of terms for $n < N$ shows that $\sum b_n$ converges as well. Since L exists and $\sum b_n$ converges, the Limit Comparison Test tells us that $\sum_{n=1}^{\infty} a_n$ converges.

47. $\sum_{n=1}^{\infty} \left(1 - \cos \frac{1}{n}\right)$ *Hint:* Compare with $\sum_{n=1}^{\infty} n^{-2}$.

SOLUTION Let $a_n = 1 - \cos \frac{1}{n}$, and apply the Limit Comparison Test with $b_n = \frac{1}{n^2}$. We find

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{1 - \cos \frac{1}{n}}{\frac{1}{n^2}} = \lim_{x\to\infty} \frac{1 - \cos \frac{1}{x}}{\frac{1}{x^2}} = \lim_{x\to\infty} \frac{-\frac{1}{x^2} \sin \frac{1}{x}}{-\frac{2}{x^3}} = \frac{1}{2} \lim_{x\to\infty} \frac{\sin \frac{1}{x}}{\frac{1}{x}}.$$

As $x \to \infty$, $u = \frac{1}{x} \to 0$, so

$$L = \frac{1}{2} \lim_{x\to\infty} \frac{\sin \frac{1}{x}}{\frac{1}{x}} = \frac{1}{2} \lim_{u\to 0} \frac{\sin u}{u} = \frac{1}{2}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a p-series with $p = 2 > 1$, so it converges. Because L exists, by the Limit Comparison Test we can conclude that the series $\sum_{n=1}^{\infty} \left(1 - \cos \frac{1}{n}\right)$ also converges.

48. $\sum_{n=1}^{\infty} (1 - 2^{-1/n})$ *Hint:* Compare with the harmonic series.

SOLUTION Let $a_n = 1 - 2^{-1/n}$, and apply the Limit Comparison Test with $b_n = \frac{1}{n}$. We find

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{1 - 2^{-1/n}}{\frac{1}{n}} = \lim_{x\to\infty} \frac{1 - 2^{-1/x}}{\frac{1}{x}} = \lim_{x\to\infty} \frac{-\frac{1}{x^2}(\ln 2)2^{-1/x}}{-\frac{1}{x^2}} = \lim_{x\to\infty} \left(2^{-1/x} \ln 2\right) = \ln 2.$$

The harmonic series $\sum_{n=1}^{\infty} \frac{1}{n}$ diverges; because $L > 0$, we can conclude by the Limit Comparison Test that the series $\sum_{n=1}^{\infty} (1 - 2^{-1/n})$ also diverges.

In Exercises 49–74, determine convergence or divergence using any method covered so far.

49. $\sum_{n=4}^{\infty} \frac{1}{n^2 - 9}$

SOLUTION Apply the Limit Comparison Test with $a_n = \frac{1}{n^2 - 9}$ and $b_n = \frac{1}{n^2}$:

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{1}{n^2-9}}{\frac{1}{n^2}} = \lim_{n\to\infty} \frac{n^2}{n^2 - 9} = 1.$$

Since the p-series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges, the series $\sum_{n=4}^{\infty} \frac{1}{n^2}$ also converges. Because L exists, by the Limit Comparison Test we can conclude that the series $\sum_{n=4}^{\infty} \frac{1}{n^2 - 9}$ converges.

50. $\sum_{n=1}^{\infty} \frac{\cos^2 n}{n^2}$

SOLUTION For all $n \geq 1$, $0 \leq \cos^2 n \leq 1$, so

$$0 \leq \frac{\cos^2 n}{n^2} \leq \frac{1}{n^2}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a convergent p-series; hence, by the Comparison Test we can conclude that the series $\sum_{n=1}^{\infty} \frac{\cos^2 n}{n^2}$ also converges.

51. $\sum_{n=1}^{\infty} \frac{\sqrt{n}}{4n + 9}$

SOLUTION Apply the Limit Comparison Test with $a_n = \frac{\sqrt{n}}{4n + 9}$ and $b_n = \frac{1}{\sqrt{n}}$:

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{\sqrt{n}}{4n+9}}{\frac{1}{\sqrt{n}}} = \lim_{n\to\infty} \frac{n}{4n + 9} = \frac{1}{4}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ is a divergent p-series. Because $L > 0$, by the Limit Comparison Test we can conclude that the series $\sum_{n=1}^{\infty} \frac{\sqrt{n}}{4n + 9}$ also diverges.

52. $\displaystyle\sum_{n=1}^{\infty} \frac{n - \cos n}{n^3}$

SOLUTION Apply the Limit Comparison Test with $a_n = \dfrac{n - \cos n}{n^3}$ and $b_n = \dfrac{1}{n^2}$:

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{n-\cos n}{n^3}}{\frac{1}{n^2}} = \lim_{n\to\infty} \left(1 - \frac{\cos n}{n}\right) = 1.$$

The series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a convergent p-series. Because L exists, by the Limit Comparison Test we can conclude that the series $\displaystyle\sum_{n=1}^{\infty} \frac{n - \cos n}{n^3}$ also converges.

53. $\displaystyle\sum_{n=1}^{\infty} \frac{n^2 - n}{n^5 + n}$

SOLUTION First rewrite $a_n = \dfrac{n^2 - n}{n^5 + n} = \dfrac{n(n-1)}{n\left(n^4+1\right)} = \dfrac{n-1}{n^4+1}$ and observe

$$\frac{n-1}{n^4+1} < \frac{n}{n^4} = \frac{1}{n^3}$$

for $n \ge 1$. The series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^3}$ is a convergent p-series, so by the Comparison Test we can conclude that the series $\displaystyle\sum_{n=1}^{\infty} \frac{n^2 - n}{n^5 + n}$ also converges.

54. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2 + \sin n}$

SOLUTION Apply the Limit Comparison Test with $a_n = \dfrac{1}{n^2 + \sin n}$ and $b_n = \dfrac{1}{n^2}$:

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{1}{n^2+\sin n}}{\frac{1}{n^2}} = \lim_{n\to\infty} \frac{1}{1 + \frac{\sin n}{n^2}} = 1.$$

The series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a convergent p-series. Because L exists, by the Limit Comparison Test we can conclude that the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2 + \sin n}$ also converges.

55. $\displaystyle\sum_{n=5}^{\infty} (4/5)^{-n}$

SOLUTION

$$\sum_{n=5}^{\infty} \left(\frac{4}{5}\right)^{-n} = \sum_{n=5}^{\infty} \left(\frac{5}{4}\right)^{n}$$

which is a geometric series starting at $n = 5$ with ratio $r = \dfrac{5}{4} > 1$. Thus the series diverges.

56. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{3^{n^2}}$

SOLUTION Because $n^2 \ge n$ for $n \ge 1$, $3^{n^2} \ge 3^n$ and

$$\frac{1}{3^{n^2}} \le \frac{1}{3^n} = \left(\frac{1}{3}\right)^n.$$

The series $\sum_{n=1}^{\infty}\left(\frac{1}{3}\right)^n$ is a geometric series with $r = \frac{1}{3}$, so it converges. By the Comparison Test we can therefore conclude that the series $\sum_{n=1}^{\infty}\frac{1}{3^{n^2}}$ also converges.

57. $\sum_{n=2}^{\infty}\frac{1}{n^{3/2}\ln n}$

SOLUTION For $n \geq 3$, $\ln n > 1$, so $n^{3/2}\ln n > n^{3/2}$ and

$$\frac{1}{n^{3/2}\ln n} < \frac{1}{n^{3/2}}.$$

The series $\sum_{n=1}^{\infty}\frac{1}{n^{3/2}}$ is a convergent p-series, so the series $\sum_{n=3}^{\infty}\frac{1}{n^{3/2}}$ also converges. By the Comparison Test we can therefore conclude that the series $\sum_{n=3}^{\infty}\frac{1}{n^{3/2}\ln n}$ converges. Hence, the series $\sum_{n=2}^{\infty}\frac{1}{n^{3/2}\ln n}$ also converges.

58. $\sum_{n=2}^{\infty}\frac{(\ln n)^{12}}{n^{9/8}}$

SOLUTION By the comment preceding Exercise 31, we can choose N so that for $n \geq N$, we have $\ln n < n^{1/192}$. Then also for $n \geq N$ we have $(\ln n)^{12} < n^{12/192} = n^{1/16}$. Then

$$\sum_{n=N}^{\infty}\frac{(\ln n)^{12}}{n^{9/8}} \leq \sum_{n=N}^{\infty}\frac{n^{1/16}}{n^{9/8}} = \sum_{n=N}^{\infty}\frac{1}{n^{17/16}}$$

which is a convergent p-series. Thus the series on the left converges as well; adding back in the finite number of terms for $n \leq N$ shows that $\sum_{n=2}^{\infty}\frac{(\ln n)^{12}}{n^{9/8}}$ converges.

59. $\sum_{k=1}^{\infty}4^{1/k}$

SOLUTION

$$\lim_{k\to\infty} a_k = \lim_{k\to\infty} 4^{1/k} = 4^0 = 1 \neq 0;$$

therefore, the series $\sum_{k=1}^{\infty}4^{1/k}$ diverges by the Divergence Test.

60. $\sum_{n=1}^{\infty}\frac{4^n}{5^n - 2n}$

SOLUTION Apply the Limit Comparison Test with $a_n = \frac{4^n}{5^n - 2n}$ and $b_n = \frac{4^n}{5^n}$:

$$L = \lim_{n\to\infty}\frac{a_n}{b_n} = \lim_{n\to\infty}\frac{\frac{4^n}{5^n-2n}}{\frac{4^n}{5^n}} = \lim_{n\to\infty}\frac{1}{1-\frac{2n}{5^n}}.$$

Now,

$$\lim_{n\to\infty}\frac{2n}{5^n} = \lim_{x\to\infty}\frac{2x}{5^x} = \lim_{x\to\infty}\frac{2}{5^x\ln 5} = 0,$$

so

$$L = \lim_{n\to\infty}\frac{a_n}{b_n} = \frac{1}{1-0} = 1.$$

The series $\sum_{n=1}^{\infty}\left(\frac{4}{5}\right)^n$ is a convergent geometric series. Because L exists, by the Limit Comparison Test we can conclude that the series $\sum_{n=1}^{\infty}\frac{4^n}{5^n - 2n}$ also converges.

61. $\displaystyle\sum_{n=2}^{\infty} \frac{1}{(\ln n)^4}$

SOLUTION By the comment preceding Exercise 31, we can choose N so that for $n \ge N$, we have $\ln n < n^{1/8}$, so that $(\ln n)^4 < n^{1/2}$. Then

$$\sum_{n=N}^{\infty} \frac{1}{(\ln n)^4} > \sum_{n=N}^{\infty} \frac{1}{n^{1/2}}$$

which is a divergent p-series. Thus the series on the left diverges as well, and adding back in the finite number of terms for $n < N$ does not affect the result. Thus $\displaystyle\sum_{n=2}^{\infty} \frac{1}{(\ln n)^4}$ diverges.

62. $\displaystyle\sum_{n=1}^{\infty} \frac{2^n}{3^n - n}$

SOLUTION Apply the Limit Comparison Test with $a_n = \dfrac{2^n}{3^n - n}$ and $b_n = \dfrac{2^n}{3^n}$:

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{2^n}{3^n - n}}{\frac{2^n}{3^n}} = \lim_{n\to\infty} \frac{1}{1 - \frac{n}{3^n}}.$$

Now,

$$\lim_{n\to\infty} \frac{n}{3^n} = \lim_{x\to\infty} \frac{x}{3^x} = \lim_{x\to\infty} \frac{1}{3^x \ln 3} = 0,$$

so

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \frac{1}{1-0} = 1.$$

The series $\displaystyle\sum_{n=1}^{\infty} \left(\frac{2}{3}\right)^n$ is a convergent geometric series. Because L exists, by the Limit Comparison Test we can conclude that the series $\displaystyle\sum_{n=1}^{\infty} \frac{2^n}{3^n - n}$ also converges.

63. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n \ln n - n}$

SOLUTION For $n \ge 2$, $n \ln n - n \le n \ln n$; therefore,

$$\frac{1}{n \ln n - n} \ge \frac{1}{n \ln n}.$$

Now, let $f(x) = \dfrac{1}{x \ln x}$. For $x \ge 2$, this function is continuous, positive and decreasing, so the Integral Test applies. Using the substitution $u = \ln x$, $du = \frac{1}{x}\,dx$, we find

$$\int_2^{\infty} \frac{dx}{x \ln x} = \lim_{R\to\infty} \int_2^R \frac{dx}{x \ln x} = \lim_{R\to\infty} \int_{\ln 2}^{\ln R} \frac{du}{u} = \lim_{R\to\infty} (\ln(\ln R) - \ln(\ln 2)) = \infty.$$

The integral diverges; hence, the series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n \ln n}$ also diverges. By the Comparison Test we can therefore conclude that the series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n \ln n - n}$ diverges.

64. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n(\ln n)^2 - n}$

SOLUTION Use the Integral Test. Note that $x(\ln x)^2 - x$ has a zero at $x = e$, so restrict the integral to $[4, \infty)$:

$$\int_4^{\infty} \frac{1}{x(\ln x)^2 - x}\,dx$$

Substitute $u = \ln x$ so that $du = \frac{1}{x}\,dx$ to get

$$\int_{\ln 4}^{\infty} \frac{1}{u^2-1}\,du = \lim_{R\to\infty}\left(\frac{1}{2}\ln\left|\frac{x-1}{x+1}\right|\Bigg|_4^R\right) = \frac{1}{2}\lim_{R\to\infty}\left(\ln\left(\frac{R-1}{R+1}\right) - \ln\left(\frac{3}{5}\right)\right)$$
$$= \frac{1}{2}\left(\ln\lim_{R\to\infty}\left(\frac{R-1}{R+1}\right) - \ln\left(\frac{3}{5}\right)\right) = \frac{1}{2}\left(\ln 1 - \ln\left(\frac{3}{5}\right)\right) = \frac{1}{2}\ln\left(\frac{5}{3}\right) < \infty$$

Since the integral converges, the series does as well starting at $n = 4$, using the Integral Test. Adding in the terms for $n = 1, 2, 3$ does not affect this result.

65. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^n}$

SOLUTION For $n \geq 2$, $n^n \geq 2^n$; therefore,

$$\frac{1}{n^n} \leq \frac{1}{2^n} = \left(\frac{1}{2}\right)^n.$$

The series $\displaystyle\sum_{n=1}^{\infty}\left(\frac{1}{2}\right)^n$ is a convergent geometric series, so $\displaystyle\sum_{n=2}^{\infty}\left(\frac{1}{2}\right)^n$ also converges. By the Comparison Test we can therefore conclude that the series $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n^n}$ converges. Hence, the series $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n^n}$ converges.

66. $\displaystyle\sum_{n=1}^{\infty} \frac{n^2 - 4n^{3/2}}{n^3}$

SOLUTION Let $a_n = \frac{1}{n}$ and $b_n = -\frac{4}{n^{3/2}}$. Then

$$\sum_{n=1}^{\infty}(a_n + b_n) = \sum_{n=1}^{\infty}\frac{n^2 - 4n^{3/2}}{n^3}$$

$$\sum_{n=1}^{\infty} a_n \quad \text{diverges since it is the harmonic series}$$

$$\sum_{n=1}^{\infty} b_n \quad \text{is a } p\text{-series with } p = \frac{3}{2} > 1\text{, so converges}$$

Since $\sum a_n$ diverges and $\sum b_n$ converges, it follows that $\sum(a_n + b_n)$ diverges.

67. $\displaystyle\sum_{n=1}^{\infty} \frac{1+(-1)^n}{n}$

SOLUTION Let

$$a_n = \frac{1+(-1)^n}{n}$$

Then

$$a_n = \begin{cases} 0 & n \text{ odd} \\ \frac{2}{2k} = \frac{1}{k} & n = 2k \text{ even} \end{cases}$$

Therefore, $\{a_n\}$ consists of 0s in the odd places and the harmonic series in the even places, so $\sum_{i=1}^{\infty} a_n$ is just the sum of the harmonic series, which diverges. Thus $\sum_{i=1}^{\infty} a_n$ diverges as well.

68. $\displaystyle\sum_{n=1}^{\infty} \frac{2+(-1)^n}{n^{3/2}}$

SOLUTION For $n \geq 1$

$$0 < \frac{2+(-1)^n}{n^{3/2}} \leq \frac{2+1}{n^{3/2}} = \frac{3}{n^{3/2}}.$$

The series $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n^{3/2}}$ is a convergent p-series; hence, the series $\displaystyle\sum_{n=1}^{\infty}\frac{3}{n^{3/2}}$ also converges. By the Comparison Test we can therefore conclude that the series $\displaystyle\sum_{n=1}^{\infty}\frac{2+(-1)^n}{n^{3/2}}$ converges.

69. $\displaystyle\sum_{n=1}^{\infty} \sin \frac{1}{n}$

SOLUTION Apply the Limit Comparison Test with $a_n = \sin \frac{1}{n}$ and $b_n = \frac{1}{n}$:

$$L = \lim_{n\to\infty} \frac{\sin \frac{1}{n}}{\frac{1}{n}} = \lim_{u\to 0} \frac{\sin u}{u} = 1,$$

where $u = \frac{1}{n}$. The harmonic series diverges. Because $L > 0$, by the Limit Comparison Test we can conclude that the series $\displaystyle\sum_{n=1}^{\infty} \sin \frac{1}{n}$ also diverges.

70. $\displaystyle\sum_{n=1}^{\infty} \frac{\sin(1/n)}{\sqrt{n}}$

SOLUTION Apply the Limit Comparison Test with $a_n = \dfrac{\sin(1/n)}{\sqrt{n}}$ and $b_n = \dfrac{1/n}{\sqrt{n}}$:

$$L = \lim_{n\to\infty} \frac{\sin(1/n)}{\sqrt{n}} \cdot \frac{\sqrt{n}}{1/n} = \lim_{n\to\infty} \frac{\sin(1/n)}{1/n} = \lim_{u\to 0} \frac{\sin u}{u} = 1$$

so that $\sum a_n$ and $\sum b_n$ either both converge or both diverge. But

$$\sum_{n=1}^{\infty} b_n = \sum_{n=1}^{\infty} \frac{1/n}{\sqrt{n}} = \sum_{n=1}^{\infty} \frac{1}{n^{3/2}}$$

is a convergent p-series. Thus $\displaystyle\sum_{n=1}^{\infty} \frac{\sin(1/n)}{\sqrt{n}}$ converges as well.

71. $\displaystyle\sum_{n=1}^{\infty} \frac{2n+1}{4^n}$

SOLUTION For $n \ge 3$, $2n + 1 < 2^n$, so

$$\frac{2n+1}{4^n} < \frac{2^n}{4^n} = \left(\frac{1}{2}\right)^n.$$

The series $\displaystyle\sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^n$ is a convergent geometric series, so $\displaystyle\sum_{n=3}^{\infty} \left(\frac{1}{2}\right)^n$ also converges. By the Comparison Test we can therefore conclude that the series $\displaystyle\sum_{n=3}^{\infty} \frac{2n+1}{4^n}$ converges. Finally, the series $\displaystyle\sum_{n=1}^{\infty} \frac{2n+1}{4^n}$ converges.

72. $\displaystyle\sum_{n=3}^{\infty} \frac{1}{e^{\sqrt{n}}}$

SOLUTION Apply the integral test, making the substitution $z = \sqrt{x}$ so that $z^2 = x$ and $2z\,dz = dx$:

$$\int_3^{\infty} \frac{1}{e^{\sqrt{x}}}\,dx = \int_3^{\infty} e^{-x^{1/2}}\,dx = \int_{\sqrt{3}}^{\infty} 2ze^{-z}\,dz$$

Evaluate this integral using integration by parts with $u = 2z$, $dv = e^{-z}\,dz$:

$$\begin{aligned}\int_{\sqrt{3}}^{\infty} 2ze^{-z}\,dz &= uv\Big|_{\sqrt{3}}^{\infty} - \int_{\sqrt{3}}^{\infty} v\,du = (-2ze^{-z})\Big|_{\sqrt{3}}^{\infty} - \int_{\sqrt{3}}^{\infty}(-2e^{-z})\,dz = 2\sqrt{3}e^{-\sqrt{3}} - (2e^{-z})\Big|_{\sqrt{3}}^{\infty} \\ &= 2\sqrt{3}e^{-\sqrt{3}} + 2e^{-\sqrt{3}} < \infty\end{aligned}$$

Since the integral converges, so does the series $\displaystyle\sum_{n=3}^{\infty} \frac{1}{e^{\sqrt{n}}}$.

73. $\displaystyle\sum_{n=4}^{\infty} \frac{\ln n}{n^2 - 3n}$

SOLUTION By the comment preceding Exercise 31, we can choose $N \geq 4$ so that for $n \geq N$, $\ln n < n^{1/2}$. Then

$$\sum_{n=N}^{\infty} \frac{\ln n}{n^2 - 3n} \leq \sum_{n=N}^{\infty} \frac{n^{1/2}}{n^2 - 3n} = \sum_{n=N}^{\infty} \frac{1}{n^{3/2} - 3n^{1/2}}$$

To evaluate convergence of the latter series, let $a_n = \dfrac{1}{n^{3/2} - 3n^{1/2}}$ and $b_n = \dfrac{1}{n^{3/2}}$, and apply the Limit Comparison Test:

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{1}{n^{3/2} - 3n^{1/2}} \cdot n^{3/2} = \lim_{n\to\infty} \frac{1}{1 - 3n^{-1}} = 0$$

Thus $\sum a_n$ converges if $\sum b_n$ does. But $\sum b_n$ is a convergent p-series. Thus $\sum a_n$ converges and, by the comparison test, so does the original series. Adding back in the finite number of terms for $n < N$ does not affect convergence.

74. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{3^{\ln n}}$

SOLUTION Note that

$$3^{\ln n} = (e^{\ln 3})^{\ln n} = (e^{\ln n})^{\ln 3} = n^{\ln 3}.$$

Thus the sum is a p-series with $p = \ln 3 > 1$, so is convergent.

75. $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n^{1/2} \ln n}$

SOLUTION By the comment preceding Exercise 31, we can choose $N \geq 2$ so that for $n \geq N$, $\ln n < n^{1/4}$. Then

$$\sum_{n=N}^{\infty} \frac{1}{n^{1/2} \ln n} > \sum_{n=N}^{\infty} \frac{1}{n^{3/4}}$$

which is a divergent p-series. Thus the original series diverges as well - as usual, adding back in the finite number of terms for $n < N$ does not affect convergence.

76. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^{3/2} - \ln^4 n}$

SOLUTION Let

$$a_n = \frac{1}{n^{3/2} - \ln^4 n}, \qquad b_n = \frac{1}{n^{3/2}},$$

and apply the Limit Comparison Test:

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{n^{3/2}}{n^{3/2} - \ln^4 n} = \lim_{n\to\infty} \frac{1}{1 - \frac{\ln^4 n}{n^{3/2}}}$$

But by the comment preceding Exercise 31, $\ln n$, and thus $\ln^4 n$, are eventually smaller than any positive power of n, so for n sufficiently large, $\dfrac{\ln^4 n}{n^{3/2}}$ is arbitrarily small. Thus $L = 1$ and $\sum a_n$ converges if and only if $\sum b_n$ does. But $\sum b_n$ is a convergent p-series, so $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^{3/2} - \ln^4 n}$ converges.

77. $\displaystyle\sum_{n=1}^{\infty} \frac{4n^2 + 15n}{3n^4 - 5n^2 - 17}$

SOLUTION Apply the Limit Comparison Test with

$$a_n = \frac{4n^2 + 15n}{3n^4 - 5n^2 - 17}, \qquad b_n = \frac{4n^2}{3n^4} = \frac{4}{3n^2}$$

We have

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{4n^2 + 15n}{3n^4 - 5n^2 - 17} \cdot \frac{3n^2}{4} = \lim_{n\to\infty} \frac{12n^4 + 45n^3}{12n^4 - 20n^2 - 68} = \lim_{n\to\infty} \frac{12 + 45/n}{12 - 20/n^2 - 68/n^4} = 1$$

Now, $\sum_{n=1}^{\infty} b_n$ is a p-series with $p = 2 > 1$, so converges. Since $L = 1$, we see that $\displaystyle\sum_{n=1}^{\infty} \frac{4n^2 + 15n}{3n^4 - 5n^2 - 17}$ converges as well.

78. $\displaystyle\sum_{n=1}^{\infty} \frac{n}{4^{-n} + 5^{-n}}$

SOLUTION Note that

$$\lim_{n\to\infty} \frac{n}{4^{-n} + 5^{-n}} = \lim_{n\to\infty} \frac{n4^n}{1 + \left(\frac{4}{5}\right)^n}$$

This limit approaches $\infty/1 = \infty$, so the terms of the sequence do not tend to zero. Thus the series is divergent.

79. For which a does $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^a}$ converge?

SOLUTION First consider the case $a > 0$ but $a \neq 1$. Let $f(x) = \dfrac{1}{x(\ln x)^a}$. This function is continuous, positive and decreasing for $x \geq 2$, so the Integral Test applies. Now,

$$\int_2^{\infty} \frac{dx}{x(\ln x)^a} = \lim_{R\to\infty} \int_2^R \frac{dx}{x(\ln x)^a} = \lim_{R\to\infty} \int_{\ln 2}^{\ln R} \frac{du}{u^a} = \frac{1}{1-a} \lim_{R\to\infty} \left(\frac{1}{(\ln R)^{a-1}} - \frac{1}{(\ln 2)^{a-1}} \right).$$

Because

$$\lim_{R\to\infty} \frac{1}{(\ln R)^{a-1}} = \begin{cases} \infty, & 0 < a < 1 \\ 0, & a > 1 \end{cases}$$

we conclude the integral diverges when $0 < a < 1$ and converges when $a > 1$. Therefore

$$\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^a} \text{ converges for } a > 1 \text{ and diverges for } 0 < a < 1.$$

Next, consider the case $a = 1$. The series becomes $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n \ln n}$. Let $f(x) = \dfrac{1}{x \ln x}$. For $x \geq 2$, this function is continuous, positive and decreasing, so the Integral Test applies. Using the substitution $u = \ln x$, $du = \frac{1}{x}\,dx$, we find

$$\int_2^{\infty} \frac{dx}{x \ln x} = \lim_{R\to\infty} \int_2^R \frac{dx}{x \ln x} = \lim_{R\to\infty} \int_{\ln 2}^{\ln R} \frac{du}{u} = \lim_{R\to\infty} (\ln(\ln R) - \ln(\ln 2)) = \infty.$$

The integral diverges; hence, the series also diverges.

Finally, consider the case $a < 0$. Let $b = -a > 0$ so the series becomes $\displaystyle\sum_{n=2}^{\infty} \frac{(\ln n)^b}{n}$. Since $\ln n > 1$ for all $n \geq 3$, it follows that

$$(\ln n)^b > 1 \quad \text{so} \quad \frac{(\ln n)^b}{n} > \frac{1}{n}.$$

The series $\displaystyle\sum_{n=3}^{\infty} \frac{1}{n}$ diverges, so by the Comparison Test we can conclude that $\displaystyle\sum_{n=3}^{\infty} \frac{(\ln n)^b}{n}$ also diverges. Consequently, $\displaystyle\sum_{n=2}^{\infty} \frac{(\ln n)^b}{n}$ diverges. Thus,

$$\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^a} \text{ diverges for } a < 0.$$

To summarize:

$$\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^a} \text{ converges if } a > 1 \text{ and diverges if } a \leq 1.$$

80. For which a does $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n^a \ln n}$ converge?

SOLUTION First consider the case $a > 1$. For $n \geq 3$, $\ln n > 1$ and

$$\frac{1}{n^a \ln n} < \frac{1}{n^a}.$$

The series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^a}$ is a p-series with $p = a > 1$, so it converges; hence, $\displaystyle\sum_{n=3}^{\infty} \frac{1}{n^a}$ also converges. By the Comparison Test we can therefore conclude that the series $\displaystyle\sum_{n=3}^{\infty} \frac{1}{n^a \ln n}$ converges, which implies the series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n^a \ln n}$ also converges.

For $a \leq 1$, $n^a \leq n$ so

$$\frac{1}{n^a \ln n} \geq \frac{1}{n \ln n}$$

for $n \geq 2$. Let $f(x) = \dfrac{1}{x \ln x}$. For $x \geq 2$, this function is continuous, positive and decreasing, so the Integral Test applies. Using the substitution $u = \ln x$, $du = \frac{1}{x}\,dx$, we find

$$\int_2^{\infty} \frac{dx}{x \ln x} = \lim_{R\to\infty} \int_2^R \frac{dx}{x \ln x} = \lim_{R\to\infty} \int_{\ln 2}^{\ln R} \frac{du}{u} = \lim_{R\to\infty} (\ln(\ln R) - \ln(\ln 2)) = \infty.$$

The integral diverges; hence, the series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n \ln n}$ also diverges. By the Comparison Test we can therefore conclude that the series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n^a \ln n}$ diverges.

To summarize,

$$\sum_{n=2}^{\infty} \frac{1}{n^a \ln n} \text{ converges for } a > 1 \text{ and diverges for } a \leq 1.$$

Approximating Infinite Sums *In Exercises 81–83, let $a_n = f(n)$, where $f(x)$ is a continuous, decreasing function such that $f(x) \geq 0$ and $\int_1^{\infty} f(x)\,dx$ converges.*

81. Show that

$$\int_1^{\infty} f(x)\,dx \leq \sum_{n=1}^{\infty} a_n \leq a_1 + \int_1^{\infty} f(x)\,dx \qquad \boxed{3}$$

SOLUTION From the proof of the Integral Test, we know that

$$a_2 + a_3 + a_4 + \cdots + a_N \leq \int_1^N f(x)\,dx \leq \int_1^{\infty} f(x)\,dx;$$

that is,

$$S_N - a_1 \leq \int_1^{\infty} f(x)\,dx \quad \text{or} \quad S_N \leq a_1 + \int_1^{\infty} f(x)\,dx.$$

Also from the proof of the Integral test, we know that

$$\int_1^N f(x)\,dx \leq a_1 + a_2 + a_3 + \cdots + a_{N-1} = S_N - a_N \leq S_N.$$

Thus,

$$\int_1^N f(x)\,dx \leq S_N \leq a_1 + \int_1^{\infty} f(x)\,dx.$$

Taking the limit as $N \to \infty$ yields Eq. (3), as desired.

82. CAS Using Eq. (3), show that

$$5 \leq \sum_{n=1}^{\infty} \frac{1}{n^{1.2}} \leq 6$$

This series converges slowly. Use a computer algebra system to verify that $S_N < 5$ for $N \leq 43{,}128$ and $S_{43,129} \approx 5.00000021$.

SOLUTION By Eq. (3), we have

$$\int_1^{\infty} \frac{dx}{x^{1.2}} \leq \sum_{n=1}^{\infty} \frac{1}{n^{1.2}} \leq 1 + \int_1^{\infty} \frac{dx}{x^{1.2}}.$$

Since

$$\int_1^{\infty} \frac{dx}{x^{1.2}} = \lim_{R\to\infty} \int_1^{R} \frac{dx}{x^{1.2}} = \lim_{R\to\infty} \left(\frac{1}{0.2} - \frac{R^{-0.2}}{0.2} \right) = 5,$$

it follows that

$$5 \leq \sum_{n=1}^{\infty} \frac{1}{n^{1.2}} \leq 6.$$

Because $a_n = n^{-1.2} \geq 0$ for all N, S_N is increasing and it suffices to show that $S_N < 5$ for $N = 43{,}128$ to conclude that $S_N < 5$ for all $N \leq 43{,}128$. Using a computer algebra system, we obtain:

$$S_{43,128} = \sum_{n=1}^{43,128} \frac{1}{n^{1.2}} = 4.9999974685$$

and

$$S_{43,129} = \sum_{n=1}^{43,129} \frac{1}{n^{1.2}} = 5.0000002118.$$

83. Let $S = \sum_{n=1}^{\infty} a_n$. Arguing as in Exercise 81, show that

$$\sum_{n=1}^{M} a_n + \int_{M+1}^{\infty} f(x)\,dx \leq S \leq \sum_{n=1}^{M+1} a_n + \int_{M+1}^{\infty} f(x)\,dx \qquad \boxed{4}$$

Conclude that

$$0 \leq S - \left(\sum_{n=1}^{M} a_n + \int_{M+1}^{\infty} f(x)\,dx \right) \leq a_{M+1} \qquad \boxed{5}$$

This provides a method for approximating S with an error of at most a_{M+1}.

SOLUTION Following the proof of the Integral Test and the argument in Exercise 81, but starting with $n = M + 1$ rather than $n = 1$, we obtain

$$\int_{M+1}^{\infty} f(x)\,dx \leq \sum_{n=M+1}^{\infty} a_n \leq a_{M+1} + \int_{M+1}^{\infty} f(x)\,dx.$$

Adding $\sum_{n=1}^{M} a_n$ to each part of this inequality yields

$$\sum_{n=1}^{M} a_n + \int_{M+1}^{\infty} f(x)\,dx \leq \sum_{n=1}^{\infty} a_n = S \leq \sum_{n=1}^{M+1} a_n + \int_{M+1}^{\infty} f(x)\,dx.$$

Subtracting $\sum_{n=1}^{M} a_n + \int_{M+1}^{\infty} f(x)\,dx$ from each part of this last inequality then gives us

$$0 \leq S - \left(\sum_{n=1}^{M} a_n + \int_{M+1}^{\infty} f(x)\,dx \right) \leq a_{M+1}.$$

84. CAS Use Eq. (4) with $M = 43{,}129$ to prove that

$$5.5915810 \le \sum_{n=1}^{\infty} \frac{1}{n^{1.2}} \le 5.5915839$$

SOLUTION Using Eq. (4) with $f(x) = \frac{1}{x^{1.2}}$, $a_n = \frac{1}{n^{1.2}}$ and $M = 43129$, we find

$$S_{43129} + \int_{43130}^{\infty} \frac{dx}{x^{1.2}} \le \sum_{n=1}^{\infty} \frac{1}{n^{1.2}} \le S_{43130} + \int_{43130}^{\infty} \frac{dx}{x^{1.2}}.$$

Now,

$$S_{43129} = 5.0000002118;$$

$$S_{43130} = S_{43129} + \frac{1}{43130^{1.2}} = 5.0000029551;$$

and

$$\int_{43130}^{\infty} \frac{dx}{x^{1.2}} = \lim_{R\to\infty} \int_{43130}^{R} \frac{dx}{x^{1.2}} = -5 \lim_{R\to\infty} \left(\frac{1}{R^{0.2}} - \frac{1}{43130^{0.2}} \right) = \frac{5}{43130^{0.2}} = 0.5915808577.$$

Thus,

$$5.0000002118 + 0.5915808577 \le \sum_{n=1}^{\infty} \frac{1}{n^{1.2}} \le 5.0000029551 + 0.5915808577,$$

or

$$5.5915810695 \le \sum_{n=1}^{\infty} \frac{1}{n^{1.2}} \le 5.5915838128.$$

85. CAS Apply Eq. (4) with $M = 40{,}000$ to show that

$$1.644934066 \le \sum_{n=1}^{\infty} \frac{1}{n^2} \le 1.644934068$$

Is this consistent with Euler's result, according to which this infinite series has sum $\pi^2/6$?

SOLUTION Using Eq. (4) with $f(x) = \frac{1}{x^2}$, $a_n = \frac{1}{n^2}$ and $M = 40{,}000$, we find

$$S_{40,000} + \int_{40,001}^{\infty} \frac{dx}{x^2} \le \sum_{n=1}^{\infty} \frac{1}{n^2} \le S_{40,001} + \int_{40,001}^{\infty} \frac{dx}{x^2}.$$

Now,

$$S_{40,000} = 1.6449090672;$$

$$S_{40,001} = S_{40,000} + \frac{1}{40{,}001} = 1.6449090678;$$

and

$$\int_{40,001}^{\infty} \frac{dx}{x^2} = \lim_{R\to\infty} \int_{40,001}^{R} \frac{dx}{x^2} = -\lim_{R\to\infty} \left(\frac{1}{R} - \frac{1}{40{,}001} \right) = \frac{1}{40{,}001} = 0.0000249994.$$

Thus,

$$1.6449090672 + 0.0000249994 \le \sum_{n=1}^{\infty} \frac{1}{n^2} \le 1.6449090678 + 0.0000249994,$$

or

$$1.6449340665 \le \sum_{n=1}^{\infty} \frac{1}{n^2} \le 1.6449340672.$$

Since $\frac{\pi^2}{6} \approx 1.6449340668$, our approximation is consistent with Euler's result.

86. CAS Using a CAS and Eq. (5), determine the value of $\sum_{n=1}^{\infty} n^{-6}$ to within an error less than 10^{-4}. Check that your result is consistent with that of Euler, who proved that the sum is equal to $\pi^6/945$.

SOLUTION According to Eq. (5), if we choose M so that $(M+1)^{-6} < 10^{-4}$, we can then approximate the sum to within 10^{-4}. Solving $(M+1)^{-6} = 10^{-4}$ gives $M+1 = 10^{-2/3} \approx 4.641$, so the smallest such integral M is $M = 4$. Denote by S the sum of the series. Then

$$0 \le S - \left(\sum_{n=1}^{4} n^{-6} + \int_5^{\infty} x^{-6}\,dx\right) \le (M+1)^{-6} < 10^{-4}$$

We have

$$\sum_{n=1}^{4} n^{-6} = \frac{1}{1} + \frac{1}{64} + \frac{1}{729} + \frac{1}{4096} \approx 1.017240883$$

$$\int_5^{\infty} x^{-6}\,dx = -\frac{1}{5}x^{-5}\Big|_5^{\infty} = \frac{1}{5^6} \approx 0.000064$$

The sum of these two is $\approx$ 1.017304883, while $\dfrac{\pi^6}{945} \approx 1.017343063$. These two values differ by approximately $0.000038180 < 10^{-4}$, so the result is consistent with Euler's calculation.

87. CAS Using a CAS and Eq. (5), determine the value of $\sum_{n=1}^{\infty} n^{-5}$ to within an error less than 10^{-4}.

SOLUTION Using Eq. (5) with $f(x) = x^{-5}$ and $a_n = n^{-5}$, we have

$$0 \le \sum_{n=1}^{\infty} n^{-5} - \left(\sum_{n=1}^{M+1} n^{-5} + \int_{M+1}^{\infty} x^{-5}\,dx\right) \le (M+1)^{-5}.$$

To guarantee an error less than 10^{-4}, we need $(M+1)^{-5} \le 10^{-4}$. This yields $M \ge 10^{4/5} - 1 \approx 5.3$, so we choose $M = 6$. Now,

$$\sum_{n=1}^{7} n^{-5} = 1.0368498887,$$

and

$$\int_7^{\infty} x^{-5}\,dx = \lim_{R\to\infty} \int_7^{R} x^{-5}\,dx = -\frac{1}{4}\lim_{R\to\infty}\left(R^{-4} - 7^{-4}\right) = \frac{1}{4\cdot 7^4} = 0.0001041233.$$

Thus,

$$\sum_{n=1}^{\infty} n^{-5} \approx \sum_{n=1}^{7} n^{-5} + \int_7^{\infty} x^{-5}\,dx = 1.0368498887 + 0.0001041233 = 1.0369540120.$$

88. How far can a stack of identical books (of mass m and unit length) extend without tipping over? The stack will not tip over if the $(n+1)$st book is placed at the bottom of the stack with its right edge located at the center of mass of the first n books (Figure 5). Let c_n be the center of mass of the first n books, measured along the x-axis, where we take the positive x-axis to the left of the origin as in Figure 6. Recall that if an object of mass m_1 has center of mass at x_1 and a second object of m_2 has center of mass x_2, then the center of mass of the system has x-coordinate

$$\frac{m_1x_1 + m_2x_2}{m_1 + m_2}$$

(a) Show that if the $(n+1)$st book is placed with its right edge at c_n, then its center of mass is located at $c_n + \frac{1}{2}$.

(b) Consider the first n books as a single object of mass nm with center of mass at c_n and the $(n+1)$st book as a second object of mass m. Show that if the $(n+1)$st book is placed with its right edge at c_n, then $c_{n+1} = c_n + \dfrac{1}{2(n+1)}$.

(c) Prove that $\lim_{n\to\infty} c_n = \infty$. Thus, by using enough books, the stack can be extended as far as desired without tipping over.

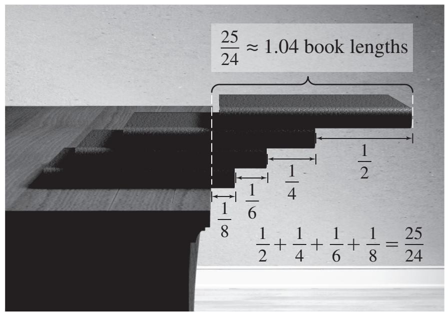

FIGURE 5

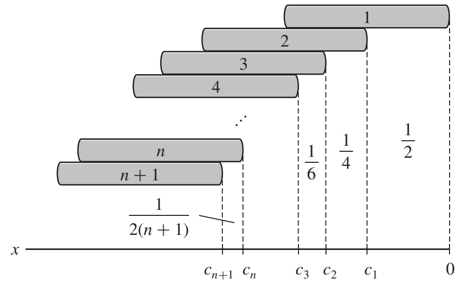

FIGURE 6

SOLUTION Let $f(x) = \frac{1}{x}$. This function is continuous, positive and decreasing, so following the argument of Exercise 81, we know that

$$\int_1^N f(x)\,dx \le S_N \le a_1 + \int_1^N f(x)\,dx,$$

or

$$\ln N \le 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{N} \le 1 + \ln N.$$

Using the inequality on the right-hand side, we know that

$$S_{8100} \le 1 + \ln 8100 = 9.999619 < 10;$$

using the inequality on the left-hand side, we can guarantee $S_N \ge 100$ by making $\ln N \ge 100$. Thus, we can take

$$N \ge e^{100} \approx 2.688 \times 10^{43}.$$

89. The following argument proves the divergence of the harmonic series $S = \sum_{n=1}^{\infty} 1/n$ without using the Integral Test. Let

$$S_1 = 1 + \frac{1}{3} + \frac{1}{5} + \cdots, \qquad S_2 = \frac{1}{2} + \frac{1}{4} + \frac{1}{6} + \cdots$$

Show that if S converges, then

(a) S_1 and S_2 also converge and $S = S_1 + S_2$.

(b) $S_1 > S_2$ and $S_2 = \frac{1}{2}S$.

Observe that (b) contradicts (a), and conclude that S diverges.

SOLUTION Assume throughout that S converges; we will derive a contradiction. Write

$$a_n = \frac{1}{n}, \quad b_n = \frac{1}{2n-1}, \quad c_n = \frac{1}{2n}$$

for the n^{th} terms in the series S, S_1, and S_2. Since $2n - 1 \ge n$ for $n \ge 1$, we have $b_n < a_n$. Since $S = \sum a_n$ converges, so does $S_1 = \sum b_n$ by the Comparison Test. Also, $c_n = \dfrac{1}{2}a_n$, so again by the Comparison Test, the convergence of S implies the convergence of $S_2 = \sum c_n$. Now, define two sequences

$$b'_n = \begin{cases} b_{(n+1)/2} & n \text{ odd} \\ 0 & n \text{ even} \end{cases}$$

$$c'_n = \begin{cases} 0 & n \text{ odd} \\ c_{n/2} & n \text{ even} \end{cases}$$

That is, b'_n and c'_n look like b_n and c_n, but have zeros inserted in the "missing" places compared to a_n. Then $a_n = b'_n + c'_n$; also $S_1 = \sum b_n = \sum b'_n$ and $S_2 = \sum c_n = \sum c'_n$. Finally, since S, S_1, and S_2 all converge, we have

$$S = \sum_{n=1}^{\infty} a_n = \sum_{n=1}^{\infty} (b'_n + c'_n) = \sum_{n=1}^{\infty} b'_n + \sum_{n=1}^{\infty} c'_n = \sum_{n=1}^{\infty} b_n + \sum_{n=1}^{\infty} c_n = S_1 + S_2$$

Now, $b_n > c_n$ for every n, so that $S_1 > S_2$. Also, we showed above that $c_n = \dfrac{1}{2}a_n$, so that $2S_2 = S$. Putting all this together gives

$$S = S_1 + S_2 > S_2 + S_2 = 2S_2 = S$$

so that $S > S$, a contradiction. Thus S must diverge.

Further Insights and Challenges

90. Let $S = \sum_{n=2}^{\infty} a_n$, where $a_n = (\ln(\ln n))^{-\ln n}$.

(a) Show, by taking logarithms, that $a_n = n^{-\ln(\ln(\ln n))}$.

(b) Show that $\ln(\ln(\ln n)) \geq 2$ if $n > C$, where $C = e^{e^{e^2}}$.

(c) Show that S converges.

SOLUTION

(a) Let $a_n = (\ln(\ln n))^{-\ln n}$. Then

$$\ln a_n = (-\ln n)\ln(\ln(\ln n)),$$

and

$$a_n = e^{(-\ln n)\ln(\ln(\ln n))} = \left(e^{\ln n}\right)^{-\ln(\ln(\ln n))} = n^{-\ln(\ln(\ln n))}.$$

(b) Suppose $n > e^{e^{e^2}}$. Then

$$\ln n > \ln e^{e^{e^2}} = e^{e^2};$$

$$\ln(\ln n) > \ln e^{e^2} = e^2; \text{ and}$$

$$\ln(\ln(\ln n)) > \ln e^2 = 2.$$

(c) Combining the results from parts (a) and (b), we have

$$a_n = \frac{1}{n^{\ln(\ln(\ln n))}} \leq \frac{1}{n^2}$$

for $n > C = e^{e^{e^2}}$. The series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a convergent p-series, so $\sum_{n=C+1}^{\infty} \frac{1}{n^2}$ also converges. By the Comparison Test we can therefore conclude that the series $\sum_{n=C+1}^{\infty} a_n$ converges, which means that the series $\sum_{n=2}^{\infty} a_n$ converges.

91. Kummer's Acceleration Method Suppose we wish to approximate $S = \sum_{n=1}^{\infty} 1/n^2$. There is a similar telescoping series whose value can be computed exactly (Example 1 in Section 10.2):

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)} = 1$$

(a) Verify that

$$S = \sum_{n=1}^{\infty} \frac{1}{n(n+1)} + \sum_{n=1}^{\infty} \left(\frac{1}{n^2} - \frac{1}{n(n+1)}\right)$$

Thus for M large,

$$S \approx 1 + \sum_{n=1}^{M} \frac{1}{n^2(n+1)} \qquad \boxed{6}$$

(b) Explain what has been gained. Why is Eq. (6) a better approximation to S than is $\sum_{n=1}^{M} 1/n^2$?

(c) CAS Compute

$$\sum_{n=1}^{1000} \frac{1}{n^2}, \qquad 1 + \sum_{n=1}^{100} \frac{1}{n^2(n+1)}$$

Which is a better approximation to S, whose exact value is $\pi^2/6$?

SOLUTION

(a) Because the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ and $\sum_{n=1}^{\infty} \frac{1}{n(n+1)}$ both converge,

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)} + \sum_{n=1}^{\infty} \left(\frac{1}{n^2} - \frac{1}{n(n+1)} \right) = \sum_{n=1}^{\infty} \frac{1}{n(n+1)} + \sum_{n=1}^{\infty} \frac{1}{n^2} - \sum_{n=1}^{\infty} \frac{1}{n(n+1)} = \sum_{n=1}^{\infty} \frac{1}{n^2} = S.$$

Now,

$$\frac{1}{n^2} - \frac{1}{n(n+1)} = \frac{n+1}{n^2(n+1)} - \frac{n}{n^2(n+1)} = \frac{1}{n^2(n+1)},$$

so, for M large,

$$S \approx 1 + \sum_{n=1}^{M} \frac{1}{n^2(n+1)}.$$

(b) The series $\sum_{n=1}^{\infty} \frac{1}{n^2(n+1)}$ converges more rapidly than $\sum_{n=1}^{\infty} \frac{1}{n^2}$ since the degree of n in the denominator is larger.

(c) Using a computer algebra system, we find

$$\sum_{n=1}^{1000} \frac{1}{n^2} = 1.6439345667 \quad \text{and} \quad 1 + \sum_{n=1}^{100} \frac{1}{n^2(n+1)} = 1.6448848903.$$

The second sum is more accurate because it is closer to the exact solution $\frac{\pi^2}{6} \approx 1.6449340668$.

92. CAS The series $S = \sum_{k=1}^{\infty} k^{-3}$ has been computed to more than 100 million digits. The first 30 digits are

$$S = 1.202056903159594285399738161511$$

Approximate S using the Acceleration Method of Exercise 91 with $M = 100$ and auxiliary series

$$R = \sum_{n=1}^{\infty} (n(n+1)(n+2))^{-1}.$$

According to Exercise 46 in Section 10.2, R is a telescoping series with the sum $R = \frac{1}{4}$.

SOLUTION We compute the difference between the general term of the given series and the general term of the auxiliary series:

$$\frac{1}{k^3} - \frac{1}{k(k+1)(k+2)} = \frac{(k+1)(k+2) - k^2}{k^3(k+1)(k+2)} = \frac{k^2 + 3k + 2 - k^2}{k^3(k+1)(k+2)} = \frac{3k+2}{k^3(k+1)(k+2)}$$

Hence,

$$\sum_{k=1}^{\infty} \frac{1}{k^3} = \sum_{k=1}^{\infty} \frac{1}{k(k+1)(k+2)} + \sum_{k=1}^{\infty} \frac{3k+2}{k^3(k+1)(k+2)} = \frac{1}{4} + \sum_{k=1}^{\infty} \frac{3k+2}{k^3(k+1)(k+2)}$$

With $M = 100$ and using a computer algebra system, we find

$$\sum_{k=1}^{\infty} \frac{1}{k^3} \approx \frac{1}{4} + \sum_{k=1}^{100} \frac{3k+2}{k^3(k+1)(k+2)} = 1.2020559349.$$

10.4 Absolute and Conditional Convergence

Preliminary Questions

1. Give an example of a series such that $\sum a_n$ converges but $\sum |a_n|$ diverges.

SOLUTION The series $\sum \frac{(-1)^n}{\sqrt[3]{n}}$ converges by the Leibniz Test, but the positive series $\sum \frac{1}{\sqrt[3]{n}}$ is a divergent p-series.

2. Which of the following statements is equivalent to Theorem 1?

(a) If $\sum_{n=0}^{\infty} |a_n|$ diverges, then $\sum_{n=0}^{\infty} a_n$ also diverges.

(b) If $\sum_{n=0}^{\infty} a_n$ diverges, then $\sum_{n=0}^{\infty} |a_n|$ also diverges.

(c) If $\sum_{n=0}^{\infty} a_n$ converges, then $\sum_{n=0}^{\infty} |a_n|$ also converges.

SOLUTION The correct answer is **(b)**: If $\sum_{n=0}^{\infty} a_n$ diverges, then $\sum_{n=0}^{\infty} |a_n|$ also diverges. Take $a_n = (-1)^n \frac{1}{n}$ to see that statements **(a)** and **(c)** are not true in general.

3. Lathika argues that $\sum_{n=1}^{\infty} (-1)^n \sqrt{n}$ is an alternating series and therefore converges. Is Lathika right?

SOLUTION No. Although $\sum_{n=1}^{\infty} (-1)^n \sqrt{n}$ is an alternating series, the terms $a_n = \sqrt{n}$ do not form a decreasing sequence that tends to zero. In fact, $a_n = \sqrt{n}$ is an increasing sequence that tends to ∞, so $\sum_{n=1}^{\infty} (-1)^n \sqrt{n}$ diverges by the Divergence Test.

4. Suppose that a_n is positive, decreasing, and tends to 0, and let $S = \sum_{n=1}^{\infty} (-1)^{n-1} a_n$. What can we say about $|S - S_{100}|$ if $a_{101} = 10^{-3}$? Is S larger or smaller than S_{100}?

SOLUTION From the text, we know that $|S - S_{100}| < a_{101} = 10^{-3}$. Also, the Leibniz test tells us that $S_{2N} < S < S_{2N+1}$ for any $N \geq 1$, so that $S_{100} < S$.

Exercises

1. Show that

$$\sum_{n=0}^{\infty} \frac{(-1)^n}{2^n}$$

converges absolutely.

SOLUTION The positive series $\sum_{n=0}^{\infty} \frac{1}{2^n}$ is a geometric series with $r = \frac{1}{2}$. Thus, the positive series converges, and the given series converges absolutely.

2. Show that the following series converges conditionally:

$$\sum_{n=1}^{\infty} (-1)^{n-1} \frac{1}{n^{2/3}} = \frac{1}{1^{2/3}} - \frac{1}{2^{2/3}} + \frac{1}{3^{2/3}} - \frac{1}{4^{2/3}} + \cdots$$

SOLUTION Let $a_n = \frac{1}{n^{2/3}}$. Then a_n forms a decreasing sequence that tends to zero; hence, the series $\sum_{n=1}^{\infty} (-1)^{n-1} \frac{1}{n^{2/3}}$ converges by the Leibniz Test. However, the positive series $\sum_{n=1}^{\infty} \frac{1}{n^{2/3}}$ is a divergent p-series, so the original series converges conditionally.

In Exercises 3–10, determine whether the series converges absolutely, conditionally, or not at all.

3. $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^{1/3}}$

SOLUTION The sequence $a_n = \frac{1}{n^{1/3}}$ is positive, decreasing, and tends to zero; hence, the series $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^{1/3}}$ converges by the Leibniz Test. However, the positive series $\sum_{n=1}^{\infty} \frac{1}{n^{1/3}}$ is a divergent p-series, so the original series converges conditionally.

4. $\sum_{n=1}^{\infty} \frac{(-1)^n n^4}{n^3+1}$

SOLUTION Because

$$\lim_{n\to\infty} \frac{n^4}{n^3+1} = \infty,$$

the general term $\frac{(-1)^n n^4}{n^3+1}$ of the series does not tend to zero; hence, this series diverges by the Divergence Test.

5. $\sum_{n=0}^{\infty} \frac{(-1)^{n-1}}{(1.1)^n}$

SOLUTION The positive series $\sum_{n=0}^{\infty} \left(\frac{1}{1.1}\right)^n$ is a convergent geometric series; thus, the original series converges absolutely.

6. $\sum_{n=1}^{\infty} \frac{\sin(\frac{\pi n}{4})}{n^2}$

SOLUTION Because

$$\left| \frac{\sin\left(\frac{\pi n}{4}\right)}{n^2} \right| = \frac{\left|\sin\left(\frac{\pi n}{4}\right)\right|}{n^2} \le \frac{1}{n^2}$$

the positive series forms a convergent p-series; thus, the original series converges absolutely.

7. $\sum_{n=2}^{\infty} \frac{(-1)^n}{n \ln n}$

SOLUTION Let $a_n = \frac{1}{n \ln n}$. Then a_n forms a decreasing sequence (note that n and $\ln n$ are both increasing functions of n) that tends to zero; hence, the series $\sum_{n=2}^{\infty} \frac{(-1)^n}{n \ln n}$ converges by the Leibniz Test. However, the positive series $\sum_{n=2}^{\infty} \frac{1}{n \ln n}$ diverges, so the original series converges conditionally.

8. $\sum_{n=1}^{\infty} \frac{(-1)^n}{1+\frac{1}{n}}$

SOLUTION Because

$$\lim_{n\to\infty} \frac{1}{1+\frac{1}{n}} = \frac{1}{1+0} = 1,$$

the general term $\frac{(-1)^n}{1+\frac{1}{n}}$ of the series does not tend to zero; hence, the series diverges by the Divergent Test.

9. $\sum_{n=2}^{\infty} \frac{\cos n\pi}{(\ln n)^2}$

SOLUTION Since $\cos n\pi$ alternates between $+1$ and -1,

$$\sum_{n=2}^{\infty} \frac{\cos n\pi}{(lnn)^2} = \sum_{n=2}^{\infty} \frac{(-1)^n}{(lnn)^2}$$

This is an alternating series whose general term decreases to zero, so it converges. The associated positive series,

$$\sum_{n=2}^{\infty} \frac{1}{(\ln n)^2}$$

is a divergent series, so the original series converges conditionally.

10. $\displaystyle\sum_{n=1}^{\infty} \frac{\cos n}{2^n}$

SOLUTION The associated positive series is

$$\sum_{n=1}^{\infty} \frac{|\cos n|}{2^n} \le \sum_{n=1}^{\infty} \frac{1}{2^n}$$

which is a convergent geometric series. Thus the associated positive series converges, so the original series converges absolutely.

11. Let $S = \displaystyle\sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n^3}$.

(a) Calculate S_n for $1 \le n \le 10$.

(b) Use Eq. (2) to show that $0.9 \le S \le 0.902$.

SOLUTION

(a)

$$S_1 = 1 \qquad S_6 = S_5 - \frac{1}{6^3} = 0.899782407$$

$$S_2 = 1 - \frac{1}{2^3} = \frac{7}{8} = 0.875 \qquad S_7 = S_6 + \frac{1}{7^3} = 0.902697859$$

$$S_3 = S_2 + \frac{1}{3^3} = 0.912037037 \qquad S_8 = S_7 - \frac{1}{8^3} = 0.900744734$$

$$S_4 = S_3 - \frac{1}{4^3} = 0.896412037 \qquad S_9 = S_8 + \frac{1}{9^3} = 0.902116476$$

$$S_5 = S_4 + \frac{1}{5^3} = 0.904412037 \qquad S_{10} = S_9 - \frac{1}{10^3} = 0.901116476$$

(b) By Eq. (2),

$$|S_{10} - S| \le a_{11} = \frac{1}{11^3},$$

so

$$S_{10} - \frac{1}{11^3} \le S \le S_{10} + \frac{1}{11^3},$$

or

$$0.900365161 \le S \le 0.901867791.$$

12. Use Eq. (2) to approximate

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n!}$$

to four decimal places.

SOLUTION Let $S = \displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n!}$, so that $a_n = \dfrac{1}{n!}$. By Eq. (2),

$$|S_N - S| \le a_{N+1} = \frac{1}{(N+1)!}.$$

To guarantee accuracy to four decimal places, we must choose N so that

$$\frac{1}{(N+1)!} < 5 \times 10^{-5} \quad \text{or} \quad (N+1)! > 20{,}000.$$

Because $7! = 5040$ and $8! = 40,320$, the smallest value that satisfies the required inequality is $N = 7$. Thus,

$$S \approx S_7 = 1 - \frac{1}{2!} + \frac{1}{3!} - \frac{1}{4!} + \frac{1}{5!} - \frac{1}{6!} + \frac{1}{7!} = 0.632142857.$$

13. Approximate $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^4}$ to three decimal places.

SOLUTION Let $S = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^4}$, so that $a_n = \frac{1}{n^4}$. By Eq. (2),

$$|S_N - S| \le a_{N+1} = \frac{1}{(N+1)^4}.$$

To guarantee accuracy to three decimal places, we must choose N so that

$$\frac{1}{(N+1)^4} < 5 \times 10^{-4} \quad \text{or} \quad N > \sqrt[4]{2000} - 1 \approx 5.7.$$

The smallest value that satisfies the required inequality is then $N = 6$. Thus,

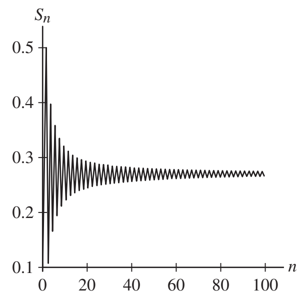
$$S \approx S_6 = 1 - \frac{1}{2^4} + \frac{1}{3^4} - \frac{1}{4^4} + \frac{1}{5^4} - \frac{1}{6^4} = 0.946767824.$$

14. CAS Let

$$S = \sum_{n=1}^{\infty} (-1)^{n-1} \frac{n}{n^2+1}$$

Use a computer algebra system to calculate and plot the partial sums S_n for $1 \le n \le 100$. Observe that the partial sums zigzag above and below the limit.

SOLUTION The partial sums associated with the alternating series $\sum_{n=1}^{\infty} (-1)^{n-1} \frac{n}{n^2+1}$ are plotted below. As expected, the partial sums alternate between overestimating and underestimating the sum.



In Exercises 15 and 16, find a value of N such that S_N approximates the series with an error of at most 10^{-5}. If you have a CAS, compute this value of S_N.

15. $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n(n+2)(n+3)}$

SOLUTION Let $S = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n\,(n+2)\,(n+3)}$, so that $a_n = \frac{1}{n\,(n+2)\,(n+3)}$. By Eq. (2),

$$|S_N - S| \le a_{N+1} = \frac{1}{(N+1)(N+3)(N+4)}.$$

We must choose N so that

$$\frac{1}{(N+1)(N+3)(N+4)} \le 10^{-5} \quad \text{or} \quad (N+1)(N+3)(N+4) \ge 10^5.$$

For $N = 43$, the product on the left hand side is 95,128, while for $N = 44$ the product is 101,520; hence, the smallest value of N which satisfies the required inequality is $N = 44$. Thus,

$$S \approx S_{44} = \sum_{n=1}^{44} \frac{(-1)^{n+1}}{n(n+2)(n+3)} = 0.0656746.$$

16. $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n+1} \ln n}{n!}$

SOLUTION Let $S = \displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n+1} \ln n}{n!}$, so that $a_n = \dfrac{\ln n}{n!}$. By Eq. (2),

$$|S_N - S| \le a_{N+1} = \frac{\ln(N+1)}{(N+1)!}.$$

To make the error at most 10^{-5}, we must choose N so that

$$\frac{\ln(N+1)}{(N+1)!} \le 10^{-5}.$$

For $N = 7$, the left-hand side of the above inequality is 5.157×10^{-5}, while for $N = 8$, the left-hand side is 6.055×10^{-6}; hence, the smallest value for N which satisfies the required inequality is $N = 8$. Thus,

$$S \approx S_8 = \sum_{n=1}^{8} \frac{(-1)^{n+1} \ln n}{n!} = -0.209975859.$$

In Exercises 17–32, determine convergence or divergence by any method.

17. $\displaystyle\sum_{n=0}^{\infty} 7^{-n}$

SOLUTION This is a (positive) geometric series with $r = \dfrac{1}{7} < 1$, so it converges.

18. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^{7.5}}$

SOLUTION This is a p-series with $p = 7.5 > 1$, so it converges.

19. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{5^n - 3^n}$

SOLUTION Use the Limit Comparison Test with $\dfrac{1}{5^n}$:

$$L = \lim_{n\to\infty} \frac{1/(5^n - 3^n)}{1/5^n} = \lim_{n\to\infty} \frac{5^n}{5^n - 3^n} = \lim_{n\to\infty} \frac{1}{1 - (3/5)^n} = 1$$

But $\sum_{n=1}^{\infty} \dfrac{1}{5^n}$ is a convergent geometric series. Since $L = 1$, the Limit Comparison Test tells us that the original series converges as well.

20. $\displaystyle\sum_{n=2}^{\infty} \frac{n}{n^2 - n}$

SOLUTION Apply the Limit Comparison Test and compare with the divergent harmonic series:

$$L = \lim_{n\to\infty} \frac{\frac{n}{n^2-n}}{\frac{1}{n}} = \lim_{n\to\infty} \frac{n^2}{n^2 - n} = 1.$$

Because $L > 0$, we conclude that the series $\displaystyle\sum_{n=2}^{\infty} \frac{n}{n^2 - n}$ diverges.

21. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{3n^4 + 12n}$

SOLUTION Use the Limit Comparison Test with $\dfrac{1}{3n^4}$:

$$L = \lim_{n\to\infty} \frac{(1/(3n^4+12n)}{1/3n^4} = \lim_{n\to\infty} \frac{3n^4}{3n^4+12n} = \lim_{n\to\infty} \frac{1}{1+4n^{-3}} = 1$$

But $\sum_{n=1}^{\infty} \dfrac{1}{3n^4} = \frac{1}{3}\sum_{n=1}^{\infty} \frac{1}{n^4}$ is a convergent p-series. Since $L = 1$, the Limit Comparison Test tells us that the original series converges as well.

22. $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n^2+1}}$

SOLUTION This is an alternating series with $a_n = \dfrac{1}{\sqrt{n^2+1}}$. Because a_n is a decreasing sequence that converges to zero, the series $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n^2+1}}$ converges by the Leibniz Test.

23. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt{n^2+1}}$

SOLUTION Apply the Limit Comparison Test and compare the series with the divergent harmonic series:

$$L = \lim_{n\to\infty} \frac{\frac{1}{\sqrt{n^2+1}}}{\frac{1}{n}} = \lim_{n\to\infty} \frac{n}{\sqrt{n^2+1}} = 1.$$

Because $L > 0$, we conclude that the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt{n^2+1}}$ diverges.

24. $\displaystyle\sum_{n=0}^{\infty} \frac{(-1)^n n}{\sqrt{n^2+1}}$

SOLUTION This series diverges, since the general term of the associated positive series tends to 1, not to 0:

$$\lim_{n\to\infty} \frac{n}{\sqrt{n^2+1}} = \lim_{n\to\infty} \sqrt{\frac{n^2}{n^2+1}} = \lim_{n\to\infty} \sqrt{\frac{1}{1+n^{-2}}} = 1$$

25. $\displaystyle\sum_{n=1}^{\infty} \frac{3^n + (-2)^n}{5^n}$

SOLUTION The series

$$\sum_{n=1}^{\infty} \frac{3^n}{5^n} = \sum_{n=1}^{\infty} \left(\frac{3}{5}\right)^n$$

is a convergent geometric series, as is the series

$$\sum_{n=1}^{\infty} \frac{(-1)^n\, 2^n}{5^n} = \sum_{n=1}^{\infty} \left(-\frac{2}{5}\right)^n.$$

Hence,

$$\sum_{n=1}^{\infty} \frac{3^n + (-1)^n 2^n}{5^n} = \sum_{n=1}^{\infty} \left(\frac{3}{5}\right)^n + \sum_{n=1}^{\infty} \left(-\frac{2}{5}\right)^n$$

also converges.

26. $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{(2n+1)!}$

SOLUTION This is an alternating series with $a_n = \dfrac{1}{(2n+1)!}$. Because a_n is a decreasing sequence which converges to zero, the series $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{(2n+1)!}$ converges by the Leibniz Test.

27. $\sum_{n=1}^{\infty} (-1)^n n^2 e^{-n^3/3}$

SOLUTION Consider the associated positive series $\sum_{n=1}^{\infty} n^2 e^{-n^3/3}$. This series can be seen to converge by the Integral Test:

$$\int_1^{\infty} x^2 e^{-x^3/3}\,dx = \lim_{R\to\infty} \int_1^R x^2 e^{-x^3/3}\,dx = -\lim_{R\to\infty} e^{-x^3/3}\Big|_1^R = e^{-1/3} + \lim_{R\to\infty} e^{-R^3/3} = e^{-1/3}.$$

The integral converges, so the original series converges absolutely.

28. $\sum_{n=1}^{\infty} n e^{-n^3/3}$

SOLUTION This is a positive series, and by the Comparison Test with the associated positive series in the previous exercise,

$$\sum_{n=1}^{\infty} n e^{-n^3/3} \le \sum_{n=1}^{\infty} n^2 e^{-n^3/3}$$

Since the series on the right converges, so does the original series.

29. $\sum_{n=2}^{\infty} \frac{(-1)^n}{n^{1/2}(\ln n)^2}$

SOLUTION This is an alternating series with $a_n = \frac{1}{n^{1/2}(\ln n)^2}$. Because a_n is a decreasing sequence which converges to zero, the series $\sum_{n=2}^{\infty} \frac{(-1)^n}{n^{1/2}(\ln n)^2}$ converges by the Leibniz Test. (Note that the series converges only conditionally, not absolutely; the associated positive series is eventually greater than $\frac{1}{n^{3/4}}$, which is a divergent p-series).

30. $\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^{1/4}}$

SOLUTION Use the Integral Test, with the substitution $u = \ln x$:

$$\int_2^{\infty} \frac{1}{x \ln^{1/4} x}\,dx = \lim_{R\to\infty} \int_2^R \frac{1}{x \ln^{1/4} x}\,dx = \lim_{R\to\infty} \int_{\ln 2}^R u^{-1/4}\,du = \lim_{R\to\infty} \frac{4}{3} u^{3/4}\Big|_{\ln 2}^R$$
$$= -\frac{4}{3}\left((\ln 2)^{3/4} + \lim_{R\to\infty} R^{3/4}\right)$$

The integral diverges, so the original series diverges as well.

31. $\sum_{n=1}^{\infty} \frac{\ln n}{n^{1.05}}$

SOLUTION Choose N so that for $n \ge N$ we have $\ln n \le n^{0.01}$. Then

$$\sum_{n=N}^{\infty} \frac{\ln n}{n^{1.05}} \le \sum_{n=N}^{\infty} \frac{n^{0.01}}{n^{1.05}} = \sum_{n=N}^{\infty} \frac{1}{n^{1.04}}$$

This is a convergent p-series, so by the Comparison Test, the original series converges as well.

32. $\sum_{n=2}^{\infty} \frac{1}{(\ln n)^2}$

SOLUTION Choose N so that for $n \ge N$ we have $\ln n < n^{0.25}$ so that $\ln^2 n < n^{0.5}$. Then

$$\sum_{n=N}^{\infty} \frac{1}{(\ln n)^2} > \sum_{n=N}^{\infty} \frac{1}{n^{0.5}}$$

This is a divergent p-series, so by the Comparison Test, the original series diverges as well.

33. Show that

$$S = \frac{1}{2} - \frac{1}{2} + \frac{1}{3} - \frac{1}{3} + \frac{1}{4} - \frac{1}{4} + \cdots$$

converges by computing the partial sums. Does it converge absolutely?

SOLUTION The sequence of partial sums is

$$S_1 = \frac{1}{2}$$

$$S_2 = S_1 - \frac{1}{2} = 0$$

$$S_3 = S_2 + \frac{1}{3} = \frac{1}{3}$$

$$S_4 = S_3 - \frac{1}{3} = 0$$

and, in general,

$$S_N = \begin{cases} \frac{1}{N}, & \text{for odd } N \\ 0, & \text{for even } N \end{cases}$$

Thus, $\lim_{N\to\infty} S_N = 0$, and the series converges to 0. The positive series is

$$\frac{1}{2} + \frac{1}{2} + \frac{1}{3} + \frac{1}{3} + \frac{1}{4} + \frac{1}{4} + \cdots = 2\sum_{n=2}^{\infty} \frac{1}{n};$$

which diverges. Therefore, the original series converges conditionally, not absolutely.

34. The Leibniz Test cannot be applied to

$$\frac{1}{2} - \frac{1}{3} + \frac{1}{2^2} - \frac{1}{3^2} + \frac{1}{2^3} - \frac{1}{3^3} + \cdots$$

Why not? Show that it converges by another method.

SOLUTION The sequence of terms $\{a_n\}$ for this alternating series is

$$\frac{1}{2}, \frac{1}{3}, \frac{1}{2^2}, \frac{1}{3^2}, \frac{1}{2^3}, \frac{1}{3^3}, \dots, \frac{1}{2^n}, \frac{1}{3^n}, \frac{1}{2^{n+1}}, \frac{1}{3^{n+1}}, \dots$$

Now,

$$\frac{1}{3^2} = \frac{1}{9} < \frac{1}{8} = \frac{1}{2^3}.$$

Moreover, if we assume that

$$\frac{1}{3^k} < \frac{1}{2^{k+1}}$$

for some k, then

$$\frac{1}{3^{k+1}} = \frac{1}{3} \cdot \frac{1}{3^k} < \frac{1}{3}\frac{1}{2^{k+1}} < \frac{1}{2}\frac{1}{2^{k+1}} = \frac{1}{2^{k+2}}.$$

Thus, by mathematical induction,

$$\frac{1}{3^n} < \frac{1}{2^{n+1}}$$

for all $n \geq 2$. The sequence $\{a_n\}$ is therefore not decreasing, and the Leibniz Test does not apply.

We may express the given series as

$$\sum_{n=1}^{\infty} \left(\frac{1}{2^n} - \frac{1}{3^n} \right).$$

Because

$$\sum_{n=1}^{\infty} \frac{1}{2^n} = \sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^n \quad \text{and} \quad \sum_{n=1}^{\infty} \frac{1}{3^n} = \sum_{n=1}^{\infty} \left(\frac{1}{3}\right)^n$$

are both convergent geometric series, it follows that this series converges, and

$$\sum_{n=1}^{\infty}\left(\frac{1}{2^n}-\frac{1}{3^n}\right)=\sum_{n=1}^{\infty}\left(\frac{1}{2}\right)^n-\sum_{n=1}^{\infty}\left(\frac{1}{3}\right)^n=\frac{\frac{1}{2}}{1-\frac{1}{2}}-\frac{\frac{1}{3}}{1-\frac{1}{3}}=1-\frac{1}{2}=\frac{1}{2}.$$

35. **Assumptions Matter** Show by counterexample that the Leibniz Test does not remain true if the sequence a_n tends to zero but is not assumed nonincreasing. *Hint:* Consider

$$R=\frac{1}{2}-\frac{1}{4}+\frac{1}{3}-\frac{1}{8}+\frac{1}{4}-\frac{1}{16}+\cdots+\left(\frac{1}{n}-\frac{1}{2^n}\right)+\cdots$$

SOLUTION Let

$$R=\frac{1}{2}-\frac{1}{4}+\frac{1}{3}-\frac{1}{8}+\frac{1}{4}-\frac{1}{16}+\cdots+\left(\frac{1}{n+1}-\frac{1}{2^{n+1}}\right)+\cdots$$

This is an alternating series with

$$a_n=\begin{cases}\dfrac{1}{k+1}, & n=2k-1\\[2mm] \dfrac{1}{2^{k+1}}, & n=2k\end{cases}$$

Note that $a_n \to 0$ as $n \to \infty$, but the sequence $\{a_n\}$ is not decreasing. We will now establish that R diverges.

For sake of contradiction, suppose that R converges. The geometric series

$$\sum_{n=1}^{\infty}\frac{1}{2^{n+1}}$$

converges, so the sum of R and this geometric series must also converge; however,

$$R+\sum_{n=1}^{\infty}\frac{1}{2^{n+1}}=\sum_{n=2}^{\infty}\frac{1}{n},$$

which diverges because the harmonic series diverges. Thus, the series R must diverge.

36. Determine whether the following series converges conditionally:

$$1-\frac{1}{3}+\frac{1}{2}-\frac{1}{5}+\frac{1}{3}-\frac{1}{7}+\frac{1}{4}-\frac{1}{9}+\frac{1}{5}-\frac{1}{11}+\cdots$$

SOLUTION Although the signs alternate, the terms a_n are not decreasing, so we cannot apply the Leibniz Test. However, we may express the series as

$$\sum_{n=1}^{\infty}\left(\frac{1}{n}-\frac{1}{2n+1}\right)=\sum_{n=1}^{\infty}\frac{n+1}{n(2n+1)}.$$

Using the Limit Comparison Test and comparing with the harmonic series, we find

$$L=\lim_{n\to\infty}\frac{\frac{n+1}{n(2n+1)}}{\frac{1}{n}}=\lim_{n\to\infty}\frac{n+1}{2n+1}=\frac{1}{2}.$$

Because $L>0$, we conclude that the series

$$1-\frac{1}{3}+\frac{1}{2}-\frac{1}{5}+\frac{1}{3}-\frac{1}{7}+\frac{1}{4}-\frac{1}{9}+\frac{1}{5}-\frac{1}{11}+\cdots$$

diverges.

37. Prove that if $\sum a_n$ converges absolutely, then $\sum a_n^2$ also converges. Then give an example where $\sum a_n$ is only conditionally convergent and $\sum a_n^2$ diverges.

SOLUTION Suppose the series $\sum a_n$ converges absolutely. Because $\sum |a_n|$ converges, we know that

$$\lim_{n\to\infty}|a_n|=0.$$

Therefore, there exists a positive integer N such that $|a_n|<1$ for all $n\ge N$. It then follows that for $n\ge N$,

$$0\le a_n^2=|a_n|^2=|a_n|\cdot|a_n|<|a_n|\cdot 1=|a_n|.$$

By the Comparison Test we can then conclude that $\sum a_n^2$ also converges.

Consider the series $\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}}$. This series converges by the Leibniz Test, but the corresponding positive series is a divergent p-series; that is, $\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}}$ is conditionally convergent. Now, $\sum_{n=1}^{\infty} a_n^2$ is the divergent harmonic series $\sum_{n=1}^{\infty} \frac{1}{n}$. Thus, $\sum a_n^2$ need not converge if $\sum a_n$ is only conditionally convergent.

Further Insights and Challenges

38. Prove the following variant of the Leibniz Test: If $\{a_n\}$ is a positive, decreasing sequence with $\lim_{n\to\infty} a_n = 0$, then the series

$$a_1 + a_2 - 2a_3 + a_4 + a_5 - 2a_6 + \cdots$$

converges. *Hint:* Show that S_{3N} is increasing and bounded by $a_1 + a_2$, and continue as in the proof of the Leibniz Test.

SOLUTION Following the hint, we first examine the sequence $\{S_{3N}\}$. Now,

$$S_{3N+3} = S_{3(N+1)} = S_{3N} + a_{3N+1} + a_{3N+2} - 2a_{3N+3} = S_{3N} + \left(a_{3N+1} - a_{3N+3}\right) + \left(a_{3N+2} - a_{3N+3}\right) \ge S_{3N}$$

because $\{a_n\}$ is a decreasing sequence. Moreover,

$$\begin{aligned} S_{3N} &= a_1 + a_2 - \sum_{k=1}^{N-1} \left(2a_{3k} - a_{3k+1} - a_{3k+2}\right) - 2a_{3N} \\ &= a_1 + a_2 - \sum_{k=1}^{N-1} \left[\left(a_{3k} - a_{3k+1}\right) + \left(a_{3k} - a_{3k+2}\right) - 2a_{3N}\right] \le a_1 + a_2 \end{aligned}$$

again because $\{a_n\}$ is a decreasing sequence. Thus, $\{S_{3N}\}$ is an increasing sequence with an upper bound; hence, $\{S_{3N}\}$ converges. Next,

$$S_{3N+1} = S_{3N} + a_{3N+1} \quad \text{and} \quad S_{3N+2} = S_{3N} + a_{3N+1} + a_{3N+2}.$$

Given that $\lim_{n\to\infty} a_n = 0$, it follows that

$$\lim_{N\to\infty} S_{3N+1} = \lim_{N\to\infty} S_{3N+2} = \lim_{N\to\infty} S_{3N}.$$

Having just established that $\lim_{N\to\infty} S_{3N}$ exists, it follows that the sequences $\{S_{3N+1}\}$ and $\{S_{3N+2}\}$ converge to the same limit. Finally, we can conclude that the sequence of partial sums $\{S_N\}$ converges, so the given series converges.

39. Use Exercise 38 to show that the following series converges:

$$S = \frac{1}{\ln 2} + \frac{1}{\ln 3} - \frac{2}{\ln 4} + \frac{1}{\ln 5} + \frac{1}{\ln 6} - \frac{2}{\ln 7} + \cdots$$

SOLUTION The given series has the structure of the generic series from Exercise 38 with $a_n = \frac{1}{\ln(n+1)}$. Because a_n is a positive, decreasing sequence with $\lim_{n\to\infty} a_n = 0$, we can conclude from Exercise 38 that the given series converges.

40. Prove the conditional convergence of

$$R = 1 + \frac{1}{2} + \frac{1}{3} - \frac{3}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7} - \frac{3}{8} + \cdots$$

SOLUTION Using Exercise 38 as a template, we first examine the sequence $\{R_{4N}\}$. Now,

$$\begin{aligned} R_{4N+4} = R_{4(N+1)} &= R_{4N} + \frac{1}{4N+1} + \frac{1}{4N+2} + \frac{1}{4N+3} - \frac{3}{4N+4} \\ &= R_N + \left(\frac{1}{4N+1} - \frac{1}{4N+4}\right) + \left(\frac{1}{4N+2} - \frac{1}{4N+4}\right) + \left(\frac{1}{4N+3} - \frac{1}{4N+4}\right) \ge R_{4N}. \end{aligned}$$

Moreover,

$$R_{4N} = 1 + \frac{1}{2} + \frac{1}{3} - \sum_{k=1}^{N-1} \left(\frac{3}{4k} - \frac{1}{4k+1} - \frac{1}{4k+2} - \frac{1}{4k+3}\right) - \frac{3}{4N} \le 1 + \frac{1}{2} + \frac{1}{3}.$$

Thus, $\{R_{4N}\}$ is an increasing sequence with an upper bound; hence, $\{R_{4N}\}$ converges. Next,

$$R_{4N+1} = R_{4N} + \frac{1}{4N+1};$$

$$R_{4N+2} = R_{4N} + \frac{1}{4N+1} + \frac{1}{4N+2}; \text{ and}$$

$$R_{4N+3} = R_{4N} + \frac{1}{4N+1} + \frac{1}{4N+2} + \frac{1}{4N+3},$$

so

$$\lim_{n\to\infty} R_{4N+1} = \lim_{N\to\infty} R_{4N+2} = \lim_{N\to\infty} R_{4N+3} = \lim_{N\to\infty} R_{4N}.$$

Having just established that $\lim_{N\to\infty} R_{4N}$ exists, it follows that the sequences $\{R_{4N+1}\}$, $\{R_{4N+2}\}$ and $\{R_{4N+3}\}$ converge to the same limit. Finally, we can conclude that the sequence of partial sums $\{R_N\}$ converges, so the series R converges.

Now, consider the positive series

$$R^+ = 1 + \frac{1}{2} + \frac{1}{3} + \frac{3}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7} + \frac{3}{8} + \cdots$$

Because the terms in this series are greater than or equal to the corresponding terms in the divergent harmonic series, it follows from the Comparison Test that R^+ diverges. Thus, by definition, R converges conditionally.

41. Show that the following series diverges:

$$S = 1 + \frac{1}{2} + \frac{1}{3} - \frac{2}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7} - \frac{2}{8} + \cdots$$

Hint: Use the result of Exercise 40 to write S as the sum of a convergent series and a divergent series.

SOLUTION Let

$$R = 1 + \frac{1}{2} + \frac{1}{3} - \frac{3}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7} - \frac{3}{8} + \cdots$$

and

$$S = 1 + \frac{1}{2} + \frac{1}{3} - \frac{2}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7} - \frac{2}{8} + \cdots$$

For sake of contradiction, suppose the series S converges. From Exercise 40, we know that the series R converges. Thus, the series $S - R$ must converge; however,

$$S - R = \frac{1}{4} + \frac{1}{8} + \frac{1}{12} + \cdots = \frac{1}{4}\sum_{k=1}^{\infty} \frac{1}{k},$$

which diverges because the harmonic series diverges. Thus, the series S must diverge.

42. Prove that

$$\sum_{n=1}^{\infty} (-1)^{n+1} \frac{(\ln n)^a}{n}$$

converges for all exponents a. *Hint:* Show that $f(x) = (\ln x)^a/x$ is decreasing for x sufficiently large.

SOLUTION This is an alternating series with $a_n = \frac{(\ln n)^a}{n}$. Following the hint, consider the function $f(x) = \dfrac{(\ln x)^a}{x}$. Now,

$$f'(x) = \frac{a(\ln x)^{a-1} - (\ln x)^a}{x^2} = \frac{(\ln x)^{a-1}}{x^2}(a - \ln x),$$

so $f'(x) < 0$ and f is decreasing for $x > e^a$. If $a \le 0$, then it is clear that

$$\lim_{x\to\infty} \frac{(\ln x)^a}{x} = 0;$$

if $a > 0$, then repeated use of L'Hôpital's Rule leads to the same conclusion. Let N be any integer greater than e^a; then, $\{a_n\}$ is a decreasing sequence for $n \ge N$ which converges to zero and the series $\displaystyle\sum_{n=N}^{\infty} (-1)^{n+1} \frac{(\ln n)^a}{n}$ converges by the Leibniz Test. Finally, the series $\displaystyle\sum_{n=1}^{\infty} (-1)^{n+1} \frac{(\ln n)^a}{n}$ also converges.

43. We say that $\{b_n\}$ is a rearrangement of $\{a_n\}$ if $\{b_n\}$ has the same terms as $\{a_n\}$ but occurring in a different order. Show that if $\{b_n\}$ is a rearrangement of $\{a_n\}$ and $S = \sum_{n=1}^{\infty} a_n$ converges absolutely, then $T = \sum_{n=1}^{\infty} b_n$ also converges absolutely. (This result does not hold if S is only conditionally convergent.) *Hint:* Prove that the partial sums $\sum_{n=1}^{N} |b_n|$ are bounded. It can be shown further that $S = T$.

SOLUTION Suppose the series $S = \sum_{n=1}^{\infty} a_n$ converges absolutely and denote the corresponding positive series by

$$S^+ = \sum_{n=1}^{\infty} |a_n|.$$

Further, let $T_N = \sum_{n=1}^{N} |b_n|$ denote the Nth partial sum of the series $\sum_{n=1}^{\infty} |b_n|$. Because $\{b_n\}$ is a rearrangement of $\{a_n\}$, we know that

$$0 \le T_N \le \sum_{n=1}^{\infty} |a_n| = S^+;$$

that is, the sequence $\{T_N\}$ is bounded. Moreover,

$$T_{N+1} = \sum_{n=1}^{N+1} |b_n| = T_N + |b_{N+1}| \ge T_N;$$

that is, $\{T_N\}$ is increasing. It follows that $\{T_N\}$ converges, so the series $\sum_{n=1}^{\infty} |b_n|$ converges, which means the series $\sum_{n=1}^{\infty} b_n$ converges absolutely.

44. Assumptions Matter In 1829, Lejeune Dirichlet pointed out that the great French mathematician Augustin Louis Cauchy made a mistake in a published paper by improperly assuming the Limit Comparison Test to be valid for nonpositive series. Here are Dirichlet's two series:

$$\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}}, \qquad \sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}} \left(1 + \frac{(-1)^n}{\sqrt{n}}\right)$$

Explain how they provide a counterexample to the Limit Comparison Test when the series are not assumed to be positive.

SOLUTION Let

$$R = \sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}} \quad \text{and} \quad S = \sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}} \left(1 + \frac{(-1)^n}{\sqrt{n}}\right)$$

R is an alternating series that converges by the Leibniz Test; however, we cannot apply the Leibniz Test to S because the absolute value of the terms in S is not decreasing. Because

$$L = \lim_{n \to \infty} \frac{\frac{(-1)^n}{\sqrt{n}} \left(1 + \frac{(-1)^n}{\sqrt{n}}\right)}{\frac{(-1)^n}{\sqrt{n}}} = \lim_{n \to \infty} \left(1 + \frac{(-1)^n}{\sqrt{n}}\right) = 1,$$

if the Limit Comparison Test were valid for nonpositive series, we would conclude that S converges. However, if we assume that S converges, then the series $S - R$ would also converge. But

$$S - R = \sum_{n=1}^{\infty} \left(\frac{(-1)^n}{\sqrt{n}} + \frac{1}{n} - \frac{(-1)^n}{\sqrt{n}}\right) = \sum_{n=1}^{\infty} \frac{1}{n},$$

which is the divergent harmonic series. Thus, S diverges, and the Limit Comparison Test is not valid for nonpositive series.

10.5 The Ratio and Root Tests

Preliminary Questions

1. In the Ratio Test, is ρ equal to $\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right|$ or $\lim_{n\to\infty}\left|\frac{a_n}{a_{n+1}}\right|$?

SOLUTION In the Ratio Test ρ is the limit $\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right|$.

2. Is the Ratio Test conclusive for $\sum_{n=1}^{\infty}\frac{1}{2^n}$? Is it conclusive for $\sum_{n=1}^{\infty}\frac{1}{n}$?

SOLUTION The general term of $\sum_{n=1}^{\infty}\frac{1}{2^n}$ is $a_n = \frac{1}{2^n}$; thus,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{2^{n+1}}\cdot\frac{2^n}{1} = \frac{1}{2},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{2} < 1.$$

Consequently, the Ratio Test guarantees that the series $\sum_{n=1}^{\infty}\frac{1}{2^n}$ converges.

The general term of $\sum_{n=1}^{\infty}\frac{1}{n}$ is $a_n = \frac{1}{n}$; thus,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{n+1}\cdot\frac{n}{1} = \frac{n}{n+1},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\frac{n}{n+1} = 1.$$

The Ratio Test is therefore inconclusive for the series $\sum_{n=1}^{\infty}\frac{1}{n}$.

3. Can the Ratio Test be used to show convergence if the series is only conditionally convergent?

SOLUTION No. The Ratio Test can only establish absolute convergence and divergence, not conditional convergence.

Exercises

In Exercises 1–20, apply the Ratio Test to determine convergence or divergence, or state that the Ratio Test is inconclusive.

1. $\sum_{n=1}^{\infty}\frac{1}{5^n}$

SOLUTION With $a_n = \frac{1}{5^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{5^{n+1}}\cdot\frac{5^n}{1} = \frac{1}{5} \quad\text{and}\quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{5} < 1.$$

Therefore, the series $\sum_{n=1}^{\infty}\frac{1}{5^n}$ converges by the Ratio Test.

2. $\sum_{n=1}^{\infty}\frac{(-1)^{n-1}n}{5^n}$

SOLUTION With $a_n = \frac{(-1)^{n-1}n}{5^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{n+1}{5^{n+1}}\cdot\frac{5^n}{n} = \frac{n+1}{5n} \quad\text{and}\quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{5} < 1.$$

Therefore, the series $\sum_{n=1}^{\infty}\frac{(-1)^{n-1}n}{5^n}$ converges by the Ratio Test.

3. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^n}$

SOLUTION With $a_n = \frac{1}{n^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{(n+1)^{n+1}} \cdot \frac{n^n}{1} = \frac{1}{n+1}\left(\frac{n}{n+1}\right)^n = \frac{1}{n+1}\left(1+\frac{1}{n}\right)^{-n},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 0 \cdot \frac{1}{e} = 0 < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^n}$ converges by the Ratio Test.

4. $\displaystyle\sum_{n=0}^{\infty} \frac{3n+2}{5n^3+1}$

SOLUTION With $a_n = \frac{3n+2}{5n^3+1}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{3(n+1)+2}{5(n+1)^3+1} \cdot \frac{5n^3+1}{3n+2} = \frac{3n+5}{3n+2} \cdot \frac{5n^3+1}{5(n+1)^3+1},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1 \cdot 1 = 1.$$

Therefore, for the series $\displaystyle\sum_{n=0}^{\infty} \frac{3n+2}{5n^3+1}$, the Ratio Test is inconclusive.

We can show that this series converges by using the Limit Comparison Test and comparing with the convergent p-series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2}$.

5. $\displaystyle\sum_{n=1}^{\infty} \frac{n}{n^2+1}$

SOLUTION With $a_n = \frac{n}{n^2+1}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{n+1}{(n+1)^2+1} \cdot \frac{n^2+1}{n} = \frac{n+1}{n} \cdot \frac{n^2+1}{n^2+2n+2},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1 \cdot 1 = 1.$$

Therefore, for the series $\displaystyle\sum_{n=1}^{\infty} \frac{n}{n^2+1}$, the Ratio Test is inconclusive.

We can show that this series diverges by using the Limit Comparison Test and comparing with the divergent harmonic series.

6. $\displaystyle\sum_{n=1}^{\infty} \frac{2^n}{n}$

SOLUTION With $a_n = \frac{2^n}{n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{2^{n+1}}{n+1} \cdot \frac{n}{2^n} = \frac{2n}{n+1} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 2 > 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{2^n}{n}$ diverges by the Ratio Test.

7. $\displaystyle\sum_{n=1}^{\infty} \frac{2^n}{n^{100}}$

SOLUTION With $a_n = \frac{2^n}{n^{100}}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{2^{n+1}}{(n+1)^{100}} \cdot \frac{n^{100}}{2^n} = 2\left(\frac{n}{n+1}\right)^{100} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 2 \cdot 1^{100} = 2 > 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{2^n}{n^{100}}$ diverges by the Ratio Test.

8. $\displaystyle\sum_{n=1}^{\infty} \frac{n^3}{3^{n^2}}$

SOLUTION With $a_n = \frac{n^3}{3^{n^2}}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)^3}{3^{(n+1)^2}} \cdot \frac{3^{n^2}}{n^3} = \left(\frac{n+1}{n}\right)^3 \cdot \frac{1}{3^{2n+1}} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1^3 \cdot 0 = 0 < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{n^3}{3^{n^2}}$ converges by the Ratio Test.

9. $\displaystyle\sum_{n=1}^{\infty} \frac{10^n}{2^{n^2}}$

SOLUTION With $a_n = \frac{10^n}{2^{n^2}}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{10^{n+1}}{2^{(n+1)^2}} \cdot \frac{2^{n^2}}{10^n} = 10 \cdot \frac{1}{2^{2n+1}} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 10 \cdot 0 = 0 < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{10^n}{2^{n^2}}$ converges by the Ratio Test.

10. $\displaystyle\sum_{n=1}^{\infty} \frac{e^n}{n!}$

SOLUTION With $a_n = \frac{e^n}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{e^{n+1}}{(n+1)!} \cdot \frac{n!}{e^n} = \frac{e}{n+1} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 0 < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{e^n}{n!}$ converges by the Ratio Test.

11. $\displaystyle\sum_{n=1}^{\infty} \frac{e^n}{n^n}$

SOLUTION With $a_n = \frac{e^n}{n^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{e^{n+1}}{(n+1)^{n+1}} \cdot \frac{n^n}{e^n} = \frac{e}{n+1}\left(\frac{n}{n+1}\right)^n = \frac{e}{n+1}\left(1+\frac{1}{n}\right)^{-n},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 0 \cdot \frac{1}{e} = 0 < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{e^n}{n^n}$ converges by the Ratio Test.

12. $\sum_{n=1}^{\infty} \frac{n^{40}}{n!}$

SOLUTION With $a_n = \frac{n^{40}}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)^{40}}{(n+1)!} \cdot \frac{n!}{n^{40}} = \frac{1}{n+1}\left(\frac{n+1}{n}\right)^{40} = \frac{1}{n+1}\left(1+\frac{1}{n}\right)^{40},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 0 \cdot 1 = 0 < 1.$$

Therefore, the series $\sum_{n=1}^{\infty} \frac{n^{40}}{n!}$ converges by the Ratio Test.

13. $\sum_{n=0}^{\infty} \frac{n!}{6^n}$

SOLUTION With $a_n = \frac{n!}{6^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)!}{6^{n+1}} \cdot \frac{6^n}{n!} = \frac{n+1}{6} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \infty > 1.$$

Therefore, the series $\sum_{n=0}^{\infty} \frac{n!}{6^n}$ diverges by the Ratio Test.

14. $\sum_{n=1}^{\infty} \frac{n!}{n^9}$

SOLUTION With $a_n = \frac{n!}{n^9}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)!}{(n+1)^9} \cdot \frac{n^9}{n!} = \frac{n^9}{(n+1)^8} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \infty > 1.$$

Therefore, the series $\sum_{n=1}^{\infty} \frac{n!}{n^9}$ diverges by the Ratio Test.

15. $\sum_{n=2}^{\infty} \frac{1}{n \ln n}$

SOLUTION With $a_n = \frac{1}{n \ln n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{(n+1)\ln(n+1)} \cdot \frac{n \ln n}{1} = \frac{n}{n+1} \frac{\ln n}{\ln(n+1)},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1 \cdot \lim_{n\to\infty} \frac{\ln n}{\ln(n+1)}.$$

Now,

$$\lim_{n\to\infty} \frac{\ln n}{\ln(n+1)} = \lim_{x\to\infty} \frac{\ln x}{\ln(x+1)} = \lim_{x\to\infty} \frac{1/(x+1)}{1/x} = \lim_{x\to\infty} \frac{x}{x+1} = 1.$$

Thus, $\rho = 1$, and the Ratio Test is inconclusive for the series $\sum_{n=2}^{\infty} \frac{1}{n \ln n}$.

Using the Integral Test, we can show that the series $\sum_{n=2}^{\infty} \frac{1}{n \ln n}$ diverges.

16. $\sum_{n=1}^{\infty} \frac{1}{(2n)!}$

SOLUTION With $a_n = \frac{1}{(2n)!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{(2n+2)!} \cdot \frac{(2n)!}{1} = \frac{1}{(2n+2)(2n+1)} \quad \text{and} \quad \rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = 0 < 1.$$

Therefore, the series $\sum_{n=1}^{\infty} \frac{1}{(2n)!}$ converges by the Ratio Test.

17. $\sum_{n=1}^{\infty} \frac{n^2}{(2n+1)!}$

SOLUTION With $a_n = \frac{n^2}{(2n+1)!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)^2}{(2n+3)!} \cdot \frac{(2n+1)!}{n^2} = \left(\frac{n+1}{n}\right)^2 \frac{1}{(2n+3)(2n+2)},$$

and

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = 1^2 \cdot 0 = 0 < 1.$$

Therefore, the series $\sum_{n=1}^{\infty} \frac{n^2}{(2n+1)!}$ converges by the Ratio Test.

18. $\sum_{n=1}^{\infty} \frac{(n!)^3}{(3n)!}$

SOLUTION With $a_n = \frac{(n!)^3}{(3n)!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{((n+1)!)^3}{(3(n+1))!} \cdot \frac{(3n)!}{(n!)^3} = \frac{(n+1)^3}{(3n+3)(3n+2)(3n+1)} = \frac{n^3+3n^2+3n+1}{27n^3+54n^2+33n+6}$$
$$= \frac{1+3n^{-1}+3n^{-2}+1n^{-3}}{27+54n^{-1}+33n^{-2}+6n^{-3}}$$

and

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{27} < 1$$

Therefore, the series $\sum_{n=1}^{\infty} \frac{(n!)^3}{(3n)!}$ converges by the Ratio Test.

19. $\sum_{n=2}^{\infty} \frac{1}{2^n+1}$

SOLUTION With $a_n = \frac{1}{2^n+1}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{2^{n+1}+1} \cdot \frac{2^n+1}{1} = \frac{1+2^{-n}}{2+2^{-n}}$$

and

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{2} < 1$$

Therefore, the series $\sum_{n=2}^{\infty} \frac{1}{2^n+1}$ converges by the Ratio Test.

20. $\displaystyle\sum_{n=2}^{\infty} \frac{1}{\ln n}$

SOLUTION With $a_n = \dfrac{1}{\ln n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{\ln n} \cdot \frac{\ln(n+1)}{1} = \frac{\ln(n+1)}{\ln n}$$

and (using L'Hôpital's rule)

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{x\to\infty} \frac{\frac{d}{dx}\ln(x+1)}{\frac{d}{dx}\ln x} = \lim_{x\to\infty}\frac{x}{x+1} = 1$$

Therefore, the Ratio Test is inconclusive for $\displaystyle\sum_{n=2}^{\infty}\frac{1}{\ln n}$. This series can be shown to diverge using the Comparison Test with the harmonic series since $\ln n < n$ for $n \geq 2$.

21. Show that $\displaystyle\sum_{n=1}^{\infty} n^k\, 3^{-n}$ converges for all exponents k.

SOLUTION With $a_n = n^k 3^{-n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)^k 3^{-(n+1)}}{n^k 3^{-n}} = \frac{1}{3}\left(1+\frac{1}{n}\right)^k,$$

and, for all k,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{3}\cdot 1 = \frac{1}{3} < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} n^k\, 3^{-n}$ converges for all exponents k by the Ratio Test.

22. Show that $\displaystyle\sum_{n=1}^{\infty} n^2 x^n$ converges if $|x| < 1$.

SOLUTION With $a_n = n^2 x^n$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)^2|x|^{n+1}}{n^2|x|^n} = \left(1+\frac{1}{n}\right)^2|x| \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1\cdot|x| = |x|.$$

Therefore, by the Ratio Test, the series $\displaystyle\sum_{n=1}^{\infty} n^2 x^n$ converges provided $|x| < 1$.

23. Show that $\displaystyle\sum_{n=1}^{\infty} 2^n x^n$ converges if $|x| < \frac{1}{2}$.

SOLUTION With $a_n = 2^n x^n$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{2^{n+1}|x|^{n+1}}{2^n|x|^n} = 2|x| \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 2|x|.$$

Therefore, $\rho < 1$ and the series $\displaystyle\sum_{n=1}^{\infty} 2^n x^n$ converges by the Ratio Test provided $|x| < \frac{1}{2}$.

24. Show that $\displaystyle\sum_{n=1}^{\infty} \frac{r^n}{n!}$ converges for all r.

SOLUTION With $a_n = \frac{r^n}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{|r|^{n+1}}{(n+1)!}\cdot\frac{n!}{|r|^n} = \frac{|r|}{n+1} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 0\cdot|r| = 0 < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty}\frac{r^n}{n!}$ converges by the Ratio Test for all r.

25. Show that $\sum_{n=1}^{\infty} \frac{r^n}{n}$ converges if $|r| < 1$.

SOLUTION With $a_n = \frac{r^n}{n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{|r|^{n+1}}{n+1} \cdot \frac{n}{|r|^n} = |r|\frac{n}{n+1} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1 \cdot |r| = |r|.$$

Therefore, by the Ratio Test, the series $\sum_{n=1}^{\infty} \frac{r^n}{n}$ converges provided $|r| < 1$.

26. Is there any value of k such that $\sum_{n=1}^{\infty} \frac{2^n}{n^k}$ converges?

SOLUTION With $a_n = \frac{2^n}{n^k}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{2^{n+1}}{(n+1)^k} \cdot \frac{n^k}{2^n} = 2\left(\frac{n}{n+1}\right)^k,$$

and, for all k,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 2 \cdot 1^k = 2 > 1.$$

Therefore, by the Ratio Test, there is no value for k such that the series $\sum_{n=1}^{\infty} \frac{2^n}{n^k}$ converges.

27. Show that $\sum_{n=1}^{\infty} \frac{n!}{n^n}$ converges. *Hint:* Use $\lim_{n\to\infty}\left(1+\frac{1}{n}\right)^n = e$.

SOLUTION With $a_n = \frac{n!}{n^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)!}{(n+1)^{n+1}} \cdot \frac{n^n}{n!} = \left(\frac{n}{n+1}\right)^n = \left(1+\frac{1}{n}\right)^{-n},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{e} < 1.$$

Therefore, the series $\sum_{n=1}^{\infty} \frac{n!}{n^n}$ converges by the Ratio Test.

In Exercises 28–33, assume that $|a_{n+1}/a_n|$ converges to $\rho = \frac{1}{3}$. What can you say about the convergence of the given series?

28. $\sum_{n=1}^{\infty} n a_n$

SOLUTION Let $b_n = n a_n$. Then

$$\rho = \lim_{n\to\infty}\left|\frac{b_{n+1}}{b_n}\right| = \lim_{n\to\infty}\frac{n+1}{n}\left|\frac{a_{n+1}}{a_n}\right| = 1 \cdot \frac{1}{3} = \frac{1}{3} < 1.$$

Therefore, the series $\sum_{n=1}^{\infty} n a_n$ converges by the Ratio Test.

29. $\sum_{n=1}^{\infty} n^3 a_n$

SOLUTION Let $b_n = n^3 a_n$. Then

$$\rho = \lim_{n\to\infty}\left|\frac{b_{n+1}}{b_n}\right| = \lim_{n\to\infty}\left(\frac{n+1}{n}\right)^3\left|\frac{a_{n+1}}{a_n}\right| = 1^3 \cdot \frac{1}{3} = \frac{1}{3} < 1.$$

Therefore, the series $\sum_{n=1}^{\infty} n^3 a_n$ converges by the Ratio Test.

30. $\sum_{n=1}^{\infty} 2^n a_n$

SOLUTION Let $b_n = 2^n a_n$. Then

$$\rho = \lim_{n\to\infty}\left|\frac{b_{n+1}}{b_n}\right| = \lim_{n\to\infty}\frac{2^{n+1}}{2^n}\left|\frac{a_{n+1}}{a_n}\right| = 2\cdot\frac{1}{3} = \frac{2}{3} < 1.$$

Therefore, the series $\sum_{n=1}^{\infty} 2^n a_n$ converges by the Ratio Test.

31. $\sum_{n=1}^{\infty} 3^n a_n$

SOLUTION Let $b_n = 3^n a_n$. Then

$$\rho = \lim_{n\to\infty}\left|\frac{b_{n+1}}{b_n}\right| = \lim_{n\to\infty}\frac{3^{n+1}}{3^n}\left|\frac{a_{n+1}}{a_n}\right| = 3\cdot\frac{1}{3} = 1.$$

Therefore, the Ratio Test is inconclusive for the series $\sum_{n=1}^{\infty} 3^n a_n$.

32. $\sum_{n=1}^{\infty} 4^n a_n$

SOLUTION Let $b_n = 4^n a_n$. Then

$$\rho = \lim_{n\to\infty}\left|\frac{b_{n+1}}{b_n}\right| = \lim_{n\to\infty}\frac{4^{n+1}}{4^n}\left|\frac{a_{n+1}}{a_n}\right| = 4\cdot\frac{1}{3} = \frac{4}{3} > 1.$$

Therefore, the series $\sum_{n=1}^{\infty} 4^n a_n$ diverges by the Ratio Test.

33. $\sum_{n=1}^{\infty} a_n^2$

SOLUTION Let $b_n = a_n^2$. Then

$$\rho = \lim_{n\to\infty}\left|\frac{b_{n+1}}{b_n}\right| = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right|^2 = \left(\frac{1}{3}\right)^2 = \frac{1}{9} < 1.$$

Therefore, the series $\sum_{n=1}^{\infty} a_n^2$ converges by the Ratio Test.

34. Assume that $|a_{n+1}/a_n|$ converges to $\rho = 4$. Does $\sum_{n=1}^{\infty} a_n^{-1}$ converge (assume that $a_n \neq 0$ for all n)?

SOLUTION Let $b_n = a_n^{-1}$. Then

$$\rho = \lim_{n\to\infty}\left|\frac{b_{n+1}}{b_n}\right| = \lim_{n\to\infty}\left|\frac{a_n}{a_{n+1}}\right| = \frac{1}{\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right|} = \frac{1}{4} < 1.$$

Therefore, the series $\sum_{n=1}^{\infty} a_n^{-1}$ converges by the Ratio Test.

35. Is the Ratio Test conclusive for the p-series $\sum_{n=1}^{\infty}\frac{1}{n^p}$?

SOLUTION With $a_n = \frac{1}{n^p}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{(n+1)^p}\cdot\frac{n^p}{1} = \left(\frac{n}{n+1}\right)^p \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1^p = 1.$$

Therefore, the Ratio Test is inconclusive for the p-series $\sum_{n=1}^{\infty}\frac{1}{n^p}$.

In Exercises 36–41, use the Root Test to determine convergence or divergence (or state that the test is inconclusive).

36. $\displaystyle\sum_{n=0}^{\infty} \frac{1}{10^n}$

SOLUTION With $a_n = \frac{1}{10^n}$,

$$\sqrt[n]{a_n} = \sqrt[n]{\frac{1}{10^n}} = \frac{1}{10} \quad \text{and} \quad \lim_{n\to\infty} \sqrt[n]{a_n} = \frac{1}{10} < 1.$$

Therefore, the series $\displaystyle\sum_{n=0}^{\infty} \frac{1}{10^n}$ converges by the Root Test.

37. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^n}$

SOLUTION With $a_n = \frac{1}{n^n}$,

$$\sqrt[n]{a_n} = \sqrt[n]{\frac{1}{n^n}} = \frac{1}{n} \quad \text{and} \quad \lim_{n\to\infty} \sqrt[n]{a_n} = 0 < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^n}$ converges by the Root Test.

38. $\displaystyle\sum_{k=0}^{\infty} \left(\frac{k}{k+10}\right)^k$

SOLUTION With $a_k = \left(\frac{k}{k+10}\right)^k$,

$$\sqrt[k]{a_k} = \sqrt[k]{\left(\frac{k}{k+10}\right)^k} = \frac{k}{k+10} \quad \text{and} \quad \lim_{k\to\infty} \sqrt[k]{a_k} = 1.$$

Therefore, the Root Test is inconclusive for the series $\displaystyle\sum_{k=0}^{\infty} \left(\frac{k}{k+10}\right)^k$. Because

$$\lim_{k\to\infty} a_k = \lim_{k\to\infty} \left(1 + \frac{10}{k}\right)^{-k} = \lim_{k\to\infty} \left[\left(1 + \frac{10}{k}\right)^{k/10}\right]^{-10} = e^{-10} \neq 0,$$

this series diverges by the Divergence Test.

39. $\displaystyle\sum_{k=0}^{\infty} \left(\frac{k}{3k+1}\right)^k$

SOLUTION With $a_k = \left(\frac{k}{3k+1}\right)^k$,

$$\sqrt[k]{a_k} = \sqrt[k]{\left(\frac{k}{3k+1}\right)^k} = \frac{k}{3k+1} \quad \text{and} \quad \lim_{k\to\infty} \sqrt[k]{a_k} = \frac{1}{3} < 1.$$

Therefore, the series $\displaystyle\sum_{k=0}^{\infty} \left(\frac{k}{3k+1}\right)^k$ converges by the Root Test.

40. $\displaystyle\sum_{n=1}^{\infty} \left(1 + \frac{1}{n}\right)^{-n}$

SOLUTION With $a_k = \left(1 + \frac{1}{n}\right)^{-n}$,

$$\sqrt[n]{a_n} = \sqrt[n]{\left(1 + \frac{1}{n}\right)^{-n}} = \left(1 + \frac{1}{n}\right)^{-1} \quad \text{and} \quad \lim_{n\to\infty} \sqrt[n]{a_n} = 1^{-1} = 1.$$

Therefore, the Root Test is inconclusive for the series $\displaystyle\sum_{n=1}^{\infty} \left(1 + \frac{1}{n}\right)^{-n}$.

Because

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty}\left(1+\frac{1}{n}\right)^{-n} = \lim_{n\to\infty}\left[\left(1+\frac{1}{n}\right)^{n}\right]^{-1} = e^{-1} \neq 0,$$

this series diverges by the Divergence Test.

41. $\displaystyle\sum_{n=4}^{\infty}\left(1+\frac{1}{n}\right)^{-n^2}$

SOLUTION With $a_k = \left(1+\frac{1}{n}\right)^{-n^2}$,

$$\sqrt[n]{a_n} = \sqrt[n]{\left(1+\frac{1}{n}\right)^{-n^2}} = \left(1+\frac{1}{n}\right)^{-n} \quad \text{and} \quad \lim_{n\to\infty}\sqrt[n]{a_n} = e^{-1} < 1.$$

Therefore, the series $\displaystyle\sum_{n=4}^{\infty}\left(1+\frac{1}{n}\right)^{-n^2}$ converges by the Root Test.

42. Prove that $\displaystyle\sum_{n=1}^{\infty}\frac{2^{n^2}}{n!}$ diverges. *Hint:* Use $2^{n^2} = (2^n)^n$ and $n! \le n^n$.

SOLUTION Because $n! \le n^n$,

$$\frac{2^{n^2}}{n!} \ge \frac{2^{n^2}}{n^n}.$$

Now, let $a_n = \frac{2^{n^2}}{n^n}$. Then

$$\sqrt[n]{a_n} = \sqrt[n]{\frac{2^{n^2}}{n^n}} = \frac{2^n}{n},$$

and

$$\lim_{n\to\infty}\sqrt[n]{a_n} = \lim_{n\to\infty}\frac{2^n}{n} = \lim_{x\to\infty}\frac{2^x}{x} = \lim_{x\to\infty}\frac{2^x\ln 2}{1} = \infty > 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty}\frac{2^{n^2}}{n^n}$ diverges by the Root Test. By the Comparison Test, we can then conclude that the series $\displaystyle\sum_{n=1}^{\infty}\frac{2^{n^2}}{n!}$ also diverges.

In Exercises 43–56, determine convergence or divergence using any method covered in the text so far.

43. $\displaystyle\sum_{n=1}^{\infty}\frac{2^n+4^n}{7^n}$

SOLUTION Because the series

$$\sum_{n=1}^{\infty}\frac{2^n}{7^n} = \sum_{n=1}^{\infty}\left(\frac{2}{7}\right)^n \quad \text{and} \quad \sum_{n=1}^{\infty}\frac{4^n}{7^n} = \sum_{n=1}^{\infty}\left(\frac{4}{7}\right)^n$$

are both convergent geometric series, it follows that

$$\sum_{n=1}^{\infty}\frac{2^n+4^n}{7^n} = \sum_{n=1}^{\infty}\left(\frac{2}{7}\right)^n + \sum_{n=1}^{\infty}\left(\frac{4}{7}\right)^n$$

also converges.

44. $\displaystyle\sum_{n=1}^{\infty}\frac{n^3}{n!}$

SOLUTION The presence of the factorial suggests applying the Ratio Test. With $a_n = \frac{n^3}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)^3}{(n+1)!}\cdot\frac{n!}{n^3} = \frac{(n+1)^2}{n^3} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 0 < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty}\frac{n^3}{n!}$ converges by the Ratio Test.

45. $\displaystyle\sum_{n=1}^{\infty} \frac{n^3}{5^n}$

SOLUTION The presence of the exponential term suggests applying the Ratio Test. With $a_n = \frac{n^3}{5^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)^3}{5^{n+1}} \cdot \frac{5^n}{n^3} = \frac{1}{5}\left(1 + \frac{1}{n}\right)^3 \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{5} \cdot 1^3 = \frac{1}{5} < 1.$$

Therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{n^3}{5^n}$ converges by the Ratio Test.

46. $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^3}$

SOLUTION The general term in this series suggests applying the Integral Test. Let $f(x) = \frac{1}{x(\ln x)^3}$. This function is continuous, positive and decreasing for $x \geq 2$, so the Integral Test does apply. Now

$$\int_2^{\infty} \frac{dx}{x(\ln x)^3} = \lim_{R\to\infty} \int_2^R \frac{dx}{x(\ln x)^3} = \lim_{R\to\infty} \int_{\ln 2}^{\ln R} \frac{du}{u^3} = -\frac{1}{2} \lim_{R\to\infty}\left(\frac{1}{(\ln R)^2} - \frac{1}{(\ln 2)^2}\right) = \frac{1}{2(\ln 2)^2}.$$

The integral converges; hence, the series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^3}$ also converges.

47. $\displaystyle\sum_{n=2}^{\infty} \frac{1}{\sqrt{n^3 - n^2}}$

SOLUTION This series is similar to a p-series; because

$$\frac{1}{\sqrt{n^3 - n^2}} \approx \frac{1}{\sqrt{n^3}} = \frac{1}{n^{3/2}}$$

for large n, we will apply the Limit Comparison Test comparing with the p-series with $p = \frac{3}{2}$. Now,

$$L = \lim_{n\to\infty} \frac{\frac{1}{\sqrt{n^3 - n^2}}}{\frac{1}{n^{3/2}}} = \lim_{n\to\infty} \sqrt{\frac{n^3}{n^3 - n^2}} = 1.$$

The p-series with $p = \frac{3}{2}$ converges and L exists; therefore, the series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{\sqrt{n^3 - n^2}}$ also converges.

48. $\displaystyle\sum_{n=1}^{\infty} \frac{n^2 + 4n}{3n^4 + 9}$

SOLUTION This series is similar to a p-series; because

$$\frac{n^2 + 4n}{3n^4 + 9} \approx \frac{n^2}{\sqrt{3n^4}} = \frac{1}{3n^2}$$

for large n, we will apply the Limit Comparison Test comparing with the p-series with $p = 2$. Now,

$$L = \lim_{n\to\infty} \frac{\frac{n^2 + 4n}{3n^4 + 9}}{\frac{1}{n^2}} = \lim_{n\to\infty} \frac{n^4 + 4n^3}{3n^4 + 9} = \frac{1}{3}.$$

The p-series with $p = 2$ converges and L exists; therefore, the series $\displaystyle\sum_{n=1}^{\infty} \frac{n^2 + 4n}{3n^4 + 9}$ also converges.

49. $\displaystyle\sum_{n=1}^{\infty} n^{-0.8}$

SOLUTION

$$\sum_{n=1}^{\infty} n^{-0.8} = \sum_{n=1}^{\infty} \frac{1}{n^{0.8}}$$

so that this is a divergent p-series.

50. $\displaystyle\sum_{n=1}^{\infty}(0.8)^{-n}n^{-0.8}$

SOLUTION

$$\sum_{n=1}^{\infty}(0.8)^{-n}n^{-0.8} = \sum_{n=1}^{\infty}(0.8^{-1})^{n}n^{-0.8} = \sum_{n=1}^{\infty}\frac{1.25^n}{n^{0.8}}$$

With $a_n = \frac{1.25^n}{n^{0.8}}$ we have

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{1.25^{n+1}}{(n+1)^{0.8}}\cdot\frac{n^{0.8}}{1.25^n} = 1.25\left(\frac{n}{n+1}\right)^{0.8}$$

so that

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1.25 > 1$$

Thus the original series diverges, by the Ratio Test.

51. $\displaystyle\sum_{n=1}^{\infty}4^{-2n+1}$

SOLUTION Observe

$$\sum_{n=1}^{\infty}4^{-2n+1} = \sum_{n=1}^{\infty}4\cdot(4^{-2})^n = \sum_{n=1}^{\infty}4\left(\frac{1}{16}\right)^n$$

is a geometric series with $r = \frac{1}{16}$; therefore, this series converges.

52. $\displaystyle\sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{\sqrt{n}}$

SOLUTION This is an alternating series with $a_n = \frac{1}{\sqrt{n}}$. Because a_n forms a decreasing sequence which converges to zero, the series $\displaystyle\sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{\sqrt{n}}$ converges by the Leibniz Test.

53. $\displaystyle\sum_{n=1}^{\infty}\sin\frac{1}{n^2}$

SOLUTION Here, we will apply the Limit Comparison Test, comparing with the p-series with $p = 2$. Now,

$$L = \lim_{n\to\infty}\frac{\sin\frac{1}{n^2}}{\frac{1}{n^2}} = \lim_{u\to 0}\frac{\sin u}{u} = 1,$$

where $u = \frac{1}{n^2}$. The p-series with $p = 2$ converges and L exists; therefore, the series $\displaystyle\sum_{n=1}^{\infty}\sin\frac{1}{n^2}$ also converges.

54. $\displaystyle\sum_{n=1}^{\infty}(-1)^n\cos\frac{1}{n}$

SOLUTION Because

$$\lim_{n\to\infty}\cos\frac{1}{n} = \cos 0 = 1 \neq 0,$$

the general term in the series $\displaystyle\sum_{n=1}^{\infty}(-1)^n\cos\frac{1}{n}$ does not tend toward zero; therefore, the series diverges by the Divergence Test.

55. $\displaystyle\sum_{n=1}^{\infty}\frac{(-2)^n}{\sqrt{n}}$

SOLUTION Because

$$\lim_{n\to\infty}\frac{2^n}{\sqrt{n}} = \lim_{x\to\infty}\frac{2^x}{\sqrt{x}} = \lim_{x\to\infty}\frac{2^x\ln 2}{\frac{1}{2\sqrt{x}}} = \lim_{x\to\infty}2^{x+1}\sqrt{x}\ln 2 = \infty \neq 0,$$

the general term in the series $\displaystyle\sum_{n=1}^{\infty}\frac{(-2)^n}{\sqrt{n}}$ does not tend toward zero; therefore, the series diverges by the Divergence Test.

56. $\displaystyle\sum_{n=1}^{\infty} \left(\frac{n}{n+12}\right)^n$

SOLUTION Because the general term has the form of a function of n raised to the nth power, we might be tempted to use the Root Test; however, the Root Test is inconclusive for this series. Instead, note

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} \left(1+\frac{12}{n}\right)^{-n} = \lim_{n\to\infty} \left[\left(1+\frac{12}{n}\right)^{n/12}\right]^{-12} = e^{-12} \neq 0.$$

Therefore, the series diverges by the Divergence Test.

Further Insights and Challenges

57. **Proof of the Root Test** Let $S = \displaystyle\sum_{n=0}^{\infty} a_n$ be a positive series, and assume that $L = \displaystyle\lim_{n\to\infty} \sqrt[n]{a_n}$ exists.

(a) Show that S converges if $L < 1$. *Hint:* Choose R with $L < R < 1$ and show that $a_n \le R^n$ for n sufficiently large. Then compare with the geometric series $\sum R^n$.

(b) Show that S diverges if $L > 1$.

SOLUTION Suppose $\displaystyle\lim_{n\to\infty} \sqrt[n]{a_n} = L$ exists.

(a) If $L < 1$, let $\epsilon = \dfrac{1-L}{2}$. By the definition of a limit, there is a positive integer N such that

$$-\epsilon \le \sqrt[n]{a_n} - L \le \epsilon$$

for $n \ge N$. From this, we conclude that

$$0 \le \sqrt[n]{a_n} \le L + \epsilon$$

for $n \ge N$. Now, let $R = L + \epsilon$. Then

$$R = L + \frac{1-L}{2} = \frac{L+1}{2} < \frac{1+1}{2} = 1,$$

and

$$0 \le \sqrt[n]{a_n} \le R \quad \text{or} \quad 0 \le a_n \le R^n$$

for $n \ge N$. Because $0 \le R < 1$, the series $\displaystyle\sum_{n=N}^{\infty} R^n$ is a convergent geometric series, so the series $\displaystyle\sum_{n=N}^{\infty} a_n$ converges by the Comparison Test. Therefore, the series $\displaystyle\sum_{n=0}^{\infty} a_n$ also converges.

(b) If $L > 1$, let $\epsilon = \dfrac{L-1}{2}$. By the definition of a limit, there is a positive integer N such that

$$-\epsilon \le \sqrt[n]{a_n} - L \le \epsilon$$

for $n \ge N$. From this, we conclude that

$$L - \epsilon \le \sqrt[n]{a_n}$$

for $n \ge N$. Now, let $R = L - \epsilon$. Then

$$R = L - \frac{L-1}{2} = \frac{L+1}{2} > \frac{1+1}{2} = 1,$$

and

$$R \le \sqrt[n]{a_n} \quad \text{or} \quad R^n \le a_n$$

for $n \ge N$. Because $R > 1$, the series $\displaystyle\sum_{n=N}^{\infty} R^n$ is a divergent geometric series, so the series $\displaystyle\sum_{n=N}^{\infty} a_n$ diverges by the Comparison Test. Therefore, the series $\displaystyle\sum_{n=0}^{\infty} a_n$ also diverges.

58. Show that the Ratio Test does not apply, but verify convergence using the Comparison Test for the series

$$\frac{1}{2}+\frac{1}{3^2}+\frac{1}{2^3}+\frac{1}{3^4}+\frac{1}{2^5}+\cdots$$

SOLUTION The general term of the series is:

$$a_n=\begin{cases}\dfrac{1}{2^n} & n \text{ odd}\\[2mm] \dfrac{1}{3^n} & n \text{ even}\end{cases}$$

First use the Ratio Test. If n is even,

$$\frac{a_{n+1}}{a_n}=\frac{\frac{1}{2^{n+1}}}{\frac{1}{3^n}}=\frac{3^n}{2^{n+1}}=\frac{1}{2}\cdot\left(\frac{3}{2}\right)^n$$

whereas, if n is odd,

$$\frac{a_{n+1}}{a_n}=\frac{\frac{1}{3^{n+1}}}{\frac{1}{2^n}}=\frac{2^n}{3^{n+1}}=\frac{1}{3}\cdot\left(\frac{2}{3}\right)^n$$

Since $\lim_{n\to\infty}\frac{1}{3}\cdot\left(\frac{2}{3}\right)^n=0$ and $\lim_{n\to\infty}\frac{1}{2}\cdot\left(\frac{3}{2}\right)^n=\infty$, the sequence $\frac{a_{n+1}}{a_n}$ does not converge, and the Ratio Test is inconclusive.

However, we have $0\le a_n\le\frac{1}{2^n}$ for all n, so the series converges by comparison with the convergent geometric series

$$\sum_{n=1}^{\infty}\frac{1}{2^n}$$

59. Let $S=\sum_{n=1}^{\infty}\frac{c^n n!}{n^n}$, where c is a constant.

(a) Prove that S converges absolutely if $|c|<e$ and diverges if $|c|>e$.

(b) It is known that $\lim_{n\to\infty}\frac{e^n n!}{n^{n+1/2}}=\sqrt{2\pi}$. Verify this numerically.

(c) Use the Limit Comparison Test to prove that S diverges for $c=e$.

SOLUTION

(a) With $a_n=\frac{c^n n!}{n^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right|=\frac{|c|^{n+1}(n+1)!}{(n+1)^{n+1}}\cdot\frac{n^n}{|c|^n n!}=|c|\left(\frac{n}{n+1}\right)^n=|c|\left(1+\frac{1}{n}\right)^{-n},$$

and

$$\rho=\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right|=|c|e^{-1}.$$

Thus, by the Ratio Test, the series $\sum_{n=1}^{\infty}\frac{c^n n!}{n^n}$ converges when $|c|e^{-1}<1$, or when $|c|<e$. The series diverges when $|c|>e$.

(b) The table below lists the value of $\frac{e^n n!}{n^{n+1/2}}$ for several increasing values of n. Since $\sqrt{2\pi}=2.506628275$, the numerical evidence verifies that

$$\lim_{n\to\infty}\frac{e^n n!}{n^{n+1/2}}=\sqrt{2\pi}.$$

n	100	1000	10000	100000
$\frac{e^n n!}{n^{n+1/2}}$	2.508717995	2.506837169	2.506649163	2.506630363

(c) With $c = e$, the series S becomes $\sum_{n=1}^{\infty} \frac{e^n n!}{n^n}$. Using the result from part (b),

$$L = \lim_{n\to\infty} \frac{\frac{e^n n!}{n^n}}{\sqrt{n}} = \lim_{n\to\infty} \frac{e^n n!}{n^{n+1/2}} = \sqrt{2\pi}.$$

Because the series $\sum_{n=1}^{\infty} \sqrt{n}$ diverges by the Divergence Test and $L > 0$, we conclude that $\sum_{n=1}^{\infty} \frac{e^n n!}{n^n}$ diverges by the Limit Comparison Test.

10.6 Power Series

Preliminary Questions

1. Suppose that $\sum a_n x^n$ converges for $x = 5$. Must it also converge for $x = 4$? What about $x = -3$?

SOLUTION The power series $\sum a_n x^n$ is centered at $x = 0$. Because the series converges for $x = 5$, the radius of convergence must be at least 5 and the series converges absolutely at least for the interval $|x| < 5$. Both $x = 4$ and $x = -3$ are inside this interval, so the series converges for $x = 4$ and for $x = -3$.

2. Suppose that $\sum a_n (x-6)^n$ converges for $x = 10$. At which of the points (a)–(d) must it also converge?

(a) $x = 8$ **(b)** $x = 11$ **(c)** $x = 3$ **(d)** $x = 0$

SOLUTION The given power series is centered at $x = 6$. Because the series converges for $x = 10$, the radius of convergence must be at least $|10 - 6| = 4$ and the series converges absolutely at least for the interval $|x - 6| < 4$, or $2 < x < 10$.

(a) $x = 8$ is inside the interval $2 < x < 10$, so the series converges for $x = 8$.

(b) $x = 11$ is not inside the interval $2 < x < 10$, so the series may or may not converge for $x = 11$.

(c) $x = 3$ is inside the interval $2 < x < 10$, so the series converges for $x = 2$.

(d) $x = 0$ is not inside the interval $2 < x < 10$, so the series may or may not converge for $x = 0$.

3. What is the radius of convergence of $F(3x)$ if $F(x)$ is a power series with radius of convergence $R = 12$?

SOLUTION If the power series $F(x)$ has radius of convergence $R = 12$, then the power series $F(3x)$ has radius of convergence $R = \frac{12}{3} = 4$.

4. The power series $F(x) = \sum_{n=1}^{\infty} n x^n$ has radius of convergence $R = 1$. What is the power series expansion of $F'(x)$ and what is its radius of convergence?

SOLUTION We obtain the power series expansion for $F'(x)$ by differentiating the power series expansion for $F(x)$ term-by-term. Thus,

$$F'(x) = \sum_{n=1}^{\infty} n^2 x^{n-1}.$$

The radius of convergence for this series is $R = 1$, the same as the radius of convergence for the series expansion for $F(x)$.

Exercises

1. Use the Ratio Test to determine the radius of convergence R of $\sum_{n=0}^{\infty} \frac{x^n}{2^n}$. Does it converge at the endpoints $x = \pm R$?

SOLUTION With $a_n = \frac{x^n}{2^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{|x|^{n+1}}{2^{n+1}} \cdot \frac{2^n}{|x|^n} = \frac{|x|}{2} \quad \text{and} \quad \rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \frac{|x|}{2}.$$

By the Ratio Test, the series converges when $\rho = \frac{|x|}{2} < 1$, or $|x| < 2$, and diverges when $\rho = \frac{|x|}{2} > 1$, or $|x| > 2$. The radius of convergence is therefore $R = 2$. For $x = -2$, the left endpoint, the series becomes $\sum_{n=0}^{\infty} (-1)^n$, which is divergent. For $x = 2$, the right endpoint, the series becomes $\sum_{n=0}^{\infty} 1$, which is also divergent. Thus the series diverges at both endpoints.

2. Use the Ratio Test to show that $\sum_{n=1}^{\infty} \frac{x^n}{\sqrt{n}2^n}$ has radius of convergence $R = 2$. Then determine whether it converges at the endpoints $R = \pm 2$.

SOLUTION With $a_n = \frac{x^n}{\sqrt{n}2^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{|x|^{n+1}}{\sqrt{n+1} \cdot 2^{n+1}} \cdot \frac{\sqrt{n} \cdot 2^n}{|x|^n} = \frac{|x|}{2} \cdot \sqrt{\frac{n}{n+1}} \quad \text{and} \quad \rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \frac{|x|}{2} \cdot 1 = \frac{|x|}{2}.$$

By the Ratio Test, the series converges when $\rho = \frac{|x|}{2} < 1$, or $|x| < 2$, and diverges when $\rho = \frac{|x|}{2} > 1$, or $|x| > 2$. The radius of convergence is therefore $R = 2$.

For the endpoint $x = 2$, the series becomes

$$\sum_{n=1}^{\infty} \frac{2^n}{\sqrt{n} \cdot 2^n} = \sum_{n=1}^{\infty} \frac{1}{\sqrt{n}},$$

which is a divergent p-series. For the endpoint $x = -2$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(-2)^n}{\sqrt{n} \cdot 2^n} = \sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}}.$$

This alternating series converges by the Leibniz Test, but its associated positive series is a divergent p-series. Thus, the series for $x = -2$ is conditionally convergent.

3. Show that the power series (a)–(c) have the same radius of convergence. Then show that (a) diverges at both endpoints, (b) converges at one endpoint but diverges at the other, and (c) converges at both endpoints.

(a) $\sum_{n=1}^{\infty} \frac{x^n}{3^n}$ **(b)** $\sum_{n=1}^{\infty} \frac{x^n}{n3^n}$ **(c)** $\sum_{n=1}^{\infty} \frac{x^n}{n^2 3^n}$

SOLUTION

(a) With $a_n = \frac{x^n}{3^n}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{3^{n+1}} \cdot \frac{3^n}{x^n}\right| = \lim_{n\to\infty} \left|\frac{x}{3}\right| = \left|\frac{x}{3}\right|$$

Then $\rho < 1$ if $|x| < 3$, so that the radius of convergence is $R = 3$. For the endpoint $x = 3$, the series becomes

$$\sum_{n=1}^{\infty} \frac{3^n}{3^n} = \sum_{n=1}^{\infty} 1,$$

which diverges by the Divergence Test. For the endpoint $x = -3$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(-3)^n}{3^n} = \sum_{n=1}^{\infty} (-1)^n,$$

which also diverges by the Divergence Test.

(b) With $a_n = \frac{x^n}{n3^n}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{(n+1)3^{n+1}} \cdot \frac{n3^n}{x^n}\right| = \lim_{n\to\infty} \left|\frac{x}{3}\left(\frac{n}{n+1}\right)\right| = \left|\frac{x}{3}\right|.$$

Then $\rho < 1$ when $|x| < 3$, so that the radius of convergence is $R = 3$. For the endpoint $x = 3$, the series becomes

$$\sum_{n=1}^{\infty} \frac{3^n}{n3^n} = \sum_{n=1}^{\infty} \frac{1}{n},$$

which is the divergent harmonic series. For the endpoint $x = -3$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(-3)^n}{n3^n} = \sum_{n=1}^{\infty} \frac{(-1)^n}{n},$$

which converges by the Leibniz Test.

(c) With $a_n = \frac{x^n}{n^2 3^n}$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{x^{n+1}}{(n+1)^2 3^{n+1}} \cdot \frac{n^2 3^n}{x^n}\right| = \lim_{n\to\infty}\left|\frac{x}{3}\left(\frac{n}{n+1}\right)^2\right| = \left|\frac{x}{3}\right|$$

Then $\rho < 1$ when $|x| < 3$, so that the radius of convergence is $R = 3$. For the endpoint $x = 3$, the series becomes

$$\sum_{n=1}^{\infty} \frac{3^n}{n^2 3^n} = \sum_{n=1}^{\infty} \frac{1}{n^2},$$

which is a convergent p-series. For the endpoint $x = -3$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(-3)^n}{n^2 3^n} = \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2},$$

which converges by the Leibniz Test.

4. Repeat Exercise 3 for the following series:

(a) $\displaystyle\sum_{n=1}^{\infty} \frac{(x-5)^n}{9^n}$ **(b)** $\displaystyle\sum_{n=1}^{\infty} \frac{(x-5)^n}{n9^n}$ **(c)** $\displaystyle\sum_{n=1}^{\infty} \frac{(x-5)^n}{n^2 9^n}$

SOLUTION

(a) With $a_n = \frac{(x-5)^n}{9^n}$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(x-5)^{n+1}}{9^{n+1}} \cdot \frac{9^n}{(x-5)^n}\right| = \lim_{n\to\infty}\left|\frac{x-5}{9}\right| = \left|\frac{x-5}{9}\right|$$

Then $\rho < 1$ when $|x-5| < 9$, so that the radius of convergence is $R = 9$. Because the series is centered at $x = 5$, the series converges absolutely on the interval $|x-5| < 9$, or $-4 < x < 14$. For the endpoint $x = 14$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(14-5)^n}{9^n} = \sum_{n=1}^{\infty} 1,$$

which diverges by the Divergence Test. For the endpoint $x = -4$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(-4-5)^n}{9^n} = \sum_{n=1}^{\infty} (-1)^n,$$

which also diverges by the Divergence Test.

(b) With $a_n = \frac{(x-5)^n}{n9^n}$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(x-5)^{n+1}}{(n+1)9^{n+1}} \cdot \frac{n9^n}{(x-5)^n}\right| = \lim_{n\to\infty}\left|\frac{x-5}{9}\frac{n}{n+1}\right| = \left|\frac{x-5}{9}\right|.$$

Then $\rho < 1$ when $|x-5| < 9$, so that the radius of convergence is $R = 9$. Because the series is centered at $x = 5$, the series converges absolutely on the interval $|x-5| < 9$, or $-4 < x < 14$. For the endpoint $x = 14$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(14-5)^n}{n9^n} = \sum_{n=1}^{\infty} \frac{1}{n},$$

which is the divergent harmonic series. For the endpoint $x = -4$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(-4-5)^n}{n9^n} = \sum_{n=1}^{\infty} \frac{(-1)^n}{n},$$

which converges by the Leibniz Test.

(c) With $a_n = \frac{(x-5)^n}{n^2 9^n}$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(x-5)^{n+1}}{(n+1)^2 9^{n+1}} \cdot \frac{n^2 9^n}{(x-5)^n}\right| = \lim_{n\to\infty}\left|\frac{x-5}{9}\left(\frac{n}{n+1}\right)^2\right| = \left|\frac{x-5}{9}\right|.$$

Then $\rho < 1$ when $|x-5| < 9$, so that the radius of convergence is $R = 9$. Because the series is centered at $x = 5$, the series converges absolutely on the interval $|x-5| < 9$, or $-4 < x < 14$. For the endpoint $x = 14$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(14-5)^n}{n^2 9^n} = \sum_{n=1}^{\infty} \frac{1}{n^2},$$

which is a convergent p-series. For the endpoint $x = -4$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(-4-5)^n}{n^2 9^n} = \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2},$$

which converges by the Leibniz Test.

5. Show that $\displaystyle\sum_{n=0}^{\infty} n^n x^n$ diverges for all $x \neq 0$.

SOLUTION With $a_n = n^n x^n$, and assuming $x \neq 0$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(n+1)^{n+1} x^{n+1}}{n^n x^n}\right| = \lim_{n\to\infty} \left| x \left(1 + \frac{1}{n}\right)^n (n+1) \right| = \infty$$

$\rho < 1$ only if $x = 0$, so that the radius of convergence is therefore $R = 0$. In other words, the power series converges only for $x = 0$.

6. For which values of x does $\displaystyle\sum_{n=0}^{\infty} n! x^n$ converge?

SOLUTION With $a_n = n! x^n$, and assuming $x \neq 0$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(n+1)! x^{n+1}}{n! x^n}\right| = \lim_{n\to\infty} |(n+1)x| = \infty$$

$\rho < 1$ only if $x = 0$, so that the radius of convergence is $R = 0$. In other words, the power series converges only for $x = 0$.

7. Use the Ratio Test to show that $\displaystyle\sum_{n=0}^{\infty} \frac{x^{2n}}{3^n}$ has radius of convergence $R = \sqrt{3}$.

SOLUTION With $a_n = \dfrac{x^{2n}}{3^n}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{2(n+1)}}{3^{n+1}} \cdot \frac{3^n}{x^{2n}}\right| = \lim_{n\to\infty} \left|\frac{x^2}{3}\right| = \left|\frac{x^2}{3}\right|$$

Then $\rho < 1$ when $|x^2| < 3$, or $x = \sqrt{3}$, so the radius of convergence is $R = \sqrt{3}$.

8. Show that $\displaystyle\sum_{n=0}^{\infty} \frac{x^{3n+1}}{64^n}$ has radius of convergence $R = 4$.

SOLUTION With $a_n = \dfrac{x^{3n+1}}{64^n}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{3(n+1)+1}}{64^{n+1}} \cdot \frac{64^n}{x^{3n+1}}\right| = \lim_{n\to\infty} \left|\frac{x^3}{64}\right| = \left|\frac{x^3}{64}\right|$$

Then $\rho < 1$ when $|x|^3 < 64$ or $|x| = 4$, so the radius of convergence is $R = 4$.

In Exercises 9–34, find the interval of convergence.

9. $\displaystyle\sum_{n=0}^{\infty} n x^n$

SOLUTION With $a_n = n x^n$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(n+1)x^{n+1}}{n x^n}\right| = \lim_{n\to\infty} \left| x \frac{n+1}{n} \right| = |x|$$

Then $\rho < 1$ when $|x| < 1$, so that the radius of convergence is $R = 1$, and the series converges absolutely on the interval $|x| < 1$, or $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\sum_{n=0}^{\infty} n$, which diverges by the Divergence Test. For the endpoint $x = -1$, the series becomes $\sum_{n=1}^{\infty} (-1)^n n$, which also diverges by the Divergence Test. Thus, the series $\sum_{n=0}^{\infty} nx^n$ converges for $-1 < x < 1$ and diverges elsewhere.

10. $\sum_{n=1}^{\infty} \frac{2^n}{n} x^n$

SOLUTION With $a_n = \frac{2^n}{n} x^n$,

$$\rho = \lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n\to\infty} \left| \frac{2^{n+1} x^{n+1}}{n+1} \cdot \frac{n}{2^n x^n} \right| = \lim_{n\to\infty} \left| 2x \frac{n}{n+1} \right| = |2x|$$

$\rho < 1$ when $|x| < \frac{1}{2}$, so the radius of convergence is $R = \frac{1}{2}$, and the series converges absolutely on the interval $|x| < \frac{1}{2}$, or $-\frac{1}{2} < x < \frac{1}{2}$. For the endpoint $x = \frac{1}{2}$, the series becomes $\sum_{n=1}^{\infty} \frac{1}{n}$, which is the divergent harmonic series. For the endpoint $x = -\frac{1}{2}$, the series becomes $\sum_{n=1}^{\infty} \frac{(-1)^n}{n}$, which converges by the Leibniz Test. Thus, the series $\sum_{n=1}^{\infty} \frac{x^n}{n} x^n$ converges for $-\frac{1}{2} \le x < \frac{1}{2}$ and diverges elsewhere.

11. $\sum_{n=1}^{\infty} (-1)^n \frac{x^{2n+1}}{2^n n}$

SOLUTION With $a_n = (-1)^n \frac{x^{2n+1}}{2^n n}$,

$$\rho = \lim_{n\to\infty} \left| \frac{x^{2(n+1)+1}}{2^{n+1}(n+1)} \cdot \frac{2^n n}{x^{2n+1}} \right| = \lim_{n\to\infty} \left| \frac{x^2}{2} \cdot \frac{n}{n+1} \right| = \left| \frac{x^2}{2} \right|$$

Then $\rho < 1$ when $|x| < \sqrt{2}$, so the radius of convergence is $R = \sqrt{2}$, and the series converges absolutely on the interval $-\sqrt{2} < x < \sqrt{2}$. For the endpoint $x = -\sqrt{2}$, the series becomes $\sum_{n=1}^{\infty} (-1)^n \frac{-\sqrt{2}}{n} = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{\sqrt{2}}{n}$, which converges by the Leibniz test. For the endpoint $x = \sqrt{2}$, the series becomes $\sum_{n=1}^{\infty} (-1)^n \frac{\sqrt{2}}{n}$ which also converges by the Leibniz test. Thus the series $\sum_{n=1}^{\infty} (-1)^n \frac{x^{2n+1}}{2^n n}$ converges for $-\sqrt{2} \le x \le \sqrt{2}$ and diverges elsewhere.

12. $\sum_{n=0}^{\infty} (-1)^n \frac{n}{4^n} x^{2n}$

SOLUTION With $a_n = (-1)^n \frac{n}{4^n} x^{2n}$,

$$\rho = \lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n\to\infty} \left| \frac{(n+1)x^{2(n+1)}}{4^{n+1}} \cdot \frac{4^n}{nx^{2n}} \right| = \lim_{n\to\infty} \left| \frac{x^2}{4} \cdot \frac{n+1}{n} \right| = \left| \frac{x^2}{4} \right|$$

Then $\rho < 1$ when $|x^2| < 4$, or $|x| < 2$, so the radius of convergence is $R = 2$, and the series converges absolutely for $-2 < x < 2$. At both endpoints $x = \pm 2$, the series becomes $\sum_{n=0}^{\infty} (-1)^n n$, which diverges by the Divergence Test. Thus, the series $\sum_{n=0}^{\infty} (-1)^n \frac{n}{4^n} x^{2n}$ converges for $-2 < x < 2$ and diverges elsewhere.

13. $\displaystyle\sum_{n=4}^{\infty} \frac{x^n}{n^5}$

SOLUTION With $a_n = \frac{x^n}{n^5}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{(n+1)^5} \cdot \frac{n^5}{x^n}\right| = \lim_{n\to\infty} \left|x\left(\frac{n}{n+1}\right)^5\right| = |x|$$

Then $\rho < 1$ when $|x| < 1$, so the radius of convergence is $R = 1$, and the series converges absolutely on the interval $|x| < 1$, or $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^5}$, which is a convergent p-series. For the endpoint $x = -1$, the series becomes $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^n}{n^5}$, which converges by the Leibniz Test. Thus, the series $\displaystyle\sum_{n=4}^{\infty} \frac{x^n}{n^5}$ converges for $-1 \le x \le 1$ and diverges elsewhere.

14. $\displaystyle\sum_{n=8}^{\infty} n^7 x^n$

SOLUTION With $a_n = n^7 x^n$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(n+1)^7 x^{n+1}}{n^7 x^n}\right| = \lim_{n\to\infty} \left|x\left(\frac{n+1}{n}\right)^7\right| = |x|$$

Then $\rho < 1$ when $|x| < 1$, so that the radius of convergence is $R = 1$, and the series converges absolutely on the intervale $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\displaystyle\sum_{n=8}^{\infty} n^7$, which diverges by the Divergence test; for the endpoints $x = -1$, the series becomes $\displaystyle\sum_{n=8}^{\infty} (-1)^n n^7$, which also diverges by the Divergence test. Thus the series $\displaystyle\sum_{n=8}^{\infty} n^7 x^n$ converges for $-1 < x < 1$ and diverges elsewhere.

15. $\displaystyle\sum_{n=0}^{\infty} \frac{x^n}{(n!)^2}$

SOLUTION With $a_n = \frac{x^n}{(n!)^2}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{((n+1)!)^2} \cdot \frac{(n!)^2}{x^n}\right| = \lim_{n\to\infty} \left|x\left(\frac{1}{n+1}\right)^2\right| = 0$$

$\rho < 1$ for all x, so the radius of convergence is $R = \infty$, and the series converges absolutely for all x.

16. $\displaystyle\sum_{n=0}^{\infty} \frac{8^n}{n!} x^n$

SOLUTION With $a_n = \frac{8^n x^n}{n!}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{8^{n+1} x^{n+1}}{(n+1)!} \cdot \frac{n!}{8^n x^n}\right| = \lim_{n\to\infty} \left|8x \cdot \frac{1}{n+1}\right| = 0$$

$\rho < 1$ for all x, so the radius of convergence is $R = \infty$, and the series converges absolutely for all x.

17. $\displaystyle\sum_{n=0}^{\infty} \frac{(2n)!}{(n!)^3} x^n$

SOLUTION With $a_n = \frac{(2n)! x^n}{(n!)^3}$, and assuming $x \neq 0$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(2(n+1))! x^{n+1}}{((n+1)!)^3} \cdot \frac{(n!)^3}{(2n)! x^n}\right| = \lim_{n\to\infty} \left|x \frac{(2n+2)(2n+1)}{(n+1)^3}\right|$$

$$= \lim_{n\to\infty} \left|x \frac{4n^2 + 6n + 2}{n^3 + 3n^2 + 3n + 1}\right| = \lim_{n\to\infty} \left|x \frac{4n^{-1} + 6n^{-1} + 2n^{-3}}{1 + 3n^{-1} + 3n^{-2} + n^{-3}}\right| = 0$$

Then $\rho < 1$ for all x, so the radius of convergence is $R = \infty$, and the series converges absolutely for all x.

18. $\displaystyle\sum_{n=0}^{\infty} \frac{4^n}{(2n+1)!} x^{2n-1}$

SOLUTION With $a_n = \frac{4^n x^{2n-1}}{(2n+1)!}$,

$$\rho = \lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n\to\infty} \left| \frac{4^{n+1} x^{2n+1}}{(2n+3)!} \cdot \frac{(2n+1)!}{4^n x^{2n-1}} \right| = \lim_{n\to\infty} \left| \frac{4x^2}{(2n+3)(2n+2)} \right| = 0$$

Then ρ is always less than 1, and the series converges absolutely for all x.

19. $\displaystyle\sum_{n=0}^{\infty} \frac{(-1)^n x^n}{\sqrt{n^2+1}}$

SOLUTION With $a_n = \frac{(-1)^n x^n}{\sqrt{n^2+1}}$,

$$\rho = \lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n\to\infty} \left| \frac{(-1)^{n+1} x^{n+1}}{\sqrt{n^2+2n+2}} \cdot \frac{\sqrt{n^2+1}}{(-1)^n x^n} \right|$$

$$= \lim_{n\to\infty} \left| x \frac{\sqrt{n^2+1}}{\sqrt{n^2+2n+2}} \right| = \lim_{n\to\infty} \left| x \sqrt{\frac{n^2+1}{n^2+2n+2}} \right| = \lim_{n\to\infty} \left| x \sqrt{\frac{1+1/n^2}{1+2/n+2/n^2}} \right|$$

$$= |x|$$

Then $\rho < 1$ when $|x| < 1$, so the radius of convergence is $R = 1$, and the series converges absolutely on the interval $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n^2+1}}$, which converges by the Leibniz Test. For the endpoint $x = -1$, the series becomes $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt{n^2+1}}$, which diverges by the Limit Comparison Test comparing with the divergent harmonic series. Thus, the series $\displaystyle\sum_{n=0}^{\infty} \frac{(-1)^n x^n}{\sqrt{n^2+1}}$ converges for $-1 < x \le 1$ and diverges elsewhere.

20. $\displaystyle\sum_{n=0}^{\infty} \frac{x^n}{n^4+2}$

SOLUTION With $a_n = \frac{x^n}{n^4+2}$,

$$\rho = \lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n\to\infty} \left| \frac{x^{n+1}}{(n+1)^4+2} \cdot \frac{n^4+2}{x^n} \right| = \lim_{n\to\infty} \left| x \frac{n^4+2}{n^4+4n^3+6n^2+4n+3} \right| = |x|$$

$\rho < 1$ when $|x| < 1$, so the radius of convergence is $R = 1$, and the series converges absolutely on the interval $|x| < 1$, or $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^4+2}$. Because $\frac{1}{n^4+2} < \frac{1}{n^4}$ and the series $\displaystyle\sum_{n=0}^{\infty} \frac{1}{n^4}$ is a convergent p-series, the endpoint series converges by the Comparison Test. For the endpoint $x = -1$, the series becomes $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^n}{n^4+2}$, which converges by the Leibniz Test. Thus, the series $\displaystyle\sum_{n=0}^{\infty} \frac{x^n}{n^4+2}$ converges for $-1 \le x \le 1$ and diverges elsewhere.

21. $\displaystyle\sum_{n=15}^{\infty} \frac{x^{2n+1}}{3n+1}$

SOLUTION With $a_n = \dfrac{x^{2n+1}}{3n+1}$,

$$\rho = \lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n\to\infty} \left| \frac{x^{2n+3}}{3n+4} \cdot \frac{3n+1}{x^{2n+1}} \right| = \lim_{n\to\infty} \left| x^2 \frac{3n+1}{3n+4} \right| = |x^2|$$

Then $\rho < 1$ when $|x^2| < 1$, so the radius of convergence is $R = 1$, and the series converges absolutely for $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\displaystyle\sum_{n=15}^{\infty} \frac{1}{3n+1}$, which diverges by the Limit Comparison Test comparing with the divergent harmonic series. For the endpoint $x = -1$, the series becomes $\sum_{n=15}^{\infty} \frac{-1}{3n+1}$, which also diverges by the Limit Comparison Test comparing with the divergent harmonic series. Thus, the series $\sum_{n=15}^{\infty} \frac{x^{2n+1}}{3n+1}$ converges for $-1 < x < 1$ and diverges elsewhere.

22. $\sum_{n=1}^{\infty} \frac{x^n}{n - 4\ln n}$

SOLUTION With $a_n = \frac{x^n}{n-4\ln n}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{(n+1) - 4\ln(n+1)} \cdot \frac{n - 4\ln n}{x^n}\right| = \lim_{n\to\infty} \left|x \frac{n - 4\ln n}{(n+1) - 4\ln(n+1)}\right|$$

$$= \lim_{n\to\infty} \left|x \frac{1 - 4(\ln n)/n}{1 + n^{-1} - 4(\ln(n+1))/n}\right| = |x|$$

Then $\rho < 1$ when $|x| < 1$, so the radius of convergence is 1, and the series converges absolutely on the interval $|x| < 1$, or $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\sum_{n=1}^{\infty} \frac{1}{n - 4\ln n}$. Because $\frac{1}{n-4\ln n} > \frac{1}{n}$ and $\sum_{n=1}^{\infty} \frac{1}{n}$ is the divergent harmonic series, the endpoint series diverges by the Comparison Test. For the endpoint $x = -1$, the series becomes $\sum_{n=1}^{\infty} \frac{(-1)^n}{n - 4\ln n}$, which converges by the Leibniz Test. Thus, the series $\sum_{n=1}^{\infty} \frac{x^n}{n - 4\ln n}$ converges for $-1 \le x < 1$ and diverges elsewhere.

23. $\sum_{n=2}^{\infty} \frac{x^n}{\ln n}$

SOLUTION With $a_n = \frac{x^n}{\ln n}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{\ln(n+1)} \cdot \frac{\ln n}{x^n}\right| = \lim_{n\to\infty} \left|x \frac{\ln(n+1)}{\ln n}\right| = \lim_{n\to\infty} \left|x \frac{1/(n+1)}{1/n}\right| = \lim_{n\to\infty} \left|x \frac{n}{n+1}\right| = |x|$$

using L'Hôpital's rule. Then $\rho < 1$ when $|x| < 1$, so the radius of convergence is 1, and the series converges absolutely on the interval $|x| < 1$, or $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\sum_{n=2}^{\infty} \frac{1}{\ln n}$. Because $\frac{1}{\ln n} > \frac{1}{n}$ and $\sum_{n=2}^{\infty} \frac{1}{n}$ is the divergent harmonic series, the endpoint series diverges by the Comparison Test. For the endpoint $x = -1$, the series becomes $\sum_{n=2}^{\infty} \frac{(-1)^n}{\ln n}$, which converges by the Leibniz Test. Thus, the series $\sum_{n=2}^{\infty} \frac{x^n}{\ln n}$ converges for $-1 \le x < 1$ and diverges elsewhere.

24. $\sum_{n=2}^{\infty} \frac{x^{3n+2}}{\ln n}$

SOLUTION With $a_n = \frac{x^{3n+2}}{\ln n}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{3n+5}}{\ln(n+1)} \cdot \frac{\ln n}{x^{3n+2}}\right| = \lim_{n\to\infty} \left|x^3 \cdot \frac{\ln(n+1)}{\ln n}\right| = \lim_{n\to\infty} \left|x^3 \cdot \frac{1/(n+1)}{1/n}\right|$$

$$= \lim_{n\to\infty} \left|x^3 \cdot \frac{n}{n+1}\right| = |x^3|$$

using L'Hôpital's rule. Thus $\rho < 1$ when $|x^3| < 1$, so the radius of convergence is 1, and the series converges absolutely on the interval $|x| < 1$, or $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\sum_{n=2}^{\infty} \frac{1}{\ln n}$. Because $\frac{1}{\ln n} > \frac{1}{n}$ and $\sum_{n=2}^{\infty} \frac{1}{n}$ is the divergent harmonic series, the endpoint series diverges by the Comparison Test. For the endpoint $x = -1$, the series becomes $\sum_{n=2}^{\infty} \frac{(-1)^{3n+2}}{\ln n} = \sum_{n=2}^{\infty} \frac{(-1)^n}{\ln n}$, which converges by the Leibniz Test. Thus, the series $\sum_{n=2}^{\infty} \frac{x^{3n+2}}{\ln n}$ converges for $-1 \le x < 1$ and diverges elsewhere.

25. $\displaystyle\sum_{n=1}^{\infty} n(x-3)^n$

SOLUTION With $a_n = n(x-3)^n$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(n+1)(x-3)^{n+1}}{n(x-3)^n}\right| = \lim_{n\to\infty}\left|(x-3)\cdot\frac{n+1}{n}\right| = |x-3|$$

Then $\rho < 1$ when $|x-3| < 1$, so the radius of convergence is 1, and the series converges absolutely on the interval $|x-3| < 1$, or $2 < x < 4$. For the endpoint $x = 4$, the series becomes $\displaystyle\sum_{n=1}^{\infty} n$, which diverges by the Divergence Test. For the endpoint $x = 2$, the series becomes $\displaystyle\sum_{n=1}^{\infty}(-1)^n n$, which also diverges by the Divergence Test. Thus, the series $\displaystyle\sum_{n=1}^{\infty} n(x-3)^n$ converges for $2 < x < 4$ and diverges elsewhere.

26. $\displaystyle\sum_{n=1}^{\infty} \frac{(-5)^n(x-3)^n}{n^2}$

SOLUTION With $a_n = \frac{(-5)^n(x-3)^n}{n^2}$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(-5)^{n+1}(x-3)^{n+1}}{(n+1)^2}\cdot\frac{n^2}{(-5)^n(x-3)^n}\right| = \lim_{n\to\infty}\left|5(x-3)\cdot\frac{n^2}{n^2+2n+1}\right|$$
$$= \lim_{n\to\infty}\left|5(x-3)\cdot\frac{1}{1+2n^{-1}+n^{-2}}\right| = |5(x-3)|$$

Then $\rho < 1$ when $|5(x-3)| < 1$, or $|x-3| < \frac{1}{5}$. Thus the radius of convergence is 5, and the series converges absolutely on the interval $|x-3| < \frac{1}{5}$, or $\frac{14}{5} < x < \frac{16}{5}$. For the endpoint $x = \frac{16}{5}$, the series becomes $\displaystyle\sum_{n=1}^{\infty}\frac{(-1)^n}{n^2}$, which converges by the Leibniz Test. For the endpoint $x = \frac{14}{5}$, the series becomes $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n^2}$, which is a convergent p-series. Thus, the series $\displaystyle\sum_{n=1}^{\infty}\frac{(-5)^n(x-3)^n}{n^2}$ converges for $\frac{14}{5} \le x \le \frac{16}{5}$ and diverges elsewhere.

27. $\displaystyle\sum_{n=1}^{\infty}(-1)^n n^5(x-7)^n$

SOLUTION With $a_n = (-1)^n n^5(x-7)^n$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(-1)^{n+1}(n+1)^5(x-7)^{n+1}}{(-1)^n n^5(x-7)^n}\right| = \lim_{n\to\infty}\left|(x-7)\cdot\frac{(n+1)^5}{n^5}\right|$$
$$= \lim_{n\to\infty}\left|(x-7)\cdot\frac{n^5+\dots}{n^5}\right| = |x-7|$$

Then $\rho < 1$ when $|x-7| < 1$, so the radius of convergence is 1, and the series converges absolutely on the interval $|x-7| < 1$, or $6 < x < 8$. For the endpoint $x = 6$, the series becomes $\displaystyle\sum_{n=1}^{\infty}(-1)^{2n}n^5 = \sum_{n=1}^{\infty}n^5$, which diverges by the Divergence Test. For the endpoint $x = 8$, the series becomes $\displaystyle\sum_{n=1}^{\infty}(-1)^n n^5$, which also diverges by the Divergence Test. Thus, the series $\displaystyle\sum_{n=1}^{\infty}(-1)^n n^5(x-7)^n$ converges for $6 < x < 8$ and diverges elsewhere.

28. $\sum_{n=0}^{\infty} 27^n (x-1)^{3n+2}$

SOLUTION With $a_n = 27^n (x-1)^{3n+2}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{27^{n+1}(x-1)^{3n+5}}{27^n (x-1)^{3n+2}}\right| = \lim_{n\to\infty} \left|27(x-1)^3\right| = |27(x-1)^3|$$

Then $\rho < 1$ when $|27(x-1)^3| < 1$, or when $|(x-1)^3| < \frac{1}{27}$, so when $|x-1| < \frac{1}{3}$. Thus the radius of convergence is $\frac{1}{3}$, and the series converges absolutely when $\frac{2}{3} < x < \frac{4}{3}$. For the endpoint $x = \frac{2}{3}$, the series becomes $\sum_{n=0}^{\infty} 27^n \left(\frac{-1}{3}\right)^{3n+2} = \frac{1}{9}\sum_{n=0}^{\infty}(-1)^n$ which diverges by the Divergence test. For the endpoint $x = \frac{4}{3}$, the series becomes $\sum_{n=0}^{\infty} 27^n \left(\frac{1}{3}\right)^{3n+2} = \frac{1}{9}\sum_{n=0}^{\infty} 1$, which also diverges by the Divergence Test. Thus the series $\sum_{n=0}^{\infty} 27^n (x-1)^{3n+2}$ converges for $\frac{2}{3} < x < \frac{4}{3}$ and diverges elsewhere.

29. $\sum_{n=1}^{\infty} \frac{2^n}{3n}(x+3)^n$

SOLUTION With $a_n = \frac{2^n (x+3)^n}{3n}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{2^{n+1}(x+3)^{n+1}}{3(n+1)} \cdot \frac{3n}{2^n (x+3)^n}\right| = \lim_{n\to\infty} \left|2(x+3) \cdot \frac{3n}{3n+3}\right|$$
$$= \lim_{n\to\infty} \left|2(x+3) \cdot \frac{1}{1+1/n}\right| = |2(x+3)|$$

Then $\rho < 1$ when $|2(x+3)| < 1$, so when $|x+3| < \frac{1}{2}$. Thus the radius of convergence is $\frac{1}{2}$, and the series converges absolutely on the interval $|x+3| < \frac{1}{2}$, or $-\frac{7}{2} < x < -\frac{5}{2}$. For the endpoint $x = -\frac{5}{2}$, the series becomes $\sum_{n=1}^{\infty} \frac{1}{3n}$, which diverges because it is a multiple of the divergent harmonic series. For the endpoint $x = -\frac{7}{2}$, the series becomes $\sum_{n=1}^{\infty} \frac{(-1)^n}{3n}$, which converges by the Leibniz Test. Thus, the series $\sum_{n=1}^{\infty} \frac{2^n}{3n}(x+3)^n$ converges for $-\frac{7}{2} \le x < -\frac{5}{2}$ and diverges elsewhere.

30. $\sum_{n=0}^{\infty} \frac{(x-4)^n}{n!}$

SOLUTION With $a_n = \frac{(x-4)^n}{n!}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(x-4)^{n+1}}{(n+1)!} \cdot \frac{n!}{(x-4)^n}\right| = \lim_{n\to\infty} \left|(x-4)\frac{1}{n}\right| = 0$$

Thus $\rho < 1$ for all x, so the radius of convergence is infinite, and $\sum_{n=0}^{\infty} \frac{(x-4)^n}{n!}$ converges for all x.

31. $\sum_{n=0}^{\infty} \frac{(-5)^n}{n!}(x+10)^n$

SOLUTION With $a_n = \frac{(-5)^n}{n!}(x+10)^n$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(-5)^{n+1}(x+10)^{n+1}}{(n+1)!} \cdot \frac{n!}{(-5)^n (x+10)^n}\right| = \lim_{n\to\infty} \left|5(x+10)\frac{1}{n}\right| = 0$$

Thus $\rho < 1$ for all x, so the radius of convergence is infinite, and $\sum_{n=0}^{\infty} \frac{(-5)^n}{n!}(x+10)^n$ converges for all x.

32. $\displaystyle\sum_{n=10}^{\infty} n!\,(x+5)^n$

SOLUTION With $a_n = n!(x+5)^n$,, and assuming $x + 5 \neq 0$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(n+1)!(x+5)^{n+1}}{n!(x+5)^n}\right| = \lim_{n\to\infty}|(n+1)(x+5)| = \infty$$

Thus $\rho < 1$ only if $x + 5 = 0$, so the radius of convergence is zero, and $\displaystyle\sum_{n=10}^{\infty} n!\,(x+5)^n$ converges only for $x = -5$.

33. $\displaystyle\sum_{n=12}^{\infty} e^n (x-2)^n$

SOLUTION With $a_n = e^n (x-2)^n$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{e^{n+1}(x-2)^{n+1}}{e^n(x-2)^n}\right| = \lim_{n\to\infty}|e(x-2)| = |e(x-2)|$$

Thus $\rho < 1$ when $|e(x-2)| < 1$, so when $|x-2| < e^{-1}$. Thus the radius of convergence is e^{-1}, and the series converges absolutely on the interval $|x-2| < e^{-1}$, or $2 - e^{-1} < x < 2 + e^{-1}$. For the endpoint $x = 2 + e^{-1}$, the series becomes $\displaystyle\sum_{n=1}^{\infty} 1$, which diverges by the Divergence Test. For the endpoint $x = 2 - e^{-1}$, the series becomes $\displaystyle\sum_{n=1}^{\infty}(-1)^n$, which also diverges by the Divergence Test. Thus, the series $\displaystyle\sum_{n=12}^{\infty} e^n (x-2)^n$ converges for $2 - e^{-1} < x < 2 + e^{-1}$ and diverges elsewhere.

34. $\displaystyle\sum_{n=2}^{\infty} \frac{(x+4)^n}{(n\ln n)^2}$

SOLUTION With $a_n = \frac{(x+4)^n}{(n\ln n)^2}$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(x+4)^{n+1}}{((n+1)\ln(n+1))^2}\cdot\frac{(n\ln n)^2}{(x+4)^n}\right| = \lim_{n\to\infty}\left|(x+4)\cdot\left(\frac{n}{n+1}\cdot\frac{\ln n}{\ln(n+1)}\right)^2\right| = |x+4|$$

applying L'Hôpital's rule to evaluate the second term in the product. Thus $\rho < 1$ when $|x+4| < 1$, so the radius of convergence is 1, and the series converges absolutely on the interval $|x+4| < 1$, or $-5 < x < -3$. For the endpoint $x = -3$, the series becomes $\displaystyle\sum_{n=1}^{\infty}\frac{1}{(n\ln n)^2}$, which converges by the Limit Comparison Test comparing with the convergent p-series $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n^2}$. For the endpoint $x = -5$, the series becomes $\displaystyle\sum_{n=1}^{\infty}\frac{(-1)^n}{(n\ln n)^2}$, which converges by the Leibniz Test. Thus, the series $\displaystyle\sum_{n=2}^{\infty}\frac{(x+4)^n}{(n\ln n)^2}$ converges for $-5 \le x \le -3$ and diverges elsewhere.

In Exercises 35–40, use Eq. (2) to expand the function in a power series with center $c = 0$ and determine the interval of convergence.

35. $f(x) = \dfrac{1}{1-3x}$

SOLUTION Substituting $3x$ for x in Eq. (2), we obtain

$$\frac{1}{1-3x} = \sum_{n=0}^{\infty}(3x)^n = \sum_{n=0}^{\infty} 3^n x^n.$$

This series is valid for $|3x| < 1$, or $|x| < \frac{1}{3}$.

36. $f(x) = \dfrac{1}{1+3x}$

SOLUTION Substituting $-3x$ for x in Eq. (2), we obtain

$$\frac{1}{1+3x} = \sum_{n=0}^{\infty}(-3x)^n = \sum_{n=0}^{\infty}(-3)^n x^n.$$

This series is valid for $|-3x| < 1$, or $|x| < \frac{1}{3}$.

37. $f(x) = \dfrac{1}{3-x}$

SOLUTION First write

$$\frac{1}{3-x} = \frac{1}{3} \cdot \frac{1}{1-\frac{x}{3}}.$$

Substituting $\frac{x}{3}$ for x in Eq. (2), we obtain

$$\frac{1}{1-\frac{x}{3}} = \sum_{n=0}^{\infty}\left(\frac{x}{3}\right)^n = \sum_{n=0}^{\infty}\frac{x^n}{3^n};$$

Thus,

$$\frac{1}{3-x} = \frac{1}{3}\sum_{n=0}^{\infty}\frac{x^n}{3^n} = \sum_{n=0}^{\infty}\frac{x^n}{3^{n+1}}.$$

This series is valid for $|x/3| < 1$, or $|x| < 3$.

38. $f(x) = \dfrac{1}{4+3x}$

SOLUTION First write

$$\frac{1}{4+3x} = \frac{1}{4} \cdot \frac{1}{1+\frac{3x}{4}}.$$

Substituting $-\frac{3x}{4}$ for x in Eq. (2), we obtain

$$\frac{1}{1+\frac{3x}{4}} = \sum_{n=0}^{\infty}\left(-\frac{3x}{4}\right)^n = \sum_{n=0}^{\infty}(-1)^n\frac{3^n x^n}{4^n};$$

Thus,

$$\frac{1}{4+3x} = \frac{1}{4}\sum_{n=0}^{\infty}(-1)^n\frac{3^n x^n}{4^n} = \sum_{n=0}^{\infty}(-1)^n\frac{3^n x^n}{4^{n+1}}.$$

This series is valid for $|-3x/4| < 1$, or $|x| < \frac{4}{3}$.

39. $f(x) = \dfrac{1}{1+x^2}$

SOLUTION Substituting $-x^2$ for x in Eq. (2), we obtain

$$\frac{1}{1+x^2} = \sum_{n=0}^{\infty}(-x^2)^n = \sum_{n=0}^{\infty}(-1)^n x^{2n}$$

This series is valid for $|x| < 1$.

40. $f(x) = \dfrac{1}{16+2x^3}$

SOLUTION First rewrite

$$\frac{1}{16+2x^3} = \frac{1}{16} \cdot \frac{1}{1+\frac{x^3}{8}}$$

Now substitute $-\frac{x^3}{8}$ for x in Eq. (2) to obtain

$$\frac{1}{1+\frac{x^3}{8}} = \sum_{n=0}^{\infty}\left(\frac{-x^3}{8}\right)^n = \sum_{n=0}^{\infty}(-1)^n\frac{x^{3n}}{8}$$

Thus,

$$\frac{1}{16+2x^3} = \frac{1}{16} \cdot \frac{1}{1+\frac{x^3}{8}} = \frac{1}{16} \cdot \sum_{n=0}^{\infty} (-1)^n \frac{x^{3n}}{8}$$

This series is valid for $|x^3| < 8$, or $|x| < 2$.

41. Use the equalities

$$\frac{1}{1-x} = \frac{1}{-3-(x-4)} = \frac{-\frac{1}{3}}{1+\left(\frac{x-4}{3}\right)}$$

to show that for $|x-4| < 3$,

$$\frac{1}{1-x} = \sum_{n=0}^{\infty} (-1)^{n+1} \frac{(x-4)^n}{3^{n+1}}$$

SOLUTION Substituting $-\frac{x-4}{3}$ for x in Eq. (2), we obtain

$$\frac{1}{1+\left(\frac{x-4}{3}\right)} = \sum_{n=0}^{\infty} \left(-\frac{x-4}{3}\right)^n = \sum_{n=0}^{\infty} (-1)^n \frac{(x-4)^n}{3^n}.$$

Thus,

$$\frac{1}{1-x} = -\frac{1}{3} \sum_{n=0}^{\infty} (-1)^n \frac{(x-4)^n}{3^n} = \sum_{n=0}^{\infty} (-1)^{n+1} \frac{(x-4)^n}{3^{n+1}}.$$

This series is valid for $|-\frac{x-4}{3}| < 1$, or $|x-4| < 3$.

42. Use the method of Exercise 41 to expand $1/(1-x)$ in power series with centers $c = 2$ and $c = -2$. Determine the interval of convergence.

SOLUTION For $c = 2$, write

$$\frac{1}{1-x} = \frac{1}{-1-(x-2)} = -\frac{1}{1+(x-2)}.$$

Substituting $-(x-2)$ for x in Eq. (2), we obtain

$$\frac{1}{1+(x-2)} = \sum_{n=0}^{\infty} (-(x-2))^n = \sum_{n=0}^{\infty} (-1)^n (x-2)^n.$$

Thus,

$$\frac{1}{1-x} = -\sum_{n=0}^{\infty} (-1)^n (x-2)^n = \sum_{n=0}^{\infty} (-1)^{n+1} (x-2)^n.$$

This series is valid for $|-(x-2)| < 1$, or $|x-2| < 1$.

For $c = -2$, write

$$\frac{1}{1-x} = \frac{1}{3-(x+2)} = \frac{1}{3} \cdot \frac{1}{1-\frac{x+2}{3}}.$$

Substituting $\frac{x+2}{3}$ for x in Eq. (2), we obtain

$$\frac{1}{1-\frac{x+2}{3}} = \sum_{n=0}^{\infty} \left(\frac{x+2}{3}\right)^n = \sum_{n=0}^{\infty} \frac{(x+2)^n}{3^n}.$$

Thus,

$$\frac{1}{1-x} = \frac{1}{3} \sum_{n=0}^{\infty} \frac{(x+2)^n}{3^n} = \sum_{n=0}^{\infty} \frac{(x+2)^n}{3^{n+1}}.$$

This series is valid for $|\frac{x+2}{3}| < 1$, or $|x+2| < 3$.

43. Use the method of Exercise 41 to expand $1/(4-x)$ in a power series with center $c = 5$. Determine the interval of convergence.

SOLUTION First write

$$\frac{1}{4-x} = \frac{1}{-1-(x-5)} = -\frac{1}{1+(x-5)}.$$

Substituting $-(x-5)$ for x in Eq. (2), we obtain

$$\frac{1}{1+(x-5)} = \sum_{n=0}^{\infty}(-(x-5))^n = \sum_{n=0}^{\infty}(-1)^n(x-5)^n.$$

Thus,

$$\frac{1}{4-x} = -\sum_{n=0}^{\infty}(-1)^n(x-5)^n = \sum_{n=0}^{\infty}(-1)^{n+1}(x-5)^n.$$

This series is valid for $|-(x-5)| < 1$, or $|x-5| < 1$.

44. Find a power series that converges only for x in $[2, 6)$.

SOLUTION The power series must be centered at $c = \frac{6+2}{2} = 4$, with radius of convergence $R = 2$. Consider the following series:

$$\sum_{n=1}^{\infty}\frac{(x-4)^n}{n2^n}.$$

With $a_n = \frac{1}{n2^n}$,

$$r = \lim_{n\to\infty}\frac{n2^n}{(n+1)2^{n+1}} = \frac{1}{2}\lim_{n\to\infty}\frac{n}{n+1} = \frac{1}{2}.$$

The radius of convergence is therefore $R = r^{-1} = 2$, and the series converges absolutely for $|x-4| < 2$, or $2 < x < 6$. For the endpoint $x = 6$, the series becomes $\sum_{n=1}^{\infty}\frac{(6-4)^n}{n{\cdot}2^n} = \sum_{n=1}^{\infty}\frac{1}{n}$, which is the divergent harmonic series. For the endpoint $x = 2$, the series becomes $\sum_{n=1}^{\infty}\frac{(2-4)^n}{n{\cdot}2^n} = \sum_{n=1}^{\infty}\frac{(-1)^n}{n}$, which converges by the Leibniz Test. Therefore, the series converges for $2 \le x < 6$, as desired.

45. Apply integration to the expansion

$$\frac{1}{1+x} = \sum_{n=0}^{\infty}(-1)^n x^n = 1 - x + x^2 - x^3 + \cdots$$

to prove that for $-1 < x < 1$,

$$\ln(1+x) = \sum_{n=1}^{\infty}\frac{(-1)^{n-1}x^n}{n} = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots$$

SOLUTION To obtain the first expansion, substitute $-x$ for x in Eq. (2):

$$\frac{1}{1+x} = \sum_{n=0}^{\infty}(-x)^n = \sum_{n=0}^{\infty}(-1)^n x^n.$$

This expansion is valid for $|-x| < 1$, or $-1 < x < 1$.

Upon integrating both sides of the above equation, we find

$$\ln(1+x) = \int\frac{dx}{1+x} = \int\left(\sum_{n=0}^{\infty}(-1)^n x^n\right)dx.$$

Integrating the series term-by-term then yields

$$\ln(1+x) = C + \sum_{n=0}^{\infty}(-1)^n \frac{x^{n+1}}{n+1}.$$

To determine the constant C, set $x = 0$. Then $0 = \ln(1+0) = C$. Finally,

$$\ln(1+x) = \sum_{n=0}^{\infty}(-1)^n \frac{x^{n+1}}{n+1} = \sum_{n=1}^{\infty}(-1)^{n-1}\frac{x^n}{n}.$$

46. Use the result of Exercise 45 to prove that

$$\ln\frac{3}{2} = \frac{1}{2} - \frac{1}{2\cdot 2^2} + \frac{1}{3\cdot 2^3} - \frac{1}{4\cdot 2^4} + \cdots$$

Use your knowledge of alternating series to find an N such that the partial sum S_N approximates $\ln\frac{3}{2}$ to within an error of at most 10^{-3}. Confirm using a calculator to compute both S_N and $\ln\frac{3}{2}$.

SOLUTION In the previous exercise we found that

$$\ln(1+x) = \sum_{n=0}^{\infty}(-1)^n \frac{x^{n+1}}{n+1}.$$

Setting $x = \frac{1}{2}$ yields:

$$\ln\frac{3}{2} = \sum_{n=1}^{\infty}(-1)^{n-1}\frac{\left(\frac{1}{2}\right)^n}{n} = \sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{n2^n} = \frac{1}{2} - \frac{1}{2\cdot 2^2} + \frac{1}{3\cdot 2^3} - \frac{1}{4\cdot 2^4} + \cdots$$

Note that the series for $\ln\frac{3}{2}$ is an alternating series with $a_n = \frac{1}{n2^n}$. The error in approximating $\ln\frac{3}{2}$ by the partial sum S_N is therefore bounded by

$$\left|\ln\frac{3}{2} - S_N\right| < a_{N+1} = \frac{1}{(N+1)2^{N+1}}.$$

To obtain an error of at most 10^{-3}, we must find an N such that

$$\frac{1}{(N+1)2^{N+1}} < 10^{-3} \quad \text{or} \quad (N+1)2^{N+1} > 1000.$$

For $N = 6$, $(N+1)2^{N+1} = 7\cdot 2^7 = 896 < 1000$, but for $N = 7$, $(N+1)2^{N+1} = 8\cdot 2^8 = 2048 > 1000$; hence, the smallest value for N is $N = 7$. The corresponding approximation is

$$S_7 = \frac{1}{2} - \frac{1}{2\cdot 2^2} + \frac{1}{3\cdot 2^3} - \frac{1}{4\cdot 2^4} + \frac{1}{5\cdot 2^5} - \frac{1}{6\cdot 2^6} + \frac{1}{7\cdot 2^7} = 0.405803571.$$

Now, $\ln\frac{3}{2} = 0.405465108$, so

$$\left|\ln\frac{3}{2} - S_7\right| = 3.385\times 10^{-4} < 10^{-3}.$$

47. Let $F(x) = (x+1)\ln(1+x) - x$.

(a) Apply integration to the result of Exercise 45 to prove that for $-1 < x < 1$,

$$F(x) = \sum_{n=1}^{\infty}(-1)^{n+1}\frac{x^{n+1}}{n(n+1)}$$

(b) Evaluate at $x = \frac{1}{2}$ to prove

$$\frac{3}{2}\ln\frac{3}{2} - \frac{1}{2} = \frac{1}{1\cdot 2\cdot 2^2} - \frac{1}{2\cdot 3\cdot 2^3} + \frac{1}{3\cdot 4\cdot 2^4} - \frac{1}{4\cdot 5\cdot 2^5} + \cdots$$

(c) Use a calculator to verify that the partial sum S_4 approximates the left-hand side with an error no greater than the term a_5 of the series.

SOLUTION

(a) Note that

$$\int \ln(x+1)\,dx = (x+1)\ln(x+1) - x + C$$

Then integrating both sides of the result of Exercise 45 gives

$$(x+1)\ln(x+1) - x = \int \ln(x+1)\,dx = \int \sum_{n=1}^{\infty} \frac{(-1)^{n-1}x^n}{n}\,dx$$

For $-1 < x < 1$, which is the interval of convergence of the series in Exercise 45, therefore, we can integrate term by term to get

$$(x+1)\ln(x+1) - x = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} \int x^n\,dx = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} \cdot \frac{x^{n+1}}{n+1} + C = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{x^{n+1}}{n(n+1)} + C$$

(noting that $(-1)^{n-1} = (-1)^{n+1}$). To determine C, evaluate both sides at $x = 0$ to get

$$0 = \ln 1 - 0 = 0 + C$$

so that $C = 0$ and we get finally

$$(x+1)\ln(x+1) - x = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{x^{n+1}}{n(n+1)}$$

(b) Evaluating the result of part(a) at $x = \frac{1}{2}$ gives

$$\begin{aligned}\frac{3}{2}\ln\frac{3}{2} - \frac{1}{2} &= \sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n(n+1)2^{n+1}} \\ &= \frac{1}{1\cdot 2\cdot 2^2} - \frac{1}{2\cdot 3\cdot 2^3} + \frac{1}{3\cdot 4\cdot 2^4} - \frac{1}{4\cdot 5\cdot 2^5} + \dots\end{aligned}$$

(c)

$$S_4 = \frac{1}{1\cdot 2\cdot 2^2} - \frac{1}{2\cdot 3\cdot 2^3} + \frac{1}{3\cdot 4\cdot 2^4} - \frac{1}{4\cdot 5\cdot 2^5} = 0.1078125$$

$$a_5 = \frac{1}{5\cdot 6\cdot 2^6} \approx 0.0005208$$

$$\frac{3}{2}\ln\frac{3}{2} - \frac{1}{2} \approx 0.10819766$$

and

$$\left| S_4 - \frac{3}{2}\ln\frac{3}{2} - \frac{1}{2} \right| \approx 0.0003852 < a_5$$

48. Prove that for $|x| < 1$,

$$\int \frac{dx}{x^4+1} = x - \frac{x^5}{5} + \frac{x^9}{9} - \cdots$$

Use the first two terms to approximate $\int_0^{1/2} dx/(x^4+1)$ numerically. Use the fact that you have an alternating series to show that the error in this approximation is at most 0.00022.

SOLUTION Substitute $-x^4$ for x in Eq. (2) to get

$$\frac{1}{1+x^4} = \sum_{n=0}^{\infty} (-x^4)^n = \sum_{n=0}^{\infty} (-1)^n x^{4n}$$

This is valid for $|x| < 1$, so for x in that range we can integrate the right-hand side term by term to get

$$\begin{aligned}\int \frac{1}{1+x^4}\,dx &= \sum_{n=0}^{\infty} \int (-1)^n x^{4n}\,dx = \sum_{n=0}^{\infty} (-1)^n \frac{x^{4n+1}}{4n+1} + C \\ &= x - \frac{x^5}{5} + \frac{x^9}{9} - \frac{x^{13}}{13} + \cdots + C\end{aligned}$$

Using the first two terms, we have

$$\int_0^{1/2} \frac{1}{1+x^4}\,dx \approx \frac{1}{2} - \frac{1}{2^5 \cdot 5} = \frac{79}{160} = 0.49375$$

Since this is an alternating series, the error in the approximation is bounded by the first unused term, so by

$$\frac{1}{2^9 \cdot 9} = \frac{1}{4608} \approx 0.000217 < 0.00022$$

49. Use the result of Example 7 to show that

$$F(x) = \frac{x^2}{1\cdot 2} - \frac{x^4}{3\cdot 4} + \frac{x^6}{5\cdot 6} - \frac{x^8}{7\cdot 8} + \cdots$$

is an antiderivative of $f(x) = \tan^{-1} x$ satisfying $F(0) = 0$. What is the radius of convergence of this power series?

SOLUTION For $-1 < x < 1$, which is the interval of convergence for the power series for arctangent, we can integrate term-by-term, so integrate that power series to get

$$\begin{aligned} F(x) &= \int \tan^{-1} x\,dx = \sum_{n=0}^{\infty} \int \frac{(-1)^n x^{2n+1}}{2n+1}\,dx = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+2}}{(2n+1)(2n+2)} \\ &= \frac{x^2}{1\cdot 2} - \frac{x^4}{3\cdot 4} + \frac{x^6}{5\cdot 6} - \frac{x^8}{7\cdot 8} + \cdots + C \end{aligned}$$

If we assume $F(0) = 0$, then we have $C = 0$. The radius of convergence of this power series is the same as that of the original power series, which is 1.

50. Verify that function $F(x) = x\tan^{-1} x - \frac{1}{2}\log(x^2+1)$ is an antiderivative of $f(x) = \tan^{-1} x$ satisfying $F(0) = 0$. Then use the result of Exercise 49 with $x = \frac{\pi}{6}$ to show that

$$\frac{\pi}{6\sqrt{3}} - \frac{1}{2}\ln\frac{4}{3} = \frac{1}{1\cdot 2(3)} - \frac{1}{3\cdot 4(3^2)} + \frac{1}{5\cdot 6(3^3)} - \frac{1}{7\cdot 8(3^4)} + \cdots$$

Use a calculator to compare the value of the left-hand side with the partial sum S_4 of the series on the right.

SOLUTION We have

$$F'(x) = \tan^{-1} x + \frac{x}{1+x^2} - \frac{1}{2}\cdot\frac{1}{x^2+1}\cdot 2x = \tan^{-1} x + \frac{x}{1+x^2} - \frac{x}{1+x^2} = \tan^{-1} x$$

so that $F(x)$ is an antiderivative of $\tan^{-1} x$, and clearly $F(0) = 0$. So applying Exercise 49 for this F, and setting $x = \frac{1}{\sqrt{3}}$, gives

$$\begin{aligned} \frac{1}{\sqrt{3}}\tan^{-1}\frac{1}{\sqrt{3}} - \frac{1}{2}\ln\left(\frac{1}{3}+1\right) &= \frac{\pi}{6\sqrt{3}} - \frac{1}{2}\ln\frac{4}{3} \\ &= \frac{(1/\sqrt{3})^2}{1\cdot 2} - \frac{(1/\sqrt{3})^4}{3\cdot 4} + \frac{(1/\sqrt{3})^6}{5\cdot 6} - \frac{(1/\sqrt{3})^8}{7\cdot 8} + \dots \\ &= \frac{1}{1\cdot 2(3)} - \frac{1}{3\cdot 4(3^2)} + \frac{1}{5\cdot 6(3^3)} - \frac{1}{7\cdot 8(3^4)} + \dots \end{aligned}$$

Now, we have

$$S_4 = \frac{1}{1\cdot 2(3)} - \frac{1}{3\cdot 4(3^2)} + \frac{1}{5\cdot 6(3^3)} - \frac{1}{7\cdot 8(3^4)} = \frac{3593}{22680} \approx 0.1548215$$

$$\frac{\pi}{6\sqrt{3}} - \frac{1}{2}\ln\frac{4}{3} \approx 0.158459$$

so the two differ by less than 0.00004.

51. Evaluate $\sum_{n=1}^{\infty} \frac{n}{2^n}$. *Hint:* Use differentiation to show that

$$(1-x)^{-2} = \sum_{n=1}^{\infty} nx^{n-1} \quad (\text{for } |x| < 1)$$

SOLUTION Differentiate both sides of Eq. (2) to obtain

$$\frac{1}{(1-x)^2} = \sum_{n=1}^{\infty} nx^{n-1}.$$

Setting $x = \frac{1}{2}$ then yields

$$\sum_{n=1}^{\infty} \frac{n}{2^{n-1}} = \frac{1}{\left(1-\frac{1}{2}\right)^2} = 4.$$

Divide this equation by 2 to obtain

$$\sum_{n=1}^{\infty} \frac{n}{2^n} = 2.$$

52. Use the power series for $(1+x^2)^{-1}$ and differentiation to prove that for $|x| < 1$,

$$\frac{2x}{(x^2+1)^2} = \sum_{n=1}^{\infty} (-1)^{n-1}(2n)x^{2n-1}$$

SOLUTION From Exercise 39, we know that for $-1 < x < 1$,

$$\frac{1}{1+x^2} = \sum_{n=0}^{\infty} (-1)^n x^{2n}$$

Thus for x in this range, we can differentiate both sides, and differentiate the right-hand side term by term, to get

$$\frac{d}{dx}\frac{1}{1+x^2} = \frac{-2x}{(x^2+1)^2} = \sum_{n=1}^{\infty} (-1)^n 2nx^{2n-1}$$

(Note the change in the lower limit of summation, since the $n = 0$ term is a constant, whose derivative is zero). Cancelling the minus sign on the left gives

$$\frac{2x}{(x^2+1)^2} = \sum_{n=1}^{\infty} (-1)^{n-1}(2n)x^{2n-1}$$

53. Show that the following series converges absolutely for $|x| < 1$ and compute its sum:

$$F(x) = 1 - x - x^2 + x^3 - x^4 - x^5 + x^6 - x^7 - x^8 + \cdots$$

Hint: Write $F(x)$ as a sum of three geometric series with common ratio x^3.

SOLUTION Because the coefficients in the power series are all ± 1, we find

$$r = \lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right| = 1.$$

The radius of convergence is therefore $R = r^{-1} = 1$, and the series converges absolutely for $|x| < 1$.

By Exercise 43 of Section 11.4, any rearrangement of the terms of an absolutely convergent series yields another absolutely convergent series with the same sum as the original series. Following the hint, we now rearrange the terms of $F(x)$ as the sum of three geometric series:

$$\begin{aligned} F(x) &= \left(1 + x^3 + x^6 + \cdots\right) - \left(x + x^4 + x^7 + \cdots\right) - \left(x^2 + x^5 + x^8 + \cdots\right) \\ &= \sum_{n=0}^{\infty} (x^3)^n - \sum_{n=0}^{\infty} x(x^3)^n - \sum_{n=0}^{\infty} x^2(x^3)^n = \frac{1}{1-x^3} - \frac{x}{1-x^3} - \frac{x^2}{1-x^3} = \frac{1-x-x^2}{1-x^3}. \end{aligned}$$

54. Show that for $|x| < 1$,

$$\frac{1+2x}{1+x+x^2} = 1 + x - 2x^2 + x^3 + x^4 - 2x^5 + x^6 + x^7 - 2x^8 + \cdots$$

Hint: Use the hint from Exercise 53.

SOLUTION The terms in the series on the right-hand side are either of the form x^n or $-2x^n$ for some n. Because

$$\lim_{n\to\infty} \sqrt[n]{2} = \lim_{n\to\infty} \sqrt[n]{1} = 1,$$

it follows that

$$\lim_{n\to\infty} \sqrt[n]{|a_n|} = |x|.$$

Hence, by the Root Test, the series converges absolutely for $|x| < 1$.

By Exercise 43 of Section 11.4, any rearrangement of the terms of an absolutely convergent series yields another absolutely convergent series with the same sum as the original series. If we let S denote the sum of the series, then

$$\begin{aligned} S &= \left(1 + x^3 + x^6 + \cdots\right) + \left(x + x^4 + x^7 + \cdots\right) - 2\left(x^2 + x^5 + x^8 + \cdots\right) \\ &= \frac{1}{1-x^3} + \frac{x}{1-x^3} - \frac{2x^2}{1-x^3} = \frac{1+x-2x^2}{1-x^3} = \frac{(1-x)(2x+1)}{(1-x)(1+x+x^2)} = \frac{2x+1}{1+x+x^2}. \end{aligned}$$

55. Find all values of x such that $\displaystyle\sum_{n=1}^{\infty} \frac{x^{n^2}}{n!}$ converges.

SOLUTION With $a_n = \frac{x^{n^2}}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{|x|^{(n+1)^2}}{(n+1)!} \cdot \frac{n!}{|x|^{n^2}} = \frac{|x|^{2n+1}}{n+1}.$$

if $|x| \le 1$, then

$$\lim_{n\to\infty} \frac{|x|^{2n+1}}{n+1} = 0,$$

and the series converges absolutely. On the other hand, if $|x| > 1$, then

$$\lim_{n\to\infty} \frac{|x|^{2n+1}}{n+1} = \infty,$$

and the series diverges. Thus, $\displaystyle\sum_{n=1}^{\infty} \frac{x^{n^2}}{n!}$ converges for $-1 \le x \le 1$ and diverges elsewhere.

56. Find all values of x such that the following series converges:

$$F(x) = 1 + 3x + x^2 + 27x^3 + x^4 + 243x^5 + \cdots$$

SOLUTION Observe that $F(x)$ can be written as the sum of two geometric series:

$$F(x) = \left(1 + x^2 + x^4 + \cdots\right) + \left(3x + 27x^3 + 243x^5 + \cdots\right) = \sum_{n=0}^{\infty} (x^2)^n + \sum_{n=0}^{\infty} 3x(9x^2)^n$$

The first geometric series converges for $|x^2| < 1$, or $|x| < 1$; the second geometric series converges for $|9x^2| < 1$, or $|x| < \frac{1}{3}$. Since both geometric series must converge for $F(x)$ to converge, we find that $F(x)$ converges for $|x| < \frac{1}{3}$, the intersection of the intervals of convergence for the two geometric series.

57. Find a power series $P(x) = \displaystyle\sum_{n=0}^{\infty} a_n x^n$ satisfying the differential equation $y' = -y$ with initial condition $y(0) = 1$. Then use Theorem 1 of Section 5.8 to conclude that $P(x) = e^{-x}$.

SOLUTION Let $P(x) = \displaystyle\sum_{n=0}^{\infty} a_n x^n$ and note that $P(0) = a_0$; thus, to satisfy the initial condition $P(0) = 1$, we must take $a_0 = 1$. Now,

$$P'(x) = \sum_{n=1}^{\infty} n a_n x^{n-1},$$

so

$$P'(x) + P(x) = \sum_{n=1}^{\infty} na_n x^{n-1} + \sum_{n=0}^{\infty} a_n x^n = \sum_{n=0}^{\infty} \left[(n+1)a_{n+1} + a_n\right] x^n.$$

In order for this series to be equal to zero, the coefficient of x^n must be equal to zero for each n; thus

$$(n+1)a_{n+1} + a_n = 0 \quad \text{or} \quad a_{n+1} = -\frac{a_n}{n+1}.$$

Starting from $a_0 = 1$, we then calculate

$$a_1 = -\frac{a_0}{1} = -1;$$

$$a_2 = -\frac{a_1}{2} = \frac{1}{2};$$

$$a_3 = -\frac{a_2}{3} = -\frac{1}{6} = -\frac{1}{3!};$$

and, in general,

$$a_n = (-1)^n \frac{1}{n!}.$$

Hence,

$$P(x) = \sum_{n=0}^{\infty} (-1)^n \frac{x^n}{n!}.$$

The solution to the initial value problem $y' = -y$, $y(0) = 1$ is $y = e^{-x}$. Because this solution is unique, it follows that

$$P(x) = \sum_{n=0}^{\infty} (-1)^n \frac{x^n}{n!} = e^{-x}.$$

58. Let $C(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots$.
(a) Show that $C(x)$ has an infinite radius of convergence.
(b) Prove that $C(x)$ and $f(x) = \cos x$ are both solutions of $y'' = -y$ with initial conditions $y(0) = 1$, $y'(0) = 0$. This initial value problem has a unique solution, so we have $C(x) = \cos x$ for all x.

SOLUTION
(a) Consider the series

$$C(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!}.$$

With $a_n = (-1)^n \frac{x^{2n}}{(2n)!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{|x|^{2n+2}}{(2n+2)!} \cdot \frac{(2n)!}{|x|^{2n}} = \frac{|x|^2}{(2n+2)(2n+1)},$$

and

$$r = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = 0.$$

The radius of convergence for $C(x)$ is therefore $R = r^{-1} = \infty$.
(b) Differentiating the series defining $C(x)$ term-by-term, we find

$$C'(x) = \sum_{n=1}^{\infty} (-1)^n (2n) \frac{x^{2n-1}}{(2n)!} = \sum_{n=1}^{\infty} (-1)^n \frac{x^{2n-1}}{(2n-1)!}$$

and

$$C''(x) = \sum_{n=1}^{\infty} (-1)^n (2n-1) \frac{x^{2n-2}}{(2n-1)!} = \sum_{n=1}^{\infty} (-1)^n \frac{x^{2n-2}}{(2n-2)!}$$

$$= \sum_{n=0}^{\infty} (-1)^{n+1} \frac{x^{2n}}{(2n)!} = -\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!} = -C(x).$$

Moreover, $C(0) = 1$ and $C'(0) = 0$.

59. Use the power series for $y = e^x$ to show that

$$\frac{1}{e} = \frac{1}{2!} - \frac{1}{3!} + \frac{1}{4!} - \cdots$$

Use your knowledge of alternating series to find an N such that the partial sum S_N approximates e^{-1} to within an error of at most 10^{-3}. Confirm this using a calculator to compute both S_N and e^{-1}.

SOLUTION Recall that the series for e^x is

$$\sum_{n=0}^{\infty} \frac{x^n}{n!} = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \cdots.$$

Setting $x = -1$ yields

$$e^{-1} = 1 - 1 + \frac{1}{2!} - \frac{1}{3!} + \frac{1}{4!} - + \cdots = \frac{1}{2!} - \frac{1}{3!} + \frac{1}{4!} - + \cdots.$$

This is an alternating series with $a_n = \frac{1}{(n+1)!}$. The error in approximating e^{-1} with the partial sum S_N is therefore bounded by

$$|S_N - e^{-1}| \le a_{N+1} = \frac{1}{(N+2)!}.$$

To make the error at most 10^{-3}, we must choose N such that

$$\frac{1}{(N+2)!} \le 10^{-3} \quad \text{or} \quad (N+2)! \ge 1000.$$

For $N = 4$, $(N+2)! = 6! = 720 < 1000$, but for $N = 5$, $(N+2)! = 7! = 5040$; hence, $N = 5$ is the smallest value that satisfies the error bound. The corresponding approximation is

$$S_5 = \frac{1}{2!} - \frac{1}{3!} + \frac{1}{4!} - \frac{1}{5!} + \frac{1}{6!} = 0.368055555$$

Now, $e^{-1} = 0.367879441$, so

$$|S_5 - e^{-1}| = 1.761 \times 10^{-4} < 10^{-3}.$$

60. Let $P(x) = \sum_{n=0} a_n x^n$ be a power series solution to $y' = 2xy$ with initial condition $y(0) = 1$.

(a) Show that the odd coefficients a_{2k+1} are all zero.

(b) Prove that $a_{2k} = a_{2k-2}/k$ and use this result to determine the coefficients a_{2k}.

SOLUTION Let $P(x) = \sum_{n=0}^{\infty} a_n x^n$ and note that $P(0) = a_0$; thus, to satisfy the initial condition $P(0) = 1$, we must take $a_0 = 1$. Now,

$$P'(x) = \sum_{n=1}^{\infty} n a_n x^{n-1},$$

so

$$P'(x) - 2xP(x) = \sum_{n=1}^{\infty} n a_n x^{n-1} - \sum_{n=0}^{\infty} 2a_n x^{n+1} = \sum_{n=1}^{\infty} n a_n x^{n-1} - \sum_{n=2}^{\infty} 2a_{n-2} x^{n-1}$$

$$= a_1 + \sum_{n=2}^{\infty} \left[n a_n - 2a_{n-2} \right] x^{n-1}.$$

In order for this series to be equal to zero, the coefficient of x^n must be equal to zero for each n; thus, $a_1 = 0$ and

$$n a_n - 2a_{n-2} = 0 \quad \text{or} \quad a_n = \frac{2a_{n-2}}{n}.$$

(a) We know that $a_1 = 0$ and

$$a_n = \frac{2a_{n-2}}{n}.$$

Thus,

$$a_3 = \frac{2a_1}{3} = 0;$$
$$a_5 = \frac{2a_3}{5} = 0;$$
$$a_7 = \frac{2a_5}{7} = 0;$$

and, in general, $a_{2k+1} = 0$ for all k.

(b) Replace n by $2k$ in the equation

$$a_n = \frac{2a_{n-2}}{n} \quad \text{to obtain} \quad a_{2k} = \frac{2a_{2k-2}}{2k} = \frac{a_{2k-2}}{k}.$$

Starting from $a_0 = 1$, we then calculate

$$a_2 = \frac{a_0}{1} = 1 = \frac{1}{1!};$$
$$a_4 = \frac{a_2}{2} = \frac{1}{2} = \frac{1}{2!};$$
$$a_6 = \frac{a_4}{3} = \frac{1}{6} = \frac{1}{3!};$$

and, in general, $a_{2k} = \frac{1}{k!}$.

61. Find a power series $P(x)$ satisfying the differential equation

$$y'' - xy' + y = 0$$ 9

with initial condition $y(0) = 1$, $y'(0) = 0$. What is the radius of convergence of the power series?

SOLUTION Let $P(x) = \sum_{n=0}^{\infty} a_n x^n$. Then

$$P'(x) = \sum_{n=1}^{\infty} n a_n x^{n-1} \quad \text{and} \quad P''(x) = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}.$$

Note that $P(0) = a_0$ and $P'(0) = a_1$; in order to satisfy the initial conditions $P(0) = 1$, $P'(0) = 0$, we must have $a_0 = 1$ and $a_1 = 0$. Now,

$$\begin{aligned} P''(x) - xP'(x) + P(x) &= \sum_{n=2}^{\infty} n(n-1)a_n x^{n-2} - \sum_{n=1}^{\infty} n a_n x^n + \sum_{n=0}^{\infty} a_n x^n \\ &= \sum_{n=0}^{\infty} (n+2)(n+1)a_{n+2} x^n - \sum_{n=1}^{\infty} n a_n x^n + \sum_{n=0}^{\infty} a_n x^n \\ &= 2a_2 + a_0 + \sum_{n=1}^{\infty} \left[(n+2)(n+1)a_{n+2} - n a_n + a_n\right] x^n. \end{aligned}$$

In order for this series to be equal to zero, the coefficient of x^n must be equal to zero for each n; thus, $2a_2 + a_0 = 0$ and $(n+2)(n+1)a_{n+2} - (n-1)a_n = 0$, or

$$a_2 = -\frac{1}{2}a_0 \quad \text{and} \quad a_{n+2} = \frac{n-1}{(n+2)(n+1)} a_n.$$

Starting from $a_1 = 0$, we calculate

$$a_3 = \frac{1-1}{(3)(2)} a_1 = 0;$$
$$a_5 = \frac{2}{(5)(4)} a_3 = 0;$$
$$a_7 = \frac{4}{(7)(6)} a_5 = 0;$$

and, in general, all of the odd coefficients are zero. As for the even coefficients, we have $a_0 = 1$, $a_2 = -\frac{1}{2}$,

$$a_4 = \frac{1}{(4)(3)}a_2 = -\frac{1}{4!};$$
$$a_6 = \frac{3}{(6)(5)}a_4 = -\frac{3}{6!};$$
$$a_8 = \frac{5}{(8)(7)}a_6 = -\frac{15}{8!}$$

and so on. Thus,

$$P(x) = 1 - \frac{1}{2}x^2 - \frac{1}{4!}x^4 - \frac{3}{6!}x^6 - \frac{15}{8!}x^8 - \cdots$$

To determine the radius of convergence, treat this as a series in the variable x^2, and observe that

$$r = \lim_{k\to\infty}\left|\frac{a_{2k+2}}{a_{2k}}\right| = \lim_{k\to\infty}\frac{2k-1}{(2k+2)(2k+1)} = 0.$$

Thus, the radius of convergence is $R = r^{-1} = \infty$.

62. Find a power series satisfying Eq. (9) with initial condition $y(0) = 0$, $y'(0) = 1$.

SOLUTION Let $P(x) = \sum_{n=0}^{\infty} a_n x^n$ be a solution to Eq. (9). From the previous exercise, we know that

$$a_2 = -\frac{1}{2}a_0 \quad \text{and} \quad a_{n+2} = \frac{n-1}{(n+2)(n+1)}a_n.$$

To satisfy the initial condition $P(0) = 0$, $P'(0) = 1$, we must have $a_0 = 0$ and $a_1 = 1$. Then

$$a_2 = -\frac{1}{2}a_0 = 0;$$
$$a_4 = \frac{1}{(4)(3)}a_2 = 0;$$
$$a_6 = \frac{3}{(6)(5)}a_4 = 0;$$

and, in general, all of the even coefficients are zero. As in the previous exercise, all of the odd coefficients past a_1 are also equal to zero. Thus,

$$P(x) = x.$$

63. Prove that

$$J_2(x) = \sum_{k=0}^{\infty}\frac{(-1)^k}{2^{2k+2}\,k!\,(k+3)!}x^{2k+2}$$

is a solution of the Bessel differential equation of order 2:

$$x^2y'' + xy' + (x^2-4)y = 0$$

SOLUTION Let $J_2(x) = \sum_{k=0}^{\infty}\frac{(-1)^k}{2^{2k+2}\,k!\,(k+2)!}x^{2k+2}$. Then

$$J_2'(x) = \sum_{k=0}^{\infty}\frac{(-1)^k(k+1)}{2^{2k+1}\,k!\,(k+2)!}x^{2k+1}$$
$$J_2''(x) = \sum_{k=0}^{\infty}\frac{(-1)^k(k+1)(2k+1)}{2^{2k+1}\,k!\,(k+2)!}x^{2k}$$

and

$$x^2J_2''(x) + xJ_2'(x) + (x^2-4)J_2(x) = \sum_{k=0}^{\infty}\frac{(-1)^k(k+1)(2k+1)}{2^{2k+1}\,k!\,(k+2)!}x^{2k+2} + \sum_{k=0}^{\infty}\frac{(-1)^k(k+1)}{2^{2k+1}\,k!\,(k+2)!}x^{2k+2}$$
$$- \sum_{k=0}^{\infty}\frac{(-1)^k}{2^{2k+2}\,k!\,(k+2)!}x^{2k+4} - \sum_{k=0}^{\infty}\frac{(-1)^k}{2^{2k}\,k!\,(k+2)!}x^{2k+2}$$

$$= \sum_{k=0}^{\infty} \frac{(-1)^k k(k+2)}{2^{2k} k!(k+2)!} x^{2k+2} + \sum_{k=1}^{\infty} \frac{(-1)^{k-1}}{2^{2k}\,(k-1)!\,(k+1)!} x^{2k+2}$$

$$= \sum_{k=1}^{\infty} \frac{(-1)^k}{2^{2k}(k-1)!(k+1)!} x^{2k+2} - \sum_{k=1}^{\infty} \frac{(-1)^k}{2^{2k}(k-1)!(k+1)!} x^{2k+2} = 0.$$

64. Why is it impossible to expand $f(x) = |x|$ as a power series that converges in an interval around $x = 0$? Explain using Theorem 2.

SOLUTION Suppose that there exists a $c > 0$ such that f can be represented by a power series on the interval $(-c, c)$; that is,

$$|x| = \sum_{n=0}^{\infty} a_n x^n$$

for $|x| < c$. Then it follows by Theorem 2 that $|x|$ is differentiable on $(-c, c)$. This contradicts the well known property that $f(x) = |x|$ is not differentiable at the point $x = 0$.

Further Insights and Challenges

65. Suppose that the coefficients of $F(x) = \sum_{n=0}^{\infty} a_n x^n$ are *periodic*; that is, for some whole number $M > 0$, we have $a_{M+n} = a_n$. Prove that $F(x)$ converges absolutely for $|x| < 1$ and that

$$F(x) = \frac{a_0 + a_1 x + \cdots + a_{M-1} x^{M-1}}{1 - x^M}$$

Hint: Use the hint for Exercise 53.

SOLUTION Suppose the coefficients of $F(x)$ are periodic, with $a_{M+n} = a_n$ for some whole number M and all n. The $F(x)$ can be written as the sum of M geometric series:

$$F(x) = a_0\left(1 + x^M + x^{2M} + \cdots\right) + a_1\left(x + x^{M+1} + x^{2M+1} + \cdots\right) +$$

$$= a_2\left(x^2 + x^{M+2} + x^{2M+2} + \cdots\right) + \cdots + a_{M-1}\left(x^{M-1} + x^{2M-1} + x^{3M-1} + \cdots\right)$$

$$= \frac{a_0}{1 - x^M} + \frac{a_1 x}{1 - x^M} + \frac{a_2 x^2}{1 - x^M} + \cdots + \frac{a_{M-1} x^{M-1}}{1 - x^M} = \frac{a_0 + a_1 x + a_2 x^2 + \cdots + a_{M-1} x^{M-1}}{1 - x^M}.$$

As each geometric series converges absolutely for $|x| < 1$, it follows that $F(x)$ also converges absolutely for $|x| < 1$.

66. Continuity of Power Series Let $F(x) = \sum_{n=0}^{\infty} a_n x^n$ be a power series with radius of convergence $R > 0$.

(a) Prove the inequality

$$|x^n - y^n| \le n|x - y|(|x|^{n-1} + |y|^{n-1}) \qquad \boxed{10}$$

Hint: $x^n - y^n = (x - y)(x^{n-1} + x^{n-2} y + \cdots + y^{n-1})$.

(b) Choose R_1 with $0 < R_1 < R$. Show that the infinite series $M = \sum_{n=0}^{\infty} 2n|a_n| R_1^n$ converges. *Hint:* Show that $n|a_n| R_1^n < |a_n| x^n$ for all n sufficiently large if $R_1 < x < R$.

(c) Use Eq. (10) to show that if $|x| < R_1$ and $|y| < R_1$, then $|F(x) - F(y)| \le M|x - y|$.

(d) Prove that if $|x| < R$, then $F(x)$ is continuous at x. *Hint:* Choose R_1 such that $|x| < R_1 < R$. Show that if $\epsilon > 0$ is given, then $|F(x) - F(y)| \le \epsilon$ for all y such that $|x - y| < \delta$, where δ is any positive number that is less than ϵ/M and $R_1 - |x|$ (see Figure 6).

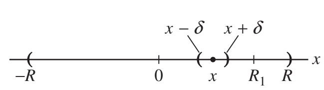


FIGURE 6 If $x > 0$, choose $\delta > 0$ less than ϵ/M and $R_1 - x$.

SOLUTION

(a) Take the absolute value of both sides of the identity

$$x^n - y^n = (x - y)(x^{n-1} + x^{n-2} y + \cdots + y^{n-1}),$$

and then apply the triangle inequality to obtain

$$|x^n - y^n| \le |x - y|\left(|x|^{n-1} + |x|^{n-2}|y| + |x|^{n-3}|y|^2 + \cdots + |x||y|^{n-2} + |y|^{n-1}\right).$$

Now, if $|x| \le |y|$ then $|x|^{n-k}|y|^{k-1} \le |y|^{n-k}|y|^{k-1} = |y|^{n-1}$, and if $|y| \le |x|$ then $|x|^{n-k}|y|^{k-1} \le |x|^{n-k}|x|^{k-1} = |x|^{n-1}$. In either case, $|x|^{n-k}|y|^{k-1} \le |x|^{n-1} + |y|^{n-1}$. Thus,

$$|x^n - y^n| \le |x - y|\left(|x|^{n-1} + (n-2)(|x|^{n-1} + |y|^{n-1}) + |y|^{n-1}\right)$$

$$= (n-1)|x-y|\left(|x|^{n-1} + |y|^{n-1}\right) \le n|x-y|\left(|x|^{n-1} + |y|^{n-1}\right).$$

(b) Let $0 < R_1 < R$. Then,

$$\rho = \lim_{n\to\infty} \frac{2(n+1)|a_{n+1}|R_1^{n+1}}{2n|a_n|R_1^n} = R_1 \lim_{n\to\infty} \frac{n+1}{n} \cdot \left|\frac{a_{n+1}}{a_n}\right| = R_1 \cdot 1 \cdot \frac{1}{R} = \frac{R_1}{R} < 1.$$

Thus, the series $M = \sum_{n=0}^{\infty} 2n|a_n|R_1^n$ converges by the Ratio Test.

(c) Suppose $|x| < R_1$ and $|y| < R_1$. Then

$$|F(x) - F(y)| = \left|\sum_{n=0}^{\infty} a_n x^n - \sum_{n=0}^{\infty} a_n y^n\right| \le \sum_{n=0}^{\infty} |a_n||x^n - y^n| \le \sum_{n=0}^{\infty} n|a_n||x-y|\left(|x|^{n-1} + |y|^{n-1}\right)$$

$$\le |x-y| \sum_{n=0}^{\infty} n|a_n|\left(R_1^{n-1} + R_1^{n-1}\right) = M|x-y|$$

(d) Let $|x| < R$, and let R_1 be a number such that $|x| < R_1 < R$. Then by part (b), $M = \sum_{n=0}^{\infty} 2n|a_n|R_1^n$ is finite and by part (c)

$$|F(x) - F(y)| \le M|x-y|$$

for $|y| < R_1$. Now, let $\epsilon > 0$, and choose $\delta > 0$ so that $\delta < \frac{\epsilon}{M}$ and $\delta < R_1 - |x|$. Then, whenever $|y - x| < \delta$,

$$|y| = |(y-x) + x| \le |y-x| + |x| < \delta + |x| < R_1,$$

so

$$|F(x) - F(y)| < M|x-y| < M\delta < M \cdot \frac{\epsilon}{M} = \epsilon.$$

Thus, F is continuous at x.

10.7 Taylor Series

Preliminary Questions

1. Determine $f(0)$ and $f'''(0)$ for a function $f(x)$ with Maclaurin series

$$T(x) = 3 + 2x + 12x^2 + 5x^3 + \cdots$$

SOLUTION The Maclaurin series for a function f has the form

$$f(0) + \frac{f'(0)}{1!}x + \frac{f''(0)}{2!}x^2 + \frac{f'''(0)}{3!}x^3 + \cdots$$

Matching this general expression with the given series, we find $f(0) = 3$ and $\frac{f'''(0)}{3!} = 5$. From this latter equation, it follows that $f'''(0) = 30$.

2. Determine $f(-2)$ and $f^{(4)}(-2)$ for a function with Taylor series

$$T(x) = 3(x+2) + (x+2)^2 - 4(x+2)^3 + 2(x+2)^4 + \cdots$$

SOLUTION The Taylor series for a function f centered at $x = -2$ has the form

$$f(-2) + \frac{f'(-2)}{1!}(x+2) + \frac{f''(-2)}{2!}(x+2)^2 + \frac{f'''(-2)}{3!}(x+2)^3 + \frac{f^{(4)}(-2)}{4!}(x+2)^4 + \cdots$$

Matching this general expression with the given series, we find $f(-2) = 0$ and $\frac{f^{(4)}(-2)}{4!} = 2$. From this latter equation, it follows that $f^{(4)}(-2) = 48$.

3. What is the easiest way to find the Maclaurin series for the function $f(x) = \sin(x^2)$?

SOLUTION The easiest way to find the Maclaurin series for $\sin\left(x^2\right)$ is to substitute x^2 for x in the Maclaurin series for $\sin x$.

4. Find the Taylor series for $f(x)$ centered at $c = 3$ if $f(3) = 4$ and $f'(x)$ has a Taylor expansion

$$f'(x) = \sum_{n=1}^{\infty} \frac{(x-3)^n}{n}$$

SOLUTION Integrating the series for $f'(x)$ term-by-term gives

$$f(x) = C + \sum_{n=1}^{\infty} \frac{(x-3)^{n+1}}{n(n+1)}.$$

Substituting $x = 3$ then yields

$$f(3) = C = 4;$$

so

$$f(x) = 4 + \sum_{n=1}^{\infty} \frac{(x-3)^{n+1}}{n(n+1)}.$$

5. Let $T(x)$ be the Maclaurin series of $f(x)$. Which of the following guarantees that $f(2) = T(2)$?

(a) $T(x)$ converges for $x = 2$.
(b) The remainder $R_k(2)$ approaches a limit as $k \to \infty$.
(c) The remainder $R_k(2)$ approaches zero as $k \to \infty$.

SOLUTION The correct response is **(c)**: $f(2) = T(2)$ if and only if the remainder $R_k(2)$ approaches zero as $k \to \infty$.

Exercises

1. Write out the first four terms of the Maclaurin series of $f(x)$ if

$$f(0) = 2, \quad f'(0) = 3, \quad f''(0) = 4, \quad f'''(0) = 12$$

SOLUTION The first four terms of the Maclaurin series of $f(x)$ are

$$f(0) + f'(0)x + \frac{f''(0)}{2!}x^2 + \frac{f'''(0)}{3!}x^3 = 2 + 3x + \frac{4}{2}x^2 + \frac{12}{6}x^3 = 2 + 3x + 2x^2 + 2x^3.$$

2. Write out the first four terms of the Taylor series of $f(x)$ centered at $c = 3$ if

$$f(3) = 1, \quad f'(3) = 2, \quad f''(3) = 12, \quad f'''(3) = 3$$

SOLUTION The first four terms of the Taylor series centered at $c = 3$ are:

$$\begin{aligned} f(3) + f'(3)(x-3) + \frac{f''(3)}{2!}(x-3)^2 + \frac{f'''(3)}{3!}(x-3)^3 &= 1 + 2(x-3) + \frac{12}{2}(x-3)^2 + \frac{3}{6}(x-3)^3 \\ &= 1 + 2(x-3) + 6(x-3)^2 + \frac{1}{2}(x-3)^3. \end{aligned}$$

In Exercises 3–18, find the Maclaurin series and find the interval on which the expansion is valid.

3. $f(x) = \dfrac{1}{1-2x}$

SOLUTION Substituting $2x$ for x in the Maclaurin series for $\frac{1}{1-x}$ gives

$$\frac{1}{1-2x} = \sum_{n=0}^{\infty} (2x)^n = \sum_{n=0}^{\infty} 2^n x^n.$$

This series is valid for $|2x| < 1$, or $|x| < \frac{1}{2}$.

4. $f(x) = \dfrac{x}{1-x^4}$

SOLUTION Substituting x^4 for x in the Maclaurin series for $\frac{1}{1-x}$ gives

$$\frac{1}{1-x^4} = \sum_{n=0}^{\infty} (x^4)^n = \sum_{n=0}^{\infty} x^{4n}.$$

Therefore

$$\frac{x}{1-x^4} = x\sum_{n=0}^{\infty} x^{4n} = \sum_{n=0}^{\infty} x^{4n+1}.$$

This series is valid for $|x^4| < 1$, or $|x| < 1$.

5. $f(x) = \cos 3x$

SOLUTION Substituting $3x$ for x in the Maclaurin series for $\cos x$ gives

$$\cos 3x = \sum_{n=0}^{\infty} (-1)^n \frac{(3x)^{2n}}{(2n)!} = \sum_{n=0}^{\infty} (-1)^n \frac{9^n x^{2n}}{(2n)!}.$$

This series is valid for all x.

6. $f(x) = \sin(2x)$

SOLUTION Substituting $2x$ for x in the Maclaurin series for $\sin x$ gives

$$\sin 2x = \sum_{n=0}^{\infty} (-1)^n \frac{(2x)^{2n+1}}{(2n+1)!} = \sum_{n=0}^{\infty} (-1)^n \frac{2^{2n+1} x^{2n+1}}{(2n+1)!}.$$

This series is valid for all x.

7. $f(x) = \sin(x^2)$

SOLUTION Substituting x^2 for x in the Maclaurin series for $\sin x$ gives

$$\sin x^2 = \sum_{n=0}^{\infty} (-1)^n \frac{(x^2)^{2n+1}}{(2n+1)!} = \sum_{n=0}^{\infty} (-1)^n \frac{x^{4n+2}}{(2n+1)!}.$$

This series is valid for all x.

8. $f(x) = e^{4x}$

SOLUTION Substituting $4x$ for x in the Maclaurin series for e^x gives

$$e^{4x} = \sum_{n=0}^{\infty} \frac{(4x)^n}{n!} = \sum_{n=o}^{\infty} \frac{4^n x^n}{n!}.$$

This series is valid for all x.

9. $f(x) = \ln(1-x^2)$

SOLUTION Substituting $-x^2$ for x in the Maclaurin series for $\ln(1+x)$ gives

$$\ln(1-x^2) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}(-x^2)^n}{n} = \sum_{n=1}^{\infty} \frac{(-1)^{2n-1}x^{2n}}{n} = -\sum_{n=1}^{\infty} \frac{x^{2n}}{n}.$$

This series is valid for $|x| < 1$.

10. $f(x) = (1-x)^{-1/2}$

SOLUTION Substituting $-x$ for x and using $a = -\frac{1}{2}$ in the Binomial series gives

$$(1-x)^{-1/2} = \sum_{n=0}^{\infty} \binom{-\frac{1}{2}}{n} (-x)^n = \sum_{n=0}^{\infty} (-1)^n \binom{-\frac{1}{2}}{n} x^n.$$

This series is valid for $|x| < 1$.

11. $f(x) = \tan^{-1}(x^2)$

SOLUTION Substituting x^2 for x in the Maclaurin series for $\tan^{-1} x$ gives

$$\tan^{-1}(x^2) = \sum_{n=0}^{\infty} (-1)^n \frac{(x^2)^{2n+1}}{2n+1} = \sum_{n=0}^{\infty} (-1)^n \frac{x^{4n+2}}{2n+1}.$$

This series is valid for $|x| \le 1$.

12. $f(x) = x^2 e^{x^2}$

SOLUTION First substitute x^2 for x in the Maclaurin series for e^x to obtain

$$e^{x^2} = \sum_{n=0}^{\infty} \frac{(x^2)^n}{n!} = \sum_{n=0}^{\infty} \frac{x^{2n}}{n!}.$$

Now, multiply by x^2 to obtain

$$x^2 e^{x^2} = x^2 \sum_{n=0}^{\infty} \frac{x^{2n}}{n!} = \sum_{n=0}^{\infty} \frac{x^{2n+2}}{n!}.$$

This series is valid for all x.

13. $f(x) = e^{x-2}$

SOLUTION $e^{x-2} = e^{-2}e^x$; thus,

$$e^{x-2} = e^{-2} \sum_{n=0}^{\infty} \frac{x^n}{n!} = \sum_{n=0}^{\infty} \frac{x^n}{e^2 n!}.$$

This series is valid for all x.

14. $f(x) = \dfrac{1 - \cos x}{x}$

SOLUTION $\cos x = \sum_{n=0}^{\infty} (-1)^n \dfrac{x^{2n}}{(2n)!}$, so

$$\frac{1 - \cos x}{x} = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{x^{2n-1}}{(2n)!}$$

This series is valid for all x.

15. $f(x) = \ln(1 - 5x)$

SOLUTION Substituting $-5x$ for x in the Maclaurin series for $\ln(1 + x)$ gives

$$\ln(1 - 5x) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}(-5x)^n}{n} = \sum_{n=1}^{\infty} \frac{(-1)^{2n-1} 5^n x^n}{n} = -\sum_{n=1}^{\infty} \frac{5^n x^n}{n}.$$

This series is valid for $|5x| < 1$, or $|x| < \frac{1}{5}$, and for $x = -\frac{1}{5}$.

16. $f(x) = (x^2 + 2x)e^x$

SOLUTION Using the Maclaurin series for e^x, we find

$$(x^2 + 2x)e^x = x^2 \sum_{n=0}^{\infty} \frac{x^n}{n!} + 2x \sum_{n=0}^{\infty} \frac{x^n}{n!} = \sum_{n=0}^{\infty} \frac{x^{n+2}}{n!} + \sum_{n=0}^{\infty} \frac{2x^{n+1}}{n!} = 2x + \sum_{n=1}^{\infty} \left(\frac{1}{(n-1)!} + \frac{2}{n!} \right) x^{n+1}$$

$$= 2x + \sum_{n=1}^{\infty} \frac{n+2}{n!} x^{n+1} = \sum_{n=0}^{\infty} \frac{n+2}{n!} x^{n+1}.$$

This series is valid for all x.

17. $f(x) = \sinh x$

SOLUTION Recall that

$$\sinh x = \frac{1}{2}(e^x - e^{-x}).$$

Therefore,

$$\sinh x = \frac{1}{2} \left(\sum_{n=0}^{\infty} \frac{x^n}{n!} - \sum_{n=0}^{\infty} \frac{(-x)^n}{n!} \right) = \sum_{n=0}^{\infty} \frac{x^n}{2(n!)} \left(1 - (-1)^n\right).$$

Now,

$$1-(-1)^n = \begin{cases} 0, & n \text{ even} \\ 2, & n \text{ odd} \end{cases}$$

so

$$\sinh x = \sum_{k=0}^{\infty} 2\frac{x^{2k+1}}{2(2k+1)!} = \sum_{k=0}^{\infty} \frac{x^{2k+1}}{(2k+1)!}.$$

This series is valid for all x.

18. $f(x) = \cosh x$

SOLUTION Recall that

$$\cosh x = \frac{1}{2}(e^x + e^{-x}).$$

Therefore,

$$\cosh x = \frac{1}{2}\left(\sum_{n=0}^{\infty} \frac{x^n}{n!} + \sum_{n=0}^{\infty} \frac{(-x)^n}{n!}\right) = \sum_{n=0}^{\infty} \frac{x^n}{2(n!)}\left(1+(-1)^n\right).$$

Now,

$$1+(-1)^n = \begin{cases} 0, & n \text{ odd} \\ 2, & n \text{ even} \end{cases}$$

so

$$\cosh x = \sum_{k=0}^{\infty} 2\frac{x^{2k}}{2(2k)!} = \sum_{k=0}^{\infty} \frac{x^{2k}}{(2k)!}.$$

This series is valid for all x.

In Exercises 19–28, find the terms through degree four of the Maclaurin series of $f(x)$. Use multiplication and substitution as necessary.

19. $f(x) = e^x \sin x$

SOLUTION Multiply the fourth-order Taylor Polynomials for e^x and $\sin x$:

$$\begin{aligned}
&\left(1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24}\right)\left(x - \frac{x^3}{6}\right) \\
&\quad = x + x^2 - \frac{x^3}{6} + \frac{x^3}{2} - \frac{x^4}{6} + \frac{x^4}{6} + \text{ higher-order terms} \\
&\quad = x + x^2 + \frac{x^3}{3} + \text{ higher-order terms.}
\end{aligned}$$

The terms through degree four in the Maclaurin series for $f(x) = e^x \sin x$ are therefore

$$x + x^2 + \frac{x^3}{3}.$$

20. $f(x) = e^x \ln(1-x)$

SOLUTION Multiply the fourth order Taylor Polynomials for e^x and $\ln(1-x)$:

$$\begin{aligned}
&\left(1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24}\right)\left(-x - \frac{x^2}{2} - \frac{x^3}{3} - \frac{x^4}{4}\right) \\
&\quad = -x - \frac{x^2}{2} - x^2 - \frac{x^3}{3} - \frac{x^3}{2} - \frac{x^3}{2} - \frac{x^4}{4} - \frac{x^4}{3} - \frac{x^4}{4} - \frac{x^4}{6} + \text{ higher-order terms} \\
&\quad = -x - \frac{3x^2}{2} - \frac{4x^3}{3} - x^4 + \text{ higher-order terms.}
\end{aligned}$$

The first four terms of the Maclaurin series for $f(x) = e^x \ln(1 - x)$ are therefore

$$-x - \frac{3x^2}{2} - \frac{4x^3}{3} - x^4.$$

21. $f(x) = \dfrac{\sin x}{1 - x}$

SOLUTION Multiply the fourth order Taylor Polynomials for $\sin x$ and $\dfrac{1}{1-x}$:

$$\begin{aligned}&\left(x - \frac{x^3}{6}\right)\left(1 + x + x^2 + x^3 + x^4\right)\\ &\qquad = x + x^2 - \frac{x^3}{6} + x^3 + x^4 - \frac{x^4}{6} + \text{ higher-order terms}\\ &\qquad = x + x^2 + \frac{5x^3}{6} + \frac{5x^4}{6} + \text{ higher-order terms.}\end{aligned}$$

The terms through order four of the Maclaurin series for $f(x) = \dfrac{\sin x}{1 - x}$ are therefore

$$x + x^2 + \frac{5x^3}{6} + \frac{5x^4}{6}.$$

22. $f(x) = \dfrac{1}{1 + \sin x}$

SOLUTION Substituting $\sin x$ for x in the Maclaurin series for $\frac{1}{1-x}$ and then using the Maclaurin series for $\sin x$ gives

$$\begin{aligned}\frac{1}{1+\sin x} &= 1 - \sin x + \sin^2 x - \sin^3 x + \sin^4 x - \dots\\ &= 1 - \left(x - \frac{x^3}{6} + \cdots\right) + \left(x - \frac{x^3}{6} + \cdots\right)^2 - \left(x - \frac{x^3}{6} + \dots\right)^3 + \left(x - \frac{x^3}{6} + \dots\right)^4 \cdots\\ &= 1 - x + \frac{x^3}{6} + x^2 - \frac{x^4}{3} - x^3 + x^4 = 1 - x + x^2 - \frac{5x^3}{6} + \frac{2x^4}{3}\end{aligned}$$

Therefore, the terms of the Maclaurin series for $f(x) = \dfrac{1}{1 + \sin x}$ through order four are

$$1 - x + x^2 - \frac{5x^3}{6} + \frac{2x^4}{3}.$$

23. $f(x) = (1 + x)^{1/4}$

SOLUTION The first five generalized binomial coefficients for $a = \frac{1}{4}$ are

$$1, \quad \frac{1}{4}, \quad \frac{\frac{1}{4}\left(\frac{-3}{4}\right)}{2!} = -\frac{3}{32}, \quad \frac{\frac{1}{4}\left(\frac{-3}{4}\right)\left(\frac{-7}{4}\right)}{3!} = \frac{7}{128}, \quad \frac{\frac{1}{4}\left(\frac{-3}{4}\right)\left(\frac{-7}{4}\right)\left(\frac{-11}{4}\right)}{4!} = \frac{-77}{2048}$$

Therefore, the first four terms in the binomial series for $(1 + x)^{1/4}$ are

$$1 + \frac{1}{4}x - \frac{3}{32}x^2 + \frac{7}{128}x^3 - \frac{77}{2048}x^4$$

24. $f(x) = (1 + x)^{-3/2}$

SOLUTION The first five generalized binomial coefficients for $a = -\frac{3}{2}$ are

$$1, \quad -\frac{3}{2}, \quad \frac{-\frac{3}{2}(-\frac{5}{2})}{2!} = \frac{15}{8}, \quad \frac{-\frac{3}{2}(-\frac{5}{2})(-\frac{7}{2})}{3!} = -\frac{35}{16}, \quad \frac{-\frac{3}{2}(-\frac{5}{2})(-\frac{7}{2})(-\frac{9}{2})}{4!} = \frac{315}{128}.$$

Therefore, the first five terms in the binomial series for $f(x) = (1 + x)^{-3/2}$ are

$$1 - \frac{3}{2}x + \frac{15}{8}x^2 - \frac{35}{16}x^3 + \frac{315}{128}x^4.$$

25. $f(x) = e^x \tan^{-1} x$

SOLUTION Using the Maclaurin series for e^x and $\tan^{-1} x$, we find

$$e^x \tan^{-1} x = \left(1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \cdots\right)\left(x - \frac{x^3}{3} + \cdots\right) = x + x^2 - \frac{x^3}{3} + \frac{x^3}{2} + \frac{x^4}{6} - \frac{x^4}{3} + \cdots$$
$$= x + x^2 + \frac{1}{6}x^3 - \frac{1}{6}x^4 + \cdots.$$

26. $f(x) = \sin(x^3 - x)$

SOLUTION Substitute $x^3 - x$ into the first two terms of the Maclaurin series for $\sin x$:

$$(x^3 - x) - \frac{(x^3 - x)^3}{3!} = x^3 - x - \frac{x^9 - 3x^7 + 3x^5 - x^3}{3!}$$

so that the terms of the Maclaurin series for $\sin(x^3 - x)$ through degree four are

$$-x + \frac{7}{6}x^3$$

27. $f(x) = e^{\sin x}$

SOLUTION Substituting $\sin x$ for x in the Maclaurin series for e^x and then using the Maclaurin series for $\sin x$, we find

$$e^{\sin x} = 1 + \sin x + \frac{\sin^2 x}{2} + \frac{\sin^3 x}{6} + \frac{\sin^4 x}{24} + \cdots$$
$$= 1 + \left(x - \frac{x^3}{6} + \cdots\right) + \frac{1}{2}\left(x - \frac{x^3}{6} + \cdots\right)^2 + \frac{1}{6}(x - \cdots)^3 + \frac{1}{24}(x - \cdots)^4$$
$$= 1 + x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{6}x^3 - \frac{1}{6}x^4 + \frac{1}{24}x^4 + \cdots$$
$$= 1 + x + \frac{1}{2}x^2 - \frac{1}{8}x^4 + \cdots.$$

28. $f(x) = e^{(e^x)}$

SOLUTION With $f(x) = e^{(e^x)}$, we find

$$f'(x) = e^{(e^x)} \cdot e^x$$
$$f''(x) = e^{(e^x)} \cdot e^x + e^{(e^x)} \cdot e^{2x} = e^{(e^x)}\left(e^{2x} + e^x\right)$$
$$f'''(x) = e^{(e^x)}\left(2e^{2x} + e^x\right) + e^{(e^x)}\left(e^{2x} + e^x\right)e^x$$
$$= e^{(e^x)}\left(e^{3x} + 3e^{2x} + e^x\right)$$
$$f^{(4)}(x) = e^{(e^x)}(3e^{3x} + 6e^{2x} + e^x) + e^{(e^x)}(e^{3x} + 3e^{2x} + e^x)e^x$$
$$= e^{(e^x)}(e^{4x} + 6e^{3x} + 7e^{2x} + e^x)$$

and

$$f(0) = e, \quad f'(0) = e, \quad f''(0) = 2e, \quad f'''(0) = 5e, \quad f^{(4)}(0) = 15e.$$

Therefore, the first four terms of the Maclaurin for $f(x) = e^{(e^x)}$ are

$$e + ex + ex^2 + \frac{5e}{6}x^3 + \frac{5e}{8}x^4.$$

In Exercises 29–38, find the Taylor series centered at c and find the interval on which the expansion is valid.

29. $f(x) = \dfrac{1}{x}, \quad c = 1$

SOLUTION Write

$$\frac{1}{x} = \frac{1}{1 + (x-1)},$$

and then substitute $-(x-1)$ for x in the Maclaurin series for $\frac{1}{1-x}$ to obtain

$$\frac{1}{x} = \sum_{n=0}^{\infty} [-(x-1)]^n = \sum_{n=0}^{\infty} (-1)^n (x-1)^n.$$

This series is valid for $|x-1| < 1$.

30. $f(x) = e^{3x}, \quad c = -1$

SOLUTION Write

$$e^{3x} = e^{3(x+1)-3} = e^{-3}e^{3(x+1)}.$$

Now, substitute $3(x+1)$ for x in the Maclaurin series for e^x to obtain

$$e^{3(x+1)} = \sum_{n=0}^{\infty} \frac{(3(x+1))^n}{n!} = \sum_{n=0}^{\infty} \frac{3^n}{n!}(x+1)^n.$$

Thus,

$$e^{3x} = e^{-3} \sum_{n=0}^{\infty} \frac{3^n}{n!}(x+1)^n = \sum_{n=0}^{\infty} \frac{3^n e^{-3}}{n!}(x+1)^n,$$

This series is valid for all x.

31. $f(x) = \dfrac{1}{1-x}, \quad c = 5$

SOLUTION Write

$$\frac{1}{1-x} = \frac{1}{-4-(x-5)} = -\frac{1}{4} \cdot \frac{1}{1 + \frac{x-5}{4}}.$$

Substituting $-\frac{x-5}{4}$ for x in the Maclaurin series for $\frac{1}{1-x}$ yields

$$\frac{1}{1 + \frac{x-5}{4}} = \sum_{n=0}^{\infty} \left(-\frac{x-5}{4}\right)^n = \sum_{n=0}^{\infty} (-1)^n \frac{(x-5)^n}{4^n}.$$

Thus,

$$\frac{1}{1-x} = -\frac{1}{4} \sum_{n=0}^{\infty} (-1)^n \frac{(x-5)^n}{4^n} = \sum_{n=0}^{\infty} (-1)^{n+1} \frac{(x-5)^n}{4^{n+1}}.$$

This series is valid for $\left|\frac{x-5}{4}\right| < 1$, or $|x-5| < 4$.

32. $f(x) = \sin x, \quad c = \dfrac{\pi}{2}$

SOLUTION Note that the odd derivatives of $\sin x$ are zero at $\frac{\pi}{2}$, and the even derivatives alternate between $+1$ and -1. Thus the Taylor series centered at $\frac{\pi}{2}$ is

$$\sum_{n=0}^{\infty} (-1)^n \frac{\left(x - \frac{\pi}{2}\right)^{2n}}{(2n)!}$$

33. $f(x) = x^4 + 3x - 1, \quad c = 2$

SOLUTION To determine the Taylor series with center $c = 2$, we compute

$$f'(x) = 4x^3 + 3, \quad f''(x) = 12x^2, \quad f'''(x) = 24x,$$

and $f^{(4)}(x) = 24$. All derivatives of order five and higher are zero. Now,

$$f(2) = 21, \quad f'(2) = 35, \quad f''(2) = 48, \quad f'''(2) = 48,$$

and $f^{(4)}(2) = 24$. Therefore, the Taylor series is

$$21 + 35(x-2) + \frac{48}{2}(x-2)^2 + \frac{48}{6}(x-2)^3 + \frac{24}{24}(x-2)^4,$$

or

$$21 + 35(x-2) + 24(x-2)^2 + 8(x-2)^3 + (x-2)^4.$$

34. $f(x) = x^4 + 3x - 1, \quad c = 0$

SOLUTION The function $x^4 + 3x - 1$ is a polynomial in x, hence it is already in the form of a Maclaurin series.

35. $f(x) = \dfrac{1}{x^2}, \quad c = 4$

SOLUTION We will first find the Taylor series for $\frac{1}{x}$ and then differentiate to obtain the series for $\frac{1}{x^2}$. Write

$$\frac{1}{x} = \frac{1}{4 + (x-4)} = \frac{1}{4} \cdot \frac{1}{1 + \frac{x-4}{4}}.$$

Now substitute $-\frac{x-4}{4}$ for x in the Maclaurin series for $\frac{1}{1-x}$ to obtain

$$\frac{1}{x} = \frac{1}{4}\sum_{n=}^{\infty}\left(-\frac{x-4}{4}\right)^n = \sum_{n=0}^{\infty}(-1)^n\frac{(x-4)^n}{4^{n+1}}.$$

Differentiating term-by-term yields

$$-\frac{1}{x^2} = \sum_{n=1}^{\infty}(-1)^n n\frac{(x-4)^{n-1}}{4^{n+1}},$$

so that

$$\frac{1}{x^2} = \sum_{n=1}^{\infty}(-1)^{n-1} n\frac{(x-4)^{n-1}}{4^{n+1}} = \sum_{n=0}^{\infty}(-1)^n(n+1)\frac{(x-4)^n}{4^{n+2}}.$$

This series is valid for $\left|\frac{x-4}{4}\right| < 1$, or $|x-4| < 4$.

36. $f(x) = \sqrt{x}, \quad c = 4$

SOLUTION Write

$$\sqrt{x} = \sqrt{4 + (x-4)} = 2\sqrt{1 + \frac{x-4}{4}}.$$

Substituting $\frac{x-4}{4}$ for x in the binomial series with $a = \frac{1}{2}$ yields

$$\sqrt{x} = 2\sum_{n=0}^{\infty}\binom{\frac{1}{2}}{n}\left(\frac{x-4}{4}\right)^n = \sum_{n=0}^{\infty}\frac{1}{2^{2n-1}}\binom{\frac{1}{2}}{n}(x-4)^n.$$

This series is valid for $\left|\frac{x-4}{4}\right| < 1$, or $|x-4| < 4$.

37. $f(x) = \dfrac{1}{1-x^2}, \quad c = 3$

SOLUTION By partial fraction decomposition

$$\frac{1}{1-x^2} = \frac{\frac{1}{2}}{1-x} + \frac{\frac{1}{2}}{1+x},$$

so

$$\frac{1}{1-x^2} = \frac{\frac{1}{2}}{-2-(x-3)} + \frac{\frac{1}{2}}{4+(x-3)} = -\frac{1}{4}\cdot\frac{1}{1+\frac{x-3}{2}} + \frac{1}{8}\cdot\frac{1}{1+\frac{x-3}{4}}.$$

Substituting $-\frac{x-3}{2}$ for x in the Maclaurin series for $\frac{1}{1-x}$ gives

$$\frac{1}{1+\frac{x-3}{2}} = \sum_{n=0}^{\infty}\left(-\frac{x-3}{2}\right)^n = \sum_{n=0}^{\infty}\frac{(-1)^n}{2^n}(x-3)^n,$$

while substituting $-\frac{x-3}{4}$ for x in the same series gives

$$\frac{1}{1+\frac{x-3}{4}} = \sum_{n=0}^{\infty}\left(-\frac{x-3}{4}\right)^n = \sum_{n=0}^{\infty}\frac{(-1)^n}{4^n}(x-3)^n.$$

Thus,

$$\begin{aligned}\frac{1}{1-x^2} &= -\frac{1}{4}\sum_{n=0}^{\infty}\frac{(-1)^n}{2^n}(x-3)^n + \frac{1}{8}\sum_{n=0}^{\infty}\frac{(-1)^n}{4^n}(x-3)^n = \sum_{n=0}^{\infty}\frac{(-1)^{n+1}}{2^{n+2}}(x-3)^n + \sum_{n=0}^{\infty}\frac{(-1)^n}{2^{2n+3}}(x-3)^n \\ &= \sum_{n=0}^{\infty}\left(\frac{(-1)^{n+1}}{2^{n+2}} + \frac{(-1)^n}{2^{2n+3}}\right)(x-3)^n = \sum_{n=0}^{\infty}\frac{(-1)^{n+1}(2^{n+1}-1)}{2^{2n+3}}(x-3)^n.\end{aligned}$$

This series is valid for $|x-3| < 2$.

38. $f(x) = \dfrac{1}{3x-2}, \quad c = -1$

SOLUTION Write

$$\frac{1}{3x-2} = \frac{1}{-5+3(x+1)} = -\frac{1}{5}\frac{1}{1-\frac{3(x+1)}{5}},$$

and then substitute $\frac{3(x+1)}{5}$ for x in the Maclaurin series for $\frac{1}{1-x}$ to obtain

$$\frac{1}{1-\frac{3(x+1)}{5}} = \sum_{n=0}^{\infty}\left(\frac{3(x+1)}{5}\right)^n = \sum_{n=0}^{\infty}\frac{3^n}{5^n}(x+1)^n.$$

Thus,

$$\frac{1}{3x-2} = -\sum_{n=0}^{\infty}\frac{3^n}{5^{n+1}}(x+1)^n.$$

This series is valid for $\left|\frac{3(x+1)}{5}\right| < 1$, or $|x+1| < \frac{5}{3}$.

39. Use the identity $\cos^2 x = \frac{1}{2}(1+\cos 2x)$ to find the Maclaurin series for $\cos^2 x$.

SOLUTION The Maclaurin series for $\cos 2x$ is

$$\sum_{n=0}^{\infty}(-1)^n\frac{(2x)^{2n}}{(2n)!} = \sum_{n=0}^{\infty}(-1)^n\frac{2^{2n}x^{2n}}{(2n)!}$$

so the Maclaurin series for $\cos^2 x = \frac{1}{2}(1+\cos 2x)$ is

$$\frac{1+\left(1+\sum_{n=1}^{\infty}(-1)^n\frac{2^{2n}x^{2n}}{(2n)!}\right)}{2} = 1 + \sum_{n=1}^{\infty}(-1)^n\frac{2^{2n-1}x^{2n}}{(2n)!}$$

40. Show that for $|x| < 1$,

$$\tanh^{-1} x = x + \frac{x^3}{3} + \frac{x^5}{5} + \cdots$$

Hint: Recall that $\dfrac{d}{dx}\tanh^{-1} x = \dfrac{1}{1-x^2}$.

SOLUTION Because

$$\frac{d}{dx}\tanh^{-1} x = \frac{1}{1-x^2} = \sum_{n=0}^{\infty}(x^2)^n = \sum_{n=0}^{\infty}x^{2n},$$

we have

$$\tanh^{-1} x = C + \sum_{n=0}^{\infty} \frac{x^{2n+1}}{2n+1} = C + x + \frac{x^3}{3} + \frac{x^5}{5} + \cdots.$$

Now, $\tanh^{-1} 0 = 0$, so it follows that $C = 0$, and

$$\tanh^{-1} x = \sum_{n=0}^{\infty} \frac{x^{2n+1}}{2n+1} = x + \frac{x^3}{3} + \frac{x^5}{5} + \cdots.$$

41. Use the Maclaurin series for $\ln(1+x)$ and $\ln(1-x)$ to show that

$$\frac{1}{2}\ln\left(\frac{1+x}{1-x}\right) = x + \frac{x^3}{3} + \frac{x^5}{5} + \cdots$$

for $|x| < 1$. What can you conclude by comparing this result with that of Exercise 40?

SOLUTION Using the Maclaurin series for $\ln(1+x)$ and $\ln(1-x)$, we have for $|x| < 1$

$$\ln(1+x) - \ln(1-x) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} x^n - \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} (-x)^n$$

$$= \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} x^n + \sum_{n=1}^{\infty} \frac{x^n}{n} = \sum_{n=1}^{\infty} \frac{1 + (-1)^{n-1}}{n} x^n.$$

Since $1 + (-1)^{n-1} = 0$ for even n and $1 + (-1)^{n-1} = 2$ for odd n,

$$\ln(1+x) - \ln(1-x) = \sum_{k=0}^{\infty} \frac{2}{2k+1} x^{2k+1}.$$

Thus,

$$\frac{1}{2}\ln\left(\frac{1+x}{1-x}\right) = \frac{1}{2}\left(\ln(1+x) - \ln(1-x)\right) = \frac{1}{2}\sum_{k=0}^{\infty} \frac{2}{2k+1} x^{2k+1} = \sum_{k=0}^{\infty} \frac{x^{2k+1}}{2k+1}.$$

Observe that this is the same series we found in Exercise 40; therefore,

$$\frac{1}{2}\ln\left(\frac{1+x}{1-x}\right) = \tanh^{-1} x.$$

42. Differentiate the Maclaurin series for $\frac{1}{1-x}$ twice to find the Maclaurin series of $\frac{1}{(1-x)^3}$.

SOLUTION Differentiating the Maclaurin series for $\frac{1}{1-x}$ term-by-term, we obtain

$$\frac{1}{(1-x)^2} = \sum_{n=1}^{\infty} n x^{n-1}.$$

Differentiating again then yields

$$\frac{2}{(1-x)^3} = \sum_{n=2}^{\infty} n(n-1)x^{n-2},$$

so that

$$\frac{1}{(1-x)^3} = \sum_{n=2}^{\infty} \frac{n(n-1)}{2} x^{n-2} = \sum_{n=0}^{\infty} \frac{(n+2)(n+1)}{2} x^n.$$

43. Show, by integrating the Maclaurin series for $f(x) = \frac{1}{\sqrt{1-x^2}}$, that for $|x| < 1$,

$$\sin^{-1} x = x + \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \frac{x^{2n+1}}{2n+1}$$

SOLUTION From Example 10, we know that for $|x| < 1$

$$\frac{1}{\sqrt{1-x^2}} = \sum_{n=0}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} x^{2n} = 1 + \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} x^{2n},$$

so, for $|x| < 1$,

$$\sin^{-1} x = \int \frac{dx}{\sqrt{1-x^2}} = C + x + \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \frac{x^{2n+1}}{2n+1}.$$

Since $\sin^{-1} 0 = 0$, we find that $C = 0$. Thus,

$$\sin^{-1} x = x + \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \frac{x^{2n+1}}{2n+1}.$$

44. Use the first five terms of the Maclaurin series in Exercise 43 to approximate $\sin^{-1} \frac{1}{2}$. Compare the result with the calculator value.

SOLUTION From Exercise 43 we know that for $|x| < 1$,

$$\sin^{-1} x = x + \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \frac{x^{2n+1}}{2n+1}.$$

The first five terms of the series are:

$$x + \frac{1}{2}\frac{x^3}{3} + \frac{1 \cdot 3}{2 \cdot 4}\frac{x^5}{5} + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}\frac{x^7}{7} + \frac{1 \cdot 3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6 \cdot 8}\frac{x^9}{9} = x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{5x^7}{112} + \frac{35x^9}{1152}$$

Setting $x = \dfrac{1}{2}$, we obtain the following approximation:

$$\sin^{-1}\frac{1}{2} \approx \frac{1}{2} + \frac{\left(\frac{1}{2}\right)^3}{6} + \frac{3 \cdot \left(\frac{1}{2}\right)^5}{40} + \frac{5 \cdot \left(\frac{1}{2}\right)^7}{112} + \frac{35 \cdot \left(\frac{1}{2}\right)^9}{1152} \approx 0.52358519539.$$

The calculator value is $\sin^{-1}\frac{1}{2} \approx 0.5235988775$.

45. How many terms of the Maclaurin series of $f(x) = \ln(1+x)$ are needed to compute $\ln 1.2$ to within an error of at most 0.0001? Make the computation and compare the result with the calculator value.

SOLUTION Substitute $x = 0.2$ into the Maclaurin series for $\ln(1+x)$ to obtain:

$$\ln 1.2 = \sum_{n=1}^{\infty} (-1)^{n-1} \frac{(0.2)^n}{n} = \sum_{n=1}^{\infty} (-1)^{n-1} \frac{1}{5^n n}.$$

This is an alternating series with $a_n = \dfrac{1}{n \cdot 5^n}$. Using the error bound for alternating series

$$|\ln 1.2 - S_N| \le a_{N+1} = \frac{1}{(N+1)5^{N+1}},$$

so we must choose N so that

$$\frac{1}{(N+1)5^{N+1}} < 0.0001 \quad \text{or} \quad (N+1)5^{N+1} > 10{,}000.$$

For $N = 3$, $(N+1)5^{N+1} = 4 \cdot 5^4 = 2500 < 10,000$, and for $N = 4$, $(N+1)5^{N+1} = 5 \cdot 5^5 = 15,625 > 10,000$; thus, the smallest acceptable value for N is $N = 4$. The corresponding approximation is:

$$S_4 = \sum_{n=1}^{4} \frac{(-1)^{n-1}}{5^n \cdot n} = \frac{1}{5} - \frac{1}{5^2 \cdot 2} + \frac{1}{5^3 \cdot 3} - \frac{1}{5^4 \cdot 4} = 0.182266666.$$

Now, $\ln 1.2 = 0.182321556$, so

$$|\ln 1.2 - S_4| = 5.489 \times 10^{-5} < 0.0001.$$

46. Show that

$$\pi - \frac{\pi^3}{3!} + \frac{\pi^5}{5!} - \frac{\pi^7}{7!} + \cdots$$

converges to zero. How many terms must be computed to get within 0.01 of zero?

SOLUTION Set $x = \pi$ in the Maclaurin series for $\sin x$ to obtain:

$$0 = \sin \pi = \pi - \frac{\pi^3}{3!} + \frac{\pi^5}{5!} - \frac{\pi^7}{7!} + \cdots .$$

Using the error bound for an alternating series, we have

$$\left| 0 - \sum_{n=0}^{N} \frac{(-1)^n \pi^{2n+1}}{(2n+1)!} \right| \le \frac{\pi^{2N+3}}{(2N+3)!}.$$

$N = 4$ is the smallest value for which the error bound is less than 0.01, so five terms are needed.

47. Use the Maclaurin expansion for e^{-t^2} to express the function $F(x) = \int_0^x e^{-t^2}\, dt$ as an alternating power series in x (Figure 4).

(a) How many terms of the Maclaurin series are needed to approximate the integral for $x = 1$ to within an error of at most 0.001?

(b) CAS Carry out the computation and check your answer using a computer algebra system.

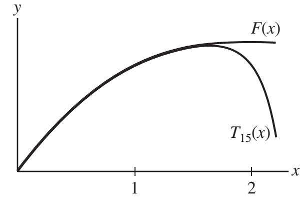

FIGURE 4 The Maclaurin polynomial $T_{15}(x)$ for $F(t) = \int_0^x e^{-t^2}\, dt$.

SOLUTION Substituting $-t^2$ for t in the Maclaurin series for e^t yields

$$e^{-t^2} = \sum_{n=0}^{\infty} \frac{(-t^2)^n}{n!} = \sum_{n=0}^{\infty} (-1)^n \frac{t^{2n}}{n!};$$

thus,

$$\int_0^x e^{-t^2}\, dt = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{n!(2n+1)}.$$

(a) For $x = 1$,

$$\int_0^1 e^{-t^2}\, dt = \sum_{n=0}^{\infty} (-1)^n \frac{1}{n!(2n+1)}.$$

This is an alternating series with $a_n = \frac{1}{n!(2n+1)}$; therefore, the error incurred by using S_N to approximate the value of the definite integral is bounded by

$$\left| \int_0^1 e^{-t^2}\, dt - S_N \right| \le a_{N+1} = \frac{1}{(N+1)!(2N+3)}.$$

To guarantee the error is at most 0.001, we must choose N so that

$$\frac{1}{(N+1)!(2N+3)} < 0.001 \quad \text{or} \quad (N+1)!(2N+3) > 1000.$$

For $N = 3$, $(N+1)!(2N+3) = 4! \cdot 9 = 216 < 1000$ and for $N = 4$, $(N+1)!(2N+3) = 5! \cdot 11 = 1320 > 1000$; thus, the smallest acceptable value for N is $N = 4$. The corresponding approximation is

$$S_4 = \sum_{n=0}^{4} \frac{(-1)^n}{n!(2n+1)} = 1 - \frac{1}{3} + \frac{1}{2! \cdot 5} - \frac{1}{3! \cdot 7} + \frac{1}{4! \cdot 9} = 0.747486772.$$

(b) Using a computer algebra system, we find

$$\int_0^1 e^{-t^2}\,dt = 0.746824133;$$

therefore

$$\left|\int_0^1 e^{-t^2}\,dt - S_4\right| = 6.626 \times 10^{-4} < 10^{-3}.$$

48. Let $F(x) = \int_0^x \frac{\sin t\,dt}{t}$. Show that

$$F(x) = x - \frac{x^3}{3 \cdot 3!} + \frac{x^5}{5 \cdot 5!} - \frac{x^7}{7 \cdot 7!} + \cdots$$

Evaluate $F(1)$ to three decimal places.

SOLUTION Divide the Maclaurin series for $\sin t$ by t to obtain

$$\frac{\sin t}{t} = \frac{1}{t}\sum_{n=0}^{\infty}(-1)^n \frac{t^{2n+1}}{(2n+1)!} = \sum_{n=0}^{\infty}(-1)^n \frac{t^{2n}}{(2n+1)!}.$$

Integrating both sides of this equation and using term-by-term integration, we find

$$F(x) = \int_0^x \frac{\sin t}{t}\,dt = \sum_{n=0}^{\infty}(-1)^n \frac{x^{2n+1}}{(2n+1)!(2n+1)} = x - \frac{x^3}{3 \cdot 3!} + \frac{x^5}{5 \cdot 5!} - \frac{x^7}{7 \cdot 7!} + \cdots$$

For $x = 1$,

$$F(1) = \sum_{n=0}^{\infty}(-1)^n \frac{1}{(2n+1)!(2n+1)}.$$

This is an alternating series with $a_n = \frac{1}{(2n+1)!(2n+1)}$; therefore, the error incurred by using S_N to approximate the value of the definite integral is bounded by

$$\left|\int_0^1 \frac{\sin t}{t}\,dt - S_N\right| \le a_{N+1} = \frac{1}{(2N+3)!(2N+3)}.$$

To guarantee the error is at most 0.0005, we must choose N so that

$$\frac{1}{(2N+3)!(2N+3)} < 0.0005 \quad \text{or} \quad (2N+3)!(2N+3) > 2000.$$

For $N = 1$, $(2N+3)!(2N+3) = 5! \cdot 5 = 600 < 2000$ and for $N = 2$, $(2N+3)!(2N+3) = 7! \cdot 7 = 35{,}280 > 2000$; thus, the smallest acceptable value for N is $N = 2$. The corresponding approximation is

$$S_2 = \sum_{n=0}^{2} \frac{(-1)^n}{(2n+1)!(2n+1)} = 1 - \frac{1}{3 \cdot 3!} + \frac{1}{5 \cdot 5!} = 0.946111111.$$

In Exercises 49–52, express the definite integral as an infinite series and find its value to within an error of at most 10^{-4}.

49. $\int_0^1 \cos(x^2)\,dx$

SOLUTION Substituting x^2 for x in the Maclaurin series for $\cos x$ yields

$$\cos(x^2) = \sum_{n=0}^{\infty}(-1)^n \frac{(x^2)^{2n}}{(2n)!} = \sum_{n=0}^{\infty}(-1)^n \frac{x^{4n}}{(2n)!};$$

therefore,

$$\int_0^1 \cos(x^2)\,dx = \sum_{n=0}^{\infty}(-1)^n \left.\frac{x^{4n+1}}{(2n)!(4n+1)}\right|_0^1 = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!(4n+1)}.$$

This is an alternating series with $a_n = \frac{1}{(2n)!(4n+1)}$; therefore, the error incurred by using S_N to approximate the value of the definite integral is bounded by

$$\left|\int_0^1 \cos(x^2)\,dx - S_N\right| \le a_{N+1} = \frac{1}{(2N+2)!(4N+5)}.$$

To guarantee the error is at most 0.0001, we must choose N so that

$$\frac{1}{(2N+2)!(4N+5)} < 0.0001 \quad \text{or} \quad (2N+2)!(4N+5) > 10{,}000.$$

For $N = 2$, $(2N+2)!(4N+5) = 6! \cdot 13 = 9360 < 10{,}000$ and for $N = 3$, $(2N+2)!(4N+5) = 8! \cdot 17 = 685{,}440 > 10{,}000$; thus, the smallest acceptable value for N is $N = 3$. The corresponding approximation is

$$S_3 = \sum_{n=0}^{3} \frac{(-1)^n}{(2n)!(4n+1)} = 1 - \frac{1}{5 \cdot 2!} + \frac{1}{9 \cdot 4!} - \frac{1}{13 \cdot 6!} = 0.904522792.$$

50. $\displaystyle\int_0^1 \tan^{-1}(x^2)\,dx$

SOLUTION Substituting x^2 for x in the Maclaurin series for $\tan^{-1} x$ yields

$$\tan^{-1}(x^2) = \sum_{n=0}^{\infty} (-1)^n \frac{(x^2)^{2n+1}}{2n+1} = \sum_{n=0}^{\infty} (-1)^n \frac{x^{4n+2}}{2n+1};$$

therefore,

$$\int_0^1 \tan^{-1}(x^2)\,dx = \sum_{n=0}^{\infty} (-1)^n \left.\frac{x^{4n+3}}{(2n+1)(4n+3)}\right|_0^1 = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)(4n+3)}.$$

This is an alternating series with $a_n = \frac{1}{(2n+1)(4n+3)}$; therefore, the error incurred by using S_N to approximate the value of the definite integral is bounded by

$$\left|\int_0^1 \tan^{-1}(x^2)\,dx - S_N\right| \le a_{N+1} = \frac{1}{(2N+3)(4N+7)}.$$

To guarantee the error is at most 0.0001, we must choose N so that

$$\frac{1}{(2N+3)(4N+7)} < 0.0001 \quad \text{or} \quad (2N+3)(4N+7) > 10{,}000.$$

For $N = 33$, $(2N+3)(4N+7) = (69)(139) = 9591 < 10{,}000$ and for $N = 34$, $(2N+3)(4N+7) = (71)(143) = 10{,}153 > 10{,}000$; thus, the smallest acceptable value for N is $N = 34$. The corresponding approximation is

$$S_{34} = \sum_{n=0}^{34} \frac{(-1)^n}{(2n)!(4n+1)} = 0.297953297.$$

51. $\displaystyle\int_0^1 e^{-x^3}\,dx$

SOLUTION Substituting $-x^3$ for x in the Maclaurin series for e^x yields

$$e^{-x^3} = \sum_{n=0}^{\infty} \frac{(-x^3)^n}{n!} = \sum_{n=0}^{\infty} (-1)^n \frac{x^{3n}}{n!};$$

therefore,

$$\int_0^1 e^{-x^3}\,dx = \sum_{n=0}^{\infty} (-1)^n \left.\frac{x^{3n+1}}{n!(3n+1)}\right|_0^1 = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!(3n+1)}.$$

This is an alternating series with $a_n = \frac{1}{n!(3n+1)}$; therefore, the error incurred by using S_N to approximate the value of the definite integral is bounded by

$$\left|\int_0^1 e^{-x^3}\,dx - S_N\right| \le a_{N+1} = \frac{1}{(N+1)!(3N+4)}.$$

To guarantee the error is at most 0.0001, we must choose N so that

$$\frac{1}{(N+1)!(3N+4)} < 0.0001 \quad \text{or} \quad (N+1)!(3N+4) > 10{,}000.$$

For $N = 4$, $(N+1)!(3N+4) = 5! \cdot 16 = 1920 < 10{,}000$ and for $N = 5$, $(N+1)!(3N+4) = 6! \cdot 19 = 13{,}680 > 10{,}000$; thus, the smallest acceptable value for N is $N = 5$. The corresponding approximation is

$$S_5 = \sum_{n=0}^{5} \frac{(-1)^n}{n!(3n+1)} = 0.807446200.$$

52. $\displaystyle\int_0^1 \frac{dx}{\sqrt{x^4+1}}$

SOLUTION From Example 10, we know that for $|x| < 1$

$$\frac{1}{\sqrt{1-x^2}} = \sum_{n=0}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} x^{2n} = \sum_{n=0}^{\infty} \frac{(2n)!}{2^{2n}(n!)^2} x^{2n};$$

therefore,

$$\frac{1}{\sqrt{x^4+1}} = \sum_{n=0}^{\infty} \frac{(2n)!}{2^{2n}(n!)^2} (-x^2)^{2n} = \sum_{n=0}^{\infty} (-1)^n \frac{(2n)!}{2^{2n}(n!)^2} x^{4n},$$

and

$$\int_0^1 \frac{dx}{\sqrt{x^4+1}} = \sum_{n=0}^{\infty} (-1)^n \frac{(2n)!}{2^{2n}(n!)^2} \left.\frac{x^{4n+1}}{4n+1}\right|_0^1 = \sum_{n=0}^{\infty} (-1)^n \frac{(2n)!}{2^{2n}(4n+1)(n!)^2}.$$

This is an alternating series with

$$a_n = \frac{(2n)!}{2^{2n}(4n+1)(n!)^2};$$

therefore, the error incurred by using S_N to approximate the value of the definite integral is bounded by

$$\left| \int_0^1 \frac{dx}{\sqrt{x^4+1}} - S_N \right| \le a_{N+1} = \frac{(2N+2)!}{2^{2N+2}(4N+5)((N+1)!)^2}.$$

To guarantee the error is at most 0.0001, we must choose N so that

$$\frac{(2N+2)!}{2^{2N+2}(4N+5)((N+1)!)^2} < 0.0001.$$

For $N = 124$,

$$\frac{(2N+2)!}{2^{2N+2}(4N+5)((N+1)!)^2} = 0.0001006 > 0.0001,$$

and for $N = 125$,

$$\frac{(2N+2)!}{2^{2N+2}(4N+5)((N+1)!)^2} = 0.00009943 < 0.0001,$$

thus, the smallest acceptable value for N is $N = 125$. The corresponding approximation is

$$S_{125} = \sum_{n=0}^{125} (-1)^n \frac{(2n)!}{2^{2n}(4n+1)(n!)^2} = 0.926987328.$$

In Exercises 53–56, express the integral as an infinite series.

53. $\displaystyle\int_0^x \frac{1-\cos(t)}{t}\,dt$, for all x

SOLUTION The Maclaurin series for $\cos t$ is

$$\cos t = \sum_{n=0}^{\infty} (-1)^n \frac{t^{2n}}{(2n)!} = 1 + \sum_{n=1}^{\infty} (-1)^n \frac{t^{2n}}{(2n)!},$$

so

$$1 - \cos t = -\sum_{n=1}^{\infty} (-1)^n \frac{t^{2n}}{(2n)!} = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{t^{2n}}{(2n)!},$$

and

$$\frac{1 - \cos t}{t} = \frac{1}{t} \sum_{n=1}^{\infty} (-1)^{n+1} \frac{t^{2n}}{(2n)!} = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{t^{2n-1}}{(2n)!}.$$

Thus,

$$\int_0^x \frac{1 - \cos(t)}{t}\, dt = \sum_{n=1}^{\infty} (-1)^{n+1} \left. \frac{t^{2n}}{(2n)!2n} \right|_0^x = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{x^{2n}}{(2n)!2n}.$$

54. $\displaystyle\int_0^x \frac{t - \sin t}{t}\, dt$, for all x

SOLUTION The Maclaurin series for $\sin t$ is

$$\sin t = \sum_{n=0}^{\infty} (-1)^n \frac{t^{2n+1}}{(2n+1)!} = t + \sum_{n=1}^{\infty} (-1)^n \frac{t^{2n+1}}{(2n+1)!},$$

so

$$t - \sin t = -\sum_{n=1}^{\infty} (-1)^n \frac{t^{2n+1}}{(2n+1)!} = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{t^{2n+1}}{(2n+1)!},$$

and

$$\frac{t - \sin t}{t} = \frac{1}{t} \sum_{n=1}^{\infty} (-1)^{n+1} \frac{t^{2n+1}}{(2n+1)!} = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{t^{2n}}{(2n+1)!}.$$

Thus,

$$\int_0^x \frac{t - \sin(t)}{t}\, dt = \sum_{n=1}^{\infty} (-1)^{n+1} \left. \frac{t^{2n+1}}{(2n+1)!(2n+1)} \right|_0^x = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{x^{2n+1}}{(2n+1)!(2n+1)}.$$

55. $\displaystyle\int_0^x \ln(1 + t^2)\, dt$, for $|x| < 1$

SOLUTION Substituting t^2 for t in the Maclaurin series for $\ln(1 + t)$ yields

$$\ln(1 + t^2) = \sum_{n=1}^{\infty} (-1)^{n-1} \frac{(t^2)^n}{n} = \sum_{n=1}^{\infty} (-1)^n \frac{t^{2n}}{n}.$$

Thus,

$$\int_0^x \ln(1 + t^2)\, dt = \sum_{n=1}^{\infty} (-1)^n \left. \frac{t^{2n+1}}{n(2n+1)} \right|_0^x = \sum_{n=1}^{\infty} (-1)^n \frac{x^{2n+1}}{n(2n+1)}.$$

56. $\displaystyle\int_0^x \frac{dt}{\sqrt{1 - t^4}}$, for $|x| < 1$

SOLUTION From Example 10, we know that for $|t| < 1$

$$\frac{1}{\sqrt{1 - t^2}} = \sum_{n=0}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} t^{2n} = \sum_{n=0}^{\infty} \frac{(2n)!}{2^{2n}(n!)^2} t^{2n};$$

therefore,

$$\frac{1}{\sqrt{1 - t^4}} = \sum_{n=0}^{\infty} \frac{(2n)!}{2^{2n}(n!)^2} (t^2)^{2n} = \sum_{n=0}^{\infty} \frac{(2n)!}{2^{2n}(n!)^2} t^{4n},$$

and

$$\int_0^x \frac{dt}{\sqrt{1-t^4}} = \sum_{n=0}^{\infty} \frac{(2n)!}{2^{2n}(n!)^2} \left.\frac{t^{4n+1}}{4n+1}\right|_0^x = \sum_{n=0}^{\infty} \frac{(2n)!}{2^{2n}(n!)^2} \frac{x^{4n+1}}{4n+1}.$$

57. Which function has Maclaurin series $\sum_{n=0}^{\infty}(-1)^n 2^n x^n$?

SOLUTION We recognize that

$$\sum_{n=0}^{\infty}(-1)^n 2^n x^n = \sum_{n=0}^{\infty}(-2x)^n$$

is the Maclaurin series for $\frac{1}{1-x}$ with x replaced by $-2x$. Therefore,

$$\sum_{n=0}^{\infty}(-1)^n 2^n x^n = \frac{1}{1-(-2x)} = \frac{1}{1+2x}.$$

58. Which function has Maclaurin series

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{3^{k+1}}(x-3)^k?$$

For which values of x is the expansion valid?

SOLUTION Write the series as

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{3^{k+1}}(x-3)^k = \frac{1}{3}\sum_{k=0}^{\infty}\left(-\frac{x-3}{3}\right)^k,$$

which we recognize as $\frac{1}{3}$ times the Maclaurin series for $\frac{1}{1-x}$ with x replaced by $-\frac{x-3}{3}$. Therefore,

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{3^{k+1}}(x-3)^k = \frac{1}{3}\cdot\frac{1}{1+\frac{x-3}{3}} = \frac{1}{3+x-3} = \frac{1}{x}.$$

The series is valid for $\left|\frac{x-3}{3}\right| < 1$, or $|x-3| < 3$.

In Exercises 59–62, use Theorem 2 to prove that the $f(x)$ is represented by its Maclaurin series on the interval I.

59. $f(x) = \sin\left(\frac{x}{2}\right) + \cos\left(\frac{x}{3}\right)$,

SOLUTION All derivatives of $f(x)$ consist of sin or cos applied to each of $x/2$ and $x/3$ and added together, so each summand is bounded by 1. Thus $\left|f^{(n)}(x)\right| \le 2$ for all n and x. By Theorem 2, $f(x)$ is represented by its Taylor series for every x.

60. $f(x) = e^{-x}$,

SOLUTION For any c, choose any $R > 0$ and consider the interval $(c-R, c+R)$. For $f(x) = e^{-x}$, we have

$$\left|f^{(n)}(x)\right| = \left|(-1)^n e^{-x}\right| = e^{-x}$$

and on $(c-R, c+R)$, e^{-x} is bounded above by $e^{-(c-R)} = e^{R-c}$. Thus all derivatives of $f(x)$ are bounded by e^{R-c} for any $x \in (c-R, c+R)$, so by Theorem 2, $f(x)$ is represented by its Taylor series centered at c.

61. $f(x) = \sinh x$,

SOLUTION By definition, $\sinh x = \frac{1}{2}(e^x - e^{-x})$, so if both e^x and e^{-x} are represented by their Taylor series centered at c, then so is $\sinh x$. But the previous exercise shows that e^{-x} is so represented, and the text shows that e^x is.

62. $f(x) = (1+x)^{100}$

SOLUTION $f(x)$ is a polynomial, so it is equal to its Taylor series and thus is obviously represented by its Taylor series.

In Exercises 63–66, find the functions with the following Maclaurin series (refer to Table 1 on page 599).

63. $1 + x^3 + \frac{x^6}{2!} + \frac{x^9}{3!} + \frac{x^{12}}{4!} + \cdots$

SOLUTION We recognize

$$1 + x^3 + \frac{x^6}{2!} + \frac{x^9}{3!} + \frac{x^{12}}{4!} + \cdots = \sum_{n=0}^{\infty} \frac{x^{3n}}{n!} = \sum_{n=0}^{\infty} \frac{(x^3)^n}{n!}$$

as the Maclaurin series for e^x with x replaced by x^3. Therefore,

$$1 + x^3 + \frac{x^6}{2!} + \frac{x^9}{3!} + \frac{x^{12}}{4!} + \cdots = e^{x^3}.$$

64. $1 - 4x + 4^2x^2 - 4^3x^3 + 4^4x^4 - 4^5x^5 + \cdots$

SOLUTION We recognize

$$1 - 4x + 4^2x^2 - 4^3x^3 + 4^4x^4 - 4^5x^5 + \cdots = \sum_{n=0}^{\infty} (-4x)^n$$

as the Maclaurin series for $\frac{1}{1-x}$ with x replaced by $-4x$. Therefore,

$$1 - 4x + 4^2x^2 - 4^3x^3 + 4^4x^4 - 4^5x^5 + \cdots = \frac{1}{1-(-4x)} = \frac{1}{1+4x}.$$

65. $1 - \frac{5^3x^3}{3!} + \frac{5^5x^5}{5!} - \frac{5^7x^7}{7!} + \cdots$

SOLUTION Note

$$\begin{aligned} 1 - \frac{5^3x^3}{3!} + \frac{5^5x^5}{5!} - \frac{5^7x^7}{7!} + \cdots &= 1 - 5x + \left(5x - \frac{5^3x^3}{3!} + \frac{5^5x^5}{5!} - \frac{5^7x^7}{7!} + \cdots\right) \\ &= 1 - 5x + \sum_{n=0}^{\infty} (-1)^n \frac{(5x)^{2n+1}}{(2n+1)!}. \end{aligned}$$

The series is the Maclaurin series for $\sin x$ with x replaced by $5x$, so

$$1 - \frac{5^3x^3}{3!} + \frac{5^5x^5}{5!} - \frac{5^7x^7}{7!} + \cdots = 1 - 5x + \sin(5x).$$

66. $x^4 - \frac{x^{12}}{3} + \frac{x^{20}}{5} - \frac{x^{28}}{7} + \cdots$

SOLUTION We recognize

$$x^4 - \frac{x^{12}}{3} + \frac{x^{20}}{5} - \frac{x^{28}}{7} + \cdots = \sum_{n=0}^{\infty} (-1)^n \frac{(x^4)^{2n+1}}{2n+1}$$

as the Maclaurin series for $\tan^{-1} x$ with x replaced by x^4. Therefore,

$$x^4 - \frac{x^{12}}{3} + \frac{x^{20}}{5} - \frac{x^{28}}{7} + \cdots = \tan^{-1}(x^4).$$

In Exercises 67 and 68, let

$$f(x) = \frac{1}{(1-x)(1-2x)}$$

67. Find the Maclaurin series of $f(x)$ using the identity

$$f(x) = \frac{2}{1-2x} - \frac{1}{1-x}$$

SOLUTION Substituting $2x$ for x in the Maclaurin series for $\frac{1}{1-x}$ gives

$$\frac{1}{1-2x} = \sum_{n=0}^{\infty}(2x)^n = \sum_{n=0}^{\infty}2^n x^n$$

which is valid for $|2x| < 1$, or $|x| < \frac{1}{2}$. Because the Maclaurin series for $\frac{1}{1-x}$ is valid for $|x| < 1$, the two series together are valid for $|x| < \frac{1}{2}$. Thus, for $|x| < \frac{1}{2}$,

$$\begin{aligned}\frac{1}{(1-2x)(1-x)} &= \frac{2}{1-2x} - \frac{1}{1-x} = 2\sum_{n=0}^{\infty}2^n x^n - \sum_{n=0}^{\infty}x^n\\ &= \sum_{n=0}^{\infty}2^{n+1}x^n - \sum_{n=0}^{\infty}x^n = \sum_{n=0}^{\infty}\left(2^{n+1}-1\right)x^n.\end{aligned}$$

68. Find the Taylor series for $f(x)$ at $c = 2$. *Hint:* Rewrite the identity of Exercise 67 as

$$f(x) = \frac{2}{-3-2(x-2)} - \frac{1}{-1-(x-2)}$$

SOLUTION Using the given identity,

$$f(x) = \frac{2}{-3-2(x-2)} - \frac{1}{-1-(x-2)} = -\frac{2}{3}\frac{1}{1+\frac{2}{3}(x-2)} + \frac{1}{1+(x-2)}.$$

Substituting $-\frac{2}{3}(x-2)$ for x in the Maclaurin series for $\frac{1}{1-x}$ yields

$$\frac{1}{1+\frac{2}{3}(x-2)} = \sum_{n=0}^{\infty}(-1)^n\left(\frac{2}{3}\right)^n(x-2)^n,$$

and substituting $-(x-2)$ for x in the same Maclaurin series yields

$$\frac{1}{1+(x-2)} = \sum_{n=0}^{\infty}(-1)^n(x-2)^n.$$

The first series is valid for $\left|-\frac{2}{3}(x-2)\right| < 1$, or $|x-2| < \frac{3}{2}$, and the second series is valid for $|x-2| < 1$; therefore, the two series together are valid for $|x-2| < 1$. Finally, for $|x-2| < 1$,

$$f(x) = -\frac{2}{3}\sum_{n=0}^{\infty}(-1)^n\left(\frac{2}{3}\right)^n(x-2)^n + \sum_{n=0}^{\infty}(-1)^n(x-2)^n = \sum_{n=0}^{\infty}(-1)^n\left[1-\left(\frac{2}{3}\right)^{n+1}\right](x-2)^n.$$

69. When a voltage V is applied to a series circuit consisting of a resistor R and an inductor L, the current at time t is

$$I(t) = \left(\frac{V}{R}\right)\left(1-e^{-Rt/L}\right)$$

Expand $I(t)$ in a Maclaurin series. Show that $I(t) \approx \frac{Vt}{L}$ for small t.

SOLUTION Substituting $-\frac{Rt}{L}$ for t in the Maclaurin series for e^t gives

$$e^{-Rt/L} = \sum_{n=0}^{\infty}\frac{\left(-\frac{Rt}{L}\right)^n}{n!} = \sum_{n=0}^{\infty}\frac{(-1)^n}{n!}\left(\frac{R}{L}\right)^n t^n = 1 + \sum_{n=1}^{\infty}\frac{(-1)^n}{n!}\left(\frac{R}{L}\right)^n t^n$$

Thus,

$$1-e^{-Rt/L} = 1-\left(1+\sum_{n=1}^{\infty}\frac{(-1)^n}{n!}\left(\frac{R}{L}\right)^n t^n\right) = \sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n!}\left(\frac{Rt}{L}\right)^n,$$

and

$$I(t) = \frac{V}{R}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n!}\left(\frac{Rt}{L}\right)^n = \frac{Vt}{L} + \frac{V}{R}\sum_{n=2}^{\infty}\frac{(-1)^{n+1}}{n!}\left(\frac{Rt}{L}\right)^n.$$

If t is small, then we can approximate $I(t)$ by the first (linear) term, and ignore terms with higher powers of t; then we find

$$V(t) \approx \frac{Vt}{L}.$$

70. Use the result of Exercise 69 and your knowledge of alternating series to show that

$$\frac{Vt}{L}\left(1 - \frac{R}{2L}t\right) \le I(t) \le \frac{Vt}{L} \qquad \text{(for all } t\text{)}$$

SOLUTION Since the series for $I(t)$ is an alternating series, we know that the true value lies between any two successive partial sums. Since the term for $n = 2$ is negative, we have

$$S_2 \le I(t) \le S_1 \qquad \text{for all } t$$

Clearly $S_1 = \frac{Vt}{L}$, and

$$S_2 = \frac{Vt}{L} + \frac{V}{R}\left(\frac{-1}{n!} \cdot \frac{R^2t^2}{L^2}\right) = \frac{Vt}{L} - \frac{VR^2t^2}{2RL^2} = \frac{Vt}{L}\left(1 - \frac{R}{2L}t\right)$$

71. Find the Maclaurin series for $f(x) = \cos(x^3)$ and use it to determine $f^{(6)}(0)$.

SOLUTION The Maclaurin series for $\cos x$ is

$$\cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!}$$

Substituting x^3 for x gives

$$\cos(x^3) = \sum_{n=0}^{\infty} (-1)^n \frac{x^{6n}}{(2n)!}$$

Now, the coefficient of x^6 in this series is

$$-\frac{1}{2!} = -\frac{1}{2} = \frac{f^{(6)}(0)}{6!}$$

so

$$f^{(6)}(0) = -\frac{6!}{2} = -360$$

72. Find $f^{(7)}(0)$ and $f^{(8)}(0)$ for $f(x) = \tan^{-1} x$ using the Maclaurin series.

SOLUTION The Maclaurin series for $f(x) = \tan^{-1} x$ is:

$$\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1}.$$

The coefficient of x^7 in this series is

$$\frac{(-1)^3}{7} = -\frac{1}{7} = \frac{f^{(7)}(0)}{7!},$$

so

$$f^{(7)}(0) = -\frac{7!}{7} = -6! = -720.$$

The coefficient of x^8 is 0, so $f^{(8)}(0) = 0$.

73. Use substitution to find the first three terms of the Maclaurin series for $f(x) = e^{x^{20}}$. How does the result show that $f^{(k)}(0) = 0$ for $1 \le k \le 19$?

SOLUTION Substituting x^{20} for x in the Maclaurin series for e^x yields

$$e^{x^{20}} = \sum_{n=0}^{\infty} \frac{(x^{20})^n}{n!} = \sum_{n=0}^{\infty} \frac{x^{20n}}{n!};$$

the first three terms in the series are then

$$1 + x^{20} + \frac{1}{2}x^{40}.$$

Recall that the coefficient of x^k in the Maclaurin series for f is $\frac{f^{(k)}(0)}{k!}$. For $1 \le k \le 19$, the coefficient of x^k in the Maclaurin series for $f(x) = e^{x^{20}}$ is zero; it therefore follows that

$$\frac{f^{(k)}(0)}{k!} = 0 \quad \text{or} \quad f^{(k)}(0) = 0$$

for $1 \le k \le 19$.

74. Use the binomial series to find $f^{(8)}(0)$ for $f(x) = \sqrt{1 - x^2}$.

SOLUTION We obtain the Maclaurin series for $f(x) = \sqrt{1 - x^2}$ by substituting $-x^2$ for x in the binomial series with $a = \frac{1}{2}$. This gives

$$\sqrt{1 - x^2} = \sum_{n=0}^{\infty} \binom{\frac{1}{2}}{n} \left(-x^2\right)^n = \sum_{n=0}^{\infty} (-1)^n \binom{\frac{1}{2}}{n} x^{2n}.$$

The coefficient of x^8 is

$$(-1)^4 \binom{\frac{1}{2}}{4} = \frac{\frac{1}{2}\left(\frac{1}{2} - 1\right)\left(\frac{1}{2} - 2\right)\left(\frac{1}{2} - 3\right)}{4!} = -\frac{15}{16 \cdot 4!} = \frac{f^{(8)}(0)}{8!},$$

so

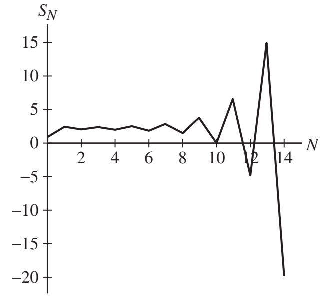
$$f^{(8)}(0) = \frac{-15 \cdot 8!}{16 \cdot 4!} = -1575.$$

75. Does the Maclaurin series for $f(x) = (1 + x)^{3/4}$ converge to $f(x)$ at $x = 2$? Give numerical evidence to support your answer.

SOLUTION The Taylor series for $f(x) = (1 + x)^{3/4}$ converges to $f(x)$ for $|x| < 1$; because $x = 2$ is not contained on this interval, the series does not converge to $f(x)$ at $x = 2$. The graph below displays

$$S_N = \sum_{n=0}^{N} \binom{\frac{3}{4}}{n} 2^n$$

for $0 \le N \le 14$. The divergent nature of the sequence of partial sums is clear.



76. Explain the steps required to verify that the Maclaurin series for $f(x) = e^x$ converges to $f(x)$ for all x.

SOLUTION To show that the Maclaurin series for e^x converges to e^x for all x, we show that for any real number c, the Maclaurin series converges to e^x on an interval containing c. To do this, it suffices to show that for any interval $I = (-R, R)$, the Maclaurin series for e^x converges to e^x on I, since each real number is contained in some such interval. By Theorem 2, it suffices to show that there is a number K that bounds all derivatives of e^x for all numbers in the interval $(-R, R)$. But each derivative of e^x is also e^x, so it suffices to show that there is a number K that bounds e^x for all $x \in (-R, R)$. But e^x is an increasing function, so that $e^x < e^R$ for all $x \in (-R, R)$. Thus $K = e^R$ is the bound we want. Theorem 2 then assures us that the Maclaurin series for e^x converges to e^x on I.

77. GU Let $f(x) = \sqrt{1 + x}$.

(a) Use a graphing calculator to compare the graph of f with the graphs of the first five Taylor polynomials for f. What do they suggest about the interval of convergence of the Taylor series?

(b) Investigate numerically whether or not the Taylor expansion for f is valid for $x = 1$ and $x = -1$.

SOLUTION

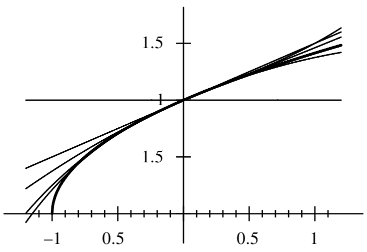
(a) The five first terms of the Binomial series with $a = \frac{1}{2}$ are

$$\sqrt{1+x} = 1 + \frac{1}{2}x + \frac{\frac{1}{2}\left(\frac{1}{2}-1\right)}{2!}x^2 + \frac{\frac{1}{2}\left(\frac{1}{2}-1\right)\left(\frac{1}{2}-2\right)}{3!}x^3 + \frac{\frac{1}{2}\left(\frac{1}{2}-1\right)\left(\frac{1}{2}-2\right)\left(\frac{1}{2}-3\right)}{4!}x^4 + \cdots$$
$$= 1 + \frac{1}{2}x - \frac{1}{8}x^2 + \frac{9}{4}x^3 - \frac{45}{2}x^4 + \cdots$$

Therefore, the first five Taylor polynomials are

$$T_0(x) = 1;$$
$$T_1(x) = 1 + \frac{1}{2}x;$$
$$T_2(x) = 1 + \frac{1}{2}x - \frac{1}{8}x^2;$$
$$T_3(x) = 1 + \frac{1}{2}x - \frac{1}{8}x^2 + \frac{1}{8}x^3;$$
$$T_4(x) = 1 + \frac{1}{2}x - \frac{1}{8}x^2 + \frac{1}{8}x^3 - \frac{5}{128}x^4.$$

The figure displays the graphs of these Taylor polynomials, along with the graph of the function $f(x) = \sqrt{1+x}$, which is shown in red.



The graphs suggest that the interval of convergence for the Taylor series is $-1 < x < 1$.

(b) Using a computer algebra system to calculate $S_N = \sum_{n=0}^{N} \binom{\frac{1}{2}}{n} x^n$ for $x = 1$ we find

$$S_{10} = 1.409931183, \quad S_{100} = 1.414073048, \quad S_{1000} = 1.414209104,$$

which appears to be converging to $\sqrt{2}$ as expected. At $x = -1$ we calculate $S_N = \sum_{n=0}^{N} \binom{\frac{1}{2}}{n} \cdot (-1)^n$, and find

$$S_{10} = 0.176197052, \quad S_{100} = 0.056348479, \quad S_{1000} = 0.017839011,$$

which appears to be converging to zero, though slowly.

78. Use the first five terms of the Maclaurin series for the elliptic function $E(k)$ to estimate the period T of a 1-meter pendulum released at an angle $\theta = \frac{\pi}{4}$ (see Example 11).

SOLUTION The period T of a pendulum of length L released from an angle θ is

$$T = 4\sqrt{\frac{L}{g}}E(k),$$

where $g \approx 9.8\ \text{m/s}^2$ is the acceleration due to gravity, $E(k)$ is the elliptic function of the first kind and $k = \sin\frac{\theta}{2}$. From Example 11, we know that

$$E(k) = \frac{\pi}{2}\sum_{n=0}^{\infty}\left(\frac{1\cdot 3\cdot 5\cdots(2n-1)}{2\cdot 4\cdot 6\cdots(2n)}\right)^2 k^{2n}.$$

With $\theta = \frac{\pi}{4}$,

$$k = \sin\frac{\pi}{8} = \frac{\sqrt{2-\sqrt{2}}}{2},$$

and using the first five terms of the series for $E(k)$, we find

$$E\left(\sin\frac{\pi}{8}\right) \approx \frac{\pi}{2}\left(1+\left(\frac{1}{2}\right)^2\sin^2\frac{\pi}{8}+\left(\frac{1\cdot 3}{2\cdot 4}\right)^2\sin^4\frac{\pi}{8}+\left(\frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\right)^2\sin^6\frac{\pi}{8}+\left(\frac{1\cdot 3\cdot 5\cdot 7}{2\cdot 4\cdot 6\cdot 8}\right)^2\sin^8\frac{\pi}{8}\right)$$
$$= 1.633578996$$

Therefore,

$$T \approx 4\sqrt{\frac{1}{9.8}}\cdot 1.633578996 = 2.09 \text{ seconds.}$$

79. Use Example 11 and the approximation $\sin x \approx x$ to show that the period T of a pendulum released at an angle θ has the following second-order approximation:

$$T \approx 2\pi\sqrt{\frac{L}{g}}\left(1+\frac{\theta^2}{16}\right)$$

SOLUTION The period T of a pendulum of length L released from an angle θ is

$$T = 4\sqrt{\frac{L}{g}}E(k),$$

where $g \approx 9.8$ m/s^2 is the acceleration due to gravity, $E(k)$ is the elliptic function of the first kind and $k = \sin\frac{\theta}{2}$. From Example 11, we know that

$$E(k) = \frac{\pi}{2}\sum_{n=0}^{\infty}\left(\frac{1\cdot 3\cdot 5\cdots(2n-1)}{2\cdot 4\cdot 6\cdots(2n)}\right)^2 k^{2n}.$$

Using the approximation $\sin x \approx x$, we have

$$k = \sin\frac{\theta}{2} \approx \frac{\theta}{2};$$

moreover, using the first two terms of the series for $E(k)$, we find

$$E(k) \approx \frac{\pi}{2}\left[1+\left(\frac{1}{2}\right)^2\left(\frac{\theta}{2}\right)^2\right] = \frac{\pi}{2}\left(1+\frac{\theta^2}{16}\right).$$

Therefore,

$$T = 4\sqrt{\frac{L}{g}}E(k) \approx 2\pi\sqrt{\frac{L}{g}}\left(1+\frac{\theta^2}{16}\right).$$

In Exercises 80–83, find the Maclaurin series of the function and use it to calculate the limit.

80. $\displaystyle\lim_{x\to 0}\frac{\cos x - 1 + \frac{x^2}{2}}{x^4}$

SOLUTION Using the Maclaurin series for $\cos x$, we find

$$\cos x = \sum_{n=0}^{\infty}(-1)^n\frac{x^{2n}}{(2n)!} = 1 - \frac{x^2}{2} + \frac{x^4}{24} + \sum_{n=3}^{\infty}(-1)^n\frac{x^{2n}}{(2n)!}.$$

Thus,

$$\cos x - 1 + \frac{x^2}{2} = \frac{x^4}{24} + \sum_{n=3}^{\infty}(-1)^n\frac{x^{2n}}{(2n)!}$$

and

$$\frac{\cos x - 1 + \frac{x^2}{2}}{x^4} = \frac{1}{24} + \sum_{n=3}^{\infty}(-1)^n\frac{x^{2n-4}}{(2n)!}$$

Note that the radius of convergence for this series is infinite, and recall from the previous section that a convergent power series is continuous within its radius of convergence. Thus to calculate the limit of this power series as $x \to 0$ it suffices to evaluate it at $x = 0$:

$$\lim_{x\to 0} \frac{\cos x - 1 + \frac{x^2}{2}}{x^4} = \lim_{x\to 0} \left(\frac{1}{24} + \sum_{n=3}^{\infty} (-1)^n \frac{x^{2n-4}}{(2n)!} \right) = \frac{1}{24} + 0 = \frac{1}{24}.$$

81. $\lim_{x\to 0} \dfrac{\sin x - x + \frac{x^3}{6}}{x^5}$

SOLUTION Using the Maclaurin series for $\sin x$, we find

$$\sin x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!} = x - \frac{x^3}{6} + \frac{x^5}{120} + \sum_{n=3}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!}.$$

Thus,

$$\sin x - x + \frac{x^3}{6} = \frac{x^5}{120} + \sum_{n=3}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!}$$

and

$$\frac{\sin x - x + \frac{x^3}{6}}{x^5} = \frac{1}{120} + \sum_{n=3}^{\infty} (-1)^n \frac{x^{2n-4}}{(2n+1)!}$$

Note that the radius of convergence for this series is infinite, and recall from the previous section that a convergent power series is continuous within its radius of convergence. Thus to calculate the limit of this power series as $x \to 0$ it suffices to evaluate it at $x = 0$:

$$\lim_{x\to 0} \frac{\sin x - x + \frac{x^3}{6}}{x^5} = \lim_{x\to 0} \left(\frac{1}{120} + \sum_{n=3}^{\infty} (-1)^n \frac{x^{2n-4}}{(2n+1)!} \right) = \frac{1}{120} + 0 = \frac{1}{120}$$

82. $\lim_{x\to 0} \dfrac{\tan^{-1} x - x\cos x - \frac{1}{6}x^3}{x^5}$

SOLUTION Start with the Maclaurin series for $\tan^{-1} x$ and $\cos x$:

$$\tan^{-1} x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1} \qquad \cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!}$$

Then

$$x\cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n)!}$$

so that

$$\begin{aligned} \tan^{-1} x - x\cos x &= \sum_{n=0}^{\infty} (-1)^n \left(\frac{1}{2n+1} - \frac{1}{(2n)!} \right) x^{2n+1} \\ &= \frac{1}{6}x^3 + \frac{19}{120}x^5 + \sum_{n=3}^{\infty} (-1)^n \left(\frac{1}{2n+1} - \frac{1}{(2n)!} \right) x^{2n+1} \end{aligned}$$

and

$$\frac{\tan^{-1} x - x\cos x - \frac{1}{6}x^3}{x^5} = \frac{19}{120} + \sum_{n=3}^{\infty} (-1)^n \left(\frac{1}{2n+1} - \frac{1}{(2n)!} \right) x^{2n-4}$$

Since the radius of convergence of the series for $\tan^{-1} x$ is 1 and that of $\cos x$ is infinite, the radius of convergence of this series is 1. Recall from the previous section that a convergent power series is continuous within its radius of convergence. Thus to calculate the limit of this power series as $x \to 0$ it suffices to evaluate it at $x = 0$:

$$\lim_{x\to 0} \frac{\tan^{-1} x - x\cos x - \frac{1}{6}x^3}{x^5} = \lim_{x\to 0}\left(\frac{19}{120} + \sum_{n=3}^{\infty}(-1)^n\left(\frac{1}{2n+1} - \frac{1}{(2n)!}\right)x^{2n-4}\right) = \frac{19}{120} + 0 = \frac{19}{120}$$

83. $\lim_{x\to 0}\left(\frac{\sin(x^2)}{x^4} - \frac{\cos x}{x^2}\right)$

SOLUTION We start with

$$\sin x = \sum_{n=0}^{\infty}(-1)^n \frac{x^{2n+1}}{(2n+1)!} \qquad \cos x = \sum_{n=0}^{\infty}(-1)^n \frac{x^{2n}}{(2n)!}$$

so that

$$\frac{\sin(x^2)}{x^4} = \sum_{n=0}^{\infty}(-1)^n \frac{x^{4n+2}}{(2n+1)!x^4} = \sum_{n=0}^{\infty}(-1)^n \frac{x^{4n-2}}{(2n+1)!}$$

$$\frac{\cos x}{x^2} = \sum_{n=0}^{\infty}(-1)^n \frac{x^{2n-2}}{(2n)!}$$

Expanding the first few terms gives

$$\frac{\sin(x^2)}{x^4} = \frac{1}{x^2} - \sum_{n=1}^{\infty}(-1)^n \frac{x^{4n-2}}{(2n+1)!}$$

$$\frac{\cos x}{x^2} = \frac{1}{x^2} - \frac{1}{2} + \sum_{n=2}^{\infty}(-1)^n \frac{x^{2n-2}}{(2n)!}$$

so that

$$\frac{\sin(x^2)}{x^4} - \frac{\cos x}{x^2} = \frac{1}{2} - \sum_{n=1}^{\infty}(-1)^n \frac{x^{4n-2}}{(2n+1)!} - \sum_{n=2}^{\infty}(-1)^n \frac{x^{2n-2}}{(2n)!}$$

Note that all terms under the summation signs have positive powers of x. Now, the radius of convergence of the series for both sin and cos is infinite, so the radius of convergence of this series is infinite. Recall from the previous section that a convergent power series is continuous within its radius of convergence. Thus to calculate the limit of this power series as $x \to 0$ it suffices to evaluate it at $x = 0$:

$$\lim_{x\to 0}\left(\frac{\sin(x^2)}{x^4} - \frac{\cos x}{x^2}\right) = \lim_{x\to 0}\left(\frac{1}{2} - \sum_{n=1}^{\infty}(-1)^n \frac{x^{4n-2}}{(2n+1)!} - \sum_{n=2}^{\infty}(-1)^n \frac{x^{2n-2}}{(2n)!}\right) = \frac{1}{2} + 0 = \frac{1}{2}$$

Further Insights and Challenges

84. In this exercise we show that the Maclaurin expansion of $f(x) = \ln(1+x)$ is valid for $x = 1$.

(a) Show that for all $x \neq -1$,

$$\frac{1}{1+x} = \sum_{n=0}^{N}(-1)^n x^n + \frac{(-1)^{N+1}x^{N+1}}{1+x}$$

(b) Integrate from 0 to 1 to obtain

$$\ln 2 = \sum_{n=1}^{N}\frac{(-1)^{n-1}}{n} + (-1)^{N+1}\int_0^1 \frac{x^{N+1}\,dx}{1+x}$$

(c) Verify that the integral on the right tends to zero as $N \to \infty$ by showing that it is smaller than $\int_0^1 x^{N+1}dx$.

(d) Prove the formula

$$\ln 2 = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots$$

SOLUTION

(a) Substituting $-x$ for x in the Maclaurin series for $\frac{1}{1-x}$ yields

$$\frac{1}{1+x} = \sum_{n=0}^{\infty} (-1)^n x^n.$$

Now, rewrite the series as

$$\sum_{n=0}^{N} (-1)^n x^n + \sum_{n=N+1}^{\infty} (-1)^n x^n,$$

and use the formula for the sum of a geometric series on the second term to obtain

$$\frac{1}{1+x} = \sum_{n=0}^{N} (-1)^n x^n + \frac{(-1)^{N+1} x^{N+1}}{1+x}.$$

(b) Integrate the equation derived in part (a) from 0 to 1 to obtain

$$\ln(1+x)\Big|_0^1 = \sum_{n=0}^{N} (-1)^n \frac{x^{n+1}}{n+1}\Big|_0^1 + (-1)^{N+1} \int_0^1 \frac{x^{N+1}}{1+x}\,dx,$$

or

$$\ln 2 = \sum_{n=0}^{N} \frac{(-1)^n}{n+1} + (-1)^{N+1} \int_0^1 \frac{x^{N+1}}{1+x}\,dx = \sum_{n=1}^{N+1} \frac{(-1)^{n-1}}{n} + (-1)^{N+1} \int_0^1 \frac{x^{N+1}}{1+x}\,dx.$$

(c) For $0 < x < 1$,

$$0 \le \frac{x^{N+1}}{1+x} \le x^{N+1} \quad \text{so} \quad 0 \le \int_0^1 \frac{x^{N+1}}{1+x}\,dx \le \int_0^1 x^{N+1}\,dx.$$

Now,

$$\int_0^1 x^{N+1}\,dx = \frac{x^{N+2}}{N+2}\Big|_0^1 = \frac{1}{N+2} \to 0 \text{ as } N \to \infty.$$

Thus, by the Squeeze Theorem,

$$\lim_{N\to\infty} \int_0^1 \frac{x^{N+1}}{1+x}\,dx = 0.$$

(d) Taking the limit as $N \to \infty$ of the equation derived in part (b) and using the result from part (c), we find

$$\ln 2 = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots.$$

85. Let $g(t) = \dfrac{1}{1+t^2} - \dfrac{t}{1+t^2}$.

(a) Show that $\displaystyle\int_0^1 g(t)\,dt = \frac{\pi}{4} - \frac{1}{2}\ln 2$.

(b) Show that $g(t) = 1 - t - t^2 + t^3 - t^4 - t^5 + \cdots$.

(c) Evaluate $S = 1 - \frac{1}{2} - \frac{1}{3} + \frac{1}{4} - \frac{1}{5} - \frac{1}{6} + \cdots$.

SOLUTION

(a)

$$\int_0^1 g(t)\,dt = \left(\tan^{-1} t - \frac{1}{2}\ln(t^2+1)\right)\Big|_0^1 = \tan^{-1} 1 - \frac{1}{2}\ln 2 = \frac{\pi}{4} - \frac{1}{2}\ln 2$$

(b) Start with the Taylor series for $\frac{1}{1+t}$:

$$\frac{1}{1+t} = \sum_{n=0}^{\infty} (-1)^n t^n$$

and substitute t^2 for t to get

$$\frac{1}{1+t^2} = \sum_{n=0}^{\infty}(-1)^n t^{2n} = 1 - t^2 + t^4 - t^6 + \dots$$

so that

$$\frac{t}{1+t^2} = \sum_{n=0}^{\infty}(-1)^n t^{2n+1} = t - t^3 + t^5 - t^7 + \dots$$

Finally,

$$g(t) = \frac{1}{1+t^2} - \frac{t}{1+t^2} = 1 - t - t^2 + t^3 + t^4 - t^5 - t^6 + t^7 + \dots$$

(c) We have

$$\int g(t)\,dt = \int (1 - t - t^2 + t^3 + t^4 - t^5 - \dots)\,dt = t - \frac{1}{2}t^2 - \frac{1}{3}t^3 + \frac{1}{4}t^4 + \frac{1}{5}t^5 - \frac{1}{6}t^6 - \dots + C$$

The radius of convergence of the series for $g(t)$ is 1, so the radius of convergence of this series is also 1. However, this series converges at the right endpoint, $t = 1$, since

$$\left(1 - \frac{1}{2}\right) - \left(\frac{1}{3} - \frac{1}{4}\right) + \left(\frac{1}{5} - \frac{1}{6}\right) - \dots$$

is an alternating series with general term decreasing to zero. Thus by part (a),

$$1 - \frac{1}{2} - \frac{1}{3} + \frac{1}{4} + \frac{1}{5} - \frac{1}{6} - \dots = \frac{\pi}{4} - \frac{1}{2}\ln 2$$

In Exercises 86 and 87, we investigate the convergence of the binomial series

$$T_a(x) = \sum_{n=0}^{\infty} \binom{a}{n} x^n$$

86. Prove that $T_a(x)$ has radius of convergence $R = 1$ if a is not a whole number. What is the radius of convergence if a is a whole number?

SOLUTION Suppose that a is not a whole number. Then

$$\binom{a}{n} = \frac{a\,(a-1)\cdots(a-n+1)}{n!}$$

is never zero. Moreover,

$$\left|\frac{\binom{a}{n+1}}{\binom{a}{n}}\right| = \left|\frac{a(a-1)\cdots(a-n+1)(a-n)}{(n+1)!} \cdot \frac{n!}{a(a-1)\cdots(a-n+1)}\right| = \left|\frac{a-n}{n+1}\right|,$$

so, by the formula for the radius of convergence

$$r = \lim_{n\to\infty}\left|\frac{a-n}{n+1}\right| = 1.$$

The radius of convergence of $T_a(x)$ is therefore $R = r^{-1} = 1$.

If a is a whole number, then $\binom{a}{n} = 0$ for all $n > a$. The infinite series then reduces to a polynomial of degree a, so it converges for all x (i.e. $R = \infty$).

87. By Exercise 86, $T_a(x)$ converges for $|x| < 1$, but we do not yet know whether $T_a(x) = (1+x)^a$.

(a) Verify the identity

$$a\binom{a}{n} = n\binom{a}{n} + (n+1)\binom{a}{n+1}$$

(b) Use (a) to show that $y = T_a(x)$ satisfies the differential equation $(1+x)y' = ay$ with initial condition $y(0) = 1$.

(c) Prove that $T_a(x) = (1+x)^a$ for $|x| < 1$ by showing that the derivative of the ratio $\dfrac{T_a(x)}{(1+x)^a}$ is zero.

SOLUTION

(a)

$$n\binom{a}{n}+(n+1)\binom{a}{n+1}=n\cdot\frac{a\,(a-1)\cdots(a-n+1)}{n!}+(n+1)\cdot\frac{a\,(a-1)\cdots(a-n+1)\,(a-n)}{(n+1)!}$$
$$=\frac{a\,(a-1)\cdots(a-n+1)}{(n-1)!}+\frac{a\,(a-1)\cdots(a-n+1)\,(a-n)}{n!}$$
$$=\frac{a\,(a-1)\cdots(a-n+1)\,(n+(a-n))}{n!}=a\cdot\binom{a}{n}$$

(b) Differentiating $T_a(x)$ term-by-term yields

$$T_a'(x)=\sum_{n=1}^{\infty}n\binom{a}{n}x^{n-1}.$$

Thus,

$$(1+x)T_a'(x)=\sum_{n=1}^{\infty}n\binom{a}{n}x^{n-1}+\sum_{n=1}^{\infty}n\binom{a}{n}x^{n}=\sum_{n=0}^{\infty}(n+1)\binom{a}{n+1}x^{n}+\sum_{n=0}^{\infty}n\binom{a}{n}x^{n}$$
$$=\sum_{n=0}^{\infty}\left[(n+1)\binom{a}{n+1}+n\binom{a}{n}\right]x^n=a\sum_{n=0}^{\infty}\binom{a}{n}x^n=aT_a(x).$$

Moreover,

$$T_a(0)=\binom{a}{0}=1.$$

(c)

$$\frac{d}{dx}\left(\frac{T_a(x)}{(1+x)^a}\right)=\frac{(1+x)^aT_a'(x)-a(1+x)^{a-1}T_a(x)}{(1+x)^{2a}}=\frac{(1+x)T_a'(x)-aT_a(x)}{(1+x)^{a+1}}=0.$$

Thus,

$$\frac{T_a(x)}{(1+x)^a}=C,$$

for some constant C. For $x=0$,

$$\frac{T_a(0)}{(1+0)^a}=\frac{1}{1}=1,\ \text{so } C=1.$$

Finally, $T_a(x)=(1+x)^a$.

88. The function $G(k)=\int_0^{\pi/2}\sqrt{1-k^2\sin^2 t}\,dt$ is called an **elliptic function of the second kind**. Prove that for $|k|<1$,

$$G(k)=\frac{\pi}{2}-\frac{\pi}{2}\sum_{n=1}^{\infty}\left(\frac{1\cdot 3\cdots(2n-1)}{2\cdots 4\cdot(2n)}\right)^2\frac{k^{2n}}{2n-1}$$

SOLUTION For $|k|<1$, $|k^2\sin^2 t|<1$ for all t. Substituting $-k^2\sin^2 t$ for t in the binomial series for $a=\frac{1}{2}$, we find

$$\sqrt{1-k^2\sin^2 t}=1+\sum_{n=1}^{\infty}\binom{\frac{1}{2}}{n}\left(-k^2\sin^2 t\right)^n$$
$$=1+\sum_{n=1}^{\infty}(-1)^n\frac{\frac{1}{2}\left(\frac{1}{2}-1\right)\left(\frac{1}{2}-2\right)\cdots\left(\frac{1}{2}-n+1\right)}{n!}k^{2n}\sin^{2n}t$$
$$=1+\sum_{n=1}^{\infty}(-1)^n\frac{1(1-2)(1-4)\cdots(1-2(n-1))}{2^n n!}k^{2n}\sin^{2n}t$$
$$=1+\sum_{n=1}^{\infty}(-1)^n(-1)^{n-1}\frac{(2-1)(4-1)\cdots(2n-3)}{2^n n!}k^{2n}\sin^{2n}t$$
$$=1-\sum_{n=1}^{\infty}\frac{1\cdot 3\cdot 5\cdots(2n-3)}{2\cdot 4\cdot 6\cdots(2n)}k^{2n}\sin^{2n}t.$$

Integrating from 0 to $\frac{\pi}{2}$ term-by-term, we obtain

$$G(k) = \frac{\pi}{2} - \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdots (2n-3)}{2 \cdot 4 \cdot 6 \cdots (2n)} k^{2n} \int_0^{\pi/2} \sin^{2n} t\, dt.$$

Finally, using the formula

$$\int_0^{\pi/2} \sin^{2n} t\, dt = \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \frac{\pi}{2},$$

we arrive at

$$G(k) = \frac{\pi}{2} - \frac{\pi}{2} \sum_{n=1}^{\infty} \left(\frac{1 \cdot 3 \cdot 5 \cdots (2n-3)}{2 \cdot 4 \cdot 6 \cdots (2n)} \right)^2 (2n-1) k^{2n} = \frac{\pi}{2} - \frac{\pi}{2} \sum_{n=1}^{\infty} \left(\frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \right)^2 \frac{k^{2n}}{2n-1}.$$

89. Assume that $a < b$ and let L be the arc length (circumference) of the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$ shown in Figure 5. There is no explicit formula for L, but it is known that $L = 4bG(k)$, with $G(k)$ as in Exercise 88 and $k = \sqrt{1 - a^2/b^2}$. Use the first three terms of the expansion of Exercise 88 to estimate L when $a = 4$ and $b = 5$.

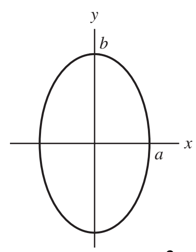


FIGURE 5 The ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$.

SOLUTION With $a = 4$ and $b = 5$,

$$k = \sqrt{1 - \frac{4^2}{5^2}} = \frac{3}{5},$$

and the arc length of the ellipse $\left(\frac{x}{4}\right)^2 + \left(\frac{y}{5}\right)^2 = 1$ is

$$L = 20G\left(\frac{3}{5}\right) = 20\left(\frac{\pi}{2} - \frac{\pi}{2}\sum_{n=1}^{\infty}\left(\frac{1 \cdot 3 \cdots (2n-1)}{2 \cdot 4 \cdots (2n)}\right)^2 \frac{\left(\frac{3}{5}\right)^{2n}}{2n-1}\right).$$

Using the first three terms in the series for $G(k)$ gives

$$L \approx 10\pi - 10\pi\left(\left(\frac{1}{2}\right)^2 \cdot \frac{(3/5)^2}{1} + \left(\frac{1 \cdot 3}{2 \cdot 4}\right)^2 \cdot \frac{(3/5)^4}{3}\right) = 10\pi\left(1 - \frac{9}{100} - \frac{243}{40{,}000}\right) = \frac{36{,}157\pi}{4000} \approx 28.398.$$

90. Use Exercise 88 to prove that if $a < b$ and a/b is near 1 (a nearly circular ellipse), then

$$L \approx \frac{\pi}{2}\left(3b + \frac{a^2}{b}\right)$$

Hint: Use the first two terms of the series for $G(k)$.

SOLUTION From the previous exercise, we know that

$$L = 4bG(k), \quad \text{where} \quad k = \sqrt{1 - \frac{a^2}{b^2}}.$$

Following the hint and using only the first two terms of the series expansion for $G(k)$ from Exercise 88, we find

$$L \approx 4b\left(\frac{\pi}{2} - \frac{\pi}{2}\left(\frac{1}{2}\right)^2 k^2\right) = \frac{\pi}{2}\left(4b - b\left(1 - \frac{a^2}{b^2}\right)\right) = \frac{\pi}{2}\left(3b + \frac{a^2}{b}\right).$$

91. Irrationality of e Prove that e is an irrational number using the following argument by contradiction. Suppose that $e = M/N$, where M, N are nonzero integers.

(a) Show that $M!\,e^{-1}$ is a whole number.

(b) Use the power series for e^x at $x = -1$ to show that there is an integer B such that $M!\,e^{-1}$ equals

$$B + (-1)^{M+1}\left(\frac{1}{M+1} - \frac{1}{(M+1)(M+2)} + \cdots\right)$$

(c) Use your knowledge of alternating series with decreasing terms to conclude that $0 < |M!\,e^{-1} - B| < 1$ and observe that this contradicts (a). Hence, e is not equal to M/N.

SOLUTION Suppose that $e = M/N$, where M, N are nonzero integers.

(a) With $e = M/N$,

$$M!e^{-1} = M!\frac{N}{M} = (M-1)!N,$$

which is a whole number.

(b) Substituting $x = -1$ into the Maclaurin series for e^x and multiplying the resulting series by $M!$ yields

$$M!e^{-1} = M!\left(1 - 1 + \frac{1}{2!} - \frac{1}{3!} + \cdots + \frac{(-1)^k}{k!} + \cdots\right).$$

For all $k \le M$, $\dfrac{M!}{k!}$ is a whole number, so

$$M!\left(1 - 1 + \frac{1}{2!} - \frac{1}{3!} + \cdots + \frac{(-1)^k}{M!}\right)$$

is an integer. Denote this integer by B. Thus,

$$M!\,e^{-1} = B + M!\left(\frac{(-1)^{M+1}}{(M+1)!} + \frac{(-1)^{M+2}}{(M+2)!} + \cdots\right) = B + (-1)^{M+1}\left(\frac{1}{M+1} - \frac{1}{(M+1)(M+2)} + \cdots\right).$$

(c) The series for $M!\,e^{-1}$ obtained in part (b) is an alternating series with $a_n = \frac{M!}{n!}$. Using the error bound for an alternating series and noting that $B = S_M$, we have

$$\left|M!\,e^{-1} - B\right| \le a_{M+1} = \frac{1}{M+1} < 1.$$

This inequality implies that $M!\,e^{-1} - B$ is not a whole number; however, B is a whole number so $M!\,e^{-1}$ cannot be a whole number. We get a contradiction to the result in part (a), which proves that the original assumption that e is a rational number is false.

92. Use the result of Exercise 73 in Section 4.5 to show that the Maclaurin series of the function

$$f(x) = \begin{cases} e^{-1/x^2} & \text{for } x \ne 0 \\ 0 & \text{for } x = 0 \end{cases}$$

is $T(x) = 0$. This provides an example of a function $f(x)$ whose Maclaurin series converges but does not converge to $f(x)$ (except at $x = 0$).

SOLUTION By the referenced exercise, $f(x)$ has continuous derivatives of all orders at 0, and $f^{(n)}(0) = 0$ for all $n > 0$. But then the Maclaurin series is

$$f(x) = \sum_{n=0}^{\infty} \frac{f^{(n)}(0)}{n!}x^n = f(0) + \sum_{n=1}^{\infty} \frac{f^{(n)}(0)}{n!}x^n = 0$$

CHAPTER REVIEW EXERCISES

1. Let $a_n = \dfrac{n-3}{n!}$ and $b_n = a_{n+3}$. Calculate the first three terms in each sequence.

(a) a_n^2

(b) b_n

(c) $a_n b_n$

(d) $2a_{n+1} - 3a_n$

SOLUTION

(a)

$$a_1^2 = \left(\frac{1-3}{1!}\right)^2 = (-2)^2 = 4;$$
$$a_2^2 = \left(\frac{2-3}{2!}\right)^2 = \left(-\frac{1}{2}\right)^2 = \frac{1}{4};$$
$$a_3^2 = \left(\frac{3-3}{3!}\right)^2 = 0.$$

(b)

$$b_1 = a_4 = \frac{4-3}{4!} = \frac{1}{24};$$
$$b_2 = a_5 = \frac{5-3}{5!} = \frac{1}{60};$$
$$b_3 = a_6 = \frac{6-3}{6!} = \frac{1}{240}.$$

(c) Using the formula for a_n and the values in (b) we obtain:

$$a_1b_1 = \frac{1-3}{1!}\cdot\frac{1}{24} = -\frac{1}{12};$$
$$a_2b_2 = \frac{2-3}{2!}\cdot\frac{1}{60} = -\frac{1}{120};$$
$$a_3b_3 = \frac{3-3}{3!}\cdot\frac{1}{240} = 0.$$

(d)

$$2a_2 - 3a_1 = 2\left(-\frac{1}{2}\right) - 3(-2) = 5;$$
$$2a_3 - 3a_2 = 2\cdot 0 - 3\left(-\frac{1}{2}\right) = \frac{3}{2};$$
$$2a_4 - 3a_3 = 2\cdot\frac{1}{24} - 3\cdot 0 = \frac{1}{12}.$$

2. Prove that $\lim_{n\to\infty}\frac{2n-1}{3n+2} = \frac{2}{3}$ using the limit definition.

SOLUTION Note

$$\left|\frac{2n-1}{3n+2} - \frac{2}{3}\right| = \left|\frac{6n-3-2(3n+2)}{3(3n+2)}\right| = \left|-\frac{7}{3(3n+2)}\right| = \frac{7}{3(3n+2)} < \frac{7}{9n}.$$

Therefore, to have $\left|a_n - \frac{2}{3}\right| < \epsilon$, we need

$$\frac{7}{9n} < \epsilon \quad \text{or} \quad n > \frac{7}{9\epsilon}.$$

Thus, let $\epsilon > 0$ and take $M = \frac{7}{9\epsilon}$. Then, whenever $n > M$,

$$\left|\frac{2n-1}{3n+2} - \frac{2}{3}\right| = \frac{7}{3(3n+2)} < \frac{7}{9n} < \frac{7}{9}\cdot\frac{9\epsilon}{7} = \epsilon.$$

In Exercises 3–8, compute the limit (or state that it does not exist) assuming that $\lim_{n\to\infty} a_n = 2$.

3. $\lim_{n\to\infty}(5a_n - 2a_n^2)$

SOLUTION

$$\lim_{n\to\infty}\left(5a_n - 2a_n^2\right) = 5\lim_{n\to\infty} a_n - 2\lim_{n\to\infty} a_n^2 = 5\lim_{n\to\infty} a_n - 2\left(\lim_{n\to\infty} a_n\right)^2 = 5\cdot 2 - 2\cdot 2^2 = 2.$$

4. $\displaystyle\lim_{n\to\infty} \frac{1}{a_n}$

SOLUTION $\displaystyle\lim_{n\to\infty} \frac{1}{a_n} = \frac{1}{\lim_{n\to\infty} a_n} = \frac{1}{2}.$

5. $\displaystyle\lim_{n\to\infty} e^{a_n}$

SOLUTION The function $f(x) = e^x$ is continuous, hence:

$$\lim_{n\to\infty} e^{a_n} = e^{\lim_{n\to\infty} a_n} = e^2.$$

6. $\displaystyle\lim_{n\to\infty} \cos(\pi a_n)$

SOLUTION The function $f(x) = \cos(\pi x)$ is continuous, hence:

$$\lim_{n\to\infty} \cos(\pi a_n) = \cos\left(\pi \lim_{n\to\infty} a_n\right) = \cos(2\pi) = 1.$$

7. $\displaystyle\lim_{n\to\infty} (-1)^n a_n$

SOLUTION Because $\displaystyle\lim_{n\to\infty} a_n \neq 0$, it follows that $\displaystyle\lim_{n\to\infty} (-1)^n a_n$ does not exist.

8. $\displaystyle\lim_{n\to\infty} \frac{a_n + n}{a_n + n^2}$

SOLUTION Because the sequence $\{a_n\}$ converges, $\{a_n\}$ is bounded and

$$\lim_{n\to\infty} \frac{a_n}{n^2} = 0.$$

Thus,

$$\lim_{n\to\infty} \frac{a_n + n}{a_n + n^2} = \lim_{n\to\infty} \frac{\frac{a_n}{n^2} + \frac{1}{n}}{\frac{a_n}{n^2} + 1} = \frac{0+0}{0+1} = 0.$$

In Exercises 9–22, determine the limit of the sequence or show that the sequence diverges.

9. $a_n = \sqrt{n+5} - \sqrt{n+2}$

SOLUTION First rewrite a_n as follows:

$$a_n = \frac{\left(\sqrt{n+5} - \sqrt{n+2}\right)\left(\sqrt{n+5} + \sqrt{n+2}\right)}{\sqrt{n+5} + \sqrt{n+2}} = \frac{(n+5) - (n+2)}{\sqrt{n+5} + \sqrt{n+2}} = \frac{3}{\sqrt{n+5} + \sqrt{n+2}}.$$

Thus,

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} \frac{3}{\sqrt{n+5} + \sqrt{n+2}} = 0.$$

10. $a_n = \dfrac{3n^3 - n}{1 - 2n^3}$

SOLUTION $\displaystyle\lim_{n\to\infty} a_n = \lim_{n\to\infty} \frac{3n^3 - n}{1 - 2n^3} = -\frac{3}{2}.$

11. $a_n = 2^{1/n^2}$

SOLUTION The function $f(x) = 2^x$ is continuous, so

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} 2^{1/n^2} = 2^{\lim_{n\to\infty}(1/n^2)} = 2^0 = 1.$$

12. $a_n = \dfrac{10^n}{n!}$

SOLUTION For $n > 10$, write a_n as

$$0 \le a_n = \underbrace{\left(\frac{10}{1} \cdot \frac{10}{2} \cdot \cdots \cdot \frac{10}{10}\right)}_{\text{equals } \frac{10^{10}}{10!}} \underbrace{\left(\frac{10}{11}\right) \cdot \left(\frac{10}{12}\right) \cdot \cdots \cdot \left(\frac{10}{n}\right)}_{\text{each factor is less than 1}} < \frac{10^{10}}{10!} \cdot \frac{10}{n} = \frac{10^{10}}{9!n};$$

Thus, by the Squeeze Theorem, $\displaystyle\lim_{n\to\infty} a_n = 0.$

13. $b_m = 1 + (-1)^m$

SOLUTION Because $1 + (-1)^m$ is equal to 0 for m odd and is equal to 2 for m even, the sequence $\{b_m\}$ does not approach one limit; hence this sequence diverges.

14. $b_m = \dfrac{1 + (-1)^m}{m}$

SOLUTION The numerator is equal to zero for m odd and is equal to 2 for m even. Therefore,

$$0 \le \frac{1 + (-1)^m}{m} \le \frac{2}{m},$$

and by the Squeeze Theorem, $\lim_{m\to\infty} b_m = 0$.

15. $b_n = \tan^{-1}\left(\dfrac{n+2}{n+5}\right)$

SOLUTION The function $\tan^{-1}x$ is continuous, so

$$\lim_{n\to\infty} b_n = \lim_{n\to\infty} \tan^{-1}\left(\frac{n+2}{n+5}\right) = \tan^{-1}\left(\lim_{n\to\infty}\frac{n+2}{n+5}\right) = \tan^{-1} 1 = \frac{\pi}{4}.$$

16. $a_n = \dfrac{100^n}{n!} - \dfrac{3+\pi^n}{5^n}$

SOLUTION For $n > 100$,

$$0 \le \frac{100^n}{n!} = \left(\frac{100}{1}\cdot\frac{100}{2}\cdots\frac{100}{100}\right)\frac{100}{101}\cdot\frac{100}{102}\cdot\frac{100}{n} < \frac{100^{100}}{99!n};$$

therefore,

$$\lim_{n\to\infty}\frac{100^n}{n!} = 0$$

by the Squeeze Theorem. Moreover,

$$\lim_{n\to\infty}\left(\frac{3+\pi^n}{5^n}\right) = \lim_{n\to\infty}\frac{3}{5^n} + \lim_{n\to\infty}\left(\frac{\pi}{5}\right)^n = 0 + 0 = 0.$$

Thus,

$$\lim_{n\to\infty} a_n = 0 + 0 = 0.$$

17. $b_n = \sqrt{n^2+n} - \sqrt{n^2+1}$

SOLUTION Rewrite b_n as

$$b_n = \frac{\left(\sqrt{n^2+n} - \sqrt{n^2+1}\right)\left(\sqrt{n^2+n} + \sqrt{n^2+1}\right)}{\sqrt{n^2+n} + \sqrt{n^2+1}} = \frac{\left(n^2+n\right) - \left(n^2+1\right)}{\sqrt{n^2+n} + \sqrt{n^2+1}} = \frac{n-1}{\sqrt{n^2+n} + \sqrt{n^2+1}}.$$

Then

$$\lim_{n\to\infty} b_n = \lim_{n\to\infty}\frac{\frac{n}{n} - \frac{1}{n}}{\sqrt{\frac{n^2}{n^2} + \frac{n}{n^2}} + \sqrt{\frac{n^2}{n^2} + \frac{1}{n^2}}} = \lim_{n\to\infty}\frac{1 - \frac{1}{n}}{\sqrt{1 + \frac{1}{n}} + \sqrt{1 + \frac{1}{n^2}}} = \frac{1-0}{\sqrt{1+0} + \sqrt{1+0}} = \frac{1}{2}.$$

18. $c_n = \sqrt{n^2+n} - \sqrt{n^2-n}$

SOLUTION Rewrite c_n as

$$c_n = \frac{\left(\sqrt{n^2+n} - \sqrt{n^2-n}\right)\left(\sqrt{n^2+n} + \sqrt{n^2-n}\right)}{\sqrt{n^2+n} + \sqrt{n^2-n}} = \frac{\left(n^2+n\right) - \left(n^2-n\right)}{\sqrt{n^2+n} + \sqrt{n^2-n}} = \frac{2n}{\sqrt{n^2+n} + \sqrt{n^2-n}}.$$

Then

$$\lim_{n\to\infty} c_n = \lim_{n\to\infty}\frac{\frac{2n}{n}}{\sqrt{\frac{n^2}{n^2} + \frac{n}{n^2}} + \sqrt{\frac{n^2}{n^2} - \frac{n}{n^2}}} = \lim_{n\to\infty}\frac{2}{\sqrt{1 + \frac{1}{n}} + \sqrt{1 - \frac{1}{n}}} = \frac{2}{\sqrt{1+0} + \sqrt{1-0}} = 1.$$

19. $b_m = \left(1 + \frac{1}{m}\right)^{3m}$

SOLUTION $\lim_{m\to\infty} b_m = \lim_{m\to\infty}\left(1 + \frac{1}{m}\right)^m = e.$

20. $c_n = \left(1 + \frac{3}{n}\right)^n$

SOLUTION Write

$$c_n = \left(1 + \frac{1}{n/3}\right)^n = \left[\left(1 + \frac{1}{n/3}\right)^{n/3}\right]^3.$$

Then, because x^3 is a continuous function,

$$\lim_{n\to\infty} c_n = \left[\lim_{n\to\infty}\left(1 + \frac{1}{n/3}\right)^{n/3}\right]^3 = e^3.$$

21. $b_n = n\big(\ln(n+1) - \ln n\big)$

SOLUTION Write

$$b_n = n\ln\left(\frac{n+1}{n}\right) = \frac{\ln\left(1 + \frac{1}{n}\right)}{\frac{1}{n}}.$$

Using L'Hôpital's Rule, we find

$$\lim_{n\to\infty} b_n = \lim_{n\to\infty}\frac{\ln\left(1+\frac{1}{n}\right)}{\frac{1}{n}} = \lim_{x\to\infty}\frac{\ln\left(1+\frac{1}{x}\right)}{\frac{1}{x}} = \lim_{x\to\infty}\frac{\left(1+\frac{1}{x}\right)^{-1}\cdot\left(-\frac{1}{x^2}\right)}{-\frac{1}{x^2}} = \lim_{x\to\infty}\left(1+\frac{1}{x}\right)^{-1} = 1.$$

22. $c_n = \frac{\ln(n^2+1)}{\ln(n^3+1)}$

SOLUTION Using L'Hôpital's Rule, we find

$$\lim_{n\to\infty} c_n = \lim_{n\to\infty}\frac{\ln(n^2+1)}{\ln(n^3+1)} = \lim_{n\to\infty}\frac{2n/(n^2+1)}{3n^2/(n^3+1)} = \lim_{n\to\infty}\frac{2n^4+2n}{3n^4+3n^2} = \lim_{n\to\infty}\frac{2+2n^{-3}}{3+3n^{-2}} = \frac{2}{3}$$

23. Use the Squeeze Theorem to show that $\lim_{n\to\infty}\frac{\arctan(n^2)}{\sqrt{n}} = 0.$

SOLUTION For all x,

$$-\frac{\pi}{2} < \arctan x < \frac{\pi}{2},$$

so

$$-\frac{\pi/2}{\sqrt{n}} < \frac{\arctan(n^2)}{\sqrt{n}} < \frac{\pi/2}{\sqrt{n}},$$

for all n. Because

$$\lim_{n\to\infty}\left(-\frac{\pi/2}{\sqrt{n}}\right) = \lim_{n\to\infty}\frac{\pi/2}{\sqrt{n}} = 0,$$

it follows by the Squeeze Theorem that

$$\lim_{n\to\infty}\frac{\arctan(n^2)}{\sqrt{n}} = 0.$$

24. Give an example of a divergent sequence $\{a_n\}$ such that $\{\sin a_n\}$ is convergent.

SOLUTION Let $a_n = (-1)^n\pi$. This is an alternating series, which does not approach 0, hence it diverges. However, a_n is a multiple of π for every n, and thus, $\sin a_n = 0$. Since $\{\sin a_n\}$ is a constant sequence, it converges.

25. Calculate $\lim_{n\to\infty} \frac{a_{n+1}}{a_n}$, where $a_n = \frac{1}{2}3^n - \frac{1}{3}2^n$.

SOLUTION Because

$$\frac{1}{2}3^n - \frac{1}{3}2^n \geq \frac{1}{2}3^n - \frac{1}{3}3^n = \frac{3^n}{6}$$

and

$$\lim_{n\to\infty} \frac{3^n}{6} = \infty,$$

we conclude that $\lim_{n\to\infty} a_n = \infty$, so L'Hôpital's rule may be used:

$$\lim_{n\to\infty} \frac{a_{n+1}}{a_n} = \lim_{n\to\infty} \frac{\frac{1}{2}3^{n+1} - \frac{1}{3}2^{n+1}}{\frac{1}{2}3^n - \frac{1}{3}2^n} = \lim_{n\to\infty} \frac{3^{n+2} - 2^{n+2}}{3^{n+1} - 2^{n+1}} = \lim_{n\to\infty} \frac{3 - 2\left(\frac{2}{3}\right)^{n+1}}{1 - \left(\frac{2}{3}\right)^{n+1}} = \frac{3-0}{1-0} = 3.$$

26. Define $a_{n+1} = \sqrt{a_n + 6}$ with $a_1 = 2$.

(a) Compute a_n for $n = 2, 3, 4, 5$.

(b) Show that $\{a_n\}$ is increasing and is bounded by 3.

(c) Prove that $\lim_{n\to\infty} a_n$ exists and find its value.

SOLUTION

(a) We compute the first four values of a_n recursively:

$$a_2 = \sqrt{a_1 + 6} = \sqrt{2+6} = \sqrt{8} = 2\sqrt{2} \approx 2.828427;$$

$$a_3 = \sqrt{a_2 + 6} = \sqrt{2\sqrt{2} + 6} \approx 2.971267;$$

$$a_4 = \sqrt{a_3 + 6} = \sqrt{\sqrt{2\sqrt{2} + 6} + 6} \approx 2.995207;$$

$$a_5 = \sqrt{a_4 + 6} = \sqrt{\sqrt{\sqrt{2\sqrt{2} + 6} + 6} + 6} \approx 2.999201.$$

(b) By part (a) and the given data, $a_2 \approx 2.8$ and $a_1 = 2$, so $a_2 > a_1$. Now, suppose that $a_k > a_{k-1}$; then

$$a_{k+1} = \sqrt{a_k + 6} > \sqrt{a_{k-1} + 6} = a_k.$$

Thus, by mathematical induction, $a_{n+1} > a_n$ for all n and $\{a_n\}$ is increasing.

Next, note that $a_1 = 2 < 3$. Suppose $a_k < 3$, then

$$a_{k+1} = \sqrt{a_k + 6} < \sqrt{3+6} = 3.$$

Thus, by mathematical induction, $a_n < 3$ for all n.

(c) Since $\{a_n\}$ is increasing and has an upper bound, $\{a_n\}$ converges. Let

$$L = \lim_{n\to\infty} a_n.$$

Then,

$$\begin{aligned} L &= \sqrt{L+6} \\ L^2 &= L + 6 \\ L^2 - L - 6 &= 0 \\ (L-3)(L+2) &= 0 \end{aligned}$$

so $L = 3$ or $L = -2$; however, the sequence is increasing and its first term is positive, so -2 cannot be the limit. Therefore,

$$\lim_{n\to\infty} a_n = 3.$$

27. Calculate the partial sums S_4 and S_7 of the series $\sum_{n=1}^{\infty} \frac{n-2}{n^2+2n}$.

SOLUTION

$$S_4 = -\frac{1}{3} + 0 + \frac{1}{15} + \frac{2}{24} = -\frac{11}{60} = -0.183333;$$

$$S_7 = -\frac{1}{3} + 0 + \frac{1}{15} + \frac{2}{24} + \frac{3}{35} + \frac{4}{48} + \frac{5}{63} = \frac{287}{4410} = 0.065079.$$

28. Find the sum $1 - \frac{1}{4} + \frac{1}{4^2} - \frac{1}{4^3} + \cdots$.

SOLUTION This is a geometric series with $r = -\frac{1}{4}$. Therefore,

$$1 - \frac{1}{4} + \frac{1}{4^2} - \frac{1}{4^3} + \cdots = \frac{1}{1-(-\frac{1}{4})} = \frac{4}{5}.$$

29. Find the sum $\frac{4}{9} + \frac{8}{27} + \frac{16}{81} + \frac{32}{243} + \cdots$.

SOLUTION This is a geometric series with common ratio $r = \frac{2}{3}$. Therefore,

$$\frac{4}{9} + \frac{8}{27} + \frac{16}{81} + \frac{32}{243} + \cdots = \frac{\frac{4}{9}}{1-\frac{2}{3}} = \frac{4}{3}.$$

30. Find the sum $\sum_{n=2}^{\infty} \left(\frac{2}{e}\right)^n$.

SOLUTION This is a geometric series with common ratio $r = \frac{2}{e}$. Therefore,

$$\sum_{n=2}^{\infty} \left(\frac{2}{e}\right)^n = \frac{\left(\frac{2}{e}\right)^2}{1-\frac{2}{e}} = \frac{\frac{4}{e^2}}{1-\frac{2}{e}} = \frac{4}{e^2-2e}.$$

31. Find the sum $\sum_{n=-1}^{\infty} \frac{2^{n+3}}{3^n}$.

SOLUTION Note

$$\sum_{n=-1}^{\infty} \frac{2^{n+3}}{3^n} = 2^3 \sum_{n=-1}^{\infty} \frac{2^n}{3^n} = 8 \sum_{n=-1}^{\infty} \left(\frac{2}{3}\right)^n;$$

therefore,

$$\sum_{n=-1}^{\infty} \frac{2^{n+3}}{3^n} = 8 \cdot \frac{3}{2} \cdot \frac{1}{1-\frac{2}{3}} = 36.$$

32. Show that $\sum_{n=1}^{\infty} \left(b - \tan^{-1} n^2\right)$ diverges if $b \neq \frac{\pi}{2}$.

SOLUTION Note

$$\lim_{n\to\infty} \left(b - \tan^{-1} n^2\right) = b - \lim_{n\to\infty} \tan^{-1} n^2 = b - \frac{\pi}{2}.$$

If $b \neq \frac{\pi}{2}$, then the limit of the terms in the series is not 0; hence, the series diverges by the Divergence Test.

33. Give an example of divergent series $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ such that $\sum_{n=1}^{\infty} (a_n + b_n) = 1$.

SOLUTION Let $a_n = \left(\frac{1}{2}\right)^n + 1$, $b_n = -1$. The corresponding series diverge by the Divergence Test; however,

$$\sum_{n=1}^{\infty} (a_n + b_n) = \sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^n = \frac{\frac{1}{2}}{1-\frac{1}{2}} = 1.$$

34. Let $S = \sum_{n=1}^{\infty} \left(\frac{1}{n} - \frac{1}{n+2} \right)$. Compute S_N for $N = 1, 2, 3, 4$. Find S by showing that

$$S_N = \frac{3}{2} - \frac{1}{N+1} - \frac{1}{N+2}$$

SOLUTION

$$S_1 = 1 - \frac{1}{3} = \frac{2}{3};$$
$$S_2 = \left(1 - \frac{1}{3}\right) + \left(\frac{1}{2} - \frac{1}{4}\right) = \frac{3}{2} - \frac{7}{12} = \frac{11}{12};$$
$$S_3 = \left(1 - \frac{1}{3}\right) + \left(\frac{1}{2} - \frac{1}{4}\right) + \left(\frac{1}{3} - \frac{1}{5}\right) = \frac{3}{2} - \frac{9}{20} = \frac{21}{20};$$
$$S_4 = \left(1 - \frac{1}{3}\right) + \left(\frac{1}{2} - \frac{1}{4}\right) + \left(\frac{1}{3} - \frac{1}{5}\right) + \left(\frac{1}{4} - \frac{1}{6}\right) = \frac{3}{2} - \frac{11}{30} = \frac{17}{15}.$$

The general term in the sequence of partial sums is

$$\begin{aligned} S_N &= \left(1 - \frac{1}{3}\right) + \left(\frac{1}{2} - \frac{1}{4}\right) + \left(\frac{1}{3} - \frac{1}{5}\right) + \left(\frac{1}{4} - \frac{1}{6}\right) + \cdots + \left(\frac{1}{N-1} - \frac{1}{N+1}\right) + \left(\frac{1}{N} - \frac{1}{N+2}\right) \\ &= 1 + \frac{1}{2} - \frac{1}{N+1} - \frac{1}{N+2} = \frac{3}{2} - \left(\frac{1}{N+1} + \frac{1}{N+2}\right). \end{aligned}$$

Finally,

$$S = \lim_{N\to\infty} S_N = \lim_{N\to\infty} \left[\frac{3}{2} - \left(\frac{1}{N+1} + \frac{1}{N+2}\right)\right] = \frac{3}{2}.$$

35. Evaluate $S = \sum_{n=3}^{\infty} \frac{1}{n(n+3)}$.

SOLUTION Note that

$$\frac{1}{n(n+3)} = \frac{1}{3}\left(\frac{1}{n} - \frac{1}{n+3}\right)$$

so that

$$\begin{aligned} \sum_{n=3}^{N} \frac{1}{n(n+3)} &= \frac{1}{3} \sum_{n=3}^{N} \left(\frac{1}{n} - \frac{1}{n+3}\right) \\ &= \frac{1}{3}\left(\left(\frac{1}{3} - \frac{1}{6}\right) + \left(\frac{1}{4} - \frac{1}{7}\right) + \left(\frac{1}{5} - \frac{1}{8}\right)\right. \\ &\qquad \left.\left(\frac{1}{6} - \frac{1}{9}\right) + \cdots + \left(\frac{1}{N-1} - \frac{1}{N+2}\right) + \left(\frac{1}{N} - \frac{1}{N+3}\right)\right) \\ &= \frac{1}{3}\left(\frac{1}{3} + \frac{1}{4} + \frac{1}{5} - \frac{1}{N+1} - \frac{1}{N+2} - \frac{1}{N+3}\right) \end{aligned}$$

Thus

$$\begin{aligned} \sum_{n=3}^{\infty} \frac{1}{n(n+3)} &= \frac{1}{3} \lim_{N\to\infty} \sum_{n=3}^{N} \left(\frac{1}{n} - \frac{1}{n+3}\right) \\ &= \frac{1}{3}\left(\frac{1}{3} + \frac{1}{4} + \frac{1}{5} - \frac{1}{N+1} - \frac{1}{N+2} - \frac{1}{N+3}\right) = \frac{1}{3}\left(\frac{1}{3} + \frac{1}{4} + \frac{1}{5}\right) = \frac{47}{180} \end{aligned}$$

36. Find the total area of the infinitely many circles on the interval [0, 1] in Figure 1.

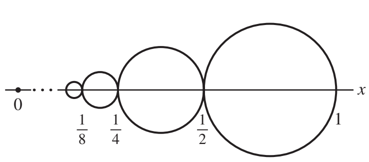

FIGURE 1

SOLUTION The diameter of the largest circle is $\frac{1}{2}$, and the diameter of each smaller circle is $\frac{1}{2}$ the diameter of the previous circle; thus, the diameter of the nth circle (for $n \geq 1$) is $\frac{1}{2^n}$ and the area is

$$\pi\left(\frac{1}{2^{n+1}}\right)^2 = \frac{\pi}{4^{n+1}}.$$

The total area of the circles is

$$\sum_{n=1}^{\infty} \frac{\pi}{4^{n+1}} = \frac{\pi}{4}\sum_{n=1}^{\infty}\left(\frac{1}{4}\right)^n = \frac{\pi}{4}\cdot\frac{\frac{1}{4}}{1-\frac{1}{4}} = \frac{\pi}{12}.$$

In Exercises 37–40, use the Integral Test to determine whether the infinite series converges.

37. $\displaystyle\sum_{n=1}^{\infty} \frac{n^2}{n^3+1}$

SOLUTION Let $f(x) = \frac{x^2}{x^3+1}$. This function is continuous and positive for $x \geq 1$. Because

$$f'(x) = \frac{(x^3+1)(2x) - x^2(3x^2)}{(x^3+1)^2} = \frac{x(2-x^3)}{(x^3+1)^2},$$

we see that $f'(x) < 0$ and f is decreasing on the interval $x \geq 2$. Therefore, the Integral Test applies on the interval $x \geq 2$. Now,

$$\int_2^{\infty} \frac{x^2}{x^3+1}\,dx = \lim_{R\to\infty}\int_2^R \frac{x^2}{x^3+1}\,dx = \frac{1}{3}\lim_{R\to\infty}\Big(\ln(R^3+1) - \ln 9\Big) = \infty.$$

The integral diverges; hence, the series $\displaystyle\sum_{n=2}^{\infty}\frac{n^2}{n^3+1}$ diverges, as does the series $\displaystyle\sum_{n=1}^{\infty}\frac{n^2}{n^3+1}$.

38. $\displaystyle\sum_{n=1}^{\infty} \frac{n^2}{(n^3+1)^{1.01}}$

SOLUTION Let $f(x) = \frac{x^2}{(x^3+1)^{1.01}}$. This function is continuous and positive for $x \geq 1$. Because

$$f'(x) = \frac{(x^3+1)^{1.01}(2x) - x^2\cdot 1.01(x^3+1)^{0.01}(3x^2)}{(x^3+1)^{2.02}} = \frac{x(x^3+1)^{0.01}(2-1.03x^3)}{(x^3+1)^{2.02}},$$

we see that $f'(x) < 0$ and f is decreasing on the interval $x \geq 2$. Therefore, the Integral Test applies on the interval $x \geq 2$. Now,

$$\int_2^{\infty}\frac{x^2}{(x^3+1)^{1.01}}\,dx = \lim_{R\to\infty}\int_2^R \frac{x^2}{(x^3+1)^{1.01}}\,dx = -\frac{1}{0.03}\lim_{R\to\infty}\left(\frac{1}{(R^3+1)^{0.01}} - \frac{1}{9^{0.01}}\right) = \frac{1}{0.03\cdot 9^{0.01}}.$$

The integral converges; hence, the series $\displaystyle\sum_{n=2}^{\infty}\frac{n^2}{(n^3+1)^{1.01}}$ converges, as does the series $\displaystyle\sum_{n=1}^{\infty}\frac{n^2}{(n^3+1)^{1.01}}$.

39. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{(n+2)(\ln(n+2))^3}$

SOLUTION Let $f(x) = \frac{1}{(x+2)\ln^3(x+2)}$. Using the substitution $u = \ln(x+2)$, so that $du = \frac{1}{x+2}\,dx$, we have

$$\int_0^{\infty} f(x)\,dx = \int_{\ln 2}^{\infty}\frac{1}{u^3}\,du = \lim_{R\to\infty}\int_{\ln 2}^{\infty}\frac{1}{u^3}\,du = \lim_{R\to\infty}\left(-\frac{1}{2u^2}\Big|_{\ln 2}^{R}\right)$$

$$= \lim_{R\to\infty}\left(\frac{1}{2(\ln 2)^2} - \frac{1}{2(\ln R)^2}\right) = \frac{1}{2(\ln 2)^2}$$

Since the integral of $f(x)$ converges, so does the series.

40. $\displaystyle\sum_{n=1}^{\infty} \frac{n^3}{e^{n^4}}$

SOLUTION Let $f(x) = x^3 e^{-x^4}$. This function is continuous and positive for $x \ge 1$. Because

$$f'(x) = x^3 \left(-4x^3 e^{-x^4}\right) + 3x^2 e^{-x^4} = x^2 e^{-x^4}\left(3 - 4x^4\right),$$

we see that $f'(x) < 0$ and f is decreasing on the interval $x \ge 1$. Therefore, the Integral Test applies on the interval $x \ge 1$. Now,

$$\int_1^{\infty} x^3 e^{-x^4}\,dx = \lim_{R\to\infty} \int_1^R x^3 e^{-x^4}\,dx = -\frac{1}{4}\lim_{R\to\infty}\left(e^{-R^4} - e^{-1}\right) = \frac{1}{4e}.$$

The integral converges; hence, the series $\displaystyle\sum_{n=1}^{\infty} \frac{n^3}{e^{n^4}}$ also converges.

In Exercises 41–48, use the Comparison or Limit Comparison Test to determine whether the infinite series converges.

41. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{(n+1)^2}$

SOLUTION For all $n \ge 1$,

$$0 < \frac{1}{n+1} < \frac{1}{n} \quad \text{so} \quad \frac{1}{(n+1)^2} < \frac{1}{n^2}.$$

The series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a convergent p-series, so the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{(n+1)^2}$ converges by the Comparison Test.

42. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}+n}$

SOLUTION Apply the Limit Comparison Test with $a_n = \frac{1}{\sqrt{n}+n}$ and $b_n = \frac{1}{n}$. Now,

$$L = \lim_{n\to\infty} \frac{\frac{1}{\sqrt{n}+n}}{\frac{1}{n}} = \lim_{n\to\infty} \frac{n}{\sqrt{n}+n} = \lim_{n\to\infty} \frac{1}{\frac{1}{\sqrt{n}}+1} = 1.$$

Because $L > 0$ and $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n}$ is the divergent harmonic series, we conclude by the Limit Comparison Test that the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}+n}$ also diverges.

43. $\displaystyle\sum_{n=2}^{\infty} \frac{n^2+1}{n^{3.5}-2}$

SOLUTION Apply the Limit Comparison Test with $a_n = \frac{n^2+1}{n^{3.5}-2}$ and $b_n = \frac{1}{n^{1.5}}$. Now,

$$L = \lim_{n\to\infty} \frac{\frac{n^2+1}{n^{3.5}-2}}{\frac{1}{n^{1.5}}} = \lim_{n\to\infty} \frac{n^{3.5}+n^{1.5}}{n^{3.5}-2} = 1.$$

Because L exists and $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^{1.5}}$ is a convergent p-series, we conclude by the Limit Comparison Test that the series $\displaystyle\sum_{n=2}^{\infty} \frac{n^2+1}{n^{3.5}-2}$ also converges.

44. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n-\ln n}$

SOLUTION Since $0 \le \ln n \le n$ for all $n \ge 1$, we have $0 \le n - \ln n \le n$ and

$$\frac{1}{n} \le \frac{1}{n-\ln n}$$

The harmonic series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n}$ diverges, so we conclude by the Comparison Test that $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n-\ln n}$ also diverges.

45. $\displaystyle\sum_{n=2}^{\infty} \frac{n}{\sqrt{n^5+5}}$

SOLUTION For all $n \geq 2$,

$$\frac{n}{\sqrt{n^5+5}} < \frac{n}{n^{5/2}} = \frac{1}{n^{3/2}}.$$

The series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n^{3/2}}$ is a convergent p-series, so the series $\displaystyle\sum_{n=2}^{\infty} \frac{n}{\sqrt{n^5+5}}$ converges by the Comparison Test.

46. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{3^n - 2^n}$

SOLUTION Apply the Limit Comparison Test with $a_n = \frac{1}{3^n-2^n}$ and $b_n = \frac{1}{3^n}$. Then,

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{3^n}{3^n - 2^n} = \lim_{n\to\infty} \frac{1}{1 - \left(\frac{2}{3}\right)^n} = 1.$$

The series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{3^n}$ is a convergent geometric series; because L exists, we may therefore conclude by the Limit Comparison Test that the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{3^n - 2^n}$ also converges.

47. $\displaystyle\sum_{n=1}^{\infty} \frac{n^{10} + 10^n}{n^{11} + 11^n}$

SOLUTION Apply the Limit Comparison Test with $a_n = \frac{n^{10}+10^n}{n^{11}+11^n}$ and $b_n = \left(\frac{10}{11}\right)^n$. Then,

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{n^{10}+10^n}{n^{11}+11^n}}{\left(\frac{10}{11}\right)^n} = \lim_{n\to\infty} \frac{\frac{n^{10}+10^n}{10^n}}{\frac{n^{11}+11^n}{11^n}} = \lim_{n\to\infty} \frac{\frac{n^{10}}{10^n}+1}{\frac{n^{11}}{11^n}+1} = 1.$$

The series $\displaystyle\sum_{n=1}^{\infty} \left(\frac{10}{11}\right)^n$ is a convergent geometric series; because L exists, we may therefore conclude by the Limit Comparison Test that the series $\displaystyle\sum_{n=1}^{\infty} \frac{n^{10} + 10^n}{n^{11} + 11^n}$ also converges.

48. $\displaystyle\sum_{n=1}^{\infty} \frac{n^{20} + 21^n}{n^{21} + 20^n}$

SOLUTION Apply the Limit Comparison Theorem with $a_n = \frac{n^{20}+21^n}{n^{21}+20^n}$ and $b_n = \left(\frac{21}{20}\right)^n$. Then

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{n^{20}+21^n}{n^{21}+20^n}}{\left(\frac{21}{20}\right)^n} = \lim_{n\to\infty} \frac{\frac{n^{20}+21^n}{21^n}}{\frac{n^{21}+20^n}{20^n}} = \lim_{n\to\infty} \frac{\frac{n^{20}}{21^n}+1}{\frac{n^{21}}{20^n}+1} = 1$$

The series $\displaystyle\sum_{n=1}^{\infty} \left(\frac{21}{20}\right)^n$ is a divergent geometric series. Since $L = 1$, the two series either both converge or both diverge; thus, we may conclude from the Limit Comparison Test that the series $\displaystyle\sum_{n=1}^{\infty} \frac{n^{20} + 21^n}{n^{21} + 20^n}$ diverges.

49. Determine the convergence of $\displaystyle\sum_{n=1}^{\infty} \frac{2^n + n}{3^n - 2}$ using the Limit Comparison Test with $b_n = \left(\frac{2}{3}\right)^n$.

SOLUTION With $a_n = \frac{2^n+n}{3^n-2}$, we have

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{2^n + n}{3^n - 2} \cdot \frac{3^n}{2^n} = \lim_{n\to\infty} \frac{6^n + n3^n}{6^n - 2^{n+1}} = \lim_{n\to\infty} \frac{1 + n\left(\frac{1}{2}\right)^n}{1 - 2\left(\frac{1}{3}\right)^n} = 1$$

Since $L = 1$, the two series either both converge or both diverge. Since $\sum_{n=1}^{\infty} \left(\frac{2}{3}\right)^n$ is a convergent geometric series, the Limit Comparison Test tells us that $\sum_{n=1}^{\infty} \frac{2^n + n}{3^n - 2}$ also converges.

50. Determine the convergence of $\sum_{n=1}^{\infty} \frac{\ln n}{1.5^n}$ using the Limit Comparison Test with $b_n = \frac{1}{1.4^n}$.

SOLUTION With $a_n = \frac{\ln n}{1.5^n}$, and using L'Hôpital's Rule,

$$L = \lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\frac{\ln n}{1.5^n}}{\frac{1}{1.4^n}} = \lim_{n\to\infty} \frac{\ln n}{\left(\frac{1.5}{1.4}\right)^n}$$

$$= \lim_{n\to\infty} \frac{1/n}{\ln(1.5/1.4)\left(\frac{1.5}{1.4}\right)^n} = \frac{1}{\ln(1.5/1.4)} \lim_{n\to\infty} \frac{\left(\frac{1.4}{1.5}\right)^n}{n} = 0$$

Since $L < \infty$ and $\sum_{n=1}^{\infty} b_n$ is a convergent geometric series, it follows from the Limit Comparison Test that $\sum_{n=1}^{\infty} \frac{\ln n}{1.5^n}$ also converges.

51. Let $a_n = 1 - \sqrt{1 - \frac{1}{n}}$. Show that $\lim_{n\to\infty} a_n = 0$ and that $\sum_{n=1}^{\infty} a_n$ diverges. *Hint:* Show that $a_n \geq \frac{1}{2n}$.

SOLUTION

$$1 - \sqrt{1 - \frac{1}{n}} = 1 - \sqrt{\frac{n-1}{n}} = \frac{\sqrt{n} - \sqrt{n-1}}{\sqrt{n}} = \frac{n - (n-1)}{\sqrt{n}(\sqrt{n} + \sqrt{n-1})} = \frac{1}{n + \sqrt{n^2 - n}}$$

$$\geq \frac{1}{n + \sqrt{n^2}} = \frac{1}{2n}.$$

The series $\sum_{n=2}^{\infty} \frac{1}{2n}$ diverges, so the series $\sum_{n=2}^{\infty} \left(1 - \sqrt{1 - \frac{1}{n}}\right)$ also diverges by the Comparison Test.

52. Determine whether $\sum_{n=2}^{\infty} \left(1 - \sqrt{1 - \frac{1}{n^2}}\right)$ converges.

SOLUTION

$$1 - \sqrt{1 - \frac{1}{n^2}} = 1 - \sqrt{\frac{n^2 - 1}{n^2}} = \frac{n - \sqrt{n^2 - 1}}{n} = \frac{n^2 - \left(n^2 - 1\right)}{n\left(n + \sqrt{n^2 - 1}\right)}$$

$$= \frac{1}{n\left(n + \sqrt{n^2 - 1}\right)} = \frac{1}{n^2 + n\sqrt{n^2 - 1}} \leq \frac{1}{n^2}$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a convergent p-series, so the series $\sum_{n=2}^{\infty} \left(1 - \sqrt{1 - \frac{1}{n^2}}\right)$ also converges by the Comparison Test.

53. Let $S = \sum_{n=1}^{\infty} \frac{n}{(n^2 + 1)^2}$.

(a) Show that S converges.

(b) CAS Use Eq. (4) in Exercise 83 of Section 10.3 with $M = 99$ to approximate S. What is the maximum size of the error?

SOLUTION

(a) For $n \geq 1$,

$$\frac{n}{(n^2 + 1)^2} < \frac{n}{(n^2)^2} = \frac{1}{n^3}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^3}$ is a convergent p-series, so the series $\sum_{n=1}^{\infty} \frac{n}{(n^2 + 1)^2}$ also converges by the Comparison Test.

(b) With $a_n = \frac{n}{(n^2+1)^2}$, $f(x) = \frac{x}{(x^2+1)^2}$ and $M = 99$, Eq. (4) in Exercise 83 of Section 10.3 becomes

$$\sum_{n=1}^{99} \frac{n}{(n^2+1)^2} + \int_{100}^{\infty} \frac{x}{(x^2+1)^2}\,dx \le S \le \sum_{n=1}^{100} \frac{n}{(n^2+1)^2} + \int_{100}^{\infty} \frac{x}{(x^2+1)^2}\,dx,$$

or

$$0 \le S - \left(\sum_{n=1}^{99} \frac{n}{(n^2+1)^2} + \int_{100}^{\infty} \frac{x}{(x^2+1)^2}\,dx \right) \le \frac{100}{(100^2+1)^2}.$$

Now,

$$\sum_{n=1}^{99} \frac{n}{(n^2+1)^2} = 0.397066274; \text{ and}$$

$$\int_{100}^{\infty} \frac{x}{(x^2+1)^2}\,dx = \lim_{R\to\infty} \int_{100}^{R} \frac{x}{(x^2+1)^2}\,dx = \frac{1}{2} \lim_{R\to\infty} \left(-\frac{1}{R^2+1} + \frac{1}{100^2+1} \right)$$
$$= \frac{1}{20002} = 0.000049995;$$

thus,

$$S \approx 0.397066274 + 0.000049995 = 0.397116269.$$

The bound on the error in this approximation is

$$\frac{100}{(100^2+1)^2} = 9.998 \times 10^{-7}.$$

In Exercises 54–57, determine whether the series converges absolutely. If it does not, determine whether it converges conditionally.

54. $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt[3]{n} + 2n}$

SOLUTION Both $\sqrt[3]{n}$ and $2n$ are increasing functions, so $\sqrt[3]{n} + 2n$ is also increasing. Therefore, $\frac{1}{\sqrt[3]{n}+2n}$ is decreasing. Moreover,

$$\lim_{n\to\infty} \frac{1}{\sqrt[3]{n} + 2n} = 0,$$

so the series $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt[3]{n} + 2n}$ converges by the Leibniz Test.

The corresponding positive series is $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt[3]{n} + 2n}$. Because

$$\frac{1}{\sqrt[3]{n} + 2n} > \frac{1}{n + 2n} = \frac{1}{3} \cdot \frac{1}{n}$$

and the harmonic series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n}$ diverges, $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt[3]{n} + 2n}$ also diverges by the Comparison Test. Thus, $\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt[3]{n}+2n}$ converges conditionally.

55. $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^n}{n^{1.1}\ln(n+1)}$

SOLUTION Consider the corresponding positive series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^{1.1}\ln(n+1)}$. Because

$$\frac{1}{n^{1.1}\ln(n+1)} < \frac{1}{n^{1.1}}$$

and $\sum_{n=1}^{\infty} \frac{1}{n^{1.1}}$ is a convergent p-series, we can conclude by the Comparison Test that $\sum_{n=1}^{\infty} \frac{(-1)^n}{n^{1.1}\ln(n+1)}$ also converges. Thus, $\sum_{n=1}^{\infty} \frac{(-1)^n}{n^{1.1}\ln(n+1)}$ converges absolutely.

56. $\sum_{n=1}^{\infty} \frac{\cos\left(\frac{\pi}{4}+\pi n\right)}{\sqrt{n}}$

SOLUTION Note

$$\cos\left(\frac{\pi}{4}+\pi n\right) = \cos\frac{\pi}{4}\cos n\pi - \sin\frac{\pi}{4}\sin n\pi = (-1)^n\frac{\sqrt{2}}{2}.$$

Therefore,

$$\sum_{n=1}^{\infty} \frac{\cos\left(\frac{\pi}{4}+\pi n\right)}{\sqrt{n}} = \sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}}\frac{2}{\sqrt{2}} = \frac{2}{\sqrt{2}}\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}}.$$

Now, the sequence $\{\frac{1}{\sqrt{n}}\}$ is decreasing and converges to 0 as $n \to \infty$. Therefore, $\sum_{n=1}^{\infty} \frac{\cos\left(\frac{\pi}{4}+\pi n\right)}{\sqrt{n}}$ converges by the Leibniz Test. However, the corresponding positive series is a divergent p-series ($p = \frac{1}{2}$), so the original series converges conditionally.

57. $\sum_{n=1}^{\infty} \frac{\cos\left(\frac{\pi}{4}+2\pi n\right)}{\sqrt{n}}$

SOLUTION $\cos\left(\frac{\pi}{4}+2\pi n\right) = \cos\frac{\pi}{4} = \frac{\sqrt{2}}{2}$, so

$$\sum_{n=1}^{\infty} \frac{\cos\left(\frac{\pi}{4}+2\pi n\right)}{\sqrt{n}} = \frac{\sqrt{2}}{2}\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}.$$

This is a divergent p-series, so the series $\sum_{n=1}^{\infty} \frac{\cos\left(\frac{\pi}{4}+2\pi n\right)}{\sqrt{n}}$ diverges.

58. CAS Use a computer algebra system to approximate $\sum_{n=1}^{\infty} \frac{(-1)^n}{n^3+\sqrt{n}}$ to within an error of at most 10^{-5}.

SOLUTION The sequence $\{\frac{1}{n^3+\sqrt{n}}\}$ is decreasing and converges to 0, so the series $\sum_{n=1}^{\infty} \frac{(-1)^n}{n^3+\sqrt{n}}$ converges by the Leibniz Test. Using the error bound for an alternating series,

$$\left| S_N - \sum_{n=1}^{\infty} \frac{(-1)^n}{n^3+\sqrt{n}} \right| \le a_{N+1} = \frac{1}{(N+1)^3+\sqrt{N+1}}.$$

If we want an approximation with an error of at most 10^{-5}, we must choose N such that

$$\frac{1}{(N+1)^3+\sqrt{N+1}} < 10^{-5} \quad \text{or} \quad (N+1)^3+\sqrt{N+1} > 10^5.$$

For $N = 45$, $(N+1)^3+\sqrt{N+1} = 97{,}342.8 < 10^5$, and for $N = 46$, $(N+1)^3+\sqrt{N+1} = 103{,}829.9 > 10^5$. The smallest acceptable value for N is therefore $N = 46$. Using a computer algebra system, we find

$$\sum_{n=1}^{\infty} \frac{(-1)^n}{n^3+\sqrt{n}} \approx S_{46} = -0.418452236.$$

59. Catalan's constant is defined by $K = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)^2}$.

(a) How many terms of the series are needed to calculate K with an error of less than 10^{-6}?

(b) CAS Carry out the calculation.

SOLUTION Using the error bound for an alternating series, we have

$$|S_N - K| \le \frac{1}{(2(N+1)+1)^2} = \frac{1}{(2N+3)^2}.$$

For accuracy to three decimal places, we must choose N so that

$$\frac{1}{(2N+3)^2} < 5 \times 10^{-3} \quad \text{or} \quad (2N+3)^2 > 2000.$$

Solving for N yields

$$N > \frac{1}{2}\left(\sqrt{2000} - 3\right) \approx 20.9.$$

Thus,

$$K \approx \sum_{k=0}^{21} \frac{(-1)^k}{(2k+1)^2} = 0.915707728.$$

60. Give an example of conditionally convergent series $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ such that $\sum_{n=1}^{\infty}(a_n + b_n)$ converges absolutely.

SOLUTION Let $a_n = \frac{(-1)^n}{n}$ and $b_n = \frac{(-1)^{n+1}}{n}$. The corresponding alternating series converge by the Leibniz Test; however, the corresponding positive series are the divergent harmonic series. Thus, $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ converge conditionally. On the other hand, the series

$$\sum_{n=1}^{\infty}(a_n + b_n) = \sum_{n=1}^{\infty}\left(\frac{(-1)^n}{n} + \frac{(-1)^{n+1}}{n}\right) = \sum_{n=1}^{\infty}(-1)^n\left(\frac{1}{n} + \frac{-1}{n}\right) = \sum_{n=1}^{\infty} 0$$

converges absolutely.

61. Let $\sum_{n=1}^{\infty} a_n$ be an absolutely convergent series. Determine whether the following series are convergent or divergent:

(a) $\sum_{n=1}^{\infty}\left(a_n + \frac{1}{n^2}\right)$

(b) $\sum_{n=1}^{\infty}(-1)^n a_n$

(c) $\sum_{n=1}^{\infty}\frac{1}{1+a_n^2}$

(d) $\sum_{n=1}^{\infty}\frac{|a_n|}{n}$

SOLUTION Because $\sum_{n=1}^{\infty} a_n$ converges absolutely, we know that $\sum_{n=1}^{\infty} a_n$ converges and that $\sum_{n=1}^{\infty} |a_n|$ converges.

(a) Because we know that $\sum_{n=1}^{\infty} a_n$ converges and the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a convergent p-series, the sum of these two series, $\sum_{n=1}^{\infty}\left(a_n + \frac{1}{n^2}\right)$ also converges.

(b) We have,

$$\sum_{n=1}^{\infty} \left|(-1)^n a_n\right| = \sum_{n=1}^{\infty} |a_n|$$

Because $\sum_{n=1}^{\infty} |a_n|$ converges, it follows that $\sum_{n=1}^{\infty}(-1)^n a_n$ converges absolutely, which implies that $\sum_{n=1}^{\infty}(-1)^n a_n$ converges.

(c) Because $\sum_{n=1}^{\infty} a_n$ converges, $\lim_{n\to\infty} a_n = 0$. Therefore,

$$\lim_{n\to\infty} \frac{1}{1+a_n^2} = \frac{1}{1+0^2} = 1 \ne 0,$$

and the series $\sum_{n=1}^{\infty} \frac{1}{1+a_n^2}$ diverges by the Divergence Test.

(d) $\frac{|a_n|}{n} \le |a_n|$ and the series $\sum_{n=1}^{\infty} |a_n|$ converges, so the series $\sum_{n=1}^{\infty} \frac{|a_n|}{n}$ also converges by the Comparison Test.

62. Let $\{a_n\}$ be a positive sequence such that $\lim_{n\to\infty} \sqrt[n]{a_n} = \frac{1}{2}$. Determine whether the following series converge or diverge:

(a) $\sum_{n=1}^{\infty} 2a_n$ **(b)** $\sum_{n=1}^{\infty} 3^n a_n$ **(c)** $\sum_{n=1}^{\infty} \sqrt{a_n}$

SOLUTION
(a)

$$L = \lim_{n\to\infty} \sqrt[n]{2a_n} = \lim_{n\to\infty} \sqrt[n]{2}\sqrt[n]{a_n} = 1 \cdot \frac{1}{2} = \frac{1}{2}.$$

Because $L < 1$, the series converges by the Root Test.
(b)

$$L = \lim_{n\to\infty} \sqrt[n]{3^n a_n} = \lim_{n\to\infty} 3\sqrt[n]{a_n} = 3 \cdot \frac{1}{2} = \frac{3}{2}.$$

Because $L > 1$, the series diverges by the Root Test.
(c)

$$L = \lim_{n\to\infty} \sqrt[n]{\sqrt{a_n}} = \lim_{n\to\infty} \sqrt{\sqrt[n]{a_n}} = \sqrt{\frac{1}{2}}.$$

Because $L < 1$, the series converges by the Root Test.

In Exercises 63–70, apply the Ratio Test to determine convergence or divergence, or state that the Ratio Test is inconclusive.

63. $\sum_{n=1}^{\infty} \frac{n^5}{5^n}$

SOLUTION With $a_n = \frac{n^5}{5^n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)^5}{5^{n+1}} \cdot \frac{5^n}{n^5} = \frac{1}{5}\left(1 + \frac{1}{n}\right)^5,$$

and

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{5} \lim_{n\to\infty} \left(1 + \frac{1}{n}\right)^5 = \frac{1}{5} \cdot 1 = \frac{1}{5}.$$

Because $\rho < 1$, the series converges by the Ratio Test.

64. $\sum_{n=1}^{\infty} \frac{\sqrt{n+1}}{n^8}$

SOLUTION With $a_n = \frac{\sqrt{n+1}}{n^8}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{\sqrt{n+2}}{(n+1)^8} \cdot \frac{n^8}{\sqrt{n+1}} = \sqrt{\frac{n+2}{n+1}}\left(\frac{n}{n+1}\right)^8,$$

and

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = 1 \cdot 1^8 = 1.$$

Because $\rho = 1$, the Ratio Test is inconclusive.

65. $\sum_{n=1}^{\infty} \frac{1}{n2^n + n^3}$

SOLUTION With $a_n = \frac{1}{n2^n+n^3}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{n2^n + n^3}{(n+1)2^{n+1} + (n+1)^3} = \frac{n2^n\left(1 + \frac{n^2}{2^n}\right)}{(n+1)2^{n+1}\left(1 + \frac{(n+1)^2}{2^{n+1}}\right)} = \frac{1}{2} \cdot \frac{n}{n+1} \cdot \frac{1 + \frac{n^2}{2^n}}{1 + \frac{(n+1)^2}{2^{n+1}}},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{2}\cdot 1\cdot 1 = \frac{1}{2}.$$

Because $\rho < 1$, the series converges by the Ratio Test.

66. $\displaystyle\sum_{n=1}^{\infty}\frac{n^4}{n!}$

SOLUTION With $a_n = \frac{n^4}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)^4}{(n+1)!}\cdot\frac{n!}{n^4} = \frac{(n+1)^3}{n^4} \quad \text{and} \quad \rho = \lim_{n\to\infty}\frac{a_{n+1}}{a_n} = 0.$$

Because $\rho < 1$, the series converges by the Ratio Test.

67. $\displaystyle\sum_{n=1}^{\infty}\frac{2^{n^2}}{n!}$

SOLUTION With $a_n = \frac{2^{n^2}}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{2^{(n+1)^2}}{(n+1)!}\cdot\frac{n!}{2^{n^2}} = \frac{2^{2n+1}}{n+1} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \infty.$$

Because $\rho > 1$, the series diverges by the Ratio Test.

68. $\displaystyle\sum_{n=4}^{\infty}\frac{\ln n}{n^{3/2}}$

SOLUTION With $a_n = \frac{\ln n}{n^{3/2}}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{\ln(n+1)}{(n+1)^{3/2}}\cdot\frac{n^{3/2}}{\ln n} = \left(\frac{n}{n+1}\right)^{3/2}\frac{\ln(n+1)}{\ln n},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1^{3/2}\cdot 1 = 1.$$

Because $\rho = 1$, the Ratio Test is inconclusive.

69. $\displaystyle\sum_{n=1}^{\infty}\left(\frac{n}{2}\right)^n\frac{1}{n!}$

SOLUTION With $a_n = \left(\frac{n}{2}\right)^n\frac{1}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \left(\frac{n+1}{2}\right)^{n+1}\frac{1}{(n+1)!}\cdot\left(\frac{2}{n}\right)^n n! = \frac{1}{2}\left(\frac{n+1}{n}\right)^n = \frac{1}{2}\left(1+\frac{1}{n}\right)^n,$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{2}e.$$

Because $\rho = \frac{e}{2} > 1$, the series diverges by the Ratio Test.

70. $\displaystyle\sum_{n=1}^{\infty}\left(\frac{n}{4}\right)^n\frac{1}{n!}$

SOLUTION With $a_n = \left(\frac{n}{4}\right)^n\frac{1}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \left(\frac{n+1}{4}\right)^{n+1}\frac{1}{(n+1)!}\cdot\left(\frac{4}{n}\right)^n n! = \frac{1}{4}\left(\frac{n+1}{n}\right)^n = \frac{1}{4}\left(1+\frac{1}{n}\right)^n,$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{1}{4}e.$$

Because $\rho = \frac{e}{4} < 1$, the series converges by the Ratio Test.

In Exercises 71–74, apply the Root Test to determine convergence or divergence, or state that the Root Test is inconclusive.

71. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{4^n}$

SOLUTION With $a_n = \frac{1}{4^n}$,

$$L = \lim_{n\to\infty} \sqrt[n]{a_n} = \lim_{n\to\infty} \sqrt[n]{\frac{1}{4^n}} = \frac{1}{4}.$$

Because $L < 1$, the series converges by the Root Test.

72. $\displaystyle\sum_{n=1}^{\infty} \left(\frac{2}{n}\right)^n$

SOLUTION With $a_n = \left(\frac{2}{n}\right)^n$,

$$L = \lim_{n\to\infty} \sqrt[n]{\left(\frac{2}{n}\right)^n} = \lim_{n\to\infty} \frac{2}{n} = 0.$$

Because $L < 1$, the series converges by the Root Test.

73. $\displaystyle\sum_{n=1}^{\infty} \left(\frac{3}{4n}\right)^n$

SOLUTION With $a_n = \left(\frac{3}{4n}\right)^n$,

$$L = \lim_{n\to\infty} \sqrt[n]{a_n} = \lim_{n\to\infty} \sqrt[n]{\left(\frac{3}{4n}\right)^n} = \lim_{n\to\infty} \frac{3}{4n} = 0.$$

Because $L < 1$, the series converges by the Root Test.

74. $\displaystyle\sum_{n=1}^{\infty} \left(\cos\frac{1}{n}\right)^{n^3}$

SOLUTION With $a_n = \left(\cos\frac{1}{n}\right)^{n^3}$,

$$L = \lim_{n\to\infty} \sqrt[n]{a_n} = \lim_{n\to\infty} \sqrt[n]{\cos\left(\frac{1}{n}\right)^{n^3}} = \lim_{n\to\infty} \cos\left(\frac{1}{n}\right)^{n^2} = \lim_{x\to\infty} \cos\left(\frac{1}{x}\right)^{x^2}.$$

Now,

$$\ln L = \lim_{x\to\infty} x^2 \ln\cos\left(\frac{1}{x}\right) = \lim_{x\to\infty} \frac{\ln\cos\left(\frac{1}{x}\right)}{\frac{1}{x^2}} = \lim_{x\to\infty} \frac{\frac{1}{\cos\left(\frac{1}{x}\right)}\left(-\sin\left(\frac{1}{x}\right)\right)\left(-\frac{1}{x^2}\right)}{-\frac{2}{x^3}}$$

$$= -\frac{1}{2}\lim_{x\to\infty} \frac{1}{\cos\left(\frac{1}{x}\right)} \cdot \lim_{x\to\infty} \frac{\sin\left(\frac{1}{x}\right)}{\frac{1}{x}} = -\frac{1}{2}\cdot 1 \cdot 1 = -\frac{1}{2}.$$

Therefore, $L = e^{-1/2}$. Because $L < 1$, the series converges by the Root Test.

In Exercises 75–92, determine convergence or divergence using any method covered in the text.

75. $\displaystyle\sum_{n=1}^{\infty} \left(\frac{2}{3}\right)^n$

SOLUTION This is a geometric series with ratio $r = \frac{2}{3} < 1$; hence, the series converges.

76. $\displaystyle\sum_{n=1}^{\infty} \frac{\pi^{7n}}{e^{8n}}$

SOLUTION This is a geometric series with ratio $r = \frac{\pi^7}{e^8} \approx 1.013$, so it diverges.

77. $\displaystyle\sum_{n=1}^{\infty} e^{-0.02n}$

SOLUTION This is a geometric series with common ratio $r = \frac{1}{e^{0.02}} \approx 0.98 < 1$; hence, the series converges.

78. $\displaystyle\sum_{n=1}^{\infty} ne^{-0.02n}$

SOLUTION With $a_n = ne^{-0.02n}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)e^{-0.02(n+1)}}{ne^{-0.02n}} = \frac{n+1}{n}e^{-0.02},$$

and

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 1 \cdot e^{-0.02} = e^{-0.02}.$$

Because $\rho < 1$, the series converges by the Ratio Test.

79. $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{\sqrt{n}+\sqrt{n+1}}$

SOLUTION In this alternating series, $a_n = \frac{1}{\sqrt{n}+\sqrt{n+1}}$. The sequence $\{a_n\}$ is decreasing, and

$$\lim_{n\to\infty} a_n = 0;$$

therefore the series converges by the Leibniz Test.

80. $\displaystyle\sum_{n=10}^{\infty} \frac{1}{n(\ln n)^{3/2}}$

SOLUTION Let $f(x) = \frac{1}{x(\ln x)^{3/2}}$. This function is continuous, positive and decreasing for $x > e^{-3/2}$ and thus for $x \ge 10$; therefore, the Integral Test applies. Now,

$$\int_{10}^{\infty} \frac{dx}{x(\ln x)^{3/2}} = \lim_{R\to\infty}\int_{10}^{R} \frac{dx}{x(\ln x)^{3/2}} = \lim_{R\to\infty}\int_{\ln 10}^{\ln R} \frac{1}{u^{3/2}}\,du$$
$$= \lim_{R\to\infty}\left(\left.\frac{-2}{\sqrt{u}}\right|_{\ln 10}^{\ln R}\right) = 2\lim_{R\to\infty}\left(\frac{1}{\sqrt{\ln 10}} - \frac{1}{\sqrt{\ln R}}\right) = 2.$$

The integral converges; hence, the series converges as well.

81. $\displaystyle\sum_{n=2}^{\infty} \frac{(-1)^n}{\ln n}$

SOLUTION The sequence $a_n = \frac{1}{\ln n}$ is decreasing for $n \ge 10$ and

$$\lim_{n\to\infty} a_n = 0;$$

therefore, the series converges by the Leibniz Test.

82. $\displaystyle\sum_{n=1}^{\infty} \frac{e^n}{n!}$

SOLUTION With $a_n = \frac{e^n}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{e^{n+1}}{(n+1)!}\cdot\frac{n!}{e^n} = \frac{e}{n+1} \quad \text{and} \quad \rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = 0.$$

Because $\rho < 1$, the series converges by the Ratio Test.

83. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n\sqrt{n+\ln n}}$

SOLUTION For $n \geq 1$,

$$\frac{1}{n\sqrt{n+\ln n}} \leq \frac{1}{n\sqrt{n}} = \frac{1}{n^{3/2}}.$$

The series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^{3/2}}$ is a convergent p-series, so the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n\sqrt{n+\ln n}}$ converges by the Comparison Test.

84. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt[3]{n}(1+\sqrt{n})}$

SOLUTION Apply the Limit Comparison Test with $a_n = \frac{1}{\sqrt[3]{n}(1+\sqrt{n})}$ and $b_n = \frac{1}{n^{5/6}}$. Then,

$$L = \lim_{n\to\infty} \frac{\frac{1}{\sqrt[3]{n}(1+\sqrt{n})}}{\frac{1}{n^{5/6}}} = \lim_{n\to\infty} \frac{n^{5/6}}{\sqrt[3]{n} + n^{5/6}} = \lim_{n\to\infty} \frac{1}{\frac{1}{\sqrt{n}}+1} = 1.$$

The series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^{5/6}}$ is a divergent p-series. Because $L > 0$, the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt[3]{n}(1+\sqrt{n})}$ also diverges by the Limit Comparison Test.

85. $\displaystyle\sum_{n=1}^{\infty} \left(\frac{1}{\sqrt{n}} - \frac{1}{\sqrt{n+1}}\right)$

SOLUTION This series telescopes:

$$\sum_{n=1}^{\infty} \left(\frac{1}{\sqrt{n}} - \frac{1}{\sqrt{n+1}}\right) = \left(1 - \frac{1}{\sqrt{2}}\right) + \left(\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{3}}\right) + \left(\frac{1}{\sqrt{3}} - \frac{1}{\sqrt{4}}\right) + \dots$$

so that the n^{th} partial sum S_n is

$$S_n = \left(1 - \frac{1}{\sqrt{2}}\right) + \left(\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{3}}\right) + \left(\frac{1}{\sqrt{3}} - \frac{1}{\sqrt{4}}\right) + \dots + \left(\frac{1}{\sqrt{n}} - \frac{1}{\sqrt{n+1}}\right) = 1 - \frac{1}{\sqrt{n+1}}$$

and then

$$\sum_{n=1}^{\infty} \left(\frac{1}{\sqrt{n}} - \frac{1}{\sqrt{n+1}}\right) = \lim_{n\to\infty} S_n = 1 - \lim_{n\to\infty} \frac{1}{\sqrt{n+1}} = 1$$

86. $\displaystyle\sum_{n=1}^{\infty} \big(\ln n - \ln(n+1)\big)$

SOLUTION This series telescopes:

$$\sum_{n=1}^{\infty} \big(\ln n - \ln(n+1)\big) = (\ln 1 - \ln 2) + (\ln 2 - \ln 3) + (\ln 3 - \ln 4) + \dots$$

so that the n^{th} partial sum S_n is

$$\begin{aligned} S_n &= (\ln 1 - \ln 2) + (\ln 2 - \ln 3) + (\ln 3 - \ln 4) + \dots + (\ln n - \ln(n+1)) \\ &= \ln 1 - \ln(n+1) = -\ln(n+1) \end{aligned}$$

and then

$$\sum_{n=1}^{\infty} \big(\ln n - \ln(n+1)\big) = \lim_{n\to\infty} S_n = -\lim_{n\to\infty} \ln(n+1) = \infty$$

so the series diverges.

87. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n+\sqrt{n}}$

SOLUTION For $n \geq 1$, $\sqrt{n} \leq n$, so that

$$\sum_{n=1}^{\infty} \frac{1}{n+\sqrt{n}} \geq \sum_{n=1}^{\infty} \frac{1}{2n}$$

which diverges since it is a constant multiple of the harmonic series. Thus $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n+\sqrt{n}}$ diverges as well, by the Comparison Test.

88. $\displaystyle\sum_{n=2}^{\infty} \frac{\cos(\pi n)}{n^{2/3}}$

SOLUTION $\cos(\pi n) = (-1)^n$, so

$$\sum_{n=2}^{\infty} \frac{\cos(\pi n)}{n^{2/3}} = \sum_{n=2}^{\infty} \frac{(-1)^n}{n^{2/3}}.$$

The sequence $a_n = \frac{1}{n^{2/3}}$ is decreasing and

$$\lim_{n\to\infty} a_n = 0;$$

therefore, the series converges by the Leibniz Test.

89. $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n^{\ln n}}$

SOLUTION For $n \geq N$ large enough, $\ln n \geq 2$ so that

$$\sum_{n=N}^{\infty} \frac{1}{n^{\ln n}} \leq \sum_{n=N}^{\infty} \frac{1}{n^2}$$

which is a convergent p-series. Thus by the Comparison Test, $\displaystyle\sum_{n=N}^{\infty} \frac{1}{n^{\ln n}}$ also converges; adding back in the terms for $n < N$ does not affect convergence.

90. $\displaystyle\sum_{n=2}^{\infty} \frac{1}{\ln^3 n}$

SOLUTION For N large enough, $\ln n \leq n^{1/4}$ when $n \geq N$ so that

$$\sum_{n=N}^{\infty} \frac{1}{\ln^3 n} > \sum_{n=N}^{\infty} \frac{1}{n^{3/4}}$$

which is a divergent p-series. Thus by the Comparison Test, $\displaystyle\sum_{n=N}^{\infty} \frac{1}{\ln^3 n}$ diverges; adding back in the terms for $n < N$ does not affect this result.

91. $\displaystyle\sum_{n=1}^{\infty} \sin^2 \frac{\pi}{n}$

SOLUTION For all $x > 0$, $\sin x < x$. Therefore, $\sin^2 x < x^2$, and for $x = \frac{\pi}{n}$,

$$\sin^2 \frac{\pi}{n} < \frac{\pi^2}{n^2} = \pi^2 \cdot \frac{1}{n^2}.$$

The series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2}$ is a convergent p-series, so the series $\displaystyle\sum_{n=1}^{\infty} \sin^2 \frac{\pi}{n}$ also converges by the Comparison Test.

92. $\displaystyle\sum_{n=0}^{\infty} \frac{2^{2n}}{n!}$

SOLUTION With $a_n = \frac{2^{2n}}{n!}$,

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{2^{2(n+1)}}{(n+1)!} \cdot \frac{n!}{2^{2n}} = \frac{4}{n+1} \quad \text{and} \quad \rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = 0.$$

Because $\rho < 1$, the series converges by the Ratio Test.

In Exercises 93–98, find the interval of convergence of the power series.

93. $\displaystyle\sum_{n=0}^{\infty} \frac{2^n x^n}{n!}$

SOLUTION With $a_n = \frac{2^n x^n}{n!}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{2^{n+1}x^{n+1}}{(n+1)!} \cdot \frac{n!}{2^n x^n}\right| = \lim_{n\to\infty} \left|x \cdot \frac{2}{n}\right| = 0$$

Then $\rho < 1$ for all x, so that the radius of convergence is $R = \infty$, and the series converges for all x.

94. $\displaystyle\sum_{n=0}^{\infty} \frac{x^n}{n+1}$

SOLUTION With $a_n = \frac{x^n}{n+1}$,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{n+2} \cdot \frac{n+1}{x^n}\right| = \lim_{n\to\infty} \left|x \cdot \frac{n+1}{n+2}\right| = \lim_{n\to\infty} \left|x \cdot \frac{1+1/n}{1+2/n}\right| = |x|$$

Then $\rho < 1$ when $|x| < 1$, so the radius of convergence is 1, and the series converges absolutely for $|x| < 1$, or $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\displaystyle\sum_{n=0}^{\infty} \frac{1}{n+1} = \sum_{n=1}^{\infty} \frac{1}{n}$, which is the divergent harmonic series. For the endpoint $x = -1$, the series becomes $\displaystyle\sum_{n=0}^{\infty} \frac{(-1)^n}{n+1}$, which converges by the Leibniz Test. The series $\displaystyle\sum_{n=0}^{\infty} \frac{x^n}{n+1}$ therefore converges for $-1 \le x < 1$.

95. $\displaystyle\sum_{n=0}^{\infty} \frac{n^6}{n^8+1}(x-3)^n$

SOLUTION With $a_n = \frac{n^6(x-3)^n}{n^8+1}$,

$$\begin{aligned}
\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| &= \lim_{n\to\infty} \left|\frac{(n+1)^6(x-3)^{n+1}}{(n+1)^8-1} \cdot \frac{n^8+1}{n^6(x-3)^n}\right| \\
&= \lim_{n\to\infty} \left|(x-3) \cdot \frac{(n+1)^6(n^8+1)}{n^6((n+1)^8+1)}\right| \\
&= \lim_{n\to\infty} \left|(x-3) \cdot \frac{n^{14} + \text{terms of lower degree}}{n^{14} + \text{terms of lower degree}}\right| = |x-3|
\end{aligned}$$

Then $\rho < 1$ when $|x-3| < 1$, so the radius of convergence is 1, and the series converges absolutely for $|x-3| < 1$, or $2 < x < 4$. For the endpoint $x = 4$, the series becomes $\displaystyle\sum_{n=0}^{\infty} \frac{n^6}{n^8+1}$, which converges by the Comparison Test comparing with the convergent p-series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2}$. For the endpoint $x = 2$, the series becomes $\displaystyle\sum_{n=0}^{\infty} \frac{n^6(-1)^n}{n^8+1}$, which converges by the Leibniz Test. The series $\displaystyle\sum_{n=0}^{\infty} \frac{n^6(x-3)^n}{n^8+1}$ therefore converges for $2 \le x \le 4$.

96. $\displaystyle\sum_{n=0}^{\infty} nx^n$

SOLUTION With $a_n = nx^n$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(n+1)x^{n+1}}{nx^n}\right| = \lim_{n\to\infty}\left|x\cdot\frac{n+1}{n}\right| = |x|$$

Then $\rho < 1$ when $|x| < 1$, so the radius of convergence is 1, and the series converges for $|x| < 1$, or $-1 < x < 1$. For the endpoint $x = 1$, the series becomes $\displaystyle\sum_{n=0}^{\infty} n$, which diverges by the Divergence Test. For the endpoint $x = -1$, the series becomes $\sum_{n=0}^{\infty}(-1)^n n$, which also diverges by the Divergence Test. The series $\displaystyle\sum_{n=0}^{\infty} nx^n$ therefore converges for $-1 < x < 1$.

97. $\displaystyle\sum_{n=0}^{\infty} (nx)^n$

SOLUTION With $a_n = n^n x^n$, and assuming $x \neq 0$,

$$\rho = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(n+1)^{n+1}x^{n+1}}{n^n x^n}\right| = \lim_{n\to\infty}\left|x(n+1)\cdot\left(\frac{n+1}{n}\right)^n\right| = \infty$$

since $\left(\frac{n+1}{n}\right)^n = \left(1+\frac{1}{n}\right)^n$ converges to e and the $(n+1)$ term diverges to ∞. Thus $\rho < 1$ only when $x = 0$, so the series converges only for $x = 0$.

98. $\displaystyle\sum_{n=0}^{\infty} \frac{(2x-3)^n}{n\ln n}$

SOLUTION With $a_n = \frac{(2x-3)^n}{n\ln n}$, and using L'Hôpital's Rule,

$$\begin{aligned}\rho &= \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(2x-3)^{n+1}}{(n+1)\ln(n+1)}\cdot\frac{n\ln n}{(2x-3)^n}\right| \\ &= \lim_{n\to\infty}\left|(2x-3)\frac{n\ln n}{(n+1)\ln(n+1)}\right| = \lim_{n\to\infty}\left|(2x-3)\frac{1+\ln n}{1+\ln(n+1)}\right| \\ &= \lim_{n\to\infty}\left|(2x-3)\frac{1/n}{1/(n+1)}\right| = \lim_{n\to\infty}\left|(2x-3)\frac{n+1}{n}\right| = |2x-3|\end{aligned}$$

Then $\rho < 1$ when $|2x-3| < 1$, so the radius of convergence is 1, and the series converges absolutely for $|2x-3| < 1$, or $1 < x < 2$. For the endpoint $x = 2$, the series becomes $\displaystyle\sum_{n=0}^{\infty}\frac{1}{n\ln n}$, which diverges by the Integral Test. For the endpoint $x = -1$, the series becomes $\displaystyle\sum_{n=0}^{\infty}\frac{(-1)^n}{n\ln n}$, which converges by the Leibniz Test. The series $\displaystyle\sum_{n=0}^{\infty}\frac{(2x-3)^n}{n\ln n}$ therefore converges for $1 \le x < 2$.

99. Expand $f(x) = \dfrac{2}{4-3x}$ as a power series centered at $c = 0$. Determine the values of x for which the series converges.

SOLUTION Write

$$\frac{2}{4-3x} = \frac{1}{2}\frac{1}{1-\frac{3}{4}x}.$$

Substituting $\frac{3}{4}x$ for x in the Maclaurin series for $\frac{1}{1-x}$, we obtain

$$\frac{1}{1-\frac{3}{4}x} = \sum_{n=0}^{\infty}\left(\frac{3}{4}\right)^n x^n.$$

This series converges for $\left|\frac{3}{4}x\right| < 1$, or $|x| < \frac{4}{3}$. Hence, for $|x| < \frac{4}{3}$,

$$\frac{2}{4-3x} = \frac{1}{2}\sum_{n=0}^{\infty}\left(\frac{3}{4}\right)^n x^n.$$

100. Prove that

$$\sum_{n=0}^{\infty} ne^{-nx} = \frac{e^{-x}}{(1-e^{-x})^2}$$

Hint: Express the left-hand side as the derivative of a geometric series.

SOLUTION For $x > 0$, $\sum_{n=0}^{\infty} e^{-nx} = \sum_{n=0}^{\infty} (e^{-x})^n$ is a convergent geometric series with ratio $r = e^{-x}$; hence,

$$\sum_{n=0}^{\infty} e^{-nx} = \frac{1}{1-e^{-x}}.$$

Differentiating term-by-term then yields

$$\sum_{n=0}^{\infty} \left(-ne^{-nx}\right) = -\frac{e^{-x}}{(1-e^{-x})^2}.$$

Therefore, for $x > 0$,

$$\sum_{n=0}^{\infty} ne^{-nx} = \frac{e^{-x}}{\left(1-e^{-x}\right)^2}.$$

101. Let $F(x) = \sum_{k=0}^{\infty} \frac{x^{2k}}{2^k \cdot k!}$.

(a) Show that $F(x)$ has infinite radius of convergence.

(b) Show that $y = F(x)$ is a solution of

$$y'' = xy' + y, \qquad y(0) = 1, \qquad y'(0) = 0$$

(c) CAS Plot the partial sums S_N for $N = 1, 3, 5, 7$ on the same set of axes.

SOLUTION

(a) With $a_k = \frac{x^{2k}}{2^k \cdot k!}$,

$$\left|\frac{a_{k+1}}{a_k}\right| = \frac{|x|^{2k+2}}{2^{k+1} \cdot (k+1)!} \cdot \frac{2^k \cdot k!}{|x|^{2k}} = \frac{x^2}{2(k+1)},$$

and

$$\rho = \lim_{k\to\infty} \left|\frac{a_{k+1}}{a_k}\right| = x^2 \cdot 0 = 0.$$

Because $\rho < 1$ for all x, we conclude that the series converges for all x; that is, $R = \infty$.

(b) Let

$$y = F(x) = \sum_{k=0}^{\infty} \frac{x^{2k}}{2^k \cdot k!}.$$

Then

$$y' = \sum_{k=1}^{\infty} \frac{2kx^{2k-1}}{2^k k!} = \sum_{k=1}^{\infty} \frac{x^{2k-1}}{2^{k-1}(k-1)!},$$

$$y'' = \sum_{k=1}^{\infty} \frac{(2k-1)x^{2k-2}}{2^{k-1}(k-1)!},$$

and

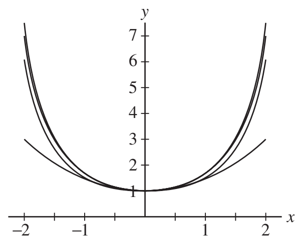
$$\begin{aligned} xy' + y &= x\sum_{k=1}^{\infty} \frac{x^{2k-1}}{2^{k-1}(k-1)!} + \sum_{k=0}^{\infty} \frac{x^{2k}}{2^k k!} = \sum_{k=1}^{\infty} \frac{x^{2k}}{2^{k-1}(k-1)!} + 1 + \sum_{k=1}^{\infty} \frac{x^{2k}}{2^k k!} \\ &= 1 + \sum_{k=1}^{\infty} \frac{(2k+1)x^{2k}}{2^k k!} = \sum_{k=0}^{\infty} \frac{(2k+1)x^{2k}}{2^k k!} = \sum_{k=1}^{\infty} \frac{(2k-1)x^{2k-2}}{2^{k-1}(k-1)!} = y''. \end{aligned}$$

Moreover,

$$y(0) = 1 + \sum_{k=1}^{\infty} \frac{0^{2k}}{2^k k!} = 1 \quad \text{and} \quad y'(0) = \sum_{k=1}^{\infty} \frac{0^{2k-1}}{2^{k-1}(k-1)!} = 0.$$

Thus, $\sum_{k=0}^{\infty} \frac{x^{2k}}{2^k k!}$ is the solution to the equation $y'' = xy' + y$ satisfying $y(0) = 1$, $y'(0) = 0$.

(c) The partial sums S_1, S_3, S_5 and S_7 are plotted in the figure below.



102. Find a power series $P(x) = \sum_{n=0}^{\infty} a_n x^n$ that satisfies the Laguerre differential equation

$$xy'' + (1 - x)y' - y = 0$$

with initial condition satisfying $P(0) = 1$.

SOLUTION Let

$$y = P(x) = \sum_{n=0}^{\infty} a_n x^n.$$

Then,

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}, \quad y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2},$$

and

$$\begin{aligned} xy'' + (1-x)y' - y &= \sum_{n=2}^{\infty} n(n-1)a_n x^{n-1} + \sum_{n=1}^{\infty} n a_n x^{n-1} - \sum_{n=1}^{\infty} n a_n x^n - \sum_{n=0}^{\infty} a_n x^n \\ &= \sum_{n=1}^{\infty} (n+1)n a_{n+1} x^n + \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n - \sum_{n=1}^{\infty} n a_n x^n - \sum_{n=0}^{\infty} a_n x^n \\ &= (a_1 - a_0) + \sum_{n=1}^{\infty} \left[(n+1)^2 a_{n+1} - (n+1) a_n \right] x^n. \end{aligned}$$

In order for this series to be equal to zero, the coefficient of x^n must be equal to zero for each n; thus

$$a_1 = a_0 \quad \text{and} \quad a_{n+1} = \frac{a_n}{n+1}.$$

Now, $y(0) = P(0) = a_0$, so to satisfy the initial condition $P(0) = 1$, we must set $a_0 = 1$. Then,

$$\begin{aligned} a_1 &= a_0 = 1; \\ a_2 &= \frac{a_1}{2} = \frac{1}{2}; \\ a_3 &= \frac{a_2}{3} = \frac{1}{6} = \frac{1}{3!}; \\ a_4 &= \frac{a_3}{4} = \frac{1}{4!}; \end{aligned}$$

and, in general, $a_n = \frac{1}{n!}$. Thus,

$$P(x) = \sum_{n=0}^{\infty} \frac{x^n}{n!} = e^x.$$

In Exercises 103–112, find the Taylor series centered at c.

103. $f(x) = e^{4x}, \quad c = 0$

SOLUTION Substituting $4x$ for x in the Maclaurin series for e^x yields

$$e^{4x} = \sum_{n=0}^{\infty} \frac{(4x)^n}{n!} = \sum_{n=0}^{\infty} \frac{4^n}{n!} x^n.$$

104. $f(x) = e^{2x}, \quad c = -1$

SOLUTION Write:

$$e^{2x} = e^{2(x+1)-2} = e^{-2} e^{2(x+1)}.$$

Substituting $2(x+1)$ for x in the Maclaurin series for e^x yields

$$e^{2(x+1)} = \sum_{n=0}^{\infty} \frac{(2(x+1))^n}{n!} = \sum_{n=0}^{\infty} \frac{2^n}{n!}(x+1)^n;$$

hence,

$$e^{2x} = e^{-2} \sum_{n=0}^{\infty} \frac{2^n (x+1)^n}{n!}.$$

105. $f(x) = x^4, \quad c = 2$

SOLUTION We have

$$f'(x) = 4x^3 \quad f''(x) = 12x^2 \quad f'''(x) = 24x \quad f^{(4)}(x) = 24$$

and all higher derivatives are zero, so that

$$f(2) = 2^4 = 16 \quad f'(2) = 4 \cdot 2^3 = 32 \quad f''(2) = 12 \cdot 2^2 = 48 \quad f'''(2) = 24 \cdot 2 = 48 \quad f^{(4)}(2) = 24$$

Thus the Taylor series centered at $c = 2$ is

$$\begin{aligned}\sum_{n=0}^{4} \frac{f^{(n)}(2)}{n!}(x-2)^n &= 16 + \frac{32}{1!}(x-2) + \frac{48}{2!}(x-2)^2 + \frac{48}{3!}(x-2)^3 + \frac{24}{4!}(x-2)^4 \\ &= 16 + 32(x-2) + 24(x-2)^2 + 8(x-2)^3 + (x-2)^4\end{aligned}$$

106. $f(x) = x^3 - x, \quad c = -2$

SOLUTION We have

$$f'(x) = 3x^2 - 1 \quad f''(x) = 6x \quad f'''(x) = 6$$

and all higher derivatives are zero, so that

$$f(-2) = -8 + 2 = -6 \quad f'(-2) = 3(-2)^2 - 1 = 11 \quad f''(-2) = 6(-2) = -12 \quad f'''(-2) = 6$$

Thus the Taylor series centered at $c = -2$ is

$$\begin{aligned}\sum_{n=0}^{3} \frac{f^{(n)}(-2)}{n!}(x+2)^n &= -6 + \frac{11}{1!}(x+2) + \frac{-12}{2!}(x+2)^2 + \frac{6}{3!}(x+2)^3 \\ &= -6 + 11(x+2) - 6(x+2)^2 + (x+2)^3\end{aligned}$$

107. $f(x) = \sin x, \quad c = \pi$

SOLUTION We have

$$f^{(4n)}(x) = \sin x \quad f^{(4n+1)}(x) = \cos x \quad f^{(4n+2)}(x) = -\sin x \quad f^{(4n+3)}(x) = -\cos x$$

so that

$$f^{(4n)}(\pi) = \sin \pi = 0 \quad f^{(4n+1)}(\pi) = \cos \pi = -1 \quad f^{(4n+2)}(\pi) = -\sin \pi = 0 \quad f^{(4n+3)}(\pi) = -\cos \pi = 1$$

Then the Taylor series centered at $c = \pi$ is

$$\sum_{n=0}^{\infty} \frac{f^{(n)}(\pi)}{n!}(x-\pi)^n = \frac{-1}{1!}(x-\pi) + \frac{1}{3!}(x-\pi)^3 + \frac{-1}{5!}(x-\pi)^5 + \frac{1}{7!}(x-\pi)^7 - \dots$$

$$= -(x-\pi) + \frac{1}{6}(x-\pi)^3 - \frac{1}{120}(x-\pi)^5 + \frac{1}{5040}(x-\pi)^7 - \dots$$

108. $f(x) = e^{x-1}, \quad c = -1$

SOLUTION Write

$$e^{x-1} = e^{x+1-1-1} = e^{-2}e^{x+1}.$$

Substituting $x+1$ for x in the Maclaurin series for e^x yields

$$e^{x+1} = \sum_{n=0}^{\infty} \frac{(x+1)^n}{n!};$$

hence,

$$e^{x-1} = e^{-2}\sum_{n=0}^{\infty} \frac{(x+1)^n}{n!} = \sum_{n=0}^{\infty} \frac{(x+1)^n}{n!e^2}.$$

109. $f(x) = \dfrac{1}{1-2x}, \quad c = -2$

SOLUTION Write

$$\frac{1}{1-2x} = \frac{1}{5-2(x+2)} = \frac{1}{5}\frac{1}{1-\frac{2}{5}(x+2)}.$$

Substituting $\frac{2}{5}(x+2)$ for x in the Maclaurin series for $\frac{1}{1-x}$ yields

$$\frac{1}{1-\frac{2}{5}(x+2)} = \sum_{n=0}^{\infty} \frac{2^n}{5^n}(x+2)^n;$$

hence,

$$\frac{1}{1-2x} = \frac{1}{5}\sum_{n=0}^{\infty} \frac{2^n}{5^n}(x+2)^n = \sum_{n=0}^{\infty} \frac{2^n}{5^{n+1}}(x+2)^n.$$

110. $f(x) = \dfrac{1}{(1-2x)^2}, \quad c = -2$

SOLUTION Note that

$$\frac{d}{dx}\frac{1}{1-2x} = \frac{2}{1-2x}$$

so that we can derive the Taylor series for $f(x)$ by differentiating the Taylor series for $\frac{1}{1-2x}$, computed in the previous exercise, and dividing by 2. Thus

$$\frac{1}{(1-2x)^2} = \frac{1}{2}\cdot\frac{d}{dx}\left(\sum_{n=0}^{\infty} \frac{2^n}{5^{n+1}}(x+2)^n\right)$$

$$= \frac{1}{2}\sum_{n=1}^{\infty} \frac{n2^n}{5^{n+1}}(x+2)^{n-1} = \frac{2}{50}\sum_{n=1}^{\infty} \frac{n2^{n-1}}{5^{n-1}}(x+2)^{n-1}$$

$$= \frac{1}{25}\sum_{k=0}^{\infty} \frac{(k+1)2^k}{5^k}(x+2)^k$$

111. $f(x) = \ln \dfrac{x}{2}, \quad c = 2$

SOLUTION Write

$$\ln \frac{x}{2} = \ln\left(\frac{(x-2)+2}{2}\right) = \ln\left(1 + \frac{x-2}{2}\right).$$

Substituting $\frac{x-2}{2}$ for x in the Maclaurin series for $\ln(1+x)$ yields

$$\ln \frac{x}{2} = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}\left(\frac{x-2}{2}\right)^n}{n} = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}(x-2)^n}{n \cdot 2^n}.$$

This series is valid for $|x-2| < 2$.

112. $f(x) = x \ln\left(1 + \dfrac{x}{2}\right), \quad c = 0$

SOLUTION Substituting $\frac{x}{2}$ for x in the Maclaurin series for $\ln(1+x)$ yields

$$\ln\left(1 + \frac{x}{2}\right) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}\left(\frac{x}{2}\right)^n}{n} = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}x^n}{n2^n}.$$

Thus,

$$x \ln\left(1 + \frac{x}{2}\right) = x\sum_{n=1}^{\infty} \frac{(-1)^{n-1}x^n}{n2^n} = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}x^{n+1}}{n2^n}.$$

In Exercises 113–116, find the first three terms of the Maclaurin series of $f(x)$ and use it to calculate $f^{(3)}(0)$.

113. $f(x) = (x^2 - x)e^{x^2}$

SOLUTION Substitute x^2 for x in the Maclaurin series for e^x to get

$$e^{x^2} = 1 + x^2 + \frac{1}{2}x^4 + \frac{1}{6}x^6 + \dots$$

so that the Maclaurin series for $f(x)$ is

$$(x^2 - x)e^{x^2} = x^2 + x^4 + \frac{1}{2}x^6 + \cdots - x - x^3 - \frac{1}{2}x^5 - \cdots = -x + x^2 - x^3 + x^4 + \dots$$

The coefficient of x^3 is

$$\frac{f'''(0)}{3!} = -1$$

so that $f'''(0) = -6$.

114. $f(x) = \tan^{-1}(x^2 - x)$

SOLUTION Substitute $x^2 - x$ for x in the Maclaurin series for $\tan^{-1} x$ to get

$$\tan^{-1}(x^2 - x) = (x^2 - x) - \frac{1}{3}(x^2 - x)^3 + \cdots = -x + x^2 + \frac{1}{3}x^3 + \dots$$

The coefficient of x^3 is

$$\frac{f'''(0)}{3!} = \frac{1}{3}$$

so that $f'''(0) = 3!\frac{1}{3} = 2$.

115. $f(x) = \dfrac{1}{1 + \tan x}$

SOLUTION Substitute $-\tan x$ in the Maclaurin series for $\frac{1}{1-x}$ to get

$$\frac{1}{1 + \tan x} = 1 - \tan x + (\tan x)^2 - (\tan x)^3 + \dots$$

We have not yet encountered the Maclaurin series for $\tan x$. We need only the terms up through x^3, so compute

$$\tan'(x) = \sec^2 x \quad \tan''(x) = 2(\tan x)\sec^2 x \quad \tan'''(x) = 2(1 + \tan^2 x)\sec^2 x + 4(\tan^2 x)\sec^2 x$$

so that

$$\tan'(0) = 1 \quad \tan''(0) = 0 \quad \tan'''(0) = 2$$

Then the Maclaurin series for $\tan x$ is

$$\tan x = \tan 0 + \frac{\tan'(0)}{1!}x + \frac{\tan''(0)}{2!}x^2 + \frac{\tan'''(0)}{3!}x^3 + \cdots = x + \frac{1}{3}x^3 + \ldots$$

Substitute these into the series above to get

$$\begin{aligned}\frac{1}{1+\tan x} &= 1 - \left(x + \frac{1}{3}x^3\right) + \left(x + \frac{1}{3}x^3\right)^2 - \left(x + \frac{1}{3}x^3\right)^3 + \ldots \\ &= 1 - x - \frac{1}{3}x^3 + x^2 - x^3 + \text{higher degree terms} \\ &= 1 - x + x^2 - \frac{4}{3}x^3 + \text{higher degree terms}\end{aligned}$$

The coefficient of x^3 is

$$\frac{f'''(0)}{3!} = -\frac{4}{3}$$

so that

$$f'''(0) = -6 \cdot \frac{4}{3} = -8$$

116. $f(x) = (\sin x)\sqrt{1+x}$

SOLUTION The binomial series for $\sqrt{1+x}$ is

$$\begin{aligned}\sqrt{1+x} = (1+x)^{1/2} &= \binom{1/2}{0} + \binom{1/2}{1}x + \binom{1/2}{2}x^2 + \binom{1/2}{3}x^3 + \ldots \\ &= 1 + \frac{1}{2}x + \frac{\frac{1}{2}\left(-\frac{1}{2}\right)}{2}x^2 + \frac{\frac{1}{2}\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)}{3!}x^3 + \ldots \\ &= 1 + \frac{1}{2}x - \frac{1}{8}x^2 + \frac{1}{16}x^3 + \ldots\end{aligned}$$

So, multiply the first few terms of the two Maclaurin series together:

$$\begin{aligned}(\sin x)\sqrt{1+x} &= \left(x - \frac{x^3}{6}\right)\left(1 + \frac{1}{2}x - \frac{1}{8}x^2 + \frac{1}{16}x^3\right) \\ &= x + \frac{1}{2}x^2 - \frac{1}{8}x^3 - \frac{1}{6}x^3 + \text{higher degree terms} \\ &= x + \frac{1}{2}x^2 - \frac{7}{24}x^3 + \text{higher degree terms}\end{aligned}$$

The coefficient of x^3 is

$$\frac{f'''(0)}{3!} = -\frac{7}{24}$$

so that

$$f'''(0) = -6 \cdot \frac{7}{24} = -\frac{7}{4}$$

117. Calculate $\frac{\pi}{2} - \frac{\pi^3}{2^3 3!} + \frac{\pi^5}{2^5 5!} - \frac{\pi^7}{2^7 7!} + \cdots$.

SOLUTION We recognize that

$$\frac{\pi}{2} - \frac{\pi^3}{2^3 3!} + \frac{\pi^5}{2^5 5!} - \frac{\pi^7}{2^7 7!} + \cdots = \sum_{n=0}^{\infty} (-1)^n \frac{(\pi/2)^{2n+1}}{(2n+1)!}$$

is the Maclaurin series for $\sin x$ with x replaced by $\pi/2$. Therefore,

$$\frac{\pi}{2} - \frac{\pi^3}{2^3 3!} + \frac{\pi^5}{2^5 5!} - \frac{\pi^7}{2^7 7!} + \cdots = \sin\frac{\pi}{2} = 1.$$

118. Find the Maclaurin series of the function $F(x) = \int_0^x \frac{e^t - 1}{t} dt$.

SOLUTION Subtracting 1 from the Maclaurin series for e^t yields

$$e^t - 1 = \sum_{n=0}^{\infty} \frac{t^n}{n!} - 1 = 1 + \sum_{n=1}^{\infty} \frac{t^n}{n!} - 1 = \sum_{n=1}^{\infty} \frac{t^n}{n!}.$$

Thus,

$$\frac{e^t - 1}{t} = \frac{1}{t} \sum_{n=1}^{\infty} \frac{t^n}{n!} = \sum_{n=1}^{\infty} \frac{t^{n-1}}{n!}.$$

Finally, integrating term-by-term yields

$$\int_0^x \frac{e^t - 1}{t} dt = \int_0^x \sum_{n=1}^{\infty} \frac{t^{n-1}}{n!} dt = \sum_{n=1}^{\infty} \int_0^x \frac{t^{n-1}}{n!} dt = \sum_{n=1}^{\infty} \frac{x^n}{n!\,n}.$$

11 PARAMETRIC EQUATIONS, POLAR COORDINATES, AND CONIC SECTIONS

11.1 Parametric Equations

Preliminary Questions

1. Describe the shape of the curve $x = 3\cos t$, $y = 3\sin t$.

SOLUTION For all t,

$$x^2 + y^2 = (3\cos t)^2 + (3\sin t)^2 = 9(\cos^2 t + \sin^2 t) = 9 \cdot 1 = 9,$$

therefore the curve is on the circle $x^2 + y^2 = 9$. Also, each point on the circle $x^2 + y^2 = 9$ can be represented in the form $(3\cos t, 3\sin t)$ for some value of t. We conclude that the curve $x = 3\cos t$, $y = 3\sin t$ is the circle of radius 3 centered at the origin.

2. How does $x = 4 + 3\cos t$, $y = 5 + 3\sin t$ differ from the curve in the previous question?

SOLUTION In this case we have

$$(x-4)^2 + (y-5)^2 = (3\cos t)^2 + (3\sin t)^2 = 9(\cos^2 t + \sin^2 t) = 9 \cdot 1 = 9$$

Therefore, the given equations parametrize the circle of radius 3 centered at the point $(4, 5)$.

3. What is the maximum height of a particle whose path has parametric equations $x = t^9$, $y = 4 - t^2$?

SOLUTION The particle's height is $y = 4 - t^2$. To find the maximum height we set the derivative equal to zero and solve:

$$\frac{dy}{dt} = \frac{d}{dt}(4 - t^2) = -2t = 0 \quad \text{or} \quad t = 0$$

The maximum height is $y(0) = 4 - 0^2 = 4$.

4. Can the parametric curve $(t, \sin t)$ be represented as a graph $y = f(x)$? What about $(\sin t, t)$?

SOLUTION In the parametric curve $(t, \sin t)$ we have $x = t$ and $y = \sin t$, therefore, $y = \sin x$. That is, the curve can be represented as a graph of a function. In the parametric curve $(\sin t, t)$ we have $x = \sin t$, $y = t$, therefore $x = \sin y$. This equation does not define y as a function of x, therefore the parametric curve $(\sin t, t)$ cannot be represented as a graph of a function $y = f(x)$.

5. Match the derivatives with a verbal description:

(a) $\dfrac{dx}{dt}$ **(b)** $\dfrac{dy}{dt}$ **(c)** $\dfrac{dy}{dx}$

(i) Slope of the tangent line to the curve

(ii) Vertical rate of change with respect to time

(iii) Horizontal rate of change with respect to time

SOLUTION

(a) The derivative $\dfrac{dx}{dt}$ is the horizontal rate of change with respect to time.

(b) The derivative $\dfrac{dy}{dt}$ is the vertical rate of change with respect to time.

(c) The derivative $\dfrac{dy}{dx}$ is the slope of the tangent line to the curve.

Hence, (a) $\leftrightarrow$ (iii), (b) $\leftrightarrow$ (ii), (c) $\leftrightarrow$ (i)

Exercises

1. Find the coordinates at times $t = 0, 2, 4$ of a particle following the path $x = 1 + t^3$, $y = 9 - 3t^2$.

SOLUTION Substituting $t = 0$, $t = 2$, and $t = 4$ into $x = 1 + t^3$, $y = 9 - 3t^2$ gives the coordinates of the particle at these times respectively. That is,

$$\begin{aligned}
&(t = 0) \quad x = 1 + 0^3 = 1,\ y = 9 - 3 \cdot 0^2 = 9 &&\Rightarrow (1, 9)\\
&(t = 2) \quad x = 1 + 2^3 = 9,\ y = 9 - 3 \cdot 2^2 = -3 &&\Rightarrow (9, -3)\\
&(t = 4) \quad x = 1 + 4^3 = 65,\ y = 9 - 3 \cdot 4^2 = -39 &&\Rightarrow (65, -39).
\end{aligned}$$

2. Find the coordinates at $t = 0, \frac{\pi}{4}, \pi$ of a particle moving along the path $c(t) = (\cos 2t, \sin^2 t)$.

SOLUTION Setting $t = 0$, $t = \frac{\pi}{4}$, and $t = \pi$ in $c(t) = (\cos 2t, \sin^2 t)$ we obtain the following coordinates of the particle:

$$\begin{aligned}
t = 0: &\quad (\cos 2 \cdot 0, \sin^2 0) = (1, 0)\\
t = \tfrac{\pi}{4}: &\quad (\cos \tfrac{2\pi}{4}, \sin^2 \tfrac{\pi}{4}) = (0, \tfrac{1}{2})\\
t = \pi: &\quad (\cos 2\pi, \sin^2 \pi) = (1, 0)
\end{aligned}$$

3. Show that the path traced by the bullet in Example 3 is a parabola by eliminating the parameter.

SOLUTION The path traced by the bullet is given by the following parametric equations:

$$x = 200t,\ \ y = 400t - 16t^2$$

We eliminate the parameter. Since $x = 200t$, we have $t = \dfrac{x}{200}$. Substituting into the equation for y we obtain:

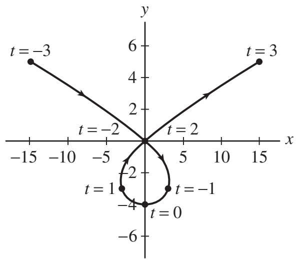
$$y = 400t - 16t^2 = 400 \cdot \frac{x}{200} - 16\left(\frac{x}{200}\right)^2 = 2x - \frac{x^2}{2500}$$

The equation $y = -\dfrac{x^2}{2500} + 2x$ is the equation of a parabola.

4. Use the table of values to sketch the parametric curve $(x(t), y(t))$, indicating the direction of motion.

t	-3	-2	-1	0	1	2	3
x	-15	0	3	0	-3	0	15
y	5	0	-3	-4	-3	0	5

SOLUTION We mark the given points on the xy-plane and connect the points corresponding to successive values of t in the direction of increasing t. We get the following trajectory (there are other correct answers):



5. Graph the parametric curves. Include arrows indicating the direction of motion.

(a) (t, t), $\ -\infty < t < \infty$

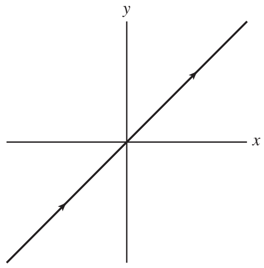
(b) $(\sin t, \sin t)$, $\ 0 \le t \le 2\pi$

(c) (e^t, e^t), $\ -\infty < t < \infty$

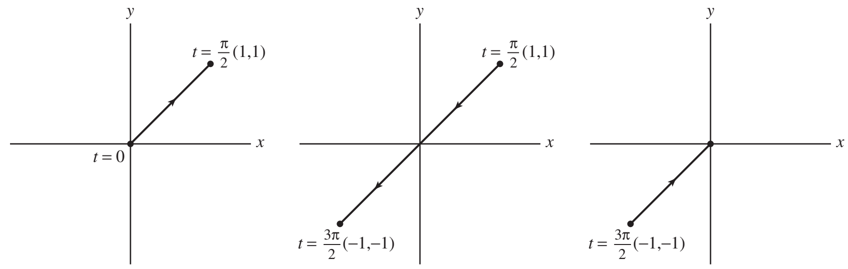
(d) (t^3, t^3), $\ -1 \le t \le 1$

SOLUTION

(a) For the trajectory $c(t) = (t, t)$, $-\infty < t < \infty$ we have $y = x$. Also the two coordinates tend to ∞ and $-\infty$ as $t \to \infty$ and $t \to -\infty$ respectively. The graph is shown next:

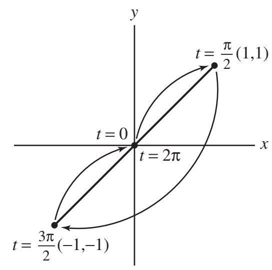


(b) For the curve $c(t) = (\sin t, \sin t)$, $0 \le t \le 2\pi$, we have $y = x$. $\sin t$ is increasing for $0 \le t \le \frac{\pi}{2}$, decreasing for $\frac{\pi}{2} \le t \le \frac{3\pi}{2}$ and increasing again for $\frac{3\pi}{2} \le t \le 2\pi$. Hence the particle moves from $c(0) = (0,0)$ to $c(\frac{\pi}{2}) = (1,1)$, then moves back to $c(\frac{3\pi}{2}) = (-1,-1)$ and then returns to $c(2\pi) = (0,0)$. We obtain the following trajectory:

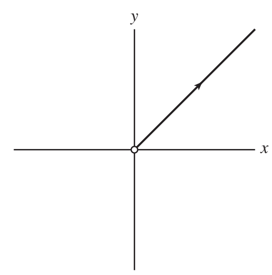


$0 < t \le \frac{\pi}{2}$ $\qquad$ $\frac{\pi}{2} \le t \le \frac{3\pi}{2}$ $\qquad$ $\frac{3\pi}{2} \le t < 2\pi$

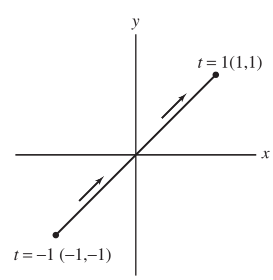
These three parts of the trajectory are shown together in the next figure:



(c) For the trajectory $c(t) = (e^t, e^t)$, $-\infty < t < \infty$, we have $y = x$. However since $\lim_{t\to-\infty} e^t = 0$ and $\lim_{t\to\infty} e^t = \infty$, the trajectory is the part of the line $y = x$, $0 < x$.



(d) For the trajectory $c(t) = (t^3, t^3)$, $-1 \le t \le 1$, we have again $y = x$. Since the function t^3 is increasing the particle moves in one direction starting at $((-1)^3, (-1)^3) = (-1,-1)$ and ending at $(1^3, 1^3) = (1,1)$. The trajectory is shown next:



6. Give two different parametrizations of the line through $(4, 1)$ with slope 2.

SOLUTION The equation of the line through $(4, 1)$ with slope 2 is $y - 1 = 2(x - 4)$ or $y = 2x - 7$. One parametrization is obtained by choosing the x coordinate as the parameter. That is, $x = t$. Hence $y = 2t - 7$ and we get $x = t$, $y = 2t - 7$, $-\infty < t < \infty$. Another parametrization is given by $x = \frac{t}{2}$, $y = t - 7$, $-\infty < t < \infty$.

In Exercises 7–14, express in the form $y = f(x)$ by eliminating the parameter.

7. $x = t + 3, \quad y = 4t$

SOLUTION We eliminate the parameter. Since $x = t + 3$, we have $t = x - 3$. Substituting into $y = 4t$ we obtain

$$y = 4t = 4(x - 3) \Rightarrow y = 4x - 12$$

8. $x = t^{-1}, \quad y = t^{-2}$

SOLUTION From $x = t^{-1}$, we have $t = x^{-1}$. Substituting in $y = t^{-2}$ we obtain

$$y = t^{-2} = (x^{-1})^{-2} = x^2 \Rightarrow y = x^2, \quad x \neq 0.$$

9. $x = t, \quad y = \tan^{-1}(t^3 + e^t)$

SOLUTION Replacing t by x in the equation for y we obtain $y = \tan^{-1}(x^3 + e^x)$.

10. $x = t^2, \quad y = t^3 + 1$

SOLUTION From $x = t^2$ we get $t = \pm\sqrt{x}$. Substituting into $y = t^3 + 1$ we obtain

$$y = t^3 + 1 = (\pm\sqrt{x})^3 + 1 = \pm\sqrt{x^3} + 1, \quad x \geq 0.$$

Since we must have y a function of x, we should probably choose either the positive or negative root.

11. $x = e^{-2t}, \quad y = 6e^{4t}$

SOLUTION We eliminate the parameter. Since $x = e^{-2t}$, we have $-2t = \ln x$ or $t = -\frac{1}{2}\ln x$. Substituting in $y = 6e^{4t}$ we get

$$y = 6e^{4t} = 6e^{4\cdot(-\frac{1}{2}\ln x)} = 6e^{-2\ln x} = 6e^{\ln x^{-2}} = 6x^{-2} \Rightarrow y = \frac{6}{x^2}, \quad x > 0.$$

12. $x = 1 + t^{-1}, \quad y = t^2$

SOLUTION From $x = 1 + t^{-1}$, we get $t^{-1} = x - 1$ or $t = \frac{1}{x-1}$. We now substitute $t = \frac{1}{x-1}$ in $y = t^2$ to obtain

$$y = t^2 = \left(\frac{1}{x-1}\right)^2 \Rightarrow y = \frac{1}{(x-1)^2}, \quad x \neq 1.$$

13. $x = \ln t, \quad y = 2 - t$

SOLUTION Since $x = \ln t$ we have $t = e^x$. Substituting in $y = 2 - t$ we obtain $y = 2 - e^x$.

14. $x = \cos t, \quad y = \tan t$

SOLUTION We use the trigonometric identity $\sin t = \pm\sqrt{1 - \cos^2 t}$ to write

$$y = \tan t = \frac{\sin t}{\cos t} = \pm\frac{\sqrt{1 - \cos^2 t}}{\cos t}.$$

We now express y in terms of x:

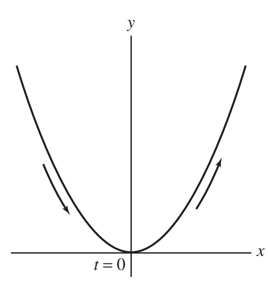
$$y = \tan t = \pm\frac{\sqrt{1 - x^2}}{x} \Rightarrow y = \pm\frac{\sqrt{1 - x^2}}{x}, \quad x \neq 0.$$

Since we must have y a function of x, we should probably choose either the positive or negative root.

In Exercises 15–18, graph the curve and draw an arrow specifying the direction corresponding to motion.

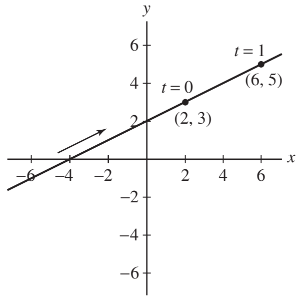
15. $x = \frac{1}{2}t, \quad y = 2t^2$

SOLUTION Let $c(t) = (x(t), y(t)) = (\frac{1}{2}t, 2t^2)$. Then $c(-t) = (-x(t), y(t))$ so the curve is symmetric with respect to the y-axis. Also, the function $\frac{1}{2}t$ is increasing. Hence there is only one direction of motion on the curve. The corresponding function is the parabola $y = 2 \cdot (2x)^2 = 8x^2$. We obtain the following trajectory:



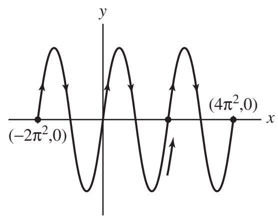
16. $x = 2 + 4t, \quad y = 3 + 2t$

SOLUTION We find the function by eliminating the parameter. Since $x = 2 + 4t$ we have $t = \frac{x-2}{4}$, hence $y = 3 + 2(\frac{x-2}{4})$ or $y = \frac{x}{2} + 2$. Also, since $2 + 4t$ and $3 + 2t$ are increasing functions, the direction of motion is the direction of increasing t. We obtain the following curve:



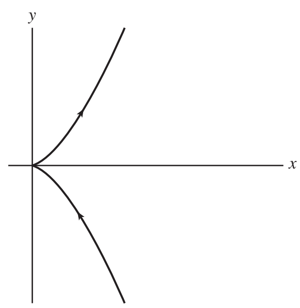
17. $x = \pi t, \quad y = \sin t$

SOLUTION We find the function by eliminating t. Since $x = \pi t$, we have $t = \frac{x}{\pi}$. Substituting $t = \frac{x}{\pi}$ into $y = \sin t$ we get $y = \sin \frac{x}{\pi}$. We obtain the following curve:



18. $x = t^2, \quad y = t^3$

SOLUTION From $x = t^2$ we have $t = \pm x^{1/2}$. Hence, $y = \pm x^{3/2}$. Since the functions t^2 and t^3 are increasing, there is only one direction of motion, which is the direction of increasing t. Notice that for $c(t) = (t^2, t^3)$ we have $c(-t) = (t^2, -t^3) = (x(t), -y(t))$. Hence the curve is symmetric with respect to the x axis. We obtain the following curve:



19. Match the parametrizations (a)–(d) below with their plots in Figure 14, and draw an arrow indicating the direction of motion.

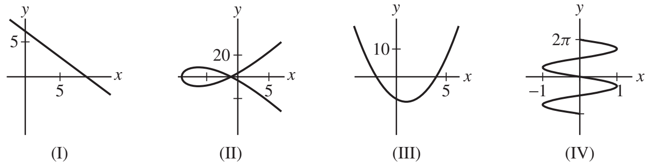


FIGURE 14

(a) $c(t) = (\sin t, -t)$

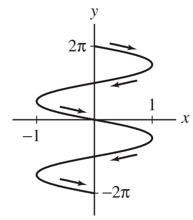
(b) $c(t) = (t^2 - 9, 8t - t^3)$

(c) $c(t) = (1 - t, t^2 - 9)$

(d) $c(t) = (4t + 2, 5 - 3t)$

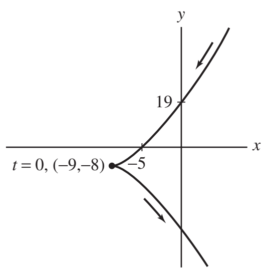
SOLUTION

(a) In the curve $c(t) = (\sin t, -t)$ the x-coordinate is varying between -1 and 1 so this curve corresponds to plot IV. As t increases, the y-coordinate $y = -t$ is decreasing so the direction of motion is downward.



(IV) $c(t) = (\sin t, -t)$

(b) The curve $c(t) = (t^2 - 9, -t^3 - 8)$ intersects the x-axis where $y = -t^3 - 8 = 0$, or $t = -2$. The x-intercept is $(-5, 0)$. The y-intercepts are obtained where $x = t^2 - 9 = 0$, or $t = \pm 3$. The y-intercepts are $(0, -35)$ and $(0, 19)$. As t increases from $-\infty$ to 0, x and y decrease, and as t increases from 0 to ∞, x increases and y decreases. We obtain the following trajectory:

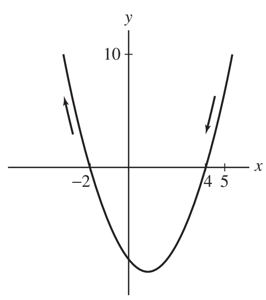


(II)

(c) The curve $c(t) = (1 - t, t^2 - 9)$ intersects the y-axis where $x = 1 - t = 0$, or $t = 1$. The y-intercept is $(0, -8)$. The x-intercepts are obtained where $t^2 - 9 = 0$ or $t = \pm 3$. These are the points $(-2, 0)$ and $(4, 0)$. Setting $t = 1 - x$ we get

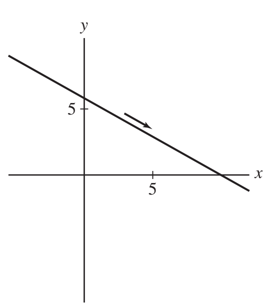
$$y = t^2 - 9 = (1 - x)^2 - 9 = x^2 - 2x - 8.$$

As t increases the x coordinate decreases and we obtain the following trajectory:



(III)

(d) The curve $c(t) = (4t + 2, 5 - 3t)$ is a straight line, since eliminating t in $x = 4t + 2$ and substituting in $y = 5 - 3t$ gives $y = 5 - 3 \cdot \frac{x-2}{4} = -\frac{3}{4}x + \frac{13}{2}$ which is the equation of a line. As t increases, the x coordinate $x = 4t + 2$ increases and the y-coordinate $y = 5 - 3t$ decreases. We obtain the following trajectory:



(I)

20. A particle follows the trajectory

$$x(t) = \frac{1}{4}t^3 + 2t, \qquad y(t) = 20t - t^2$$

with t in seconds and distance in centimeters.

(a) What is the particle's maximum height?

(b) When does the particle hit the ground and how far from the origin does it land?

SOLUTION

(a) To find the maximum height $y(t)$, we set the derivative of $y(t)$ equal to zero and solve:

$$\frac{dy}{dt} = \frac{d}{dt}(20t - t^2) = 20 - 2t = 0 \Rightarrow t = 10.$$

The maximum height is $y(10) = 20 \cdot 10 - 10^2 = 100$ cm.

(b) The object hits the ground when its height is zero. That is, when $y(t) = 0$. Solving for t we get

$$20t - t^2 = t(20 - t) = 0 \Rightarrow t = 0, t = 20.$$

$t = 0$ is the initial time, so the solution is $t = 20$. At that time, the object's x coordinate is $x(20) = \frac{1}{4} \cdot 20^3 + 2 \cdot 20 = 2040$. Thus, when it hits the ground, the object is 2040 cm away from the origin.

21. Find an interval of t-values such that $c(t) = (\cos t, \sin t)$ traces the lower half of the unit circle.

SOLUTION For $t = \pi$, we have $c(\pi) = (-1, 0)$. As t increases from π to 2π, the x-coordinate of $c(t)$ increases from -1 to 1, and the y-coordinate decreases from 0 to -1 (at $t = 3\pi/2$) and then returns to 0. Thus, for t in $[\pi, 2\pi]$, the equation traces the lower part of the circle.

22. Find an interval of t-values such that $c(t) = (2t + 1, 4t - 5)$ parametrizes the segment from $(0, -7)$ to $(7, 7)$.

SOLUTION Note that $2t + 1 = 0$ at $t = -1/2$, and $2t + 1 = 7$ at $t = 3$. Also, $4t - 5$ takes on the values of -7 and 7 at $t = -1/2$ and $t = 3$. Thus, the interval is $[-1/2, 3]$.

In Exercises 23–38, find parametric equations for the given curve.

23. $y = 9 - 4x$

SOLUTION This is a line through $P = (0, 9)$ with slope $m = -4$. Using the parametric representation of a line, as given in Example 3, we obtain $c(t) = (t, 9 - 4t)$.

24. $y = 8x^2 - 3x$

SOLUTION Letting $t = x$ yields the parametric representation $c(t) = (t, 8t^2 - 3t)$.

25. $4x - y^2 = 5$

SOLUTION We define the parameter $t = y$. Then, $x = \dfrac{5 + y^2}{4} = \dfrac{5 + t^2}{4}$, giving us the parametrization $c(t) = \left(\dfrac{5 + t^2}{4}, t\right)$.

26. $x^2 + y^2 = 49$

SOLUTION The curve $x^2 + y^2 = 49$ is a circle of radius 7 centered at the origin. We use the parametric representation of a circle to obtain the representation $c(t) = (7\cos t, 7\sin t)$.

27. $(x + 9)^2 + (y - 4)^2 = 49$

SOLUTION This is a circle of radius 7 centered at $(-9, 4)$. Using the parametric representation of a circle we get $c(t) = (-9 + 7\cos t, 4 + 7\sin t)$.

28. $\left(\dfrac{x}{5}\right)^2 + \left(\dfrac{y}{12}\right)^2 = 1$

SOLUTION This is an ellipse centered at the origin with $a = 5$ and $b = 12$. Using the parametric representation of an ellipse we get $c(t) = (5\cos t, 12\sin t)$ for $-\pi \le t \le \pi$.

29. Line of slope 8 through $(-4, 9)$

SOLUTION Using the parametric representation of a line given in Example 3, we get the parametrization $c(t) = (-4 + t, 9 + 8t)$.

30. Line through $(2, 5)$ perpendicular to $y = 3x$

SOLUTION The line perpendicular to $y = 3x$ has slope $m = -\frac{1}{3}$. We use the parametric representation of a line given in Example 3 to obtain the parametrization $c(t) = (2 + t, 5 - \frac{1}{3}t)$.

31. Line through $(3, 1)$ and $(-5, 4)$

SOLUTION We use the two-point parametrization of a line with $P = (a, b) = (3, 1)$ and $Q = (c, d) = (-5, 4)$. Then $c(t) = (3 - 8t, 1 + 3t)$ for $-\infty < t < \infty$.

32. Line through $\left(\frac{1}{3}, \frac{1}{6}\right)$ and $\left(-\frac{7}{6}, \frac{5}{3}\right)$

SOLUTION We use the two-point parametrization of a line with $P = (a, b) = \left(\frac{1}{3}, \frac{1}{6}\right)$ and $Q = (c, d) = \left(-\frac{7}{6}, \frac{5}{3}\right)$. Then

$$c(t) = \left(\frac{1}{3} - \frac{3}{2}t, \frac{1}{6} + \frac{3}{2}t\right)$$

for $-\infty < t < \infty$.

33. Segment joining $(1, 1)$ and $(2, 3)$

SOLUTION We use the two-point parametrization of a line with $P = (a, b) = (1, 1)$ and $Q = (c, d) = (2, 3)$. Then $c(t) = (1 + t, 1 + 2t)$; since we want only the segment joining the two points, we want $0 \le t \le 1$.

34. Segment joining $(-3, 0)$ and $(0, 4)$

SOLUTION We use the two-point parametrization of a line with $P = (a, b) = (-3, 0)$ and $Q = (c, d) = (0, 4)$. Then $c(t) = (-3 + 3t, 4t)$; since we want only the segment joining the two points, we want $0 \le t \le 1$.

35. Circle of radius 4 with center $(3, 9)$

SOLUTION Substituting $(a, b) = (3, 9)$ and $R = 4$ in the parametric equation of the circle we get $c(t) = (3 + 4\cos t, 9 + 4\sin t)$.

36. Ellipse of Exercise 28, with its center translated to $(7, 4)$

SOLUTION Since the center is translated by $(7, 4)$, so is every point. Thus the original parametrization becomes $c(t) = (7 + 5\cos t, 4 + 12\sin t)$ for $-\pi \le t \le \pi$.

37. $y = x^2$, translated so that the minimum occurs at $(-4, -8)$

SOLUTION We may parametrize $y = x^2$ by (t, t^2) for $-\infty < t < \infty$. The minimum of $y = x^2$ occurs at $(0, 0)$, so the desired curve is translated by $(-4, -8)$ from $y = x^2$. Thus a parametrization of the desired curve is $c(t) = (-4 + t, -8 + t^2)$.

38. $y = \cos x$ translated so that a maximum occurs at $(3, 5)$

SOLUTION A maximum value 1 of $y = \cos x$ occurs at $x = 0$. Hence, the curve $y - 4 = \cos(x - 3)$, or $y = 4 + \cos(x - 3)$ has a maximum at the point $(3, 5)$. We let $t = x - 3$, then $x = t + 3$ and $y = 4 + \cos t$. We obtain the representation $c(t) = (t + 3, 4 + \cos t)$.

In Exercises 39–42, find a parametrization $c(t)$ of the curve satisfying the given condition.

39. $y = 3x - 4, \quad c(0) = (2, 2)$

SOLUTION Let $x(t) = t + a$ and $y(t) = 3x - 4 = 3(t + a) - 4$. We want $x(0) = 2$, thus we must use $a = 2$. Our line is $c(t) = (x(t), y(t)) = (t + 2, 3(t + 2) - 4) = (t + 2, 3t + 2)$.

40. $y = 3x - 4, \quad c(3) = (2, 2)$

SOLUTION Let $x(t) = t + a$; since $x(3) = 2$ we have $2 = 3 + a$ so that $a = -1$. Then $y = 3x - 4 = 3(t - 1) - 4 = 3t - 7$, so that the line is $c(t) = (t - 1, 3t - 7)$ for $-\infty < t < \infty$.

41. $y = x^2, \quad c(0) = (3, 9)$

SOLUTION Let $x(t) = t + a$ and $y(t) = x^2 = (t + a)^2$. We want $x(0) = 3$, thus we must use $a = 3$. Our curve is $c(t) = (x(t), y(t)) = (t + 3, (t + 3)^2) = (t + 3, t^2 + 6t + 9)$.

42. $x^2 + y^2 = 4, \quad c(0) = (1, \sqrt{3})$

SOLUTION This is a circle of radius 2 centered at the origin, so we are looking for a parametrization of that circle that starts at a different point. Thus instead of the standard parametrization $(2\cos\theta, 2\sin\theta)$, $\theta = 0$ must correspond to some other angle ω. We choose the parametrization $(2\cos(\theta + \omega), 2\sin(\theta + \omega))$ and must determine the value of ω. Now,

$$x(0) = 1, \quad \text{so} \quad 1 = 2\cos(0 + \omega) = 2\cos\omega \quad \text{and} \quad \omega = \cos^{-1}\frac{1}{2} = \frac{\pi}{3} \text{ or } \frac{5\pi}{3}$$

Since

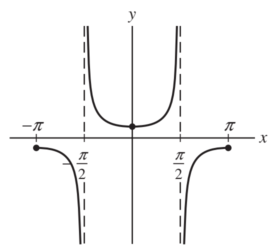
$$y(0) = \sqrt{3}, \quad \text{we have} \quad \sqrt{3} = 2\sin(0 + \omega) = 2\sin\omega \quad \text{and} \quad \omega = \sin^{-1}\frac{\sqrt{3}}{2} = \frac{\pi}{3} \text{ or } \frac{2\pi}{3}$$

Comparing these results we see that we must have $\omega = \dfrac{\pi}{3}$ so that the parametrization is

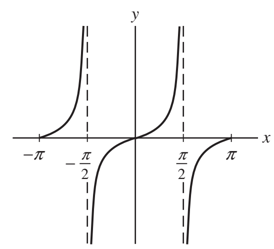
$$c(t) = \left(2\cos\left(\theta + \frac{\pi}{3}\right), 2\sin\left(\theta + \frac{\pi}{3}\right)\right)$$

43. Describe $c(t) = (\sec t, \tan t)$ for $0 \le t < \frac{\pi}{2}$ in the form $y = f(x)$. Specify the domain of x.

SOLUTION The function $x = \sec t$ has period 2π and $y = \tan t$ has period π. The graphs of these functions in the interval $-\pi \le t \le \pi$, are shown below:



$x = \sec t$

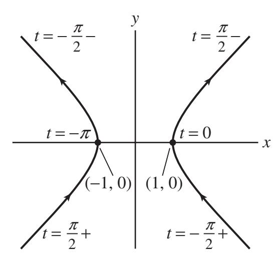


$y = \tan t$

$$x = \sec t \Rightarrow x^2 = \sec^2 t$$

$$y = \tan t \Rightarrow y^2 = \tan^2 t = \frac{\sin^2 t}{\cos^2 t} = \frac{1 - \cos^2 t}{\cos^2 t} = \sec^2 t - 1 = x^2 - 1$$

Hence the graph of the curve is the hyperbola $x^2 - y^2 = 1$. The function $x = \sec t$ is an even function while $y = \tan t$ is odd. Also x has period 2π and y has period π. It follows that the intervals $-\pi \le t < -\frac{\pi}{2}$, $\frac{-\pi}{2} < t < \frac{\pi}{2}$ and $\frac{\pi}{2} < t < \pi$ trace the curve exactly once. The corresponding curve is shown next:



$c(t) = (\sec t, \tan t)$

44. Find a parametrization of the right branch ($x > 0$) of the hyperbola

$$\left(\frac{x}{a}\right)^2 - \left(\frac{y}{b}\right)^2 = 1$$

using the functions $\cosh t$ and $\sinh t$. How can you parametrize the branch $x < 0$?

SOLUTION We show first that $x = \cosh t$, $y = \sinh t$ parametrizes the hyperbola when $a = b = 1$: then

$$x^2 - y^2 = (\cosh t)^2 - (\sinh t)^2 = 1.$$

using the identity $\cosh^2 - \sinh^2 = 1$. Generalize this parametrization to get a parametrization for the general hyperbola $(\frac{x}{a})^2 - (\frac{y}{b})^2 = 1$:

$$x = a \cosh t, \ \ y = b \sinh t.$$

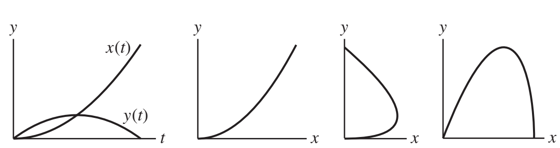
We must of course check that this parametrization indeed parametrizes the curve, i.e. that $x = a \cosh t$ and $y = b \sin t$ satisfy the equation $(\frac{x}{a})^2 - (\frac{y}{b})^2 = 1$:

$$\left(\frac{x}{a}\right)^2 - \left(\frac{y}{b}\right)^2 = \left(\frac{a \cosh t}{a}\right)^2 - \left(\frac{b \sinh t}{b}\right)^2 = (\cosh t)^2 - (\sinh t)^2 = 1.$$

The left branch of the hyperbola is the reflection of the right branch around the line $x = 0$, so it clearly has the parametrization

$$x = -a \cosh t, \ \ y = b \sinh t.$$

45. The graphs of $x(t)$ and $y(t)$ as functions of t are shown in Figure 15(A). Which of (I)–(III) is the plot of $c(t) = (x(t), y(t))$? Explain.



(A) (I) (II) (III)

FIGURE 15

SOLUTION As seen in Figure 15(A), the x-coordinate is an increasing function of t, while $y(t)$ is first increasing and then decreasing. In Figure I, x and y are both increasing or both decreasing (depending on the direction on the curve). In Figure II, x does not maintain one tendency, rather, it is decreasing and increasing for certain values of t. The plot $c(t) = (x(t), y(t))$ is plot III.

46. Which graph, (I) or (II), is the graph of $x(t)$ and which is the graph of $y(t)$ for the parametric curve in Figure 16(A)?

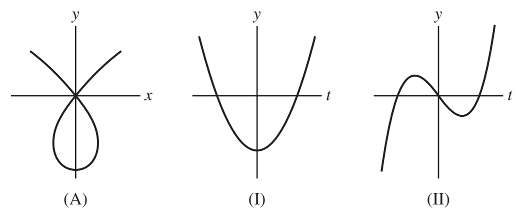


FIGURE 16

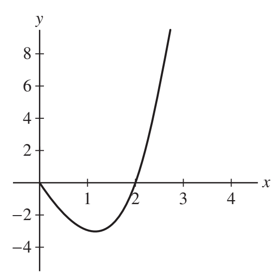
SOLUTION As indicated by Figure 16(A), the y-coordinate is decreasing and then increasing, so plot I is the graph of y. Figure 16(A) also shows that the x-coordinate is increasing, decreasing and then increasing, so plot II is the graph for x.

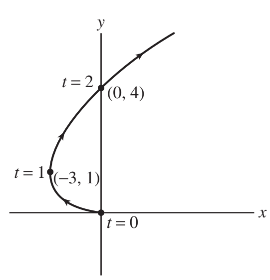
47. Sketch $c(t) = (t^3 - 4t, t^2)$ following the steps in Example 7.

SOLUTION We note that $x(t) = t^3 - 4t$ is odd and $y(t) = t^2$ is even, hence $c(-t) = (x(-t), y(-t)) = (-x(t), y(t))$. It follows that $c(-t)$ is the reflection of $c(t)$ across y-axis. That is, $c(-t)$ and $c(t)$ are symmetric with respect to the y-axis; thus, it suffices to graph the curve for $t \geq 0$. For $t = 0$, we have $c(0) = (0, 0)$ and the y-coordinate $y(t) = t^2$ tends to ∞ as $t \to \infty$. To analyze the x-coordinate, we graph $x(t) = t^3 - 4t$ for $t \geq 0$:

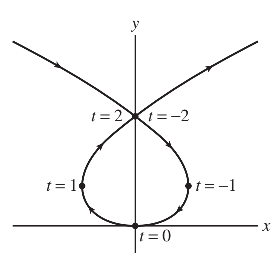


$x = t^3 - 4t$

We see that $x(t) < 0$ and decreasing for $0 < t < 2/\sqrt{3}$, $x(t) < 0$ and increasing for $2/\sqrt{3} < t < 2$ and $x(t) > 0$ and increasing for $t > 2$. Also $x(t)$ tends to ∞ as $t \to \infty$. Therefore, starting at the origin, the curve first directs to the left of the y-axis, then at $t = 2/\sqrt{3}$ it turns to the right, always keeping an upward direction. The part of the path for $t \leq 0$ is obtained by reflecting across the y-axis. We also use the points $c(0) = (0, 0)$, $c(1) = (-3, 1)$, $c(2) = (0, 4)$ to obtain the following graph for $c(t)$:



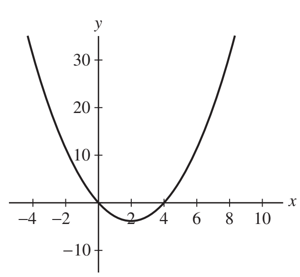
Graph of $c(t)$ for $t \geq 0$.



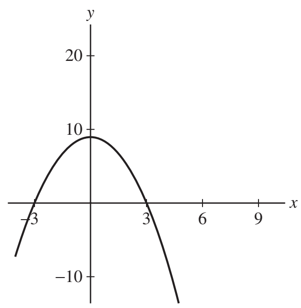
Graph of $c(t)$ for all t.

48. Sketch $c(t) = (t^2 - 4t, 9 - t^2)$ for $-4 \leq t \leq 10$.

SOLUTION The graphs of $x(t) = t^2 - 4t$ and $y(t) = 9 - t^2$ for $-4 \leq t \leq 10$ are shown in the following figures:



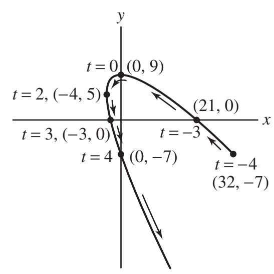
$x(t) = t^2 - 4t$



$y(t) = 9 - t^2$

The curve starts at $c(-4) = (32, -7)$. For $-4 < t < 0$, $x(t)$ is decreasing and $y(t)$ is increasing, so the graph turns to the left and upwards to $c(0) = (0, 9)$. Then for $0 < t < 2$, $x(t)$ is decreasing and so is $y(t)$, hence the graph turns to the left and downwards towards $c(2) = (-4, 5)$.

For $2 < t < 10$, $x(t)$ is increasing and $y(t)$ is decreasing, hence the graph turns to the right and downwards, ending at $c(10) = (60, -91)$. The intercept are the points where $t^2 - 4t = t(t-4) = 0$ or $9 - t^2 = 0$, that is $t = 0, 4, \pm 3$. These are the points $c(0) = (0, 9)$, $c(4) = (0, -7)$, $c(3) = (-3, 0)$, $c(-3) = (21, 0)$. These properties lead to the following path:



In Exercises 49–52, use Eq. (7) to find dy/dx at the given point.

49. $(t^3, t^2 - 1), \quad t = -4$

SOLUTION By Eq. (7) we have

$$\frac{dy}{dx} = \frac{y'(t)}{x'(t)} = \frac{(t^2-1)'}{(t^3)'} = \frac{2t}{3t^2} = \frac{2}{3t}$$

Substituting $t = -4$ we get

$$\frac{dy}{dx} = \frac{2}{3t}\bigg|_{t=-4} = \frac{2}{3 \cdot (-4)} = -\frac{1}{6}.$$

50. $(2t + 9, 7t - 9), \quad t = 1$

SOLUTION We find $\frac{dy}{dx}$:

$$\frac{dy}{dx} = \frac{(7t-9)'}{(2t+9)'} = \frac{7}{2} \Rightarrow \frac{dy}{dx}\bigg|_{t=1} = \frac{7}{2}.$$

51. $(s^{-1} - 3s, s^3), \quad s = -1$

SOLUTION Using Eq. (7) we get

$$\frac{dy}{dx} = \frac{y'(s)}{x'(s)} = \frac{(s^3)'}{(s^{-1} - 3s)'} = \frac{3s^2}{-s^{-2} - 3} = \frac{3s^4}{-1 - 3s^2}$$

Substituting $s = -1$ we obtain

$$\frac{dy}{dx} = \frac{3s^4}{-1 - 3s^2}\bigg|_{s=-1} = \frac{3 \cdot (-1)^4}{-1 - 3 \cdot (-1)^2} = -\frac{3}{4}.$$

52. $(\sin 2\theta, \cos 3\theta), \quad \theta = \frac{\pi}{6}$

SOLUTION Using Eq. (7) we get

$$\frac{dy}{dx} = \frac{y'(\theta)}{x'(\theta)} = \frac{-3\sin 3\theta}{2\cos 2\theta}$$

Substituting $\theta = \dfrac{\pi}{6}$ we get

$$\frac{dy}{dx} = \left.\frac{-3\sin 3\theta}{2\cos 2\theta}\right|_{\theta=\pi/6} = \frac{-3\sin\frac{\pi}{2}}{2\cos\frac{\pi}{3}} = \frac{-3}{2\cdot\frac{1}{2}} = -3$$

In Exercises 53–56, find an equation $y = f(x)$ for the parametric curve and compute dy/dx in two ways: using Eq. (7) and by differentiating $f(x)$.

53. $c(t) = (2t+1, 1-9t)$

SOLUTION Since $x = 2t+1$, we have $t = \dfrac{x-1}{2}$. Substituting in $y = 1 - 9t$ we have

$$y = 1 - 9\left(\frac{x-1}{2}\right) = -\frac{9}{2}x + \frac{11}{2}$$

Differentiating $y = -\dfrac{9}{2}x + \dfrac{11}{2}$ gives $\dfrac{dy}{dx} = -\dfrac{9}{2}$. We now find $\dfrac{dy}{dx}$ using Eq. (7):

$$\frac{dy}{dx} = \frac{y'(t)}{x'(t)} = \frac{(1-9t)'}{(2t+1)'} = -\frac{9}{2}$$

54. $c(t) = \left(\frac{1}{2}t, \frac{1}{4}t^2 - t\right)$

SOLUTION Since $x = \frac{1}{2}t$ we have $t = 2x$. Substituting in $y = \frac{1}{4}t^2 - t$ yields

$$y = \frac{1}{4}(2x)^2 - 2x = x^2 - 2x.$$

We differentiate $y = x^2 - 2x$:

$$\frac{dy}{dx} = 2x - 2$$

Now, we find $\frac{dy}{dx}$ using Eq. (7). Thus,

$$\frac{dy}{dx} = \frac{y'(t)}{x'(t)} = \frac{\left(\frac{1}{4}t^2 - t\right)'}{\left(\frac{1}{2}t\right)'} = \frac{\frac{1}{2}t - 1}{\frac{1}{2}} = t - 2.$$

Since $t = 2x$, then this $t - 2$ is the same as $2x - 2$.

55. $x = s^3, \quad y = s^6 + s^{-3}$

SOLUTION We find y as a function of x:

$$y = s^6 + s^{-3} = \left(s^3\right)^2 + \left(s^3\right)^{-1} = x^2 + x^{-1}.$$

We now differentiate $y = x^2 + x^{-1}$. This gives

$$\frac{dy}{dx} = 2x - x^{-2}.$$

Alternatively, we can use Eq. (7) to obtain the following derivative:

$$\frac{dy}{dx} = \frac{y'(s)}{x'(s)} = \frac{\left(s^6 + s^{-3}\right)'}{\left(s^3\right)'} = \frac{6s^5 - 3s^{-4}}{3s^2} = 2s^3 - s^{-6}.$$

Hence, since $x = s^3$,

$$\frac{dy}{dx} = 2x - x^{-2}.$$

56. $x = \cos\theta, \quad y = \cos\theta + \sin^2\theta$

SOLUTION To find y as a function of x, we first use the trigonometric identity $\sin^2\theta = 1 - \cos^2\theta$ to write

$$y = \cos\theta + 1 - \cos^2\theta.$$

We substitute $x = \cos\theta$ to obtain $y = x + 1 - x^2$. Differentiating this function yields

$$\frac{dy}{dx} = 1 - 2x.$$

Alternatively, we can compute $\frac{dy}{dx}$ using Eq. (7). That is,

$$\frac{dy}{dx} = \frac{y'(\theta)}{x'(\theta)} = \frac{\left(\cos\theta + \sin^2\theta\right)'}{(\cos\theta)'} = \frac{-\sin\theta + 2\sin\theta\cos\theta}{-\sin\theta} = 1 - 2\cos\theta.$$

Hence, since $x = \cos\theta$,

$$\frac{dy}{dx} = 1 - 2x.$$

57. Find the points on the curve $c(t) = (3t^2 - 2t, t^3 - 6t)$ where the tangent line has slope 3.

SOLUTION We solve

$$\frac{dy}{dx} = \frac{3t^2 - 6}{6t - 2} = 3$$

or $3t^2 - 6 = 18t - 6$, or $t^2 - 6t = 0$, so the slope is 3 at $t = 0, 6$ and the points are $(0, 0)$ and $(96, 180)$

58. Find the equation of the tangent line to the cycloid generated by a circle of radius 4 at $t = \frac{\pi}{2}$.

SOLUTION The cycloid generated by a circle of radius 4 can be parametrized by

$$c(t) = (4t - 4\sin t, 4 - 4\cos t)$$

Then we compute

$$\left.\frac{dy}{dx}\right|_{t=\pi/2} = \left.\frac{4\sin t}{4 - 4\cos t}\right|_{t=\pi/2} = \frac{4}{4} = 1$$

so that the slope of the tangent line is 1 and the equation of the tangent line is

$$y - \left(4 - 4\cos\frac{\pi}{2}\right) = 1 \cdot \left(x - \left(4 \cdot \frac{\pi}{2} - 4\sin\frac{\pi}{2}\right)\right) \quad \text{or} \quad y = x + 8 - 2\pi$$

In Exercises 59–62, let $c(t) = (t^2 - 9, t^2 - 8t)$ (see Figure 17).

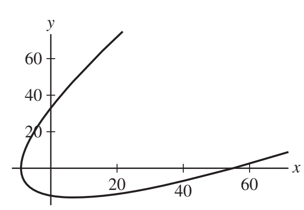


FIGURE 17 Plot of $c(t) = (t^2 - 9, t^2 - 8t)$.

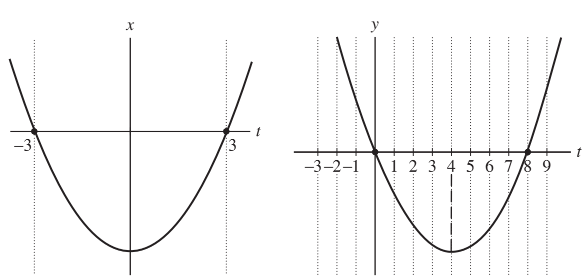
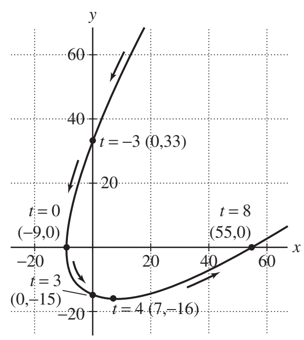
59. Draw an arrow indicating the direction of motion, and determine the interval of t-values corresponding to the portion of the curve in each of the four quadrants.

SOLUTION We plot the functions $x(t) = t^2 - 9$ and $y(t) = t^2 - 8t$:



$x = t^2 - 9$ $\qquad$ $y = t^2 - 8t$

We note carefully where each of these graphs are positive or negative, increasing or decreasing. In particular, $x(t)$ is decreasing for $t < 0$, increasing for $t > 0$, positive for $|t| > 3$, and negative for $|t| < 3$. Likewise, $y(t)$ is decreasing for $t < 4$, increasing for $t > 4$, positive for $t > 8$ or $t < 0$, and negative for $0 < t < 8$. We now draw arrows on the path following the decreasing/increasing behavior of the coordinates as indicated above. We obtain:



This plot also shows that:

- The graph is in the first quadrant for $t < -3$ or $t > 8$.
- The graph is in the second quadrant for $-3 < t < 0$.
- The graph is in the third quadrant for $0 < t < 3$.
- The graph is in the fourth quadrant for $3 < t < 8$.

60. Find the equation of the tangent line at $t = 4$.

SOLUTION Using the formula for the slope m of the tangent line we have:

$$m = \frac{dy}{dx}\bigg|_{t=4} = \frac{\left(t^2 - 8t\right)'}{\left(t^2 - 9\right)'}\bigg|_{t=4} = \frac{2t - 8}{2t}|_{t=4} = 1 - \frac{4}{t}|_{t=4} = 0.$$

Since the slope is zero, the tangent line is horizontal. The y-coordinate corresponding to $t = 4$ is $y = 4^2 - 8 \cdot 4 = -16$. Hence the equation of the tangent line is $y = -16$.

61. Find the points where the tangent has slope $\frac{1}{2}$.

SOLUTION The slope of the tangent at t is

$$\frac{dy}{dx} = \frac{\left(t^2 - 8t\right)'}{\left(t^2 - 9\right)'} = \frac{2t - 8}{2t} = 1 - \frac{4}{t}$$

The point where the tangent has slope $\frac{1}{2}$ corresponds to the value of t that satisfies

$$\frac{dy}{dx} = 1 - \frac{4}{t} = \frac{1}{2} \Rightarrow \frac{4}{t} = \frac{1}{2} \Rightarrow t = 8.$$

We substitute $t = 8$ in $x(t) = t^2 - 9$ and $y(t) = t^2 - 8t$ to obtain the following point:

$$\begin{aligned} x(8) &= 8^2 - 9 = 55 \\ y(8) &= 8^2 - 8 \cdot 8 = 0 \end{aligned} \quad \Rightarrow \quad (55, 0)$$

62. Find the points where the tangent is horizontal or vertical.

SOLUTION In Exercise 61 we found that the slope of the tangent at t is

$$\frac{dy}{dx} = 1 - \frac{4}{t} = \frac{t - 4}{t}$$

The tangent is horizontal where its slope is zero. We set the slope equal to zero and solve for t. This gives

$$\frac{t - 4}{t} = 0 \Rightarrow t = 4.$$

The corresponding point is

$$(x(4), y(4)) = (4^2 - 9, 4^2 - 8 \cdot 4) = (7, -16).$$

The tangent is vertical where it has infinite slope; that is, at $t = 0$. The corresponding point is

$$(x(0), y(0)) = (0^2 - 9, 0^2 - 8 \cdot 0) = (-9, 0).$$

63. Let A and B be the points where the ray of angle θ intersects the two concentric circles of radii $r < R$ centered at the origin (Figure 18). Let P be the point of intersection of the horizontal line through A and the vertical line through B. Express the coordinates of P as a function of θ and describe the curve traced by P for $0 \le \theta \le 2\pi$.

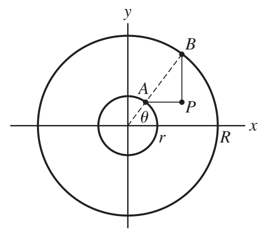


FIGURE 18

SOLUTION We use the parametric representation of a circle to determine the coordinates of the points A and B. That is,

$$A = (r\cos\theta, r\sin\theta), \; B = (R\cos\theta, R\sin\theta)$$

The coordinates of P are therefore

$$P = (R\cos\theta, r\sin\theta)$$

In order to identify the curve traced by P, we notice that the x and y coordinates of P satisfy $\frac{x}{R} = \cos\theta$ and $\frac{y}{r} = \sin\theta$. Hence

$$\left(\frac{x}{R}\right)^2 + \left(\frac{y}{r}\right)^2 = \cos^2\theta + \sin^2\theta = 1.$$

The equation

$$\left(\frac{x}{R}\right)^2 + \left(\frac{y}{r}\right)^2 = 1$$

is the equation of ellipse. Hence, the coordinates of P, $(R\cos\theta, r\sin\theta)$ describe an ellipse for $0 \le \theta \le 2\pi$.

64. A 10-ft ladder slides down a wall as its bottom B is pulled away from the wall (Figure 19). Using the angle θ as parameter, find the parametric equations for the path followed by (a) the top of the ladder A, (b) the bottom of the ladder B, and (c) the point P located 4 ft from the top of the ladder. Show that P describes an ellipse.

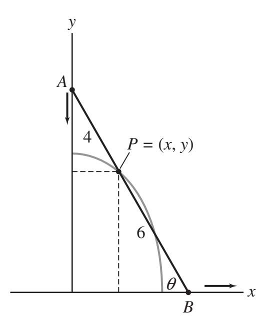

FIGURE 19

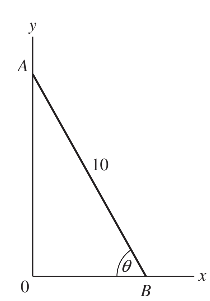
SOLUTION

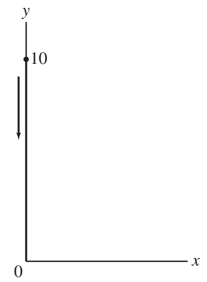
(a) We define the xy-coordinate system as shown in the figure:



As the ladder slides down the wall, the x-coordinate of A is always zero and the y-coordinate is $y = 10\sin\theta$. The parametric equations for the path followed by A are thus

$$x = 0, \; y = 10\sin\theta, \quad \theta \text{ is between } \tfrac{\pi}{2} \text{ and } 0.$$

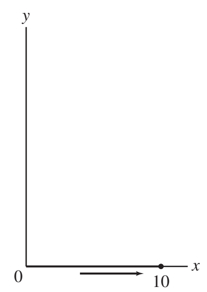
The path described by A is the segment [0, 10] on the y-axis.



(b) As the ladder slides down the wall, the y-coordinate of B is always zero and the x-coordinate is $x = 10\cos\theta$. The parametric equations for the path followed by B are therefore

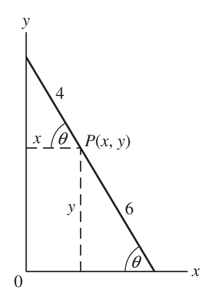
$$x = 10\cos\theta, \; y = 0, \quad \theta \text{ is between } \tfrac{\pi}{2} \text{ and } 0.$$

The path is the segment [0, 10] on the x-axis.

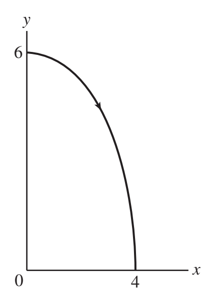


(c) The x and y coordinates of P are $x = 4\cos\theta$, $y = 6\sin\theta$. The path followed by P has the following parametrization:

$$c(\theta) = (4\cos\theta, 6\sin\theta), \quad \theta \text{ is between } \tfrac{\pi}{2} \text{ and } 0.$$



As shown in Example 4, the corresponding path is a part of an ellipse. Since θ is varying between $\frac{\pi}{2}$ and 0, we obtain the part of the ellipse in the first quadrant.



In Exercises 65–68, refer to the Bézier curve defined by Eqs. (8) and (9).

65. Show that the Bézier curve with control points

$$P_0 = (1, 4), \quad P_1 = (3, 12), \quad P_2 = (6, 15), \quad P_3 = (7, 4)$$

has parametrization

$$c(t) = (1 + 6t + 3t^2 - 3t^3, 4 + 24t - 15t^2 - 9t^3)$$

Verify that the slope at $t = 0$ is equal to the slope of the segment $\overline{P_0 P_1}$.

SOLUTION For the given Bézier curve we have $a_0 = 1, a_1 = 3, a_2 = 6, a_3 = 7$, and $b_0 = 4, b_1 = 12, b_2 = 15, b_3 = 4$. Substituting these values in Eq. (8)–(9) and simplifying gives

$$\begin{aligned} x(t) &= (1-t)^3 + 9t(1-t)^2 + 18t^2(1-t) + 7t^3 \\ &= 1 - 3t + 3t^2 - t^3 + 9t(1 - 2t + t^2) + 18t^2 - 18t^3 + 7t^3 \\ &= 1 - 3t + 3t^2 - t^3 + 9t - 18t^2 + 9t^3 + 18t^2 - 18t^3 + 7t^3 \\ &= -3t^3 + 3t^2 + 6t + 1 \\ y(t) &= 4(1-t)^3 + 36t(1-t)^2 + 45t^2(1-t) + 4t^3 \\ &= 4(1 - 3t + 3t^2 - t^3) + 36t(1 - 2t + t^2) + 45t^2 - 45t^3 + 4t^3 \\ &= 4 - 12t + 12t^2 - 4t^3 + 36t - 72t^2 + 36t^3 + 45t^2 - 45t^3 + 4t^3 \\ &= 4 + 24t - 15t^2 - 9t^3 \end{aligned}$$

Then

$$c(t) = (1 + 6t + 3t^2 - 3t^3, 4 + 24t - 15t^2 - 9t^3), \quad 0 \le t \le 1.$$

We find the slope at $t = 0$. Using the formula for slope of the tangent line we get

$$\frac{dy}{dx} = \frac{(4 + 24t - 15t^2 - 9t^3)'}{(1 + 6t + 3t^2 - 3t^3)'} = \frac{24 - 30t - 27t^2}{6 + 6t - 9t^2} \Rightarrow \left.\frac{dy}{dx}\right|_{t=0} = \frac{24}{6} = 4.$$

The slope of the segment $\overline{P_0 P_1}$ is the slope of the line determined by the points $P_0 = (1, 4)$ and $P_1 = (3, 12)$. That is, $\frac{12-4}{3-1} = \frac{8}{2} = 4$. We see that the slope of the tangent line at $t = 0$ is equal to the slope of the segment $\overline{P_0 P_1}$, as expected.

66. Find an equation of the tangent line to the Bézier curve in Exercise 65 at $t = \frac{1}{3}$.

SOLUTION We have

$$\frac{dy}{dx} = \frac{y(t)'}{x(t)'} = \frac{24 - 30t - 27t^2}{6_6t - 9t^2}$$

so that at $t = \frac{1}{3}$,

$$\left.\frac{dy}{dx}\right|_{t=1/3} = \left.\frac{24 - 30t - 27t^2}{6 + 6t - 9t^2}\right|_{t=1/3} = \frac{11}{7}$$

and

$$x\left(\frac{1}{3}\right) = \frac{29}{9}, \qquad y\left(\frac{1}{3}\right) = 10$$

Thus the tangent line is

$$y - 10 = \frac{11}{7}\left(x - \frac{29}{9}\right) \qquad \text{or} \qquad y = \frac{11}{7}x + \frac{311}{63}$$

67. CAS Find and plot the Bézier curve $c(t)$ passing through the control points

$$P_0 = (3, 2), \quad P_1 = (0, 2), \quad P_2 = (5, 4), \quad P_3 = (2, 4)$$

SOLUTION Setting $a_0 = 3, a_1 = 0, a_2 = 5, a_3 = 2$, and $b_0 = 2, b_1 = 2, b_2 = 4, b_3 = 4$ into Eq. (8)–(9) and simplifying gives

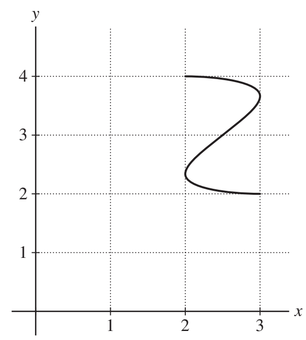
$$\begin{aligned} x(t) &= 3(1-t)^3 + 0 + 15t^2(1-t) + 2t^3 \\ &= 3(1 - 3t + 3t^2 - t^3) + 15t^2 - 15t^3 + 2t^3 = 3 - 9t + 24t^2 - 16t^3 \end{aligned}$$

$$\begin{aligned} y(t) &= 2(1-t)^3 + 6t(1-t)^2 + 12t^2(1-t) + 4t^3 \\ &= 2(1-3t+3t^2-t^3) + 6t(1-2t+t^2) + 12t^2 - 12t^3 + 4t^3 \\ &= 2 - 6t + 6t^2 - 2t^3 + 6t - 12t^2 + 6t^3 + 12t^2 - 12t^3 + 4t^3 = 2 + 6t^2 - 4t^3 \end{aligned}$$

We obtain the following equation

$$c(t) = (3 - 9t + 24t^2 - 16t^3, 2 + 6t^2 - 4t^3), \quad 0 \le t \le 1.$$

The graph of the Bézier curve is shown in the following figure:



68. Show that a cubic Bézier curve is tangent to the segment $\overline{P_2P_3}$ at P_3.

SOLUTION The equations of the cubic Bézier curve are

$$\begin{aligned} x(t) &= a_0(1-t)^3 + 3a_1t(1-t)^2 + 3a_2t^2(1-t) + a_3t^3 \\ y(t) &= b_0(1-t)^3 + 3b_1t(1-t)^2 + 3b_2t^2(1-t) + b_3t^3 \end{aligned}$$

We use the formula for the slope of the tangent line to find the slope of the tangent line at P_3. We obtain

$$\frac{dy}{dx} = \frac{y'(t)}{x'(t)} = \frac{-3b_0(1-t)^2 + 3b_1((1-t)^2 - 2t(1-t)) + 3b_2(2t(1-t) - t^2) + 3b_3t^2}{-3a_0(1-t)^2 + 3a_1((1-t)^2 - 2t(1-t)) + 3a_2(2t(1-t) - t^2) + 3a_3t^2} \tag{1}$$

The slope of the tangent line at P_3 is obtained by setting $t = 1$ in (1). That is,

$$m_1 = \frac{0 + 0 - 3b_2 + 3b_3}{0 + 0 - 3a_2 + 3a_3} = \frac{b_3 - b_2}{a_3 - a_2} \tag{2}$$

We compute the slope of the segment $\overline{P_2P_3}$ for $P_2 = (a_2, b_2)$ and $P_3 = (a_3, b_3)$. We get

$$m_2 = \frac{b_3 - b_2}{a_3 - a_2}$$

Since the two slopes are equal, we conclude that the tangent line to the curve at the point P_3 is the segment $\overline{P_2P_3}$.

69. A bullet fired from a gun follows the trajectory

$$x = at, \qquad y = bt - 16t^2 \quad (a, b > 0)$$

Show that the bullet leaves the gun at an angle $\theta = \tan^{-1}\left(\frac{b}{a}\right)$ and lands at a distance $ab/16$ from the origin.

SOLUTION The height of the bullet equals the value of the y-coordinate. When the bullet leaves the gun, $y(t) = t(b - 16t) = 0$. The solutions to this equation are $t = 0$ and $t = \frac{b}{16}$, with $t = 0$ corresponding to the moment the bullet leaves the gun. We find the slope m of the tangent line at $t = 0$:

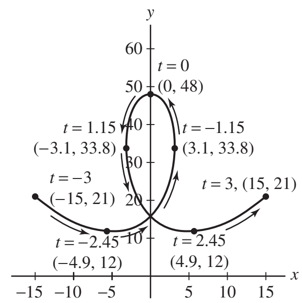
$$\frac{dy}{dx} = \frac{y'(t)}{x'(t)} = \frac{b - 32t}{a} \Rightarrow m = \left.\frac{b - 32t}{a}\right|_{t=0} = \frac{b}{a}$$

It follows that $\tan\theta = \frac{b}{a}$ or $\theta = \tan^{-1}\left(\frac{b}{a}\right)$. The bullet lands at $t = \frac{b}{16}$. We find the distance of the bullet from the origin at this time, by substituting $t = \frac{b}{16}$ in $x(t) = at$. This gives

$$x\left(\frac{b}{16}\right) = \frac{ab}{16}$$

70. CAS Plot $c(t) = (t^3 - 4t, t^4 - 12t^2 + 48)$ for $-3 \le t \le 3$. Find the points where the tangent line is horizontal or vertical.

SOLUTION The graph of $c(t) = (t^3 - 4t, t^4 - 12t^2 + 48)$, $-3 \le t \le 3$ is shown in the following figure:



We find the slope of the tangent line at t:

$$\frac{dy}{dx} = \frac{y'(t)}{x'(x)} = \frac{\left(t^4 - 12t^2 + 48\right)'}{\left(t^3 - 4t\right)'} = \frac{4t^3 - 24t}{3t^2 - 4} \tag{1}$$

The tangent line is horizontal where $\frac{dy}{dx} = 0$. That is,

$$\frac{4t^3 - 24t}{3t^2 - 4} = 0 \Rightarrow 4t(t^2 - 6) = 0 \Rightarrow t = 0,\ t = -\sqrt{6},\ t = \sqrt{6}.$$

We find the corresponding points by substituting these values of t in $c(t)$. We obtain:

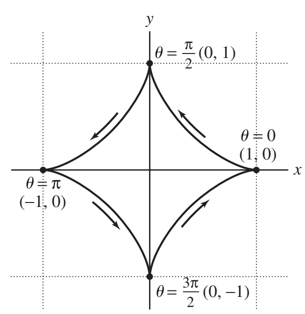
$$c(0) = (0, 48),\ c(-\sqrt{6}) \approx (-4.9, 12),\ c(\sqrt{6}) \approx (4.9, 12).$$

The tangent line is vertical where the slope in (1) is infinite, that is, where $3t^2 - 4 = 0$ or $t = \pm\frac{2}{\sqrt{3}} \approx \pm 1.15$. We find the points by setting $t = \pm\frac{2}{\sqrt{3}}$ in $c(t)$. We get

$$c\left(\frac{2}{\sqrt{3}}\right) \approx (-3.1, 33.8), \quad c\left(-\frac{2}{\sqrt{3}}\right) \approx (3.1, 33.8).$$

71. CAS Plot the astroid $x = \cos^3\theta$, $y = \sin^3\theta$ and find the equation of the tangent line at $\theta = \frac{\pi}{3}$.

SOLUTION The graph of the astroid $x = \cos^3\theta$, $y = \sin^3\theta$ is shown in the following figure:



The slope of the tangent line at $\theta = \frac{\pi}{3}$ is

$$m = \left.\frac{dy}{dx}\right|_{\theta=\pi/3} = \left.\frac{(\sin^3\theta)'}{(\cos^3\theta)'}\right|_{\theta=\pi/3} = \left.\frac{3\sin^2\theta\cos\theta}{3\cos^2\theta(-\sin\theta)}\right|_{\theta=\pi/3} = -\left.\frac{\sin\theta}{\cos\theta}\right|_{\theta=\pi/3} = -\tan\theta\Big|_{\pi/3} = -\sqrt{3}$$

We find the point of tangency:

$$\left(x\left(\frac{\pi}{3}\right), y\left(\frac{\pi}{3}\right)\right) = \left(\cos^3\frac{\pi}{3}, \sin^3\frac{\pi}{3}\right) = \left(\frac{1}{8}, \frac{3\sqrt{3}}{8}\right)$$

The equation of the tangent line at $\theta = \frac{\pi}{3}$ is, thus,

$$y - \frac{3\sqrt{3}}{8} = -\sqrt{3}\left(x - \frac{1}{8}\right) \Rightarrow y = -\sqrt{3}x + \frac{\sqrt{3}}{2}$$

72. Find the equation of the tangent line at $t = \frac{\pi}{4}$ to the cycloid generated by the unit circle with parametric equation (5).

SOLUTION We find the equation of the tangent line at $t = \frac{\pi}{4}$ to the cycloid $x = t - \sin t$, $y = 1 - \cos t$. We first find the derivative $\frac{dy}{dx}$:

$$\frac{dy}{dx} = \frac{y'(t)}{x'(t)} = \frac{(1-\cos t)'}{(t-\sin t)'} = \frac{\sin t}{1-\cos t}$$

The slope of the tangent line at $t = \frac{\pi}{4}$ is therefore:

$$m = \left.\frac{dy}{dx}\right|_{t=\pi/4} = \frac{\sin\frac{\pi}{4}}{1-\cos\frac{\pi}{4}} = \frac{\frac{\sqrt{2}}{2}}{1-\frac{\sqrt{2}}{2}} = \frac{1}{\sqrt{2}-1}$$

We find the point of tangency:

$$\left(x\left(\frac{\pi}{4}\right), y\left(\frac{\pi}{4}\right)\right) = \left(\frac{\pi}{4} - \sin\frac{\pi}{4}, 1-\cos\frac{\pi}{4}\right) = \left(\frac{\pi}{4} - \frac{\sqrt{2}}{2}, 1 - \frac{\sqrt{2}}{2}\right)$$

The equation of the tangent line is, thus,

$$y - \left(1 - \frac{\sqrt{2}}{2}\right) = \frac{1}{\sqrt{2}-1}\left(x - \left(\frac{\pi}{4} - \frac{\sqrt{2}}{2}\right)\right) \Rightarrow y = \frac{1}{\sqrt{2}-1}x + \left(2 - \frac{\frac{\pi}{4}}{\sqrt{2}-1}\right)$$

73. Find the points with horizontal tangent line on the cycloid with parametric equation (5).

SOLUTION The parametric equations of the cycloid are

$$x = t - \sin t, \quad y = 1 - \cos t$$

We find the slope of the tangent line at t:

$$\frac{dy}{dx} = \frac{(1-\cos t)'}{(t-\sin t)'} = \frac{\sin t}{1-\cos t}$$

The tangent line is horizontal where it has slope zero. That is,

$$\frac{dy}{dx} = \frac{\sin t}{1-\cos t} = 0 \quad \Rightarrow \quad \begin{array}{c}\sin t = 0\\ \cos t \neq 1\end{array} \quad \Rightarrow \quad t = (2k-1)\pi, \quad k = 0, \pm 1, \pm 2, \ldots$$

We find the coordinates of the points with horizontal tangent line, by substituting $t = (2k-1)\pi$ in $x(t)$ and $y(t)$. This gives

$$x = (2k-1)\pi - \sin(2k-1)\pi = (2k-1)\pi$$
$$y = 1 - \cos((2k-1)\pi) = 1 - (-1) = 2$$

The required points are

$$((2k-1)\pi, 2), \quad k = 0, \pm 1, \pm 2, \ldots$$

74. Property of the Cycloid Prove that the tangent line at a point P on the cycloid always passes through the top point on the rolling circle as indicated in Figure 20. Assume the generating circle of the cycloid has radius 1.

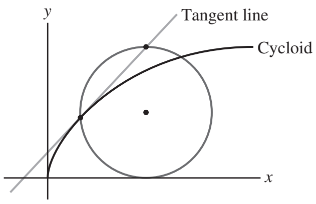


FIGURE 20

SOLUTION The definition of the cycloid is such that at time t, the top of the circle has coordinates $Q = (t, 2)$ (since at time $t = 2\pi$ the circle has rotated exactly once, and its circumference is 2π). Let L be the line through P and Q. To show that L is tangent to the cycloid at P it suffices to show that the slope of L equals the slope of the tangent at P. Recall that the cycloid is parametrized by $c(t) = (t - \sin t, 1 - \cos t)$. Then the slope of L is

$$\frac{2-(1-\cos t)}{t-(t-\sin t)} = \frac{1+\cos t}{\sin t}$$

and the slope of the tangent line is

$$\frac{y'(t)}{x'(t)} = \frac{(1-\cos t)'}{(t-\sin t)'} = \frac{\sin t}{1-\cos t} = \frac{\sin t(1+\cos t)}{1-\cos^2 t} = \frac{\sin t(1+\cos t)}{\sin^2 t} = \frac{1+\cos t}{\sin t}$$

and the two are equal.

75. A *curtate cycloid* (Figure 21) is the curve traced by a point at a distance h from the center of a circle of radius R rolling along the x-axis where $h < R$. Show that this curve has parametric equations $x = Rt - h\sin t$, $y = R - h\cos t$.

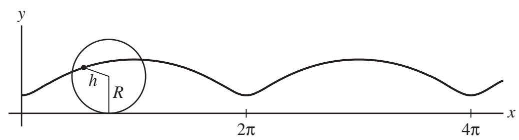

FIGURE 21 Curtate cycloid.

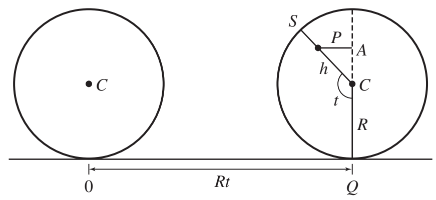
SOLUTION Let P be a point at a distance h from the center C of the circle. Assume that at $t = 0$, the line of CP is passing through the origin. When the circle rolls a distance Rt along the x-axis, the length of the arc $\widehat{SQ}$ (see figure) is also Rt and the angle $\angle SCQ$ has radian measure t. We compute the coordinates x and y of P.



$$x = Rt - \overline{PA} = Rt - h\sin(\pi - t) = Rt - h\sin t$$

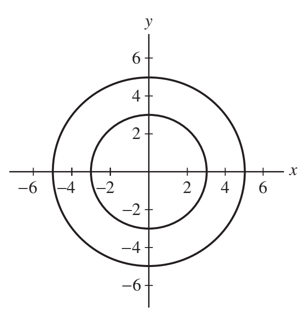
$$y = R + \overline{AC} = R + h\cos(\pi - t) = R - h\cos t$$

We obtain the following parametrization:

$$x = Rt - h\sin t, \;\; y = R - h\cos t.$$

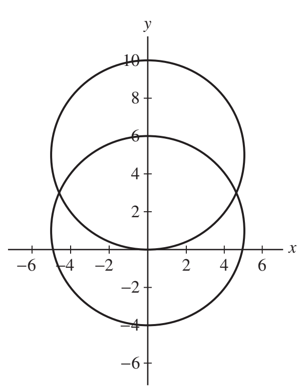
76. CAS Use a computer algebra system to explore what happens when $h > R$ in the parametric equations of Exercise 75. Describe the result.

SOLUTION Look first at the parametric equations $x = -h\sin t$, $y = -h\cos t$. These describe a circle of radius h. See for instance the graphs below obtained for $h = 3$ and $h = 5$.



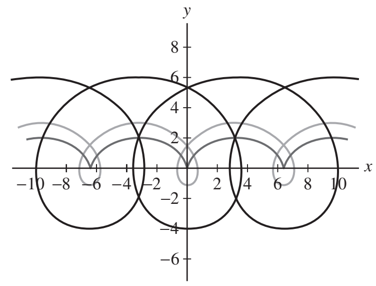
$c(t) = (-h^*\sin(t), -h^*\cos(t))$ $h = 3, 5$

Adding R to the y coordinate to obtain the parametric equations $x = -h\sin t$, $y = R - h\cos t$, yields a circle with its center moved up by R units:



$c(t) = (-h^*\sin(t), R-h^*\cos(t))$ $R = 1, 5$ $h = 5$

Now, we add Rt to the x coordinate to obtain the given parametric equation; the curve becomes a spring. The figure below shows the graphs obtained for $R = 1$ and various values of h. We see the inner loop formed for $h > R$.



77. Show that the line of slope t through $(-1, 0)$ intersects the unit circle in the point with coordinates

$$x = \frac{1 - t^2}{t^2 + 1}, \qquad y = \frac{2t}{t^2 + 1}$$ **10**

Conclude that these equations parametrize the unit circle with the point $(-1, 0)$ excluded (Figure 22). Show further that $t = y/(x + 1)$.

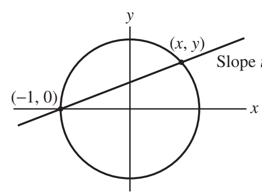


FIGURE 22 Unit circle.

SOLUTION The equation of the line of slope t through $(-1, 0)$ is $y = t(x + 1)$. The equation of the unit circle is $x^2 + y^2 = 1$. Hence, the line intersects the unit circle at the points (x, y) that satisfy the equations:

$$y = t(x + 1) \tag{1}$$

$$x^2 + y^2 = 1 \tag{2}$$

Substituting y from equation (1) into equation (2) and solving for x we obtain

$$\begin{aligned} x^2 + t^2(x + 1)^2 &= 1 \\ x^2 + t^2x^2 + 2t^2x + t^2 &= 1 \\ (1 + t^2)x^2 + 2t^2x + (t^2 - 1) &= 0 \end{aligned}$$

This gives

$$x_{1,2} = \frac{-2t^2 \pm \sqrt{4t^4 - 4(t^2 + 1)(t^2 - 1)}}{2(1 + t^2)} = \frac{-2t^2 \pm 2}{2(1 + t^2)} = \frac{\pm 1 - t^2}{1 + t^2}$$

So $x_1 = -1$ and $x_2 = \dfrac{1 - t^2}{t^2 + 1}$. The solution $x = -1$ corresponds to the point $(-1, 0)$. We are interested in the second point of intersection that is varying as t varies. Hence the appropriate solution is

$$x = \frac{1 - t^2}{t^2 + 1}$$

We find the y-coordinate by substituting x in equation (1). This gives

$$y = t(x + 1) = t\left(\frac{1 - t^2}{t^2 + 1} + 1\right) = t \cdot \frac{1 - t^2 + t^2 + 1}{t^2 + 1} = \frac{2t}{t^2 + 1}$$

We conclude that the line and the unit circle intersect, besides at $(-1, 0)$, at the point with the following coordinates:

$$x = \frac{1 - t^2}{t^2 + 1}, \quad y = \frac{2t}{t^2 + 1} \tag{3}$$

Since these points determine all the points on the unit circle except for $(-1, 0)$ and no other points, the equations in (3) parametrize the unit circle with the point $(-1, 0)$ excluded.

We show that $t = \frac{y}{x+1}$. Using (3) we have

$$\frac{y}{x+1} = \frac{\frac{2t}{t^2+1}}{\frac{1-t^2}{t^2+1}+1} = \frac{\frac{2t}{t^2+1}}{\frac{1-t^2+t^2+1}{t^2+1}} = \frac{\frac{2t}{t^2+1}}{\frac{2}{t^2+1}} = \frac{2t}{2} = t.$$

78. The **folium of Descartes** is the curve with equation $x^3 + y^3 = 3axy$, where $a \neq 0$ is a constant (Figure 23).

(a) Show that the line $y = tx$ intersects the folium at the origin and at one other point P for all $t \neq -1, 0$. Express the coordinates of P in terms of t to obtain a parametrization of the folium. Indicate the direction of the parametrization on the graph.

(b) Describe the interval of t-values parametrizing the parts of the curve in quadrants I, II, and IV. Note that $t = -1$ is a point of discontinuity of the parametrization.

(c) Calculate dy/dx as a function of t and find the points with horizontal or vertical tangent.

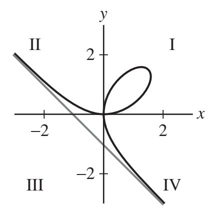

FIGURE 23 Folium $x^3 + y^3 = 3axy$.

SOLUTION

(a) We find the points where the line $y = tx$ $(t \neq -1, 0)$ and the folium intersect, by solving the following equations:

$$y = tx \tag{1}$$
$$x^3 + y^3 = 3axy \tag{2}$$

Substituting y from (1) in (2) and solving for x we get

$$x^3 + t^3x^3 = 3axtx$$
$$(1 + t^3)x^3 - 3atx^2 = 0$$
$$x^2(x(1 + t^3) - 3at) = 0 \Rightarrow x_1 = 0,\ x_2 = \frac{3at}{1+t^3}$$

Substituting in (1) we find the corresponding y-coordinates. That is,

$$y_1 = t \cdot 0 = 0,\ y_2 = t \cdot \frac{3at}{1+t^3} = \frac{3at^2}{1+t^3}$$

We conclude that the line $y = \text{tx}$, $t \neq 0, -1$ intersects the folium in a unique point P besides the origin. The coordinates of P are:

$$x = \frac{3at}{1+t^3},\ y = \frac{3at^2}{1+t^3},\quad t \neq 0, -1$$

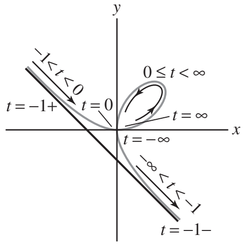
The coordinates of P determine a parametrization for the folium. We add the origin so $t = 0$ must be included in the interval of t. We get

$$c(t) = \left(\frac{3at}{1+t^3}, \frac{3at^2}{1+t^3}\right),\quad t \neq -1$$

To indicate the direction on the curve (for $a > 0$), we first consider the following limits:

$$\lim_{t\to -1-} x(t) = \infty \qquad \lim_{t\to -1-} y(t) = -\infty$$
$$\lim_{t\to -\infty} x(t) = \lim_{t\to\infty} x(t) = 0 \qquad \lim_{t\to -\infty} y(t) = \lim_{t\to\infty} y(t) = 0$$
$$\lim_{t\to -1+} x(t) = -\infty \qquad \lim_{t\to -1+} y(t) = \infty$$
$$\lim_{t\to 0} x(t) = 0 \qquad \lim_{t\to 0} y(t) = 0$$

These limits determine the directions of the two parts of the folium in the second and fourth quadrant. The loop in the first quadrant, corresponds to the values $0 \le t < \infty$, and it is directed from $c(1) = (\frac{3a}{2}, \frac{3a}{2})$ to $c(2) = (\frac{2a}{3}, \frac{4a}{3})$ where $t = 1$ and $t = 2$ are two chosen values in the interval $0 \le t < \infty$. The following graph shows the directed folium:



(b) The limits computed in part (a) indicate that the parts of the curve in the second and fourth quadrants correspond to the values $-1 < t < 0$ and $-\infty < t < -1$ respectively. The loop in the first quadrant corresponds to the remaining interval $0 \le t < \infty$.

(c) We find the derivative $\frac{dy}{dx}$, using the Formula for the Slope of the Tangent Line. We get

$$\frac{dy}{dx} = \frac{y'(t)}{x'(t)} = \frac{\left(\frac{3at^2}{1+t^3}\right)'}{\left(\frac{3at}{1+t^3}\right)'} = \frac{\frac{6at(1+t^3)-3at^2\cdot 3t^2}{(1+t^3)^2}}{\frac{3a(1+t^3)-3at\cdot 3t^2}{(1+t^3)^2}} = \frac{6at - 3at^4}{3a - 6at^3} = \frac{t(2-t^3)}{1-2t^3}$$

Horizontal tangent occurs when $\frac{dy}{dx} = 0$. That is,

$$\frac{t(2-t^3)}{1-2t^3} = 0 \Rightarrow t(2-t^3) = 0,\ 1 - 2t^3 \ne 0 \Rightarrow t = 0,\ t = \sqrt[3]{2}.$$

The corresponding points are:

$$c(0) = (x(0), y(0)) = (0, 0)$$

$$c\left(\sqrt[3]{2}\right) = \left(x\left(\sqrt[3]{2}\right), y\left(\sqrt[3]{2}\right)\right) = \left(\frac{3a\sqrt[3]{2}}{1+2}, \frac{3a\sqrt[3]{4}}{1+2}\right) = \left(a\sqrt[3]{2}, a\sqrt[3]{4}\right)$$

Vertical tangent line occurs when $\frac{dy}{dx}$ is infinite. That is,

$$1 - 2t^3 = 0 \Rightarrow t = \frac{1}{\sqrt[3]{2}}$$

The corresponding point is

$$c\left(\frac{1}{\sqrt[3]{2}}\right) = \left(x\left(\frac{1}{\sqrt[3]{2}}\right), y\left(\frac{1}{\sqrt[3]{2}}\right)\right) = \left(\frac{\frac{3a}{\sqrt[3]{2}}}{1+\frac{1}{2}}, \frac{\frac{3a}{\sqrt[3]{4}}}{1+\frac{1}{2}}\right) = \left(\sqrt[3]{4}a, \sqrt[3]{2}a\right).$$

79. Use the results of Exercise 78 to show that the asymptote of the folium is the line $x + y = -a$. *Hint:* Show that $\lim_{t\to -1}(x + y) = -a$.

SOLUTION We must show that as $x \to \infty$ or $x \to -\infty$ the graph of the folium is getting arbitrarily close to the line $x + y = -a$, and the derivative $\frac{dy}{dx}$ is approaching the slope -1 of the line.

In Exercise 78 we showed that $x \to \infty$ when $t \to (-1^-)$ and $x \to -\infty$ when $t \to (-1^+)$. We first show that the graph is approaching the line $x + y = -a$ as $x \to \infty$ or $x \to -\infty$, by showing that $\lim_{t\to -1-} x + y = \lim_{t\to -1+} x + y = -a$.

For $x(t) = \dfrac{3at}{1+t^3}$, $y(t) = \dfrac{3at^2}{1+t^3}$, $a > 0$, calculated in Exercise 78, we obtain using L'Hôpital's Rule:

$$\lim_{t\to -1-}(x+y) = \lim_{t\to -1-}\frac{3at + 3at^2}{1+t^3} = \lim_{t\to -1-}\frac{3a + 6at}{3t^2} = \frac{3a - 6a}{3} = -a$$

$$\lim_{t\to -1+}(x+y) = \lim_{t\to -1+}\frac{3at + 3at^2}{1+t^3} = \lim_{t\to -1+}\frac{3a + 6at}{3t^2} = \frac{3a - 6a}{3} = -a$$

We now show that $\dfrac{dy}{dx}$ is approaching -1 as $t \to -1-$ and as $t \to -1+$. We use $\dfrac{dy}{dx} = \dfrac{6at - 3at^4}{3a - 6at^3}$ computed in Exercise 78 to obtain

$$\lim_{t\to -1-}\frac{dy}{dx} = \lim_{t\to -1-}\frac{6at - 3at^4}{3a - 6at^3} = \frac{-9a}{9a} = -1$$

$$\lim_{t\to -1+} \frac{dy}{dx} = \lim_{t\to -1+} \frac{6at - 3at^4}{3a - 6at^3} = \frac{-9a}{9a} = -1$$

We conclude that the line $x + y = -a$ is an asymptote of the folium as $x \to \infty$ and as $x \to -\infty$.

80. Find a parametrization of $x^{2n+1} + y^{2n+1} = ax^n y^n$, where a and n are constants.

SOLUTION Following the method in Exercise 78, we first find the coordinates of the point P where the curve and the line $y = tx$ intersect. We solve the following equations:

$$y = tx$$
$$x^{2n+1} + y^{2n+1} = ax^n y^n$$

Substituting $y = tx$ in the second equation and solving for x yields

$$x^{2n+1} + t^{2n+1}x^{2n+1} = ax^n \cdot t^n x^n$$
$$(1 + t^{2n+1})x^{2n+1} - at^n x^{2n} = 0$$
$$x^{2n}((1 + t^{2n+1})x - at^n) = 0 \Rightarrow x = 0,\ x = \frac{at^n}{1 + t^{2n+1}}$$

We assume that $t \neq -1$ (so $1 + t^{2n+1} \neq 0$) and obtain one solution besides the origin. The corresponding y coordinates are

$$y = tx = t \cdot \frac{at^n}{1 + t^{2n+1}} = \frac{at^{n+1}}{1 + t^{2n+1}}$$

Hence, the points $x = \dfrac{at^n}{1 + t^{2n+1}}$, $y = \dfrac{at^{n+1}}{1 + t^{2n+1}}$, $t \neq -1$, are exactly the points on the curve. We obtain the following parametrization:

$$x = \frac{at^n}{1 + t^{2n+1}},\ y = \frac{at^{n+1}}{1 + t^{2n+1}}, \quad t \neq -1.$$

81. Second Derivative for a Parametrized Curve Given a parametrized curve $c(t) = (x(t), y(t))$, show that

$$\frac{d}{dt}\left(\frac{dy}{dx}\right) = \frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^2}$$

Use this to prove the formula

$$\boxed{\frac{d^2y}{dx^2} = \frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^3}} \qquad \boxed{11}$$

SOLUTION By the formula for the slope of the tangent line we have

$$\frac{dy}{dx} = \frac{y'(t)}{x'(t)}$$

Differentiating with respect to t, using the Quotient Rule, gives

$$\frac{d}{dt}\left(\frac{dy}{dx}\right) = \frac{d}{dt}\left(\frac{y'(t)}{x'(t)}\right) = \frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^2}$$

By the Chain Rule we have

$$\frac{d^2y}{dx^2} = \frac{d}{dx}\left(\frac{dy}{dx}\right) = \frac{d}{dt}\left(\frac{dy}{dx}\right) \cdot \frac{dt}{dx}$$

Substituting into the above equation $\left(\text{and using } \dfrac{dt}{dx} = \dfrac{1}{dx/dt} = \dfrac{1}{x'(t)}\right)$ gives

$$\frac{d^2y}{dx^2} = \frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^2} \cdot \frac{1}{x'(t)} = \frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^3}$$

82. The second derivative of $y = x^2$ is $dy^2/d^2x = 2$. Verify that Eq. (11) applied to $c(t) = (t, t^2)$ yields $dy^2/d^2x = 2$. In fact, any parametrization may be used. Check that $c(t) = (t^3, t^6)$ and $c(t) = (\tan t, \tan^2 t)$ also yield $dy^2/d^2x = 2$.

SOLUTION For the parametrization $c(t) = (t, t^2)$, we have

$$x'(t) = 1, \quad x''(t) = 0, \quad y'(t) = 2t, \quad y''(t) = 2$$

so that indeed

$$\frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^3} = \frac{1 \cdot 2 - 2t \cdot 0}{1^3} = 2$$

For $c(t) = (t^3, t^6)$, we have

$$x'(t) = 3t^2, \quad x''(t) = 6t, \quad y'(t) = 6t^5, \quad y''(t) = 30t^4$$

so that again

$$\frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^3} = \frac{3t^2 \cdot 30t^4 - 6t^5 \cdot 6t}{(3t^2)^3} = \frac{54t^6}{27t^6} = 2$$

Finally, for $c(t) = (\tan t, \tan^2 t)$,

$$x'(t) = \sec^2 t, \quad x''(t) = 2\tan t \sec^2 t, \quad y'(t) = 2\tan t \sec^2 t, \quad y''(t) = 6\sec^4 t - 4\sec^2 t$$

and

$$\begin{aligned}\frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^3} &= \frac{\sec^2 t(6\sec^4 t - 4\sec^2 t) - 2\tan t \sec^2 t(2\tan t \sec^2 t)}{\sec^6 t} \\ &= \frac{6\sec^6 t - 4\sec^4 t - 4\sec^4 t \tan^2 t}{\sec^6 t} = \frac{6\sec^6 t - 4\sec^4 t(1 - (1 + \sec^2 t)))}{\sec^6 t} \\ &= \frac{2\sec^6 t}{\sec^6 t} = 2\end{aligned}$$

In Exercises 83–86, use Eq. (11) to find d^2y/dx^2.

83. $x = t^3 + t^2, \quad y = 7t^2 - 4, \quad t = 2$

SOLUTION We find the first and second derivatives of $x(t)$ and $y(t)$:

$$\begin{aligned} x'(t) &= 3t^2 + 2t \Rightarrow x'(2) = 3 \cdot 2^2 + 2 \cdot 2 = 16 \\ x''(t) &= 6t + 2 \quad \Rightarrow x''(2) = 6 \cdot 2 + 2 = 14 \\ y'(t) &= 14t \qquad \Rightarrow y'(2) = 14 \cdot 2 = 28 \\ y''(t) &= 14 \qquad \Rightarrow y''(2) = 14 \end{aligned}$$

Using Eq. (11) we get

$$\left.\frac{d^2y}{dx^2}\right|_{t=2} = \left.\frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^3}\right|_{t=2} = \frac{16 \cdot 14 - 28 \cdot 14}{16^3} = \frac{-21}{512}$$

84. $x = s^{-1} + s, \quad y = 4 - s^{-2}, \quad s = 1$

SOLUTION Since $x'(s) = -s^{-2} + 1 = 1 - \frac{1}{s^2}$, we have $x'(1) = 0$. Hence, Eq. (11) cannot be used to compute $\frac{d^2y}{dx^2}$ at $s = 1$.

85. $x = 8t + 9, \quad y = 1 - 4t, \quad t = -3$

SOLUTION We compute the first and second derivatives of $x(t)$ and $y(t)$:

$$\begin{aligned} x'(t) &= 8 \quad \Rightarrow x'(-3) = 8 \\ x''(t) &= 0 \quad \Rightarrow x''(-3) = 0 \\ y'(t) &= -4 \Rightarrow y'(-3) = -4 \\ y''(t) &= 0 \quad \Rightarrow y''(-3) = 0 \end{aligned}$$

Using Eq. (11) we get

$$\left.\frac{d^2y}{dx^2}\right|_{t=-3} = \frac{x'(-3)y''(-3) - y'(-3)x''(-3)}{x'(-3)^3} = \frac{8 \cdot 0 - (-4) \cdot 0}{8^3} = 0$$

86. $x = \cos\theta, \quad y = \sin\theta, \quad \theta = \frac{\pi}{4}$

SOLUTION We find the first and second derivatives of $x(\theta)$ and $y(\theta)$:

$$x'(\theta) = -\sin\theta \Rightarrow x'\left(\frac{\pi}{4}\right) = -\frac{\sqrt{2}}{2}$$

$$x''(\theta) = -\cos\theta \Rightarrow x''\left(\frac{\pi}{4}\right) = -\frac{\sqrt{2}}{2}$$

$$y'(\theta) = \cos\theta \quad \Rightarrow y'\left(\frac{\pi}{4}\right) = \frac{\sqrt{2}}{2}$$

$$y''(\theta) = -\sin\theta \Rightarrow y''\left(\frac{\pi}{4}\right) = -\frac{\sqrt{2}}{2}$$

Using Eq. (11) we get

$$\left.\frac{d^2y}{dx^2}\right|_{\theta=\frac{\pi}{4}} = \frac{x'\left(\frac{\pi}{4}\right)y''\left(\frac{\pi}{4}\right) - y'\left(\frac{\pi}{4}\right)x''\left(\frac{\pi}{4}\right)}{\left(x'\left(\frac{\pi}{4}\right)\right)^3} = \frac{\left(-\frac{\sqrt{2}}{2}\right)\left(-\frac{\sqrt{2}}{2}\right) - \frac{\sqrt{2}}{2} \cdot \left(-\frac{\sqrt{2}}{2}\right)}{\left(-\frac{\sqrt{2}}{2}\right)^3} = -2\sqrt{2}$$

87. Use Eq. (11) to find the t-intervals on which $c(t) = (t^2, t^3 - 4t)$ is concave up.

SOLUTION The curve is concave up where $\frac{d^2y}{dx^2} > 0$. Thus,

$$\frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^3} > 0 \tag{1}$$

We compute the first and second derivatives:

$$x'(t) = 2t, \qquad x''(t) = 2$$

$$y'(t) = 3t^2 - 4, \quad y''(t) = 6t$$

Substituting in (1) and solving for t gives

$$\frac{12t^2 - (6t^2 - 8)}{8t^3} = \frac{6t^2 + 8}{8t^3}$$

Since $6t^2 + 8 > 0$ for all t, the quotient is positive if $8t^3 > 0$. We conclude that the curve is concave up for $t > 0$.

88. Use Eq. (11) to find the t-intervals on which $c(t) = (t^2, t^4 - 4t)$ is concave up.

SOLUTION The curve is concave up where $\frac{d^2y}{dx^2} > 0$. That is,

$$\frac{x'(t)y''(t) - y'(t)x''(t)}{x'(t)^3} > 0 \tag{1}$$

We compute the first and second derivatives:

$$x'(t) = 2t, \qquad x''(t) = 2$$

$$y'(t) = 4t^3 - 4, \quad y''(t) = 12t^2$$

Substituting in (1) and solving for t gives

$$\frac{24t^3 - (8t^3 - 8)}{8t^3} = \frac{16t^3 + 8}{8t^3} = 1 + \frac{1}{2t^3}$$

This is clearly positive for $t > 0$. For $t < 0$, we want $1 + \frac{1}{2t^3} > 0$, which means $\frac{1}{2t^3} > -1$, so $2t^3 < -1$ (by taking the reciprocal of both sides), so $t < -\frac{1}{\sqrt[3]{2}}$. Thus, we see that our curve is concave up for $t < -\frac{1}{\sqrt[3]{2}}$ and for $t > 0$.

89. Area Under a Parametrized Curve Let $c(t) = (x(t), y(t))$, where $y(t) > 0$ and $x'(t) > 0$ (Figure 24). Show that the area A under $c(t)$ for $t_0 \le t \le t_1$ is

$$A = \int_{t_0}^{t_1} y(t)x'(t)\,dt \qquad \boxed{12}$$

Hint: Because it is increasing, the function $x(t)$ has an inverse $t = g(x)$ and $c(t)$ is the graph of $y = y(g(x))$. Apply the change-of-variables formula to $A = \int_{x(t_0)}^{x(t_1)} y(g(x))\,dx$.

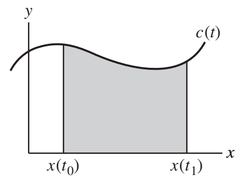


FIGURE 24

SOLUTION Let $x_0 = x(t_0)$ and $x_1 = x(t_1)$. We are given that $x'(t) > 0$, hence $x = x(t)$ is an increasing function of t, so it has an inverse function $t = g(x)$. The area A is given by $\int_{x_0}^{x_1} y(g(x))\,dx$. Recall that y is a function of t and $t = g(x)$, so the height y at any point x is given by $y = y(g(x))$. We find the new limits of integration. Since $x_0 = x(t_0)$ and $x_1 = x(t_1)$, the limits for t are t_0 and t_1, respectively. Also since $x'(t) = \frac{dx}{dt}$, we have $dx = x'(t)dt$. Performing this substitution gives

$$A = \int_{x_0}^{x_1} y(g(x))\,dx = \int_{t_0}^{t_1} y(g(x))x'(t)\,dt.$$

Since $g(x) = t$, we have $A = \displaystyle\int_{t_0}^{t_1} y(t)x'(t)\,dt$.

90. Calculate the area under $y = x^2$ over $[0, 1]$ using Eq. (12) with the parametrizations (t^3, t^6) and (t^2, t^4).

SOLUTION The area A under $y = x^2$ on $[0, 1]$ is given by the integral

$$A = \int_{t_0}^{t_1} y(t)x'(t)\,dt$$

where $x(t_0) = 0$ and $x(t_1) = 1$. We first use the parametrization (t^3, t^6). We have $x(t) = t^3$, $y(t) = t^6$. Hence,

$$0 = x(t_0) = t_0^3 \Rightarrow t_0 = 0$$
$$1 = x(t_1) = t_1^3 \Rightarrow t_1 = 1$$

Also $x'(t) = 3t^2$. Substituting these values in Eq. (12) we obtain

$$A = \int_0^1 t^6 \cdot 3t^2\,dt = \int_0^1 3t^8\,dt = \frac{3}{9}t^9\Big|_0^1 = \frac{3}{9} = \frac{1}{3}$$

Using the parametrization $x(t) = t^2$, $y(t) = t^4$, we have $x'(t) = 2t$. We find t_0 and t_1:

$$0 = x(t_0) = t_0^2 \Rightarrow t_0 = 0$$
$$1 = x(t_1) = t_1^2 \Rightarrow t_1 = 1 \quad \text{or} \quad t_1 = -1.$$

Equation (12) is valid if $x'(t) > 0$, that is if $t > 0$. Hence we choose the positive value, $t_1 = 1$. We now use Eq. (12) to obtain

$$A = \int_0^1 t^4 \cdot 2t\,dt = \int_0^1 2t^5\,dt = \frac{2}{6}t^6\Big|_0^1 = \frac{2}{6} = \frac{1}{3}$$

Both answers agree, as expected.

91. What does Eq. (12) say if $c(t) = (t, f(t))$?

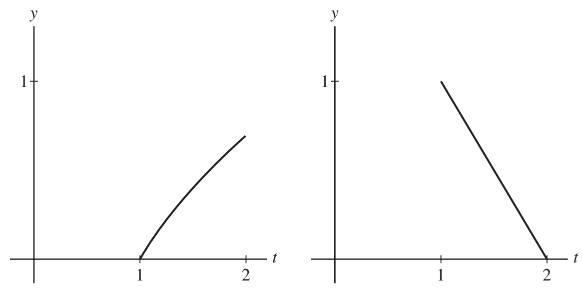
SOLUTION In the parametrization $x(t) = t$, $y(t) = f(t)$ we have $x'(t) = 1$, $t_0 = x(t_0)$, $t_1 = x(t_1)$. Hence Eq. (12) becomes

$$A = \int_{t_0}^{t_1} y(t)x'(t)\,dt = \int_{x(t_0)}^{x(t_1)} f(t)\,dt$$

We see that in this parametrization Eq. (12) is the familiar formula for the area under the graph of a positive function.

92. Sketch the graph of $c(t) = (\ln t, 2 - t)$ for $1 \le t \le 2$ and compute the area under the graph using Eq. (12).

SOLUTION We use the following graphs of $x(t) = \ln t$ and $y(t) = 2 - t$ for $1 \le t \le 2$:



$x(t) = \ln t$ $\quad$ $y(t) = 2 - t$

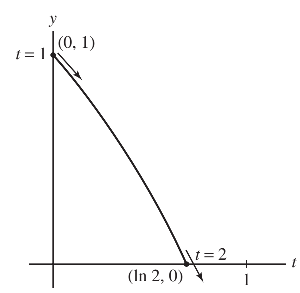
We see that for $1 < t < 2$, $x(t)$ is positive and increasing and $y(t)$ is positive and decreasing. Also $c(1) = (\ln 1, 2 - 1) = (0, 1)$ and $c(2) = (\ln 2, 2 - 2) = (\ln 2, 0)$. Additional information is obtained from the derivative

$$\frac{dy}{dx} = \frac{(2-t)'}{(\ln t)'} = -\frac{1}{1/t} = -t,$$

yielding

$$\left.\frac{dy}{dx}\right|_{t=1} - 1 \quad \text{and} \quad \left.\frac{dy}{dx}\right|_{t=2} - 2.$$

We obtain the following graph:



We now use Eq. (12) to compute the area A under the graph. We have $x(t) = \ln t$, $x'(t) = \frac{1}{t}$, $y(t) = 2 - t$, $t_0 = 1$, $t_1 = 2$. Hence,

$$\begin{aligned} A &= \int_{t_0}^{t_1} y(t)x'(t)\,dt = \int_1^2 (2-t)\cdot\frac{1}{t}\,dt = \int_1^2 \left(\frac{2}{t} - 1\right) dt \\ &= 2\ln t - t\Big|_1^2 = (2\ln 2 - 2) - (2\ln 1 - 1) = 2\ln 2 - 1 \approx 0.386 \end{aligned}$$

93. Galileo tried unsuccessfully to find the area under a cycloid. Around 1630, Gilles de Roberval proved that the area under one arch of the cycloid $c(t) = (Rt - R\sin t, R - R\cos t)$ generated by a circle of radius R is equal to three times the area of the circle (Figure 25). Verify Roberval's result using Eq. (12).

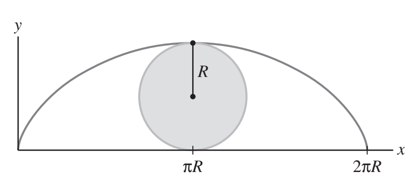


FIGURE 25 The area of one arch of the cycloid equals three times the area of the generating circle.

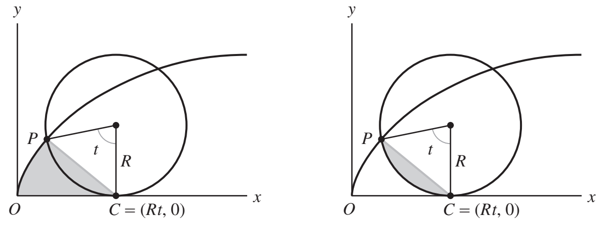
SOLUTION This reduces to

$$\int_0^{2\pi} (R - R\cos t)(Rt - R\sin t)'\,dt = \int_0^{2\pi} R^2(1-\cos t)^2\,dt = 3\pi R^2.$$

Further Insights and Challenges

94. Prove the following generalization of Exercise 93: For all $t > 0$, the area of the cycloidal sector OPC is equal to three times the area of the circular segment cut by the chord PC in Figure 26.



(A) Cycloidal sector OPC (B) Circular segment cut by the chord PC

FIGURE 26

SOLUTION Drop a perpendicular from point P to the x-axis and label the point of intersection T, and denote by D the center of the circle. Then the area of the cycloidal sector is equal to the area of OPT plus the area of PTC. The latter is a triangle with height $y(t) = R - R\cos t$ and base $Rt - (Rt - R\sin t) = R\sin t$, so its area is $\frac{1}{2}R^2\sin t(1-\cos t)$. The area of OPT, using Eq. (12), is

$$\int_0^t y(u)x'(u)\,du = \int_0^t (R - R\cos u)(Ru - R\sin u)'\,du = R^2\int_0^t (1-\cos u)^2\,du$$
$$= R^2\left(\frac{3}{2}t - 2\sin t + \frac{1}{2}\sin t\cos t\right)$$

so that the total area of the cycloidal sector is

$$R^2\left(\frac{3}{2}t - 2\sin t + \frac{1}{2}\sin t\cos t\right) + R^2\frac{1}{2}\sin t(1-\cos t) = 3\left(\frac{1}{2}R^2 t - \frac{1}{2}R^2\sin t\right) = 3\cdot\frac{1}{2}R^2(t - \sin t)$$

The area of the circular segment is the area of the circular sector DPC subtended by the angle t less the area of the triangle DPC. The triangle DPC has height $R\cos\frac{t}{2}$ and base $2R\sin\frac{t}{2}$ so that its area is $R^2\cos\frac{t}{2}\sin\frac{t}{2} = \frac{1}{2}R^2\sin t$, and the area of the circular sector is $\pi R^2\cdot\frac{t}{2\pi} = \frac{1}{2}R^2 t$. Thus the area of the circular segment is

$$\frac{1}{2}R^2(t - \sin t)$$

which is one third the area of the cycloidal sector.

95.  Derive the formula for the slope of the tangent line to a parametric curve $c(t) = (x(t), y(t))$ using a method different from that presented in the text. Assume that $x'(t_0)$ and $y'(t_0)$ exist and that $x'(t_0) \neq 0$. Show that

$$\lim_{h\to 0}\frac{y(t_0+h) - y(t_0)}{x(t_0+h) - x(t_0)} = \frac{y'(t_0)}{x'(t_0)}$$

Then explain why this limit is equal to the slope dy/dx. Draw a diagram showing that the ratio in the limit is the slope of a secant line.

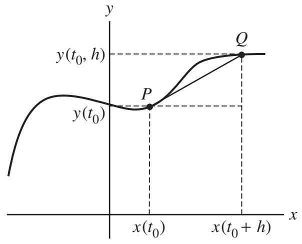
SOLUTION Since $y'(t_0)$ and $x'(t_0)$ exist, we have the following limits:

$$\lim_{h\to 0}\frac{y(t_0+h) - y(t_0)}{h} = y'(t_0), \quad \lim_{h\to 0}\frac{x(t_0+h) - x(t_0)}{h} = x'(t_0) \tag{1}$$

We use Basic Limit Laws, the limits in (1) and the given data $x'(t_0) \neq 0$, to write

$$\lim_{h\to 0}\frac{y(t_0+h) - y(t_0)}{x(t_0+h) - x(t_0)} = \lim_{h\to 0}\frac{\frac{y(t_0+h)-y(t_0)}{h}}{\frac{x(t_0+h)-x(t_0)}{h}} = \frac{\lim_{h\to 0}\frac{y(t_0+h)-y(t_0)}{h}}{\lim_{h\to 0}\frac{x(t_0+h)-x(t_0)}{h}} = \frac{y'(t_0)}{x'(t_0)}$$

Notice that the quotient $\frac{y(t_0+h) - y(t_0)}{x(t_0+h) - x(t_0)}$ is the slope of the secant line determined by the points $P = (x(t_0), y(t_0))$ and $Q = (x(t_0+h), y(t_0+h))$. Hence, the limit of the quotient as $h \to 0$ is the slope of the tangent line at P, that is the derivative $\frac{dy}{dx}$.



96. Verify that the **tractrix** curve ($\ell > 0$)

$$c(t) = \left(t - \ell \tanh \frac{t}{\ell}, \ell \operatorname{sech} \frac{t}{\ell}\right)$$

has the following property: For all t, the segment from $c(t)$ to $(t, 0)$ is tangent to the curve and has length ℓ (Figure 27).

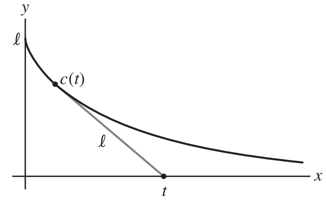


FIGURE 27 The tractrix $c(t) = \left(t - \ell \tanh \frac{t}{\ell}, \ell \operatorname{sech} \frac{t}{\ell}\right)$.

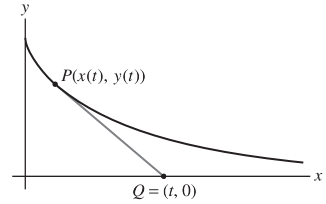
SOLUTION Let $P = c(t)$ and $Q = (t, 0)$.



The slope of the segment $\overline{PQ}$ is

$$m_1 = \frac{y(t) - 0}{x(t) - t} = \frac{\ell \operatorname{sech}\left(\frac{t}{\ell}\right)}{-\ell \tanh\left(\frac{t}{\ell}\right)} = -\frac{1}{\sinh\left(\frac{t}{\ell}\right)}$$

We compute the slope of the tangent line at P:

$$m_2 = \frac{dy}{dx} = \frac{y'(t)}{x'(t)} = \frac{\left(\ell \operatorname{sech}\left(\frac{t}{\ell}\right)\right)'}{\left(t - \ell \tanh\left(\frac{t}{\ell}\right)\right)'} = \frac{\ell \cdot \frac{1}{\ell}\left(-\operatorname{sech}\left(\frac{t}{\ell}\right)\tanh\left(\frac{t}{\ell}\right)\right)}{1 - \ell \cdot \frac{1}{\ell}\operatorname{sech}^2\left(\frac{t}{\ell}\right)}$$

$$= -\frac{-\operatorname{sech}\left(\frac{t}{\ell}\right)\tanh\left(\frac{t}{\ell}\right)}{1 - \operatorname{sech}^2\left(\frac{t}{\ell}\right)} = \frac{-\operatorname{sech}\left(\frac{t}{\ell}\right)\tanh\left(\frac{t}{\ell}\right)}{\tanh^2\left(\frac{t}{\ell}\right)} = \frac{-\operatorname{sech}\left(\frac{t}{\ell}\right)}{\tanh\left(\frac{t}{\ell}\right)} = -\frac{1}{\sinh\left(\frac{t}{\ell}\right)}$$

Since $m_1 = m_2$, we conclude that the segment from $c(t)$ to $(t, 0)$ is tangent to the curve.

We now show that $|\overline{PQ}| = \ell$:

$$|\overline{PQ}| = \sqrt{(x(t) - t)^2 + (y(t) - 0)^2} = \sqrt{\left(-\ell \tanh \frac{t}{\ell}\right)^2 + \left(\ell \operatorname{sech}\left(\frac{t}{\ell}\right)\right)^2}$$

$$= \sqrt{\ell^2\left(\tanh^2\left(\frac{t}{\ell}\right) + \operatorname{sech}^2\left(\frac{t}{\ell}\right)\right)} = \ell\sqrt{\operatorname{sech}^2\left(\frac{t}{\ell}\right)\sinh^2\left(\frac{t}{\ell}\right) + \operatorname{sech}^2\left(\frac{t}{\ell}\right)}$$

$$= \ell \operatorname{sech}\left(\frac{t}{\ell}\right)\sqrt{\sinh^2\left(\frac{t}{\ell}\right) + 1} = \ell \operatorname{sech}\left(\frac{t}{\ell}\right)\cosh\left(\frac{t}{\ell}\right) = \ell \cdot 1 = \ell$$

97. In Exercise 54 of Section 10.1 (ET Exercise 54 of Section 9.1), we described the tractrix by the differential equation

$$\frac{dy}{dx} = -\frac{y}{\sqrt{\ell^2 - y^2}}$$

Show that the curve $c(t)$ identified as the tractrix in Exercise 96 satisfies this differential equation. Note that the derivative on the left is taken with respect to x, not t.

SOLUTION Note that $dx/dt = 1 - \operatorname{sech}^2(t/\ell) = \tanh^2(t/\ell)$ and $dy/dt = -\operatorname{sech}(t/\ell)\tanh(t/\ell)$. Thus,

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{-\operatorname{sech}(t/\ell)}{\tanh(t/\ell)} = \frac{-y/\ell}{\sqrt{1 - y^2/\ell^2}}$$

Multiplying top and bottom by ℓ/ℓ gives

$$\frac{dy}{dx} = \frac{-y}{\sqrt{\ell^2 - y^2}}$$

In Exercises 98 and 99, refer to Figure 28.

98. In the parametrization $c(t) = (a\cos t, b\sin t)$ of an ellipse, t is *not* an angular parameter unless $a = b$ (in which case the ellipse is a circle). However, t can be interpreted in terms of area: Show that if $c(t) = (x, y)$, then $t = (2/ab)A$, where A is the area of the shaded region in Figure 28. *Hint:* Use Eq. (12).

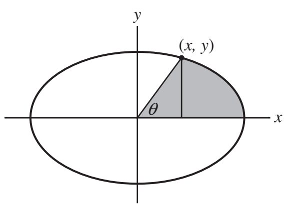


FIGURE 28 The parameter θ on the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$.

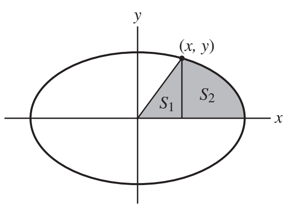
SOLUTION We compute the area A of the shaded region as the sum of the area S_1 of the triangle and the area S_2 of the region under the curve. The area of the triangle is

$$S_1 = \frac{xy}{2} = \frac{(a\cos t)(b\sin t)}{2} = \frac{ab\sin 2t}{4} \qquad (1)$$



The area S_2 under the curve can be computed using Eq. (12). The lower limit of the integration is $t_0 = 0$ (corresponds to $(a, 0)$) and the upper limit is t (corresponds to $(x(t), y(t))$). Also $y(t) = b\sin t$ and $x'(t) = -a\sin t$. Since $x'(t) < 0$ on the interval $0 < t < \frac{\pi}{2}$ (which represents the ellipse on the first quadrant), we use the positive value $a\sin t$ to obtain a positive value for the area. This gives

$$\begin{aligned} S_2 &= \int_0^t b\sin u \cdot a\sin u\,du = ab\int_0^t \sin^2 u\,du \\ &= ab\int_0^t \left(\frac{1}{2} - \frac{1}{2}\cos 2u\right) du = ab\left[\frac{u}{2} - \frac{\sin 2u}{4}\right]\Bigg|_0^t \\ &= ab\left[\frac{t}{2} - \frac{\sin 2t}{4} - 0\right] = \frac{abt}{2} - \frac{ab\sin 2t}{4} \end{aligned} \qquad (2)$$

Combining (1) and (2) we obtain

$$A = S_1 + S_2 = \frac{ab\sin 2t}{4} + \frac{abt}{2} - \frac{ab\sin 2t}{4} = \frac{abt}{2}$$

Hence, $t = \frac{2A}{ab}$.

99. Show that the parametrization of the ellipse by the angle θ is

$$x = \frac{ab\cos\theta}{\sqrt{a^2\sin^2\theta + b^2\cos^2\theta}}$$
$$y = \frac{ab\sin\theta}{\sqrt{a^2\sin^2\theta + b^2\cos^2\theta}}$$

SOLUTION We consider the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1.$$

For the angle θ we have $\tan\theta = \frac{y}{x}$, hence,

$$y = x\tan\theta \tag{1}$$

Substituting in the equation of the ellipse and solving for x we obtain

$$\frac{x^2}{a^2} + \frac{x^2\tan^2\theta}{b^2} = 1$$
$$b^2x^2 + a^2x^2\tan^2\theta = a^2b^2$$
$$(a^2\tan^2\theta + b^2)x^2 = a^2b^2$$
$$x^2 = \frac{a^2b^2}{a^2\tan^2\theta + b^2} = \frac{a^2b^2\cos^2\theta}{a^2\sin^2\theta + b^2\cos^2\theta}$$

We now take the square root. Since the sign of the x-coordinate is the same as the sign of $\cos\theta$, we take the positive root, obtaining

$$x = \frac{ab\cos\theta}{\sqrt{a^2\sin^2\theta + b^2\cos^2\theta}} \tag{2}$$

Hence by (1), the y-coordinate is

$$y = x\tan\theta = \frac{ab\cos\theta\tan\theta}{\sqrt{a^2\sin^2\theta + b^2\cos^2\theta}} = \frac{ab\sin\theta}{\sqrt{a^2\sin^2\theta + b^2\cos^2\theta}} \tag{3}$$

Equalities (2) and (3) give the following parametrization for the ellipse:

$$c_1(\theta) = \left(\frac{ab\cos\theta}{\sqrt{a^2\sin^2\theta + b^2\cos^2\theta}}, \frac{ab\sin\theta}{\sqrt{a^2\sin^2\theta + b^2\cos^2\theta}}\right)$$

11.2 Arc Length and Speed

Preliminary Questions

1. What is the definition of arc length?

SOLUTION A curve can be approximated by a polygonal path obtained by connecting points

$$p_0 = c(t_0),\ p_1 = c(t_1),\ \ldots,\ p_N = c(t_N)$$

on the path with segments. One gets an approximation by summing the lengths of the segments. The definition of arc length is the limit of that approximation when increasing the number of points so that the lengths of the segments approach zero. In doing so, we obtain the following theorem for the arc length:

$$S = \int_a^b \sqrt{x'(t)^2 + y'(t)^2}\, dt,$$

which is the length of the curve $c(t) = (x(t), y(t))$ for $a \le t \le b$.

2. What is the interpretation of $\sqrt{x'(t)^2 + y'(t)^2}$ for a particle following the trajectory $(x(t), y(t))$?

SOLUTION The expression $\sqrt{x'(t)^2 + y'(t)^2}$ denotes the speed at time t of a particle following the trajectory $(x(t), y(t))$.

3. A particle travels along a path from (0, 0) to (3, 4). What is the displacement? Can the distance traveled be determined from the information given?

SOLUTION The net displacement is the distance between the initial point (0, 0) and the endpoint (3, 4). That is

$$\sqrt{(3-0)^2+(4-0)^2}=\sqrt{25}=5.$$

The distance traveled can be determined only if the trajectory $c(t)=(x(t),y(t))$ of the particle is known.

4. A particle traverses the parabola $y=x^2$ with constant speed 3 cm/s. What is the distance traveled during the first minute? *Hint:* No computation is necessary.

SOLUTION Since the speed is constant, the distance traveled is the following product: $L=st=3\cdot 60=180$ cm.

Exercises

In Exercises 1–10, use Eq. (3) to find the length of the path over the given interval.

1. $(3t+1,9-4t)$, $\quad 0\le t\le 2$

SOLUTION Since $x=3t+1$ and $y=9-4t$ we have $x'=3$ and $y'=-4$. Hence, the length of the path is

$$S=\int_0^2\sqrt{3^2+(-4)^2}\,dt=5\int_0^2 dt=10.$$

2. $(1+2t,2+4t)$, $\quad 1\le t\le 4$

SOLUTION We have $x=1+2t$ and $y=2+4t$, hence $x'=2$ and $y'=4$. Using the formula for arc length we obtain

$$S=\int_1^4\sqrt{2^2+4^2}\,dt=\int_1^4\sqrt{20}\,dt=\sqrt{20}(4-1)=6\sqrt{5}$$

3. $(2t^2,3t^2-1)$, $\quad 0\le t\le 4$

SOLUTION Since $x=2t^2$ and $y=3t^2-1$, we have $x'=4t$ and $y'=6t$. By the formula for the arc length we get

$$S=\int_0^4\sqrt{x'(t)^2+y'(t)^2}\,dt=\int_0^4\sqrt{16t^2+36t^2}\,dt=\sqrt{52}\int_0^4 t\,dt=\sqrt{52}\cdot\frac{t^2}{2}\Big|_0^4=16\sqrt{13}$$

4. $(3t,4t^{3/2})$, $\quad 0\le t\le 1$

SOLUTION We have $x=3t$ and $y=4t^{3/2}$, hence $x'=3$ and $y'=6t^{1/2}$. Using the formula for the arc length we obtain

$$S=\int_0^1\sqrt{x'(t)^2+y'(t)^2}\,dt=\int_0^1\sqrt{3^2+\left(6t^{1/2}\right)^2}\,dt=\int_0^1\sqrt{9+36t}\,dt=3\int_0^1\sqrt{1+4t}\,dt$$

Setting $u=1+4t$ we get

$$S=\frac{3}{4}\int_1^5\sqrt{u}\,du=\frac{3}{4}\cdot\frac{2}{3}u^{3/2}\Big|_1^5=\frac{1}{2}(5^{3/2}-1)\approx 5.09$$

5. $(3t^2,4t^3)$, $\quad 1\le t\le 4$

SOLUTION We have $x=3t^2$ and $y=4t^3$. Hence $x'=6t$ and $y'=12t^2$. By the formula for the arc length we get

$$S=\int_1^4\sqrt{x'(t)^2+y'(t)^2}\,dt=\int_1^4\sqrt{36t^2+144t^4}\,dt=6\int_1^4\sqrt{1+4t^2}\,t\,dt.$$

Using the substitution $u=1+4t^2$, $du=8t\,dt$ we obtain

$$S=\frac{6}{8}\int_5^{65}\sqrt{u}\,du=\frac{3}{4}\cdot\frac{2}{3}u^{3/2}\Big|_5^{65}=\frac{1}{2}(65^{3/2}-5^{3/2})\approx 256.43$$

6. $(t^3+1, t^2-3), \quad 0 \le t \le 1$

SOLUTION We have $x = t^3+1$, $y = t^2-3$, hence, $x' = 3t^2$ and $y' = 2t$. By the formula for the arc length we get

$$S = \int_0^1 \sqrt{x'(t)^2 + y'(t)^2}\,dt = \int_0^1 \sqrt{9t^4+4t^2}\,dt = \int_0^1 t\sqrt{9t^2+4}\,dt$$

We compute the integral using the substitution $u = 4+9t^2$. This gives

$$S = \frac{1}{18}\int_4^{13} \sqrt{u}\,du = \frac{1}{18}\cdot\frac{2}{3}u^{3/2}\Big|_4^{13} = \frac{1}{27}(13^{3/2} - 4^{3/2}) = \frac{1}{27}(13^{3/2} - 8) \approx 1.44.$$

7. $(\sin 3t, \cos 3t), \quad 0 \le t \le \pi$

SOLUTION We have $x = \sin 3t$, $y = \cos 3t$, hence $x' = 3\cos 3t$ and $y' = -3\sin 3t$. By the formula for the arc length we obtain:

$$S = \int_0^\pi \sqrt{x'(t)^2 + y'(t)^2}\,dt = \int_0^\pi \sqrt{9\cos^2 3t + 9\sin^2 3t}\,dt = \int_0^\pi \sqrt{9}\,dt = 3\pi$$

8. $(\sin\theta - \theta\cos\theta, \cos\theta + \theta\sin\theta), \quad 0 \le \theta \le 2$

SOLUTION We have $x = \sin\theta - \theta\cos\theta$ and $y = \cos\theta + \theta\sin\theta$. Hence, $x' = \cos\theta - (\cos\theta - \theta\sin\theta) = \theta\sin\theta$ and $y' = -\sin\theta + \sin\theta + \theta\cos\theta = \theta\cos\theta$. Using the formula for the arc length we obtain:

$$S = \int_0^2 \sqrt{x'(\theta)^2 + y'(\theta)^2}\,d\theta = \int_0^2 \sqrt{(\theta\sin\theta)^2 + (\theta\cos\theta)^2}\,d\theta$$

$$= \int_0^2 \sqrt{\theta^2(\sin^2\theta + \cos^2\theta)}\,d\theta = \int_0^2 \theta\,d\theta = \frac{\theta^2}{2}\Big|_0^2 = 2$$

In Exercises 9 and 10, use the identity

$$\frac{1-\cos t}{2} = \sin^2\frac{t}{2}$$

9. $(2\cos t - \cos 2t, 2\sin t - \sin 2t), \quad 0 \le t \le \frac{\pi}{2}$

SOLUTION We have $x = 2\cos t - \cos 2t$, $y = 2\sin t - \sin 2t$. Thus, $x' = -2\sin t + 2\sin 2t$ and $y' = 2\cos t - 2\cos 2t$. We get

$$\begin{aligned}
x'(t)^2 + y'(t)^2 &= (-2\sin t + 2\sin 2t)^2 + (2\cos t - 2\cos 2t)^2 \\
&= 4\sin^2 t - 8\sin t\sin 2t + 4\sin^2 2t + 4\cos^2 t - 8\cos t\cos 2t + 4\cos^2 2t \\
&= 4(\sin^2 t + \cos^2 t) + 4(\sin^2 2t + \cos^2 2t) - 8(\sin t\sin 2t + \cos t\cos 2t) \\
&= 4 + 4 - 8\cos(2t - t) = 8 - 8\cos t = 8(1-\cos t)
\end{aligned}$$

We now use the formula for the arc length to obtain

$$S = \int_0^{\pi/2} \sqrt{x'(t)^2 + y'(t)^2} = \int_0^{\pi/2} \sqrt{8(1-\cos t)}\,dt = \int_0^{\pi/2} \sqrt{16\sin^2\frac{t}{2}}\,dt = 4\int_0^{\pi/2} \sin\frac{t}{2}\,dt$$

$$= -8\cos\frac{t}{2}\Big|_0^{\pi/2} = -8\left(\cos\frac{\pi}{4} - \cos 0\right) = -8\left(\frac{\sqrt{2}}{2} - 1\right) \approx 2.34$$

10. $(5(\theta - \sin\theta), 5(1-\cos\theta)), \quad 0 \le \theta \le 2\pi$

SOLUTION Since $x = 5(\theta - \sin\theta)$ and $y = 5(1-\cos\theta)$, we have $x' = 5(1-\cos\theta)$ and $y' = 5\sin\theta$. Using the formula for the arc length we obtain:

$$\begin{aligned}
S &= \int_0^{2\pi} \sqrt{x'(\theta)^2 + y'(\theta)^2}\,d\theta = \int_0^{2\pi} \sqrt{25(1-\cos\theta)^2 + 25\sin^2\theta}\,d\theta \\
&= 5\int_0^{2\pi} \sqrt{1 - 2\cos\theta + \cos^2\theta + \sin^2\theta}\,d\theta = 5\int_0^{2\pi} \sqrt{2(1-\cos\theta)}\,d\theta \\
&= 5\int_0^{2\pi} \sqrt{4\sin^2\frac{\theta}{2}}\,d\theta = 10\int_0^{2\pi} \sin\frac{\theta}{2}\,d\theta = 20\int_0^{\pi} \sin u\,du \\
&= 20(-\cos u)\Big|_0^{\pi} = -20(-1-1) = 40.
\end{aligned}$$

11. Show that one arch of a cycloid generated by a circle of radius R has length $8R$.

SOLUTION Recall from earlier that the cycloid generated by a circle of radius R has parametric equations $x = Rt - R\sin t$, $y = R - R\cos t$. Hence, $x' = R - R\cos t$, $y' = R\sin t$. Using the identity $\sin^2 \frac{t}{2} = \frac{1-\cos t}{2}$, we get

$$\begin{aligned} x'(t)^2 + y'(t)^2 &= R^2(1-\cos t)^2 + R^2\sin^2 t = R^2(1 - 2\cos t + \cos^2 t + \sin^2 t) \\ &= R^2(1 - 2\cos t + 1) = 2R^2(1-\cos t) = 4R^2 \sin^2 \frac{t}{2} \end{aligned}$$

One arch of the cycloid is traced as t varies from 0 to 2π. Hence, using the formula for the arc length we obtain:

$$\begin{aligned} S &= \int_0^{2\pi} \sqrt{x'(t)^2 + y'(t)^2}\,dt = \int_0^{2\pi} \sqrt{4R^2 \sin^2 \frac{t}{2}}\,dt = 2R\int_0^{2\pi} \sin\frac{t}{2}\,dt = 4R\int_0^{\pi} \sin u\,du \\ &= -4R\cos u\Big|_0^{\pi} = -4R(\cos\pi - \cos 0) = 8R \end{aligned}$$

12. Find the length of the spiral $c(t) = (t\cos t, t\sin t)$ for $0 \le t \le 2\pi$ to three decimal places (Figure 7). *Hint:* Use the formula

$$\int \sqrt{1+t^2}\,dt = \frac{1}{2}t\sqrt{1+t^2} + \frac{1}{2}\ln\left(t + \sqrt{1+t^2}\right)$$

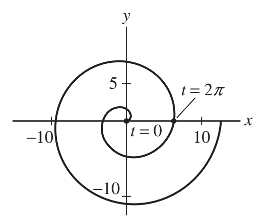


FIGURE 7 The spiral $c(t) = (t\cos t, t\sin t)$.

SOLUTION We use the formula for the arc length:

$$S = \int_0^{2\pi} \sqrt{x'(t)^2 + y'(t)^2}\,dt \tag{1}$$

Differentiating $x = t\cos t$ and $y = t\sin t$ yields

$$\begin{aligned} x'(t) &= \frac{d}{dt}(t\cos t) = \cos t - t\sin t \\ y'(t) &= \frac{d}{dt}(t\sin t) = \sin t + t\cos t \end{aligned}$$

Thus,

$$\begin{aligned} \sqrt{x'(t)^2 + y'(t)^2} &= \sqrt{(\cos t - t\sin t)^2 + (\sin t + t\cos t)^2} \\ &= \sqrt{\cos^2 t - 2t\cos t\sin t + t^2\sin^2 t + \sin^2 t + 2t\sin t\cos t + t^2\cos^2 t} \\ &= \sqrt{(\cos^2 t + \sin^2 t)(1+t^2)} = \sqrt{1+t^2} \end{aligned}$$

We substitute into (1) and use the integral given in the hint to obtain the following arc length:

$$\begin{aligned} S &= \int_0^{2\pi} \sqrt{1+t^2}\,dt = \frac{1}{2}t\sqrt{1+t^2} + \frac{1}{2}\ln\left(t + \sqrt{1+t^2}\right)\Big|_0^{2\pi} \\ &= \frac{1}{2}\cdot 2\pi\sqrt{1+(2\pi)^2} + \frac{1}{2}\ln\left(2\pi + \sqrt{1+(2\pi)^2}\right) - \left(0 + \frac{1}{2}\ln 1\right) \\ &= \pi\sqrt{1+4\pi^2} + \frac{1}{2}\ln\left(2\pi + \sqrt{1+4\pi^2}\right) \approx 21.256 \end{aligned}$$

13. Find the length of the tractrix (see Figure 6)

$$c(t) = (t - \tanh(t), \operatorname{sech}(t)), \qquad 0 \le t \le A$$

SOLUTION Since $x = t - \tanh(t)$ and $y = \operatorname{sech}(t)$ we have $x' = 1 - \operatorname{sech}^2(t)$ and $y' = -\operatorname{sech}(t)\tanh(t)$. Hence,

$$\begin{aligned} x'(t)^2 + y'(t)^2 &= \left(1 - \operatorname{sech}^2(t)\right)^2 + \operatorname{sech}^2(t)\tanh^2(t) \\ &= 1 - 2\operatorname{sech}^2(t) + \operatorname{sech}^4(t) + \operatorname{sech}^2(t)\tanh^2(t) \\ &= 1 - 2\operatorname{sech}^2(t) + \operatorname{sech}^2(t)(\operatorname{sech}^2(t) + \tanh^2(t)) \\ &= 1 - 2\operatorname{sech}^2(t) + \operatorname{sech}^2(t) = 1 - \operatorname{sech}^2(t) = \tanh^2(t) \end{aligned}$$

Hence, using the formula for the arc length we get:

$$\begin{aligned} S &= \int_0^A \sqrt{x'(t)^2 + y'(t)^2}\,dt = \int_0^A \sqrt{\tanh^2(t)}\,dt = \int_0^A \tanh(t)\,dt = \ln(\cosh(t))\Big|_0^A \\ &= \ln(\cosh(A)) - \ln(\cosh(0)) = \ln(\cosh(A)) - \ln 1 = \ln(\cosh(A)) \end{aligned}$$

14. CAS Find a numerical approximation to the length of $c(t) = (\cos 5t, \sin 3t)$ for $0 \le t \le 2\pi$ (Figure 8).

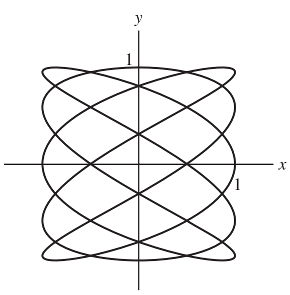

FIGURE 8

SOLUTION Since $x = \cos 5t$ and $y = \sin 3t$, we have

$$x'(t) = -5\sin 5t, \qquad y'(t) = 3\cos 3t$$

so that

$$x'(t)^2 + y'(t)^2 = 25\sin^2 5t + 9\cos^2 3t$$

Then the arc length is

$$\int_0^{2\pi} \sqrt{x'(t)^2 + y'(t)^2}\,dt = \int_0^{2\pi} \sqrt{25\sin^2 5t + 9\cos^2 3t}\,dt \approx 24.60296$$

In Exercises 15–18, determine the speed s at time t (assume units of meters and seconds).

15. $(t^3, t^2), \quad t = 2$

SOLUTION We have $x(t) = t^3$, $y(t) = t^2$ hence $x'(t) = 3t^2$, $y'(t) = 2t$. The speed of the particle at time t is thus, $\frac{ds}{dt} = \sqrt{x'(t)^2 + y'(t)^2} = \sqrt{9t^4 + 4t^2} = t\sqrt{9t^2 + 4}$. At time $t = 2$ the speed is

$$\left.\frac{ds}{dt}\right|_{t=2} = 2\sqrt{9 \cdot 2^2 + 4} = 2\sqrt{40} = 4\sqrt{10} \approx 12.65 \text{ m/s}.$$

16. $(3\sin 5t, 8\cos 5t), \quad t = \frac{\pi}{4}$

SOLUTION We have $x = 3\sin 5t$, $y = 8\cos 5t$, hence $x' = 15\cos 5t$, $y' = -40\sin 5t$. Thus, the speed of the particle at time t is

$$\begin{aligned} \frac{ds}{dt} &= \sqrt{x'(t)^2 + y'(t)^2} = \sqrt{225\cos^2 5t + 1600\sin^2 5t} \\ &= \sqrt{225(\cos^2 5t + \sin^2 5t) + 1375\sin^2 5t} = 5\sqrt{9 + 55\sin^2 5t} \end{aligned}$$

Thus,

$$\frac{ds}{dt} = 5\sqrt{9 + 55\sin^2 5t}.$$

The speed at time $t = \frac{\pi}{4}$ is thus

$$\left.\frac{ds}{dt}\right|_{t=\pi/4} = 5\sqrt{9 + 55\sin^2\left(5 \cdot \frac{\pi}{4}\right)} \cong 30.21 \text{ m/s}$$

17. $(5t + 1, 4t - 3), \quad t = 9$

SOLUTION Since $x = 5t + 1$, $y = 4t - 3$, we have $x' = 5$ and $y' = 4$. The speed of the particle at time t is

$$\frac{ds}{dt} = \sqrt{x'(t) + y'(t)} = \sqrt{5^2 + 4^2} = \sqrt{41} \approx 6.4 \text{ m/s}.$$

We conclude that the particle has constant speed of 6.4 m/s.

18. $(\ln(t^2 + 1), t^3), \quad t = 1$

SOLUTION We have $x = \ln(t^2 + 1)$, $y = t^3$, so $x' = \dfrac{2t}{t^2 + 1}$ and $y' = 3t^2$. The speed of the particle at time t is thus

$$\frac{ds}{dt} = \sqrt{x'(t)^2 + y'(t)^2} = \sqrt{\frac{4t^2}{\left(t^2 + 1\right)^2} + 9t^4} = t\sqrt{\frac{4}{\left(t^2 + 1\right)^2} + 9t^2}.$$

The speed at time $t = 1$ is

$$\left.\frac{ds}{dt}\right|_{t=1} = \sqrt{\frac{4}{2^2} + 9} = \sqrt{10} \approx 3.16 \text{ m/s}.$$

19. Find the minimum speed of a particle with trajectory $c(t) = (t^3 - 4t, t^2 + 1)$ for $t \geq 0$. *Hint:* It is easier to find the minimum of the square of the speed.

SOLUTION We first find the speed of the particle. We have $x(t) = t^3 - 4t$, $y(t) = t^2 + 1$, hence $x'(t) = 3t^2 - 4$ and $y'(t) = 2t$. The speed is thus

$$\frac{ds}{dt} = \sqrt{\left(3t^2 - 4\right)^2 + (2t)^2} = \sqrt{9t^4 - 24t^2 + 16 + 4t^2} = \sqrt{9t^4 - 20t^2 + 16}.$$

The square root function is an increasing function, hence the minimum speed occurs at the value of t where the function $f(t) = 9t^4 - 20t^2 + 16$ has minimum value. Since $\lim_{t\to\infty} f(t) = \infty$, f has a minimum value on the interval $0 \leq t < \infty$, and it occurs at a critical point or at the endpoint $t = 0$. We find the critical point of f on $t \geq 0$:

$$f'(t) = 36t^3 - 40t = 4t(9t^2 - 10) = 0 \Rightarrow t = 0, t = \sqrt{\frac{10}{9}}.$$

We compute the values of f at these points:

$$f(0) = 9 \cdot 0^4 - 20 \cdot 0^2 + 16 = 16$$

$$f\left(\sqrt{\frac{10}{9}}\right) = 9\left(\sqrt{\frac{10}{9}}\right)^4 - 20\left(\sqrt{\frac{10}{9}}\right)^2 + 16 = \frac{44}{9} \approx 4.89$$

We conclude that the minimum value of f on $t \geq 0$ is 4.89. The minimum speed is therefore

$$\left(\frac{ds}{dt}\right)_{\min} \approx \sqrt{4.89} \approx 2.21.$$

20. Find the minimum speed of a particle with trajectory $c(t) = (t^3, t^{-2})$ for $t \geq 0.5$.

SOLUTION We first compute the speed of the particle. Since $x(t) = t^3$ and $y(t) = t^{-2}$, we have $x'(t) = 3t^2$ and $y'(t) = -2t^{-3}$. The speed is

$$\frac{ds}{dt} = \sqrt{x'(t)^2 + y'(t)^2} = \sqrt{9t^4 + 4t^{-6}}.$$

The square root function is an increasing function, hence the minimum value of $\frac{ds}{dt}$ occurs at the point where the function $f(t) = 9t^4 + 4t^{-6}$ attains its minimum value. We find the critical points of f on the interval $t \geq 0.5$:

$$f'(t) = 36t^3 - 24t^{-7} = 0$$

$$3t^{10} - 2 = 0 \Rightarrow t = \sqrt[10]{\frac{2}{3}} \approx 0.96$$

Since $\lim_{t\to\infty} f(t) = \infty$, the minimum value on $0.5 \le t < \infty$ exists, and it occurs at the critical point $t = 0.96$ or at the endpoint $t = 0.5$. We compute the values of f at these points:

$$f(0.96) = 9 \cdot (0.96)^4 + 4 \cdot (0.96)^{-6} = 12.75$$
$$f(0.5) = 9(0.5)^4 + 4(0.5)^{-6} = 256.56$$

We conclude that the minimum value of f on the interval $t \ge 0.5$ is 12.75. The minimum speed for $t \ge 0.5$ is therefore

$$\left(\frac{ds}{dt}\right)_{\min} = \sqrt{12.75} \approx 3.57$$

21. Find the speed of the cycloid $c(t) = (4t - 4\sin t, 4 - 4\cos t)$ at points where the tangent line is horizontal.

SOLUTION We first find the points where the tangent line is horizontal. The slope of the tangent line is the following quotient:

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{4\sin t}{4 - 4\cos t} = \frac{\sin t}{1 - \cos t}.$$

To find the points where the tangent line is horizontal we solve the following equation for $t \ge 0$:

$$\frac{dy}{dx} = 0, \quad \frac{\sin t}{1 - \cos t} = 0 \Rightarrow \sin t = 0 \quad \text{and} \quad \cos t \ne 1.$$

Now, $\sin t = 0$ and $t \ge 0$ at the points $t = \pi k$, $k = 0, 1, 2, \dots$. Since $\cos \pi k = (-1)^k$, the points where $\cos t \ne 1$ are $t = \pi k$ for k odd. The points where the tangent line is horizontal are, therefore:

$$t = \pi(2k - 1), \quad k = 1, 2, 3, \dots$$

The speed at time t is given by the following expression:

$$\begin{aligned}
\frac{ds}{dt} &= \sqrt{x'(t)^2 + y'(t)^2} = \sqrt{(4 - 4\cos t)^2 + (4\sin t)^2} \\
&= \sqrt{16 - 32\cos t + 16\cos^2 t + 16\sin^2 t} = \sqrt{16 - 32\cos t + 16} \\
&= \sqrt{32(1 - \cos t)} = \sqrt{32 \cdot 2\sin^2 \frac{t}{2}} = 8\left|\sin \frac{t}{2}\right|
\end{aligned}$$

That is, the speed of the cycloid at time t is

$$\frac{ds}{dt} = 8\left|\sin \frac{t}{2}\right|.$$

We now substitute

$$t = \pi(2k - 1), \quad k = 1, 2, 3, \dots$$

to obtain

$$\frac{ds}{dt} = 8\left|\sin \frac{\pi(2k - 1)}{2}\right| = 8|(-1)^{k+1}| = 8$$

22. Calculate the arc length integral $s(t)$ for the *logarithmic spiral* $c(t) = (e^t \cos t, e^t \sin t)$.

SOLUTION We have $x'(t) = e^t(\cos t - \sin t)$, $y'(t) = e^t(\cos t + \sin t)$ so that

$$x'(t)^2 + y'(t)^2 = e^{2t}(\cos^2 t - 2\cos t \sin t + \sin^2 t + \cos^2 t + 2\cos t \sin t + \sin^2 t) = 2e^{2t}(\cos^2 t + \sin^2 t) = 2e^{2t}$$

so that the arc length integral is

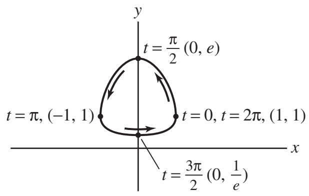
$$\int_a^b \sqrt{x'(t)^2 + y'(t)^2}\, dt = \sqrt{2}\int_a^b e^t\, dt$$

If neither a nor b is $\pm\infty$, then this equals $\sqrt{2}(e^b - e^a)$. Note that the origin corresponds to $t = -\infty$.

CAS *In Exercises 23–26, plot the curve and use the Midpoint Rule with N = 10, 20, 30, and 50 to approximate its length.*

23. $c(t) = (\cos t, e^{\sin t})$ for $0 \le t \le 2\pi$

SOLUTION The curve of $c(t) = (\cos t, e^{\sin t})$ for $0 \le t \le 2\pi$ is shown in the figure below:



$c(t) = (\cos t, e^{\sin t}), 0 \le t \le 2\pi.$

The length of the curve is given by the following integral:

$$S = \int_0^{2\pi} \sqrt{x'(t)^2 + y'(t)^2}\, dt = \int_0^{2\pi} \sqrt{(-\sin t)^2 + (\cos t\, e^{\sin t})^2}\, dt.$$

That is, $S = \int_0^{2\pi} \sqrt{\sin^2 t + \cos^2 t\, e^{2\sin t}}\, dt$. We approximate the integral using the Mid-Point Rule with $N = 10, 20, 30, 50$. For $f(t) = \sqrt{\sin^2 t + \cos^2 t\, e^{2\sin t}}$ we obtain

$$(N = 10): \quad \Delta x = \frac{2\pi}{10} = \frac{\pi}{5},\ c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{5}$$

$$M_{10} = \frac{\pi}{5} \sum_{i=1}^{10} f(c_i) = 6.903734$$

$$(N = 20): \quad \Delta x = \frac{2\pi}{20} = \frac{\pi}{10},\ c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{10}$$

$$M_{20} = \frac{\pi}{10} \sum_{i=1}^{20} f(c_i) = 6.915035$$

$$(N = 30): \quad \Delta x = \frac{2\pi}{30} = \frac{\pi}{15},\ c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{15}$$

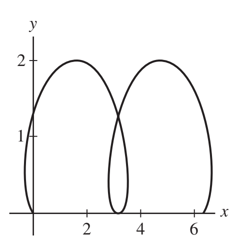
$$M_{30} = \frac{\pi}{15} \sum_{i=1}^{30} f(c_i) = 6.914949$$

$$(N = 50): \quad \Delta x = \frac{2\pi}{50} = \frac{\pi}{25},\ c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{25}$$

$$M_{50} = \frac{\pi}{25} \sum_{i=1}^{50} f(c_i) = 6.914951$$

24. $c(t) = (t - \sin 2t, 1 - \cos 2t)$ for $0 \le t \le 2\pi$

SOLUTION The curve is shown in the figure below:



$c(t) = (t - \sin 2t, 1 - \cos 2t), 0 \le t \le 2\pi.$

The length of the curve is given by the following integral:

$$S = \int_0^{2\pi} \sqrt{(1 - 2\cos 2t)^2 + (2\sin 2t)^2}\, dt = \int_0^{2\pi} \sqrt{1 - 4\cos 2t + 4\cos^2 2t + 4\sin^2 2t}\, dt = \int_0^{2\pi} \sqrt{5 - 4\cos 2t}\, dt.$$

That is,

$$S = \int_0^{2\pi} \sqrt{5 - 4\cos 2t}\, dt.$$

Approximating the length using the Mid-Point Rule with $N = 10, 20, 30, 50$ for $f(t) = \sqrt{5 - 4\cos 2t}$ we obtain

$$(N = 10): \quad \Delta x = \frac{2\pi}{10} = \frac{\pi}{5}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{5}$$

$$M_{10} = \frac{\pi}{5} \sum_{i=1}^{10} f(c_i) = 13.384047$$

$$(N = 20): \quad \Delta x = \frac{2\pi}{20} = \frac{\pi}{10}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{10}$$

$$M_{20} = \frac{\pi}{10} \sum_{i=1}^{20} f(c_i) = 13.365095$$

$$(N = 30): \quad \Delta x = \frac{2\pi}{30} = \frac{\pi}{15}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{15}$$

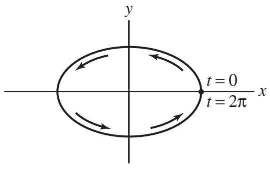
$$M_{30} = \frac{\pi}{15} \sum_{i=1}^{30} f(c_i) = 13.364897$$

$$(N = 50): \quad \Delta x = \frac{2\pi}{50} = \frac{\pi}{25}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{25}$$

$$M_{50} = \frac{\pi}{25} \sum_{i=1}^{50} f(c_i) = 13.364893$$

25. The ellipse $\left(\frac{x}{5}\right)^2 + \left(\frac{y}{3}\right)^2 = 1$

SOLUTION We use the parametrization given in Example 4, section 12.1, that is, $c(t) = (5\cos t, 3\sin t)$, $0 \le t \le 2\pi$. The curve is shown in the figure below:



$c(t) = (5\cos t, 3\sin t)$, $0 \le t \le 2\pi$.

The length of the curve is given by the following integral:

$$S = \int_0^{2\pi} \sqrt{x'(t)^2 + y'(t)^2}\, dt = \int_0^{2\pi} \sqrt{(-5\sin t)^2 + (3\cos t)^2}\, dt$$
$$= \int_0^{2\pi} \sqrt{25\sin^2 t + 9\cos^2 t}\, dt = \int_0^{2\pi} \sqrt{9(\sin^2 t + \cos^2 t) + 16\sin^2 t}\, dt = \int_0^{2\pi} \sqrt{9 + 16\sin^2 t}\, dt.$$

That is,

$$S = \int_0^{2\pi} \sqrt{9 + 16\sin^2 t}\, dt.$$

We approximate the integral using the Mid-Point Rule with $N = 10, 20, 30, 50$, for $f(t) = \sqrt{9 + 16\sin^2 t}$. We obtain

$$(N = 10): \quad \Delta x = \frac{2\pi}{10} = \frac{\pi}{5}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{5}$$

$$M_{10} = \frac{\pi}{5} \sum_{i=1}^{10} f(c_i) = 25.528309$$

$$(N = 20): \quad \Delta x = \frac{2\pi}{20} = \frac{\pi}{10}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{10}$$

$$M_{20} = \frac{\pi}{10} \sum_{i=1}^{20} f(c_i) = 25.526999$$

$$(N = 30): \quad \Delta x = \frac{2\pi}{30} = \frac{\pi}{15}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{15}$$

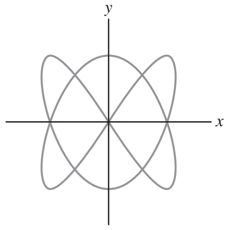
$$M_{30} = \frac{\pi}{15} \sum_{i=1}^{30} f(c_i) = 25.526999$$

$$(N = 50): \quad \Delta x = \frac{2\pi}{50} = \frac{\pi}{25}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{25}$$

$$M_{50} = \frac{\pi}{25} \sum_{i=1}^{50} f(c_i) = 25.526999$$

26. $x = \sin 2t, \quad y = \sin 3t \quad$ for $0 \le t \le 2\pi$

SOLUTION The curve is shown in the figure below:



$c(t) = (\sin 2t, \sin 3t), 0 \le t \le 2\pi.$

The length of the curve is given by the following integral:

$$S = \int_0^{2\pi} \sqrt{x'(t)^2 + y'(t)^2}\, dt = \int_0^{2\pi} \sqrt{(2\cos 2t)^2 + (3\cos 3t)^2}\, dt = \int_0^{2\pi} \sqrt{4\cos^2 2t + 9\cos^2 3t}\, dt.$$

We approximate the length using the Mid-Point Rule with $N = 10, 20, 30, 50$ for $f(t) = \sqrt{4\cos^2 2t + 9\cos^2 3t}$. We obtain

$$(N = 10): \quad \Delta x = \frac{2\pi}{10} = \frac{\pi}{5}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{5}$$

$$M_{10} = \frac{\pi}{5} \sum_{i=1}^{10} f(c_i) = 15.865169$$

$$(N = 20): \quad \Delta x = \frac{2\pi}{20} = \frac{\pi}{10}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{10}$$

$$M_{20} = \frac{\pi}{10} \sum_{i=1}^{20} f(c_i) = 15.324697$$

$$(N = 30): \quad \Delta x = \frac{2\pi}{30} = \frac{\pi}{15}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{15}$$

$$M_{30} = \frac{\pi}{15} \sum_{i=1}^{30} f(c_i) = 15.279322$$

$$(N = 50): \quad \Delta x = \frac{2\pi}{50} = \frac{\pi}{25}, c_i = \left(i - \frac{1}{2}\right) \cdot \frac{\pi}{25}$$

$$M_{50} = \frac{\pi}{25} \sum_{i=1}^{50} f(c_i) = 15.287976$$

27. If you unwind thread from a stationary circular spool, keeping the thread taut at all times, then the endpoint traces a curve $\mathcal{C}$ called the **involute** of the circle (Figure 9). Observe that $\overline{PQ}$ has length $R\theta$. Show that $\mathcal{C}$ is parametrized by

$$c(\theta) = \big(R(\cos\theta + \theta\sin\theta),\, R(\sin\theta - \theta\cos\theta)\big)$$

Then find the length of the involute for $0 \le \theta \le 2\pi$.

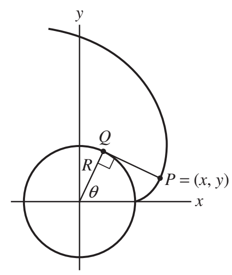


FIGURE 9 Involute of a circle.

SOLUTION Suppose that the arc $\widehat{QT}$ corresponding to the angle θ is unwound. Then the length of the segment $\overline{QP}$ equals the length of this arc. That is, $\overline{QP} = R\theta$. With the help of the figure we can see that

$$x = \overline{OA} + \overline{AB} = \overline{OA} + \overline{EP} = R\cos\theta + \overline{QP}\sin\theta = R\cos\theta + R\theta\sin\theta = R(\cos\theta + \theta\sin\theta).$$

Furthermore,

$$y = \overline{QA} - \overline{QE} = R\sin\theta - \overline{QP}\cos\theta = R\sin\theta - R\theta\cos\theta = R(\sin\theta - \theta\cos\theta)$$

The coordinates of P with respect to the parameter θ form the following parametrization of the curve:

$$c(\theta) = (R(\cos\theta + \theta\sin\theta), R(\sin\theta - \theta\cos\theta)), \qquad 0 \le \theta \le 2\pi.$$

We find the length of the involute for $0 \le \theta \le 2\pi$, using the formula for the arc length:

$$S = \int_0^{2\pi} \sqrt{x'(\theta)^2 + y'(\theta)^2}\, d\theta.$$

We compute the integrand:

$$x'(\theta) = \frac{d}{d\theta}(R(\cos\theta + \theta\sin\theta)) = R(-\sin\theta + \sin\theta + \theta\cos\theta) = R\theta\cos\theta$$
$$y'(\theta) = \frac{d}{d\theta}(R(\sin\theta - \theta\cos\theta)) = R(\cos\theta - (\cos\theta - \theta\sin\theta)) = R\theta\sin\theta$$
$$\sqrt{x'(\theta)^2 + y'(\theta)^2} = \sqrt{(R\theta\cos\theta)^2 + (R\theta\sin\theta)^2} = \sqrt{R^2\theta^2(\cos^2\theta + \sin^2\theta)} = \sqrt{R^2\theta^2} = R\theta$$

We now compute the arc length:

$$S = \int_0^{2\pi} R\theta\, d\theta = \frac{R\theta^2}{2}\bigg|_0^{2\pi} = \frac{R\cdot(2\pi)^2}{2} = 2\pi^2 R.$$

28. Let $a > b$ and set

$$k = \sqrt{1 - \frac{b^2}{a^2}}$$

Use a parametric representation to show that the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$ has length $L = 4aG\left(\frac{\pi}{2}, k\right)$, where

$$G(\theta, k) = \int_0^{\theta} \sqrt{1 - k^2\sin^2 t}\, dt$$

is the *elliptic integral of the second kind*.

SOLUTION Since the ellipse is symmetric with respect to the x and y axis, its length L is four times the length of the part of the ellipse which is in the first quadrant. This part is represented by the following parametrization: $x(t) = a\sin t$, $y(t) = b\cos t$, $0 \le t \le \frac{\pi}{2}$. Using the formula for the arc length we get:

$$L = 4\int_0^{\pi/2} \sqrt{x'(t)^2 + y'(t)^2}\, dt = 4\int_0^{\pi/2} \sqrt{(a\cos t)^2 + (-b\sin t)^2}\, dt$$
$$= 4\int_0^{\pi/2} \sqrt{a^2\cos^2 t + b^2\sin^2 t}\, dt$$

We rewrite the integrand as follows:

$$\begin{aligned}
L &= 4\int_0^{\pi/2}\sqrt{a^2\cos^2 t + a^2\sin^2 t + (b^2-a^2)\sin^2 t}\,dt \\
&= 4\int_0^{\pi/2}\sqrt{a^2(\cos^2 t + \sin^2 t) + (b^2-a^2)\sin^2 t}\,dt \\
&= 4\int_0^{\pi/2}\sqrt{a^2 + (b^2-a^2)\sin^2 t}\,dt = 4a\int_0^{\pi/2}\sqrt{\frac{a^2}{a^2} + \frac{b^2-a^2}{a^2}\sin^2 t}\,dt \\
&= 4a\int_0^{\pi/2}\sqrt{1-\left(1-\frac{b^2}{a^2}\right)\sin^2 t}\,dt = 4a\int_0^{\pi/2}\sqrt{1-k^2\sin^2 t}\,dt = 4aG\left(\frac{\pi}{2},k\right)
\end{aligned}$$

where $k = \sqrt{1-\frac{b^2}{a^2}}$.

In Exercises 29–32, use Eq. (4) to compute the surface area of the given surface.

29. The cone generated by revolving $c(t) = (t, mt)$ about the x-axis for $0 \le t \le A$

SOLUTION Substituting $y(t) = mt$, $y'(t) = m$, $x'(t) = 1$, $a = 0$, and $b = 0$ in the formula for the surface area, we get

$$S = 2\pi\int_0^A mt\sqrt{1+m^2}\,dt = 2\pi\sqrt{1+m^2}\,m\int_0^A t\,dt = 2\pi m\sqrt{1+m^2}\cdot\frac{t^2}{2}\bigg|_0^A = m\sqrt{1+m^2}\pi A^2$$

30. A sphere of radius R

SOLUTION The sphere of radius R is generated by revolving the half circle $c(t) = (R\cos t, R\sin t)$, $0 \le t \le \pi$ about the x-axis. We have $x(t) = R\cos t$, $x'(t) = -R\sin t$, $y(t) = R\sin t$, $y'(t) = R\cos t$. Using the formula for the surface area, we get

$$\begin{aligned}
S &= 2\pi\int_0^{\pi} y(t)\sqrt{x'(t)^2 + y'(t)^2}\,dt = 2\pi\int_0^{\pi} R\sin t\sqrt{R^2\sin^2 t + R^2\cos^2 t}\,dt \\
&= 2\pi R^2\int_0^{\pi}\sin t\,dt = -2\pi R^2\cos t\bigg|_0^{\pi} = -2\pi R^2(-1-1) = 4\pi R^2
\end{aligned}$$

31. The surface generated by revolving one arch of the cycloid $c(t) = (t - \sin t, 1 - \cos t)$ about the x-axis

SOLUTION One arch of the cycloid is traced as t varies from 0 to 2π. Since $x(t) = t - \sin t$ and $y(t) = 1 - \cos t$, we have $x'(t) = 1 - \cos t$ and $y'(t) = \sin t$. Hence, using the identity $1 - \cos t = 2\sin^2\frac{t}{2}$, we get

$$x'(t)^2 + y'(t)^2 = (1-\cos t)^2 + \sin^2 t = 1 - 2\cos t + \cos^2 t + \sin^2 t = 2 - 2\cos t = 4\sin^2\frac{t}{2}$$

By the formula for the surface area we obtain:

$$\begin{aligned}
S &= 2\pi\int_0^{2\pi} y(t)\sqrt{x'(t)^2 + y'(t)^2}\,dt = 2\pi\int_0^{2\pi}(1-\cos t)\cdot 2\sin\frac{t}{2}\,dt \\
&= 2\pi\int_0^{2\pi} 2\sin^2\frac{t}{2}\cdot 2\sin\frac{t}{2}\,dt = 8\pi\int_0^{2\pi}\sin^3\frac{t}{2}\,dt = 16\pi\int_0^{\pi}\sin^3 u\,du
\end{aligned}$$

We use a reduction formula to compute this integral, obtaining

$$S = 16\pi\left[\frac{1}{3}\cos^3 u - \cos u\right]\bigg|_0^{\pi} = 16\pi\left[\frac{4}{3}\right] = \frac{64\pi}{3}$$

32. The surface generated by revolving the astroid $c(t) = (\cos^3 t, \sin^3 t)$ about the x-axis for $0 \le t \le \frac{\pi}{2}$

SOLUTION We have $x(t) = \cos^3 t$, $y(t) = \sin^3 t$, $x'(t) = -3\cos^2 t\sin t$, $y'(t) = 3\sin^2 t\cos t$. Hence,

$$x'(t)^2 + y'(t)^2 = 9\cos^4 t\sin^2 t + 9\sin^4 t\cos^2 t = 9\cos^2 t\sin^2 t(\cos^2 t + \sin^2 t) = 9\cos^2 t\sin^2 t$$

Using the formula for the surface area we get

$$S = 2\pi\int_0^{\pi/2} y(t)\sqrt{x'(t)^2 + y'(t)^2}\,dt = 2\pi\int_0^{\pi/2}\sin^3 t\cdot 3\cos t\sin t\,dt = 6\pi\int_0^{\pi/2}\sin^4 t\cos t\,dt$$

We compute the integral using the substitution $u = \sin t$ $du = \cos t\,dt$. We obtain

$$S = 6\pi\int_0^1 u^4\,du = 6\pi\frac{u^5}{5}\bigg|_0^1 = \frac{6\pi}{5}.$$

Further Insights and Challenges

33. CAS Let $b(t)$ be the "Butterfly Curve":

$$x(t) = \sin t \left(e^{\cos t} - 2\cos 4t - \sin\left(\frac{t}{12}\right)^5 \right)$$

$$y(t) = \cos t \left(e^{\cos t} - 2\cos 4t - \sin\left(\frac{t}{12}\right)^5 \right)$$

(a) Use a computer algebra system to plot $b(t)$ and the speed $s'(t)$ for $0 \le t \le 12\pi$.
(b) Approximate the length $b(t)$ for $0 \le t \le 10\pi$.

SOLUTION

(a) Let $f(t) = e^{\cos t} - 2\cos 4t - \sin\left(\frac{t}{12}\right)^5$, then

$$x(t) = \sin t f(t)$$
$$y(t) = \cos t f(t)$$

and so

$$(x'(t))^2 + (y'(t))^2 = [\sin t f'(t) + \cos t f(t)]^2 + [\cos t f'(t) - \sin t f(t)]^2$$

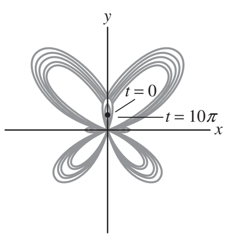
Using the identity $\sin^2 t + \cos^2 t = 1$, we get

$$(x'(t))^2 + (y'(t))^2 = (f'(t))^2 + (f(t))^2.$$

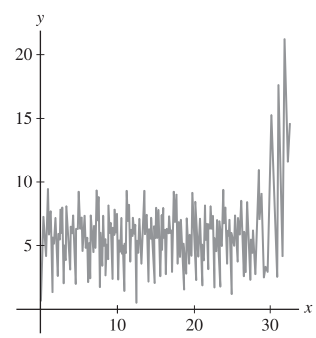
Thus, $s'(t)$ is the following:

$$\sqrt{\left[e^{\cos t} - 2\cos 4t - \sin\left(\frac{t}{12}\right)^5\right]^2 + \left[-\sin t e^{\cos t} + 8\sin 4t - \frac{5}{12}\left(\frac{t}{12}\right)^4 \cos\left(\frac{t}{12}\right)^5\right]^2}.$$

The following figures show the curves of $b(t)$ and the speed $s'(t)$ for $0 \le t \le 10\pi$:



The "Butterfly Curve" $b(t)$, $0 \le t \le 10\pi$



$s'(t)$, $0 \le t \le 10\pi$

Looking at the graph, we see it would be difficult to compute the length using numeric integration; due to the high frequency oscillations, very small steps would be needed.

(b) The length of $b(t)$ for $0 \le t \le 10\pi$ is given by the integral: $L = \int_0^{10\pi} s'(t)\,dt$ where $s'(t)$ is given in part (a). We approximate the length using the Midpoint Rule with $N = 30$. The numerical methods in Mathematica approximate the answer by 211.952. Using the Midpoint Rule with $N = 50$, we get 204.48; with $N = 500$, we get 211.6; and with $N = 5000$, we get 212.09.

34. CAS Let $a \ge b > 0$ and set $k = \dfrac{2\sqrt{ab}}{a-b}$. Show that the **trochoid**

$$x = at - b\sin t, \qquad y = a - b\cos t, \quad 0 \le t \le T$$

has length $2(a-b)G\left(\frac{T}{2}, k\right)$ with $G(\theta, k)$ as in Exercise 28.

SOLUTION We have $x'(t) = a - b\cos t$, $y'(t) = b\sin t$. Hence,

$$\begin{aligned} x'(t)^2 + y'(t)^2 &= (a - b\cos t)^2 + (b\sin t)^2 = a^2 - 2ab\cos t + b^2\cos^2 t + b^2\sin^2 t \\ &= a^2 + b^2 - 2ab\cos t \end{aligned}$$

The length of the trochoid for $0 \le t \le T$ is

$$L = \int_0^T \sqrt{a^2 + b^2 - 2ab\cos t}\, dt$$

We rewrite the integrand as follows to bring it to the required form. We use the identity $1 - \cos t = 2\sin^2 \frac{t}{2}$ to obtain

$$\begin{aligned} L &= \int_0^T \sqrt{(a-b)^2 + 2ab - 2ab\cos t}\, dt = \int_0^T \sqrt{(a-b)^2 + 2ab(1-\cos t)}\, dt \\ &= \int_0^T \sqrt{(a-b)^2 + 4ab\sin^2 \frac{t}{2}}\, dt = \int_0^T \sqrt{(a-b)^2 \left(1 + \frac{4ab}{(a-b)^2}\sin^2 \frac{t}{2}\right)}\, dt \\ &= (a-b)\int_0^T \sqrt{1 + k^2 \sin^2 \frac{t}{2}}\, dt \end{aligned}$$

(where $k = \frac{2\sqrt{ab}}{a-b}$).

Substituting $u = \frac{t}{2}$, $du = \frac{1}{2}\,dt$, we get

$$L = 2(a-b)\int_0^{T/2} \sqrt{1 + k^2 \sin^2 u}\, du = 2(a-b)E(T/2, k)$$

35. A satellite orbiting at a distance R from the center of the earth follows the circular path $x = R\cos\omega t$, $y = R\sin\omega t$.

(a) Show that the period T (the time of one revolution) is $T = 2\pi/\omega$.

(b) According to Newton's laws of motion and gravity,

$$x''(t) = -Gm_e \frac{x}{R^3}, \qquad y''(t) = -Gm_e \frac{y}{R^3}$$

where G is the universal gravitational constant and m_e is the mass of the earth. Prove that $R^3/T^2 = Gm_e/4\pi^2$. Thus, R^3/T^2 has the same value for all orbits (a special case of Kepler's Third Law).

SOLUTION

(a) As shown in Example 4, the circular path has constant speed of $\frac{ds}{dt} = \omega R$. Since the length of one revolution is $2\pi R$, the period T is

$$T = \frac{2\pi R}{\omega R} = \frac{2\pi}{\omega}.$$

(b) Differentiating $x = R\cos\omega t$ twice with respect to t gives

$$\begin{aligned} x'(t) &= -R\omega\sin\omega t \\ x''(t) &= -R\omega^2\cos\omega t \end{aligned}$$

Substituting $x(t)$ and $x''(t)$ in the equation $x''(t) = -Gm_e \dfrac{x}{R^3}$ and simplifying, we obtain

$$\begin{aligned} -R\omega^2\cos\omega t &= -Gm_e \cdot \frac{R\cos\omega t}{R^3} \\ -R\omega^2 &= -\frac{Gm_e}{R^2} \Rightarrow R^3 = \frac{Gm_e}{\omega^2} \end{aligned}$$

By part (a), $T = \dfrac{2\pi}{\omega}$. Hence, $\omega = \dfrac{2\pi}{T}$. Substituting yields

$$R^3 = \frac{Gm_e}{\frac{4\pi^2}{T^2}} = \frac{T^2 Gm_e}{4\pi^2} \Rightarrow \frac{R^3}{T^2} = \frac{Gm_e}{4\pi^2}$$

36. The acceleration due to gravity on the surface of the earth is

$$g = \frac{Gm_e}{R_e^2} = 9.8 \text{ m/s}^2, \quad \text{where } R_e = 6378 \text{ km}$$

Use Exercise 35(b) to show that a satellite orbiting at the earth's surface would have period $T_e = 2\pi\sqrt{R_e/g} \approx 84.5$ min. Then estimate the distance R_m from the moon to the center of the earth. Assume that the period of the moon (sidereal month) is $T_m \approx 27.43$ days.

SOLUTION By part (b) of Exercise 35, it follows that

$$\frac{R_e^3}{T_e^2} = \frac{Gm_e}{4\pi^2} \Rightarrow T_e^2 = \frac{4\pi^2 R_e^3}{Gm_e} = \frac{4\pi^2 R_e}{\frac{Gm_e}{R_e^2}} = \frac{4\pi^2 R_e}{g}$$

Hence,

$$T_e = 2\pi\sqrt{\frac{R_e}{g}} = 2\pi\sqrt{\frac{6378 \cdot 10^3}{9.8}} \approx 5068.8 \text{ s} \approx 84.5 \text{ min}.$$

In part (b) of Exercise 35 we showed that $\frac{R^3}{T^2}$ is the same for all orbits. It follows that this quotient is the same for the satellite orbiting at the earth's surface and for the moon orbiting around the earth. Thus,

$$\frac{R_m^3}{T_m^2} = \frac{R_e^3}{T_e^2} \Rightarrow R_m = R_e\left(\frac{T_m}{T_e}\right)^{2/3}.$$

Setting $T_m = 27.43 \cdot 1440 = 39{,}499.2$ minutes, $T_e = 84.5$ minutes, and $R_e = 6378$ km we get

$$R_m = 6378\left(\frac{39{,}499.2}{84.5}\right)^{2/3} \approx 384{,}154 \text{ km}.$$

11.3 Polar Coordinates

Preliminary Questions

1. Points P and Q with the same radial coordinate (choose the correct answer):

(a) Lie on the same circle with the center at the origin.

(b) Lie on the same ray based at the origin.

SOLUTION Two points with the same radial coordinate are equidistant from the origin, therefore they lie on the same circle centered at the origin. The angular coordinate defines a ray based at the origin. Therefore, if the two points have the same angular coordinate, they lie on the same ray based at the origin.

2. Give two polar representations for the point $(x, y) = (0, 1)$, one with negative r and one with positive r.

SOLUTION The point $(0, 1)$ is on the y-axis, distant one unit from the origin, hence the polar representation with positive r is $(r, \theta) = \left(1, \frac{\pi}{2}\right)$. The point $(r, \theta) = \left(-1, \frac{\pi}{2}\right)$ is the reflection of $(r, \theta) = \left(1, \frac{\pi}{2}\right)$ through the origin, hence we must add π to return to the original point.

We obtain the following polar representation of $(0, 1)$ with negative r:

$$(r, \theta) = \left(-1, \frac{\pi}{2} + \pi\right) = \left(-1, \frac{3\pi}{2}\right).$$

3. Describe each of the following curves:

(a) $r = 2$ **(b)** $r^2 = 2$ **(c)** $r\cos\theta = 2$

SOLUTION

(a) Converting to rectangular coordinates we get

$$\sqrt{x^2 + y^2} = 2 \quad \text{or} \quad x^2 + y^2 = 2^2.$$

This is the equation of the circle of radius 2 centered at the origin.

(b) We convert to rectangular coordinates, obtaining $x^2 + y^2 = 2$. This is the equation of the circle of radius $\sqrt{2}$, centered at the origin.

(c) We convert to rectangular coordinates. Since $x = r\cos\theta$ we obtain the following equation: $x = 2$. This is the equation of the vertical line through the point $(2, 0)$.

4. If $f(-\theta) = f(\theta)$, then the curve $r = f(\theta)$ is symmetric with respect to the (choose the correct answer):

(a) x-axis **(b)** y-axis **(c)** origin

SOLUTION The equality $f(-\theta) = f(\theta)$ for all θ implies that whenever a point (r, θ) is on the curve, also the point $(r, -\theta)$ is on the curve. Since the point $(r, -\theta)$ is the reflection of (r, θ) with respect to the x-axis, we conclude that the curve is symmetric with respect to the x-axis.

Exercises

1. Find polar coordinates for each of the seven points plotted in Figure 16.

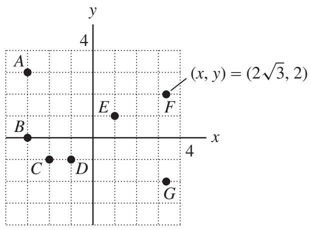


FIGURE 16

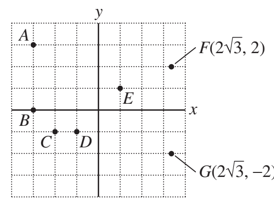
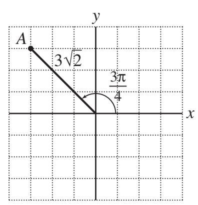
SOLUTION We mark the points as shown in the figure.

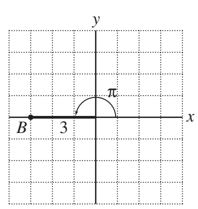


Using the data given in the figure for the x and y coordinates and the quadrants in which the point are located, we obtain:

(A), with rectangular coordinates $(-3, 4)$: $\begin{array}{l} r = \sqrt{(-3)^2 + 3^2} = \sqrt{18} \\ \theta = \pi - \frac{\pi}{4} = \frac{3\pi}{4} \end{array} \Rightarrow (r, \theta) = \left(3\sqrt{2}, \frac{3\pi}{4}\right)$

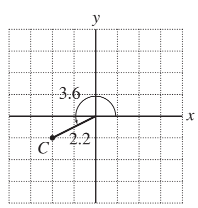


(B), with rectangular coordinates $(-3, 0)$: $\begin{array}{l} r = 3 \\ \theta = \pi \end{array} \Rightarrow (r, \theta) = (3, \pi)$

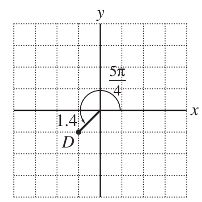


(C), with rectangular coordinates $(-2, -1)$:

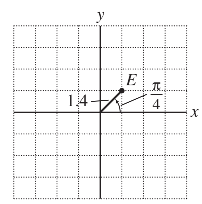
$$\begin{array}{l} r = \sqrt{2^2 + 1^2} = \sqrt{5} \approx 2.2 \\ \theta = \tan^{-1}\left(\frac{-1}{-2}\right) = \tan^{-1}\left(\frac{1}{2}\right) = \pi + 0.46 \approx 3.6 \end{array} \Rightarrow (r, \theta) \approx \left(\sqrt{5}, 3.6\right)$$



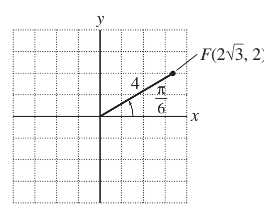
(D), with rectangular coordinates $(-1,-1)$: $\begin{array}{l} r=\sqrt{1^2+1^2}=\sqrt{2}\approx 1.4 \\ \theta=\pi+\frac{\pi}{4}=\frac{5\pi}{4} \end{array}$ $\Rightarrow (r,\theta)\approx\left(\sqrt{2},\frac{5\pi}{4}\right)$



(E), with rectangular coordinates $(1,1)$: $\begin{array}{l} r=\sqrt{1^2+1^2}=\sqrt{2}\approx 1.4 \\ \theta=\tan^{-1}\left(\frac{1}{1}\right)=\frac{\pi}{4} \end{array}$ $\Rightarrow (r,\theta)\approx\left(\sqrt{2},\frac{\pi}{4}\right)$



(F), with rectangular coordinates $(2\sqrt{3},2)$: $\begin{array}{l} r=\sqrt{\left(2\sqrt{3}\right)^2+2^2}=\sqrt{16}=4 \\ \theta=\tan^{-1}\left(\frac{2}{2\sqrt{3}}\right)=\tan^{-1}\left(\frac{1}{\sqrt{3}}\right)=\frac{\pi}{6} \end{array}$ $\Rightarrow (r,\theta)=\left(4,\frac{\pi}{6}\right)$

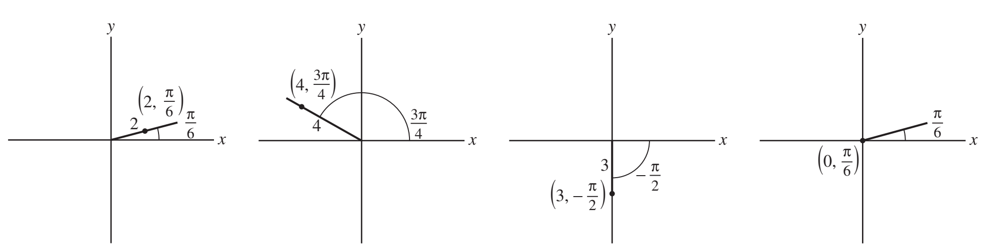


(G), with rectangular coordinates $(2\sqrt{3},-2)$: G is the reflection of F about the x axis, hence the two points have equal radial coordinates, and the angular coordinate of G is obtained from the angular coordinate of F: $\theta=2\pi-\frac{\pi}{6}=\frac{11\pi}{6}$. Hence, the polar coordinates of G are $\left(4,\frac{11\pi}{6}\right)$.

2. Plot the points with polar coordinates:

(a) $\left(2,\frac{\pi}{6}\right)$ **(b)** $\left(4,\frac{3\pi}{4}\right)$ **(c)** $\left(3,-\frac{\pi}{2}\right)$ **(d)** $\left(0,\frac{\pi}{6}\right)$

SOLUTION We first plot the ray $\theta=\theta_0$ for the given angle θ_0, and then mark the point on this line distanced $r=r_0$ from the origin. We obtain the following points:



(a) (b) (c) (d)

$R=0$ is the point $(0,0)$ in rect. coords.

3. Convert from rectangular to polar coordinates.

(a) $(1,0)$ **(b)** $(3,\sqrt{3})$ **(c)** $(-2,2)$ **(d)** $(-1,\sqrt{3})$

SOLUTION

(a) The point $(1,0)$ is on the positive x axis distanced one unit from the origin. Hence, $r=1$ and $\theta=0$. Thus, $(r,\theta)=(1,0)$.

(b) The point $\left(3,\sqrt{3}\right)$ is in the first quadrant so $\theta=\tan^{-1}\left(\frac{\sqrt{3}}{3}\right)=\frac{\pi}{6}$. Also, $r=\sqrt{3^2+\left(\sqrt{3}\right)^2}=\sqrt{12}$. Hence, $(r,\theta)=\left(\sqrt{12},\frac{\pi}{6}\right)$.

(c) The point $(-2, 2)$ is in the second quadrant. Hence,

$$\theta = \tan^{-1}\left(\frac{2}{-2}\right) = \tan^{-1}(-1) = \pi - \frac{\pi}{4} = \frac{3\pi}{4}.$$

Also, $r = \sqrt{(-2)^2 + 2^2} = \sqrt{8}$. Hence, $(r, \theta) = \left(\sqrt{8}, \frac{3\pi}{4}\right)$.

(d) The point $\left(-1, \sqrt{3}\right)$ is in the second quadrant, hence,

$$\theta = \tan^{-1}\left(\frac{\sqrt{3}}{-1}\right) = \tan^{-1}\left(-\sqrt{3}\right) = \pi - \frac{\pi}{3} = \frac{2\pi}{3}.$$

Also, $r = \sqrt{(-1)^2 + \left(\sqrt{3}\right)^2} = \sqrt{4} = 2$. Hence, $(r, \theta) = \left(2, \frac{2\pi}{3}\right)$.

4. Convert from rectangular to polar coordinates using a calculator (make sure your choice of θ gives the correct quadrant).

(a) $(2, 3)$ **(b)** $(4, -7)$ **(c)** $(-3, -8)$ **(d)** $(-5, 2)$

SOLUTION

(a) The point $(2, 3)$ is in the first quadrant, with $x = 2$ and $y = 3$. Hence

$$\begin{aligned} \theta &= \tan^{-1}\left(\frac{3}{2}\right) \approx 0.98 \\ r &= \sqrt{2^2 + 3^2} = \sqrt{13} \approx 3.6 \end{aligned} \quad \Rightarrow \quad (r, \theta) \approx (3.6, 0.98)\,.$$

(b) The point $(4, -7)$ is in the fourth quadrant with $x = 4$ and $y = -7$. We have

$$\tan^{-1}\left(\frac{-7}{4}\right) \approx -1.05$$

$$r = \sqrt{(-7)^2 + 4^2} = \sqrt{65} \approx 8.1$$

Note that $\tan^{-1}$ an angle less that zero in the fourth quadrant; since we want an angle between 0 and 2π, we add 2π to get $\theta \approx 2\pi - 1.05 \approx 5.232$. Thus $(r, \theta) \approx (8.1, 5.2)$.

(c) The point $(-3, -8)$ is in the third quadrant, with $x = -3$ and $y = -8$. We have

$$\tan^{-1}\left(\frac{-8}{-3}\right) = \tan^{-1}\left(\frac{8}{3}\right) \approx 1.212$$

$$r = \sqrt{(-3)^2 + (-8)^2} = \sqrt{73} \approx 8.54$$

Note that $\tan^{-1}$ produced an angle in the first quadrant; we want the third quadrant angle with the same tangent, so we add π to get $\theta \approx \pi + 1.212 \approx 4.35$. Thus $(r, \theta) \approx (8.54, 4.35)$

(d) The point $(-5, 2)$ is in the second quadrant, with $x = -5$ and $y = 2$. We have

$$\tan^{-1}\left(\frac{2}{-5}\right) \approx -0.38$$

$$r = \sqrt{2^2 + (-5)^2} = \sqrt{29} \approx 5.39$$

Note that the angle is in the fourth quadrant; to get the second quadrant angle with the same tangent and in the range $[0, 2\pi)$, we add π to get $\theta \approx \pi - 0.38 \approx 2.76$. Thus $(r, \theta) \approx (5.39, 2.76)$.

5. Convert from polar to rectangular coordinates:

(a) $\left(3, \frac{\pi}{6}\right)$ **(b)** $\left(6, \frac{3\pi}{4}\right)$ **(c)** $\left(0, \frac{\pi}{5}\right)$ **(d)** $\left(5, -\frac{\pi}{2}\right)$

SOLUTION

(a) Since $r = 3$ and $\theta = \frac{\pi}{6}$, we have:

$$\begin{aligned} x &= r\cos\theta = 3\cos\frac{\pi}{6} = 3 \cdot \frac{\sqrt{3}}{2} \approx 2.6 \\ y &= r\sin\theta = 3\sin\frac{\pi}{6} = 3 \cdot \frac{1}{2} = 1.5 \end{aligned} \quad \Rightarrow \quad (x, y) \approx (2.6, 1.5)\,.$$

(b) For $\left(6, \frac{3\pi}{4}\right)$ we have $r = 6$ and $\theta = \frac{3\pi}{4}$. Hence,

$$\begin{aligned} x &= r\cos\theta = 6\cos\frac{3\pi}{4} \approx -4.24 \\ y &= r\sin\theta = 6\sin\frac{3\pi}{4} \approx 4.24 \end{aligned} \quad \Rightarrow \quad (x, y) \approx (-4.24, 4.24)\,.$$

(c) For $\left(0, \frac{\pi}{5}\right)$, we have $r = 0$, so that the rectangular coordinates are $(x, y) = (0, 0)$.

(d) Since $r = 5$ and $\theta = -\frac{\pi}{2}$ we have

$$\begin{aligned} x &= r\cos\theta = 5\cos\left(-\frac{\pi}{2}\right) = 5\cdot 0 = 0 \\ y &= r\sin\theta = 5\sin\left(-\frac{\pi}{2}\right) = 5\cdot(-1) = -5 \end{aligned} \quad \Rightarrow \quad (x, y) = (0, -5)$$

6. Which of the following are possible polar coordinates for the point P with rectangular coordinates $(0, -2)$?

(a) $\left(2, \frac{\pi}{2}\right)$

(b) $\left(2, \frac{7\pi}{2}\right)$

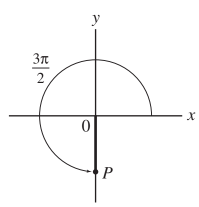
(c) $\left(-2, -\frac{3\pi}{2}\right)$

(d) $\left(-2, \frac{7\pi}{2}\right)$

(e) $\left(-2, -\frac{\pi}{2}\right)$

(f) $\left(2, -\frac{7\pi}{2}\right)$

SOLUTION The point P has distance 2 from the origin and the angle between $\overline{OP}$ and the positive x-axis in the positive direction is $\frac{3\pi}{2}$. Hence, $(r, \theta) = \left(2, \frac{3\pi}{2}\right)$ is one choice for the polar coordinates for P.



The polar coordinates $(2, \theta)$ are possible for P if $\theta - \frac{3\pi}{2}$ is a multiple of 2π. The polar coordinate $(-2, \theta)$ are possible for P if $\theta - \frac{3\pi}{2}$ is an odd multiple of π. These considerations lead to the following conclusions:

(a) $\left(2, \frac{\pi}{2}\right)$ $\frac{\pi}{2} - \frac{3\pi}{2} = -\pi \Rightarrow \left(2, \frac{\pi}{2}\right)$ does not represent P.

(b) $\left(2, \frac{7\pi}{2}\right)$ $\frac{7\pi}{2} - \frac{3\pi}{2} = 2\pi \Rightarrow \left(2, \frac{7\pi}{2}\right)$ represents P.

(c) $\left(-2, -\frac{3\pi}{2}\right)$ $-\frac{3\pi}{2} - \frac{3\pi}{2} = -3\pi \Rightarrow \left(-2, -\frac{3\pi}{2}\right)$ represents P.

(d) $\left(-2, \frac{7\pi}{2}\right)$ $\frac{7\pi}{2} - \frac{3\pi}{2} = 2\pi \Rightarrow \left(-2, \frac{7\pi}{2}\right)$ does not represent P.

(e) $\left(-2, -\frac{\pi}{2}\right)$ $-\frac{\pi}{2} - \frac{3\pi}{2} = -2\pi \Rightarrow \left(-2, -\frac{\pi}{2}\right)$ does not represent P.

(f) $\left(2, -\frac{7\pi}{2}\right)$ $-\frac{7\pi}{2} - \frac{3\pi}{2} = -5\pi \Rightarrow \left(2, -\frac{7\pi}{2}\right)$ does not represent P.

7. Describe each shaded sector in Figure 17 by inequalities in r and θ.

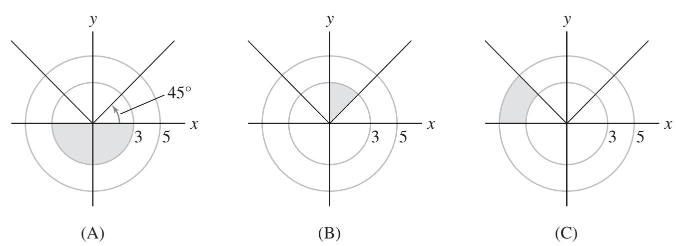


FIGURE 17

SOLUTION

(a) In the sector shown below r is varying between 0 and 3 and θ is varying between π and 2π. Hence the following inequalities describe the sector:

$$0 \le r \le 3$$
$$\pi \le \theta \le 2\pi$$

(b) In the sector shown below r is varying between 0 and 3 and θ is varying between $\frac{\pi}{4}$ and $\frac{\pi}{2}$. Hence, the inequalities for the sector are:

$$0 \le r \le 3$$
$$\frac{\pi}{4} \le \theta \le \frac{\pi}{2}$$

(c) In the sector shown below r is varying between 3 and 5 and θ is varying between $\frac{3\pi}{4}$ and π. Hence, the inequalities are:

$$3 \le r \le 5$$
$$\frac{3\pi}{4} \le \theta \le \pi$$

8. Find the equation in polar coordinates of the line through the origin with slope $\frac{1}{2}$.

SOLUTION A line of slope $m = \frac{1}{2}$ makes an angle $\theta_0 = \tan^{-1}\frac{1}{2} \approx 0.46$ with the positive x-axis. The equation of the line is $\theta \approx 0.46$, while r is arbitrary.

9. What is the slope of the line $\theta = \frac{3\pi}{5}$?

SOLUTION This line makes an angle $\theta_0 = \frac{3\pi}{5}$ with the positive x-axis, hence the slope of the line is $m = \tan\frac{3\pi}{5} \approx -3.1$.

10. Which of $r = 2\sec\theta$ and $r = 2\csc\theta$ defines a horizontal line?

SOLUTION The equation $r = 2\csc\theta$ is the polar equation of a horizontal line, as it can be written as $r = 2/\sin\theta$, so $r\sin\theta = 2$, which becomes $y = 2$. On the other hand, the equation $r = 2\sec\theta$ is the polar equation of a vertical line, as it can be written as $r = 2/\cos\theta$, so $r\cos\theta = 2$, which becomes $x = 2$.

In Exercises 11–16, convert to an equation in rectangular coordinates.

11. $r = 7$

SOLUTION $r = 7$ describes the points having distance 7 from the origin, that is, the circle with radius 7 centered at the origin. The equation of the circle in rectangular coordinates is

$$x^2 + y^2 = 7^2 = 49.$$

12. $r = \sin\theta$

SOLUTION Multiplying by r and substituting $y = r\sin\theta$ and $r^2 = x^2 + y^2$ gives

$$r^2 = r\sin\theta$$
$$x^2 + y^2 = y$$

We move the y and then complete the square to obtain

$$x^2 + y^2 - y = 0$$
$$x^2 + \left(y - \frac{1}{2}\right)^2 = \left(\frac{1}{2}\right)^2$$

Thus, $r = \sin\theta$ is the equation of a circle of radius $\frac{1}{2}$ and center $\left(0, \frac{1}{2}\right)$.

13. $r = 2\sin\theta$

SOLUTION We multiply the equation by r and substitute $r^2 = x^2 + y^2$, $r\sin\theta = y$. This gives

$$r^2 = 2r\sin\theta$$
$$x^2 + y^2 = 2y$$

Moving the $2y$ and completing the square yield: $x^2 + y^2 - 2y = 0$ and $x^2 + (y-1)^2 = 1$. Thus, $r = 2\sin\theta$ is the equation of a circle of radius 1 centered at $(0, 1)$.

14. $r = 2\csc\theta$

SOLUTION We multiply the equation by $\sin\theta$ and substitute $y = r\sin\theta$. We get

$$r\sin\theta = 2$$
$$y = 2$$

Thus, $r = 2\csc\theta$ is the equation of the line $y = 2$.

15. $r = \dfrac{1}{\cos\theta - \sin\theta}$

SOLUTION We multiply the equation by $\cos\theta - \sin\theta$ and substitute $y = r\sin\theta$, $x = r\cos\theta$. This gives

$$r(\cos\theta - \sin\theta) = 1$$
$$r\cos\theta - r\sin\theta = 1$$

$x - y = 1 \Rightarrow y = x - 1$. Thus,

$$r = \frac{1}{\cos\theta - \sin\theta}$$

is the equation of the line $y = x - 1$.

16. $r = \dfrac{1}{2 - \cos\theta}$

SOLUTION We multiply the equation by $2 - \cos\theta$. Then we substitute $x = r\cos\theta$ and $r = \sqrt{x^2 + y^2}$, to obtain

$$r(2 - \cos\theta) = 1$$
$$2r - r\cos\theta = 1$$
$$2\sqrt{x^2 + y^2} - x = 1$$

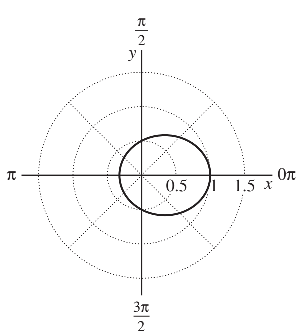
Moving the x, then squaring and simplifying, we obtain

$$2\sqrt{x^2 + y^2} = x + 1$$
$$4\left(x^2 + y^2\right) = x^2 + 2x + 1$$
$$3x^2 - 2x + 4y^2 = 1$$

We complete the square:

$$3\left(x^2 - \frac{2}{3}x\right) + 4y^2 = 1$$
$$3\left(x - \frac{1}{3}\right)^2 + 4y^2 = \frac{4}{3}$$
$$\frac{\left(x - \frac{1}{3}\right)^2}{\frac{4}{9}} + \frac{y^2}{\frac{1}{3}} = 1$$

This is the equation of the ellipse shown in the figure:



In Exercises 17–20, convert to an equation in polar coordinates.

17. $x^2 + y^2 = 5$

SOLUTION We make the substitution $x^2 + y^2 = r^2$ to obtain; $r^2 = 5$ or $r = \sqrt{5}$.

18. $x = 5$

SOLUTION Substituting $x = r\cos\theta$ gives the polar equation $r\cos\theta = 5$ or $r = 5\sec\theta$.

19. $y = x^2$

SOLUTION Substituting $y = r\sin\theta$ and $x = r\cos\theta$ yields

$$r\sin\theta = r^2\cos^2\theta.$$

Then, dividing by $r\cos^2\theta$ we obtain,

$$\frac{\sin\theta}{\cos^2\theta} = r \qquad \text{so} \qquad r = \tan\theta\sec\theta$$

20. $xy = 1$

SOLUTION We substitute $x = r\cos\theta$, $y = r\sin\theta$ to obtain

$$(r\cos\theta)(r\sin\theta) = 1$$
$$r^2\cos\theta\sin\theta = 1$$

Using the identity $\cos\theta\sin\theta = \frac{1}{2}\sin 2\theta$ yields

$$r^2\cdot\frac{\sin 2\theta}{2} = 1 \Rightarrow r^2 = 2\csc 2\theta.$$

21. Match each equation with its description.

(a) $r = 2$	**(i)** Vertical line
(b) $\theta = 2$	**(ii)** Horizontal line
(c) $r = 2\sec\theta$	**(iii)** Circle
(d) $r = 2\csc\theta$	**(iv)** Line through origin

SOLUTION

(a) $r = 2$ describes the points 2 units from the origin. Hence, it is the equation of a circle.

(b) $\theta = 2$ describes the points P so that $\overline{OP}$ makes an angle of $\theta_0 = 2$ with the positive x-axis. Hence, it is the equation of a line through the origin.

(c) This is $r\cos\theta = 2$, which is $x = 2$, a vertical line.

(d) Converting to rectangular coordinates, we get $r = 2\csc\theta$, so $r\sin\theta = 2$ and $y = 2$. This is the equation of a horizontal line.

22. Find the values of θ in the plot of $r = 4\cos\theta$ corresponding to points A, B, C, D in Figure 18. Then indicate the portion of the graph traced out as θ varies in the following intervals:

(a) $0 \le \theta \le \frac{\pi}{2}$ **(b)** $\frac{\pi}{2} \le \theta \le \pi$ **(c)** $\pi \le \theta \le \frac{3\pi}{2}$

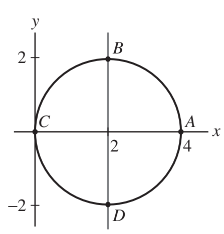


FIGURE 18 Plot of $r = 4\cos\theta$.

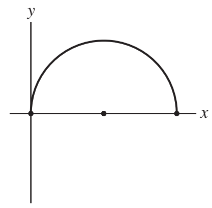
SOLUTION The point A is on the x-axis hence $\theta = 0$. The point B is in the first quadrant with $x = y = 2$ hence $\theta = \tan^{-1}\left(\frac{2}{2}\right) = \tan^{-1}(1) = \frac{\pi}{4}$. The point C is at the origin. Thus,

$$r = 0 \Rightarrow 4\cos\theta = 0 \Rightarrow \theta = \frac{\pi}{2},\ \frac{3\pi}{2}.$$

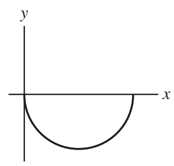
The point D is in the fourth quadrant with $x = 2$, $y = -2$, hence

$$\theta = \tan^{-1}\left(\frac{-2}{2}\right) = \tan^{-1}(-1) = 2\pi - \frac{\pi}{4} = \frac{7\pi}{4}.$$

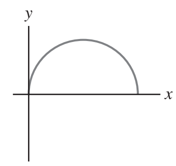
$0 \le \theta \le \frac{\pi}{2}$ represents the first quadrant, hence the points (r,θ) where $r = 4\cos\theta$ and $0 \le \theta \le \frac{\pi}{2}$ are the points on the circle which are in the first quadrant, as shown below:



If we insist that $r \geq 0$, then since $\frac{\pi}{2} \leq \theta \leq \pi$ represents the second quadrant and $\pi \leq \theta \leq \frac{3\pi}{2}$ represents the third quadrant, and since the circle $r = 4\cos\theta$ has no points in the left xy -plane, then there are no points for (b) and (c). However, if we allow $r < 0$ then (b) represents the semi-circle



and (c) like (a) represent

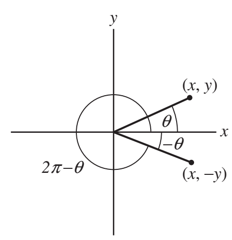


23. Suppose that $P = (x, y)$ has polar coordinates (r, θ). Find the polar coordinates for the points:

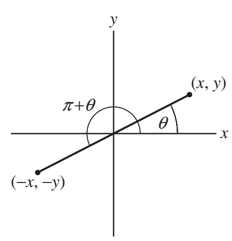
(a) $(x, -y)$ **(b)** $(-x, -y)$ **(c)** $(-x, y)$ **(d)** (y, x)

SOLUTION

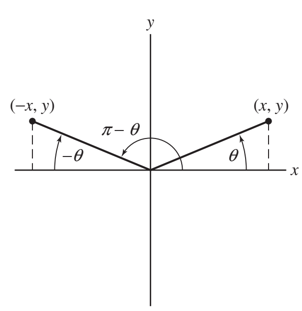
(a) $(x, -y)$ is the symmetric point of (x, y) with respect to the x-axis, hence the two points have the same radial coordinate, and the angular coordinate of $(x, -y)$ is $2\pi - \theta$. Hence, $(x, -y) = (r, 2\pi - \theta)$.



(b) $(-x, -y)$ is the symmetric point of (x, y) with respect to the origin. Hence, $(-x, -y) = (r, \theta + \pi)$.



(c) $(-x, y)$ is the symmetric point of (x, y) with respect to the y-axis. Hence the two points have the same radial coordinates and the angular coordinate of $(-x, y)$ is $\pi - \theta$. Hence, $(-x, y) = (r, \pi - \theta)$.

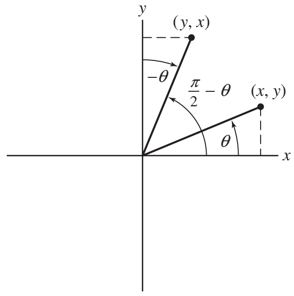


(d) Let (r_1, θ_1) denote the polar coordinates of (y, x). Hence,

$$r_1 = \sqrt{y^2 + x^2} = \sqrt{x^2 + y^2} = r$$

$$\tan\theta_1 = \frac{x}{y} = \frac{1}{y/x} = \frac{1}{\tan\theta} = \cot\theta = \tan\left(\frac{\pi}{2} - \theta\right)$$

Since the points (x, y) and (y, x) are in the same quadrant, the solution for θ_1 is $\theta_1 = \frac{\pi}{2} - \theta$. We obtain the following polar coordinates: $(y, x) = \left(r, \frac{\pi}{2} - \theta\right)$.



24. Match each equation in rectangular coordinates with its equation in polar coordinates.

(a) $x^2 + y^2 = 4$	**(i)** $r^2(1 - 2\sin^2\theta) = 4$
(b) $x^2 + (y-1)^2 = 1$	**(ii)** $r(\cos\theta + \sin\theta) = 4$
(c) $x^2 - y^2 = 4$	**(iii)** $r = 2\sin\theta$
(d) $x + y = 4$	**(iv)** $r = 2$

SOLUTION

(a) Since $x^2 + y^2 = r^2$, we have $r^2 = 4$ or $r = 2$.
(b) Using Example 7, the equation of the circle $x^2 + (y-1)^2 = 1$ has polar equation $r = 2\sin\theta$.
(c) Setting $x = r\cos\theta$, $y = r\sin\theta$ in $x^2 - y^2 = 4$ gives

$$x^2 - y^2 = r^2\cos^2\theta - r^2\sin^2\theta = r^2\left(\cos^2\theta - \sin^2\theta\right) = 4.$$

We now use the identity $\cos^2\theta - \sin^2\theta = 1 - 2\sin^2\theta$ to obtain the following equation:

$$r^2\left(1 - 2\sin^2\theta\right) = 4.$$

(d) Setting $x = r\cos\theta$ and $y = r\sin\theta$ in $x + y = 4$ we get:

$$x + y = 4$$
$$r\cos\theta + r\sin\theta = 4$$

so

$$r(\cos\theta + \sin\theta) = 4$$

25. What are the polar equations of the lines parallel to the line $r\cos\left(\theta - \frac{\pi}{3}\right) = 1$?

SOLUTION The line $r\cos\left(\theta - \frac{\pi}{3}\right) = 1$, or $r = \sec\left(\theta - \frac{\pi}{3}\right)$, is perpendicular to the ray $\theta = \frac{\pi}{3}$ and at distance $d = 1$ from the origin. Hence, the lines parallel to this line are also perpendicular to the ray $\theta = \frac{\pi}{3}$, so the polar equations of these lines are $r = d\sec\left(\theta - \frac{\pi}{3}\right)$ or $r\cos\left(\theta - \frac{\pi}{3}\right) = d$.

26. Show that the circle with center at $\left(\frac{1}{2}, \frac{1}{2}\right)$ in Figure 19 has polar equation $r = \sin\theta + \cos\theta$ and find the values of θ between 0 and π corresponding to points A, B, C, and D.

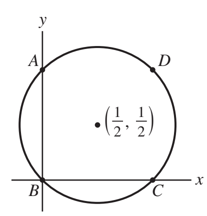


FIGURE 19 Plot of $r = \sin\theta + \cos\theta$.

SOLUTION We show that the rectangular equation of $r = \sin\theta + \cos\theta$ is

$$\left(x - \frac{1}{2}\right)^2 + \left(y - \frac{1}{2}\right)^2 = \frac{1}{2}.$$

We multiply the polar equation by r and substitute $r^2 = x^2 + y^2$, $r\sin\theta = y$, $r\cos\theta = x$. This gives

$$r = \sin\theta + \cos\theta$$
$$r^2 = r\sin\theta + r\cos\theta$$
$$x^2 + y^2 = y + x$$

Transferring sides and completing the square yields

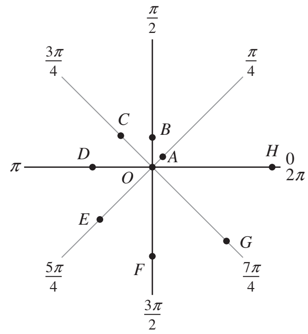
$$x^2 - x + y^2 - y = 0$$
$$\left(x - \frac{1}{2}\right)^2 + \left(y - \frac{1}{2}\right)^2 = \frac{1}{4} + \frac{1}{4} = \frac{1}{2}$$

Clearly point C corresponds to $\theta = 0$ since $\cos 0 + \sin 0 = 1$. The circle is traced out counterclockwise as θ increases to π, so A corresponds to $\theta = \frac{\pi}{2}$ since again $\cos\frac{\pi}{2} + \sin\frac{\pi}{2} = 0$. Next, D clearly corresponds to $\theta = \frac{\pi}{4}$, and indeed $\cos\frac{\pi}{4} + \sin\frac{\pi}{4} = \sqrt{2}$, which is the diameter of the circle. Finally, point A corresponds to $\theta = \frac{3\pi}{4}$, since there $\cos\theta = -\sin\theta$.

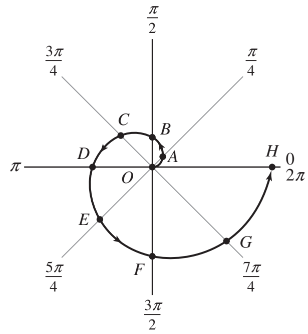
27. Sketch the curve $r = \frac{1}{2}\theta$ (the spiral of Archimedes) for θ between 0 and 2π by plotting the points for $\theta = 0, \frac{\pi}{4}, \frac{\pi}{2}, \ldots, 2\pi$.

SOLUTION We first plot the following points (r, θ) on the spiral:

$$O = (0,0),\ A = \left(\frac{\pi}{8}, \frac{\pi}{4}\right),\ B = \left(\frac{\pi}{4}, \frac{\pi}{2}\right),\ C = \left(\frac{3\pi}{8}, \frac{3\pi}{4}\right),\ D = \left(\frac{\pi}{2}, \pi\right),$$
$$E = \left(\frac{5\pi}{8}, \frac{5\pi}{4}\right),\ F = \left(\frac{3\pi}{4}, \frac{3\pi}{2}\right),\ G = \left(\frac{7\pi}{8}, \frac{7\pi}{4}\right),\ H = (\pi, 2\pi).$$



Since $r(0) = \frac{0}{2} = 0$, the graph begins at the origin and moves toward the points A, B, C, D, E, F, G and H as θ varies from $\theta = 0$ to the other values stated above. Connecting the points in this direction we obtain the following graph for $0 \le \theta \le 2\pi$:



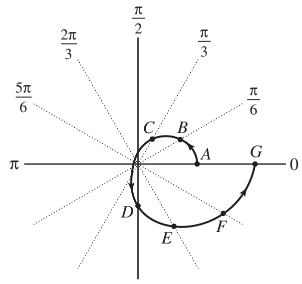
28. Sketch $r = 3\cos\theta - 1$ (see Example 8).

SOLUTION We first choose some values of θ between 0 and π and mark the corresponding points on the graph. Then we use symmetry (due to $\cos(2\pi - \theta) = \cos\theta$) to plot the other half of the graph by reflecting the first half through the x-axis. Since $r = 3\cos\theta - 1$ is periodic, the entire curve is obtained as θ varies from 0 to 2π. We start with the values $\theta = 0, \frac{\pi}{6}, \frac{\pi}{3}, \frac{\pi}{2}, \frac{2\pi}{3}, \frac{5\pi}{6}, \pi$, and compute the corresponding values of r:

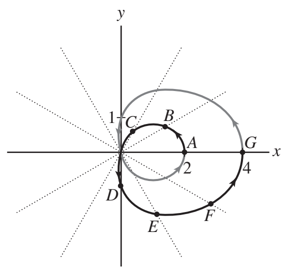
$$r = 3\cos 0 - 1 = 3 - 1 = 2 \Rightarrow A = (2, 0)$$
$$r = 3\cos\frac{\pi}{6} - 1 = \frac{3\sqrt{3}}{2} - 1 \approx 1.6 \Rightarrow B = \left(1.6, \frac{\pi}{6}\right)$$
$$r = 3\cos\frac{\pi}{3} - 1 = \frac{3}{2} - 1 = 0.5 \Rightarrow C = \left(0.5, \frac{\pi}{3}\right)$$
$$r = 3\cos\frac{\pi}{2} - 1 = 3 \cdot 0 - 1 = -1 \Rightarrow D = \left(-1, \frac{\pi}{2}\right)$$

$$r = 3\cos\frac{2\pi}{3} - 1 = -2.5 \Rightarrow E = \left(-2.5, \frac{2\pi}{3}\right)$$
$$r = 3\cos\frac{5\pi}{6} - 1 = -3.6 \Rightarrow F = \left(-3.6, \frac{5\pi}{6}\right)$$
$$r = 3\cos\pi - 1 = -4 \Rightarrow G = (-4, \pi)$$

The graph begins at the point $(r, \theta) = (2, 0)$ and moves toward the other points in this order, as θ varies from 0 to π. Since r is negative for $\frac{\pi}{2} \le \theta \le \pi$, the curve continues into the fourth quadrant, rather than into the second quadrant. We obtain the following graph:



Now we have half the curve and we use symmetry to plot the rest. Reflecting the first half through the x axis we obtain the whole curve:

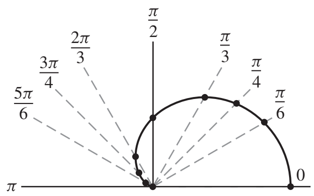


29. Sketch the cardioid curve $r = 1 + \cos\theta$.

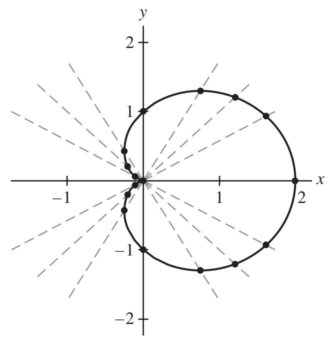
SOLUTION Since $\cos\theta$ is period with period 2π, the entire curve will be traced out as θ varies from 0 to 2π. Additionally, since $\cos(2\pi - \theta) = \cos(\theta)$, we can sketch the curve for θ between 0 and π and reflect the result through the x axis to obtain the whole curve. Use the values $\theta = 0, \frac{\pi}{6}, \frac{\pi}{4}, \frac{\pi}{3}, \frac{\pi}{2}, \frac{2\pi}{3}, \frac{3\pi}{4}, \frac{5\pi}{6}$, and π:

θ	r	point
0	$1 + \cos 0 = 2$	$(2, 0)$
$\frac{\pi}{6}$	$1 + \cos\frac{\pi}{6} = \frac{2+\sqrt{3}}{2}$	$\left(\frac{2+\sqrt{3}}{2}, \frac{\pi}{6}\right)$
$\frac{\pi}{4}$	$1 + \cos\frac{\pi}{4} = \frac{2+\sqrt{2}}{2}$	$\left(\frac{2+\sqrt{2}}{2}, \frac{\pi}{4}\right)$
$\frac{\pi}{3}$	$1 + \cos\frac{\pi}{3} = \frac{3}{2}$	$\left(\frac{3}{2}, \frac{\pi}{3}\right)$
$\frac{\pi}{2}$	$1 + \cos\frac{\pi}{2} = 1$	$\left(1, \frac{\pi}{2}\right)$
$\frac{2\pi}{3}$	$1 + \cos\frac{2\pi}{3} = \frac{1}{2}$	$\left(\frac{1}{2}, \frac{2\pi}{3}\right)$
$\frac{3\pi}{4}$	$1 + \cos\frac{3\pi}{4} = \frac{2-\sqrt{2}}{2}$	$\left(\frac{2-\sqrt{2}}{2}, \frac{3\pi}{4}\right)$
$\frac{5\pi}{6}$	$1 + \cos\frac{5\pi}{6} = \frac{2-\sqrt{3}}{2}$	$\left(\frac{2-\sqrt{3}}{2}, \frac{5\pi}{6}\right)$

$\theta = 0$ corresponds to the point $(2, 0)$, and the graph moves clockwise as θ increases from 0 to π. Thus the graph is



Reflecting through the x axis gives the other half of the curve:



30. Show that the cardioid of Exercise 29 has equation

$$(x^2 + y^2 - x)^2 = x^2 + y^2$$

in rectangular coordinates.

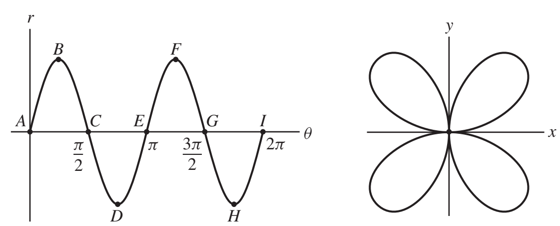
SOLUTION Multiply through by r and substitute for r, r^2, and $r\cos\theta$ to get

$$r = 1 + \cos\theta$$
$$r^2 = r + r\cos\theta$$
$$x^2 + y^2 = \sqrt{x^2 + y^2} + x$$
$$x^2 + y^2 - x = \sqrt{x^2 + y^2}$$
$$(x^2 + y^2 - x)^2 = x^2 + y^2$$

31. Figure 20 displays the graphs of $r = \sin 2\theta$ in rectangular coordinates and in polar coordinates, where it is a "rose with four petals." Identify:

(a) The points in (B) corresponding to points A–I in (A).

(b) The parts of the curve in (B) corresponding to the angle intervals $\left[0, \frac{\pi}{2}\right]$, $\left[\frac{\pi}{2}, \pi\right]$, $\left[\pi, \frac{3\pi}{2}\right]$, and $\left[\frac{3\pi}{2}, 2\pi\right]$.



(A) Graph of r as a function of θ, where $r = \sin 2\theta$

(B) Graph of $r = \sin 2\theta$ in polar coordinates

FIGURE 20

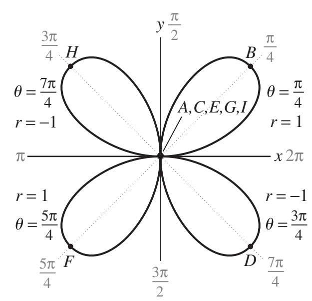
SOLUTION

(a) The graph (A) gives the following polar coordinates of the labeled points:

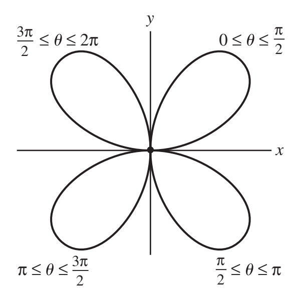
$$A: \quad \theta = 0, \quad r = 0$$
$$B: \quad \theta = \frac{\pi}{4}, \quad r = \sin\frac{2\pi}{4} = 1$$
$$C: \quad \theta = \frac{\pi}{2}, \quad r = 0$$
$$D: \quad \theta = \frac{3\pi}{4}, \quad r = \sin\frac{2\cdot 3\pi}{4} = -1$$
$$E: \quad \theta = \pi, \quad r = 0$$
$$F: \quad \theta = \frac{5\pi}{4}, \quad r = 1$$
$$G: \quad \theta = \frac{3\pi}{2}, \quad r = 0$$

$$H: \quad \theta = \frac{7\pi}{4}, \quad r = -1$$
$$I: \quad \theta = 2\pi, \quad r = 0.$$

Since the maximal value of $|r|$ is 1, the points with $r = 1$ or $r = -1$ are the furthest points from the origin. The corresponding quadrant is determined by the value of θ and the sign of r. If $r_0 < 0$, the point (r_0, θ_0) is on the ray $\theta = -\theta_0$. These considerations lead to the following identification of the points in the xy plane. Notice that A, C, G, E, and I are the same point.



(b) We use the graph (A) to find the sign of $r = \sin 2\theta$: $0 \le \theta \le \frac{\pi}{2} \Rightarrow r \ge 0 \Rightarrow (r, \theta)$ is in the first quadrant. $\frac{\pi}{2} \le \theta \le \pi \Rightarrow r \le 0 \Rightarrow (r, \theta)$ is in the fourth quadrant. $\pi \le \theta \le \frac{3\pi}{2} \Rightarrow r \ge 0 \Rightarrow (r, \theta)$ is in the third quadrant. $\frac{3\pi}{2} \le \theta \le 2\pi \Rightarrow r \le 0 \Rightarrow (r, \theta)$ is in the second quadrant. That is,



32. Sketch the curve $r = \sin 3\theta$. First fill in the table of r-values below and plot the corresponding points of the curve. Notice that the three petals of the curve correspond to the angle intervals $\left[0, \frac{\pi}{3}\right]$, $\left[\frac{\pi}{3}, \frac{2\pi}{3}\right]$, and $\left[\frac{\pi}{3}, \pi\right]$. Then plot $r = \sin 3\theta$ in rectangular coordinates and label the points on this graph corresponding to (r, θ) in the table.

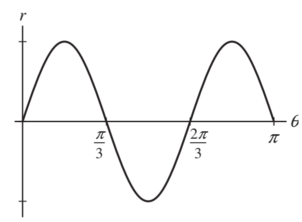
θ	0	$\frac{\pi}{12}$	$\frac{\pi}{6}$	$\frac{\pi}{4}$	$\frac{\pi}{3}$	$\frac{5\pi}{12}$	$\cdots$	$\frac{11\pi}{12}$	π
r									

SOLUTION We compute the values of r corresponding to the given values of θ:

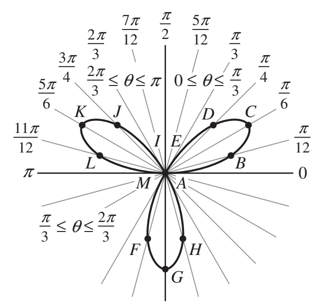
$$\theta = 0, \qquad r = \sin 0 = 0 \qquad (A)$$
$$\theta = \frac{\pi}{12}, \qquad r = \sin \frac{3\pi}{12} \approx 0.71 \qquad (B)$$
$$\theta = \frac{\pi}{6}, \qquad r = \sin \frac{3\pi}{6} = 1 \qquad (C)$$
$$\theta = \frac{\pi}{4}, \qquad r = \sin \frac{3\pi}{4} \approx 0.71 \qquad (D)$$
$$\theta = \frac{\pi}{3}, \qquad r = \sin \frac{3\pi}{3} = 0 \qquad (E)$$
$$\theta = \frac{5\pi}{12}, \qquad r = \sin \frac{15\pi}{12} \approx -0.71 \qquad (F)$$
$$\theta = \frac{\pi}{2}, \qquad r = \sin \frac{3\pi}{2} = -1 \qquad (G)$$
$$\theta = \frac{7\pi}{12}, \qquad r = \sin \frac{21\pi}{12} \approx -0.71 \qquad (H)$$
$$\theta = \frac{3\pi}{2}, \qquad r = \sin \frac{9\pi}{2} = 0 \qquad (I)$$

$$\theta = \frac{3\pi}{4}, \quad r = \sin\frac{9\pi}{4} \approx 0.71 \qquad (J)$$
$$\theta = \frac{5\pi}{6}, \quad r = \sin\frac{15\pi}{6} = 1 \qquad (K)$$
$$\theta = \frac{11\pi}{12}, \quad r = \sin\frac{33\pi}{12} \approx 0.71 \qquad (L)$$
$$\theta = \pi, \quad r = \sin 3\pi = 0 \qquad (M)$$

We plot the points on the xy -plane and join them to obtain the following curve:



Using the graph of $r = \sin 3\theta$ we find the sign of r and determine the parts of the graph corresponding to the angle intervals. We get

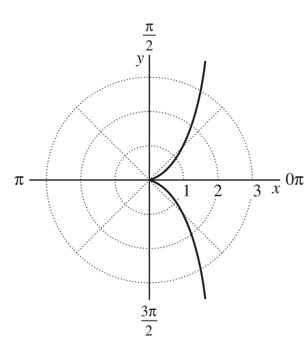


$$r = \sin 3\theta \quad \begin{cases} 0 \le \theta \le \frac{\pi}{3} \Rightarrow r \ge 0 \Rightarrow (r,\theta) \text{ in the first quadrant.} \\ \frac{\pi}{3} \le \theta \le \frac{2\pi}{3} \Rightarrow r \le 0 \Rightarrow (r,\theta) \text{ in the third and fourth quadrant.} \\ \frac{2\pi}{3} \le \theta \le \pi \Rightarrow r \ge 0 \Rightarrow (r,\theta) \text{ in the second quadrant.} \end{cases}$$

33. CAS Plot the **cissoid** $r = 2\sin\theta\tan\theta$ and show that its equation in rectangular coordinates is

$$y^2 = \frac{x^3}{2-x}$$

SOLUTION Using a CAS we obtain the following curve of the cissoid:



We substitute $\sin\theta = \frac{y}{r}$ and $\tan\theta = \frac{y}{x}$ in $r = 2\sin\theta\tan\theta$ to obtain

$$r = 2\frac{y}{r}\cdot\frac{y}{x}.$$

Multiplying by rx, setting $r^2 = x^2 + y^2$ and simplifying, yields

$$r^2 x = 2y^2$$
$$(x^2 + y^2)x = 2y^2$$

$$x^3 + y^2x = 2y^2$$
$$y^2(2-x) = x^3$$

so

$$y^2 = \frac{x^3}{2-x}$$

34. Prove that $r = 2a\cos\theta$ is the equation of the circle in Figure 21 using only the fact that a triangle inscribed in a circle with one side a diameter is a right triangle.

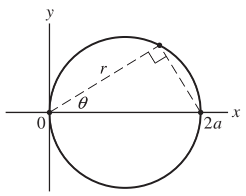


FIGURE 21

SOLUTION Since the triangle inscribed in the circle has a diameter as one of its sides, it is a right triangle, so we may use the definition of cosine for angles in right triangles to write

$$\cos\theta = \frac{r}{2a} \Rightarrow r = 2a\cos\theta.$$

35. Show that

$$r = a\cos\theta + b\sin\theta$$

is the equation of a circle passing through the origin. Express the radius and center (in rectangular coordinates) in terms of a and b.

SOLUTION We multiply the equation by r and then make the substitution $x = r\cos\theta$, $y = r\sin\theta$, and $r^2 = x^2 + y^2$. This gives

$$r^2 = ar\cos\theta + br\sin\theta$$
$$x^2 + y^2 = ax + by$$

Transferring sides and completing the square yields

$$x^2 - ax + y^2 - by = 0$$
$$\left(x^2 - 2\cdot\frac{a}{2}x + \left(\frac{a}{2}\right)^2\right) + \left(y^2 - 2\cdot\frac{b}{2}y + \left(\frac{b}{2}\right)^2\right) = \left(\frac{a}{2}\right)^2 + \left(\frac{b}{2}\right)^2$$
$$\left(x - \frac{a}{2}\right)^2 + \left(y - \frac{b}{2}\right)^2 = \frac{a^2+b^2}{4}$$

This is the equation of the circle with radius $\frac{\sqrt{a^2+b^2}}{2}$ centered at the point $\left(\frac{a}{2}, \frac{b}{2}\right)$. By plugging in $x = 0$ and $y = 0$ it is clear that the circle passes through the origin.

36. Use the previous exercise to write the equation of the circle of radius 5 and center $(3, 4)$ in the form $r = a\cos\theta + b\sin\theta$.

SOLUTION In the previous exercise we showed that $r = a\cos\theta + b\sin\theta$ is the equation of the circle with radius $\frac{\sqrt{a^2+b^2}}{2}$ centered at $\left(\frac{a}{2}, \frac{b}{2}\right)$. Thus, we must have

$$\left(\frac{a}{2}, \frac{b}{2}\right) = (3, 4) \Rightarrow \frac{a}{2} = 3, \frac{b}{2} = 4 \Rightarrow a = 6, b = 8.$$

The radius of the circle is $\frac{\sqrt{a^2+b^2}}{2} = \frac{\sqrt{6^2+8^2}}{2} = 5$. Thus, the corresponding equation is $r = 6\cos\theta + 8\sin\theta$.

37. Use the identity $\cos 2\theta = \cos^2\theta - \sin^2\theta$ to find a polar equation of the hyperbola $x^2 - y^2 = 1$.

SOLUTION We substitute $x = r\cos\theta$, $y = r\sin\theta$ in $x^2 - y^2 = 1$ to obtain

$$r^2\cos^2\theta - r^2\sin^2\theta = 1$$
$$r^2(\cos^2\theta - \sin^2\theta) = 1$$

Using the identity $\cos 2\theta = \cos^2\theta - \sin^2\theta$ we obtain the following equation of the hyperbola:

$$r^2\cos 2\theta = 1 \quad \text{or} \quad r^2 = \sec 2\theta.$$

38. Find an equation in rectangular coordinates for the curve $r^2 = \cos 2\theta$.

SOLUTION We first use the identity $\cos 2\theta = \cos^2\theta - \sin^2\theta$ to rewrite the equation of the curve as follows: $r^2 = \cos^2\theta - \sin^2\theta$. Multiplying by r^2 and substituting $r^2 = x^2 + y^2$, $r\cos\theta = x$ and $r\sin\theta = y$, we get

$$r^4 = (r\cos\theta)^2 - (r\sin\theta)^2(x^2 + y^2)^2 = x^2 - y^2.$$

Thus, the curve has the equation $(x^2 + y^2)^2 = x^2 - y^2$ in rectangular coordinates.

39. Show that $\cos 3\theta = \cos^3\theta - 3\cos\theta\sin^2\theta$ and use this identity to find an equation in rectangular coordinates for the curve $r = \cos 3\theta$.

SOLUTION We use the identities $\cos(\alpha + \beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta$, $\cos 2\alpha = \cos^2\alpha - \sin^2\alpha$, and $\sin 2\alpha = 2\sin\alpha\cos\alpha$ to write

$$\begin{aligned}\cos 3\theta = \cos(2\theta + \theta) &= \cos 2\theta\cos\theta - \sin 2\theta\sin\theta \\ &= (\cos^2\theta - \sin^2\theta)\cos\theta - 2\sin\theta\cos\theta\sin\theta \\ &= \cos^3\theta - \sin^2\theta\cos\theta - 2\sin^2\theta\cos\theta \\ &= \cos^3\theta - 3\sin^2\theta\cos\theta\end{aligned}$$

Using this identity we may rewrite the equation $r = \cos 3\theta$ as follows:

$$r = \cos^3\theta - 3\sin^2\theta\cos\theta \tag{1}$$

Since $x = r\cos\theta$ and $y = r\sin\theta$, we have $\cos\theta = \frac{x}{r}$ and $\sin\theta = \frac{y}{r}$. Substituting into (1) gives:

$$r = \left(\frac{x}{r}\right)^3 - 3\left(\frac{y}{r}\right)^2\left(\frac{x}{r}\right)$$
$$r = \frac{x^3}{r^3} - \frac{3y^2x}{r^3}$$

We now multiply by r^3 and make the substitution $r^2 = x^2 + y^2$ to obtain the following equation for the curve:

$$r^4 = x^3 - 3y^2x$$
$$(x^2 + y^2)^2 = x^3 - 3y^2x$$

40. Use the addition formula for the cosine to show that the line $\mathcal{L}$ with polar equation $r\cos(\theta - \alpha) = d$ has the equation in rectangular coordinates $(\cos\alpha)x + (\sin\alpha)y = d$. Show that $\mathcal{L}$ has slope $m = -\cot\alpha$ and y-intercept $d/\sin\alpha$.

SOLUTION We use the identity $\cos(a - b) = \cos a\cos b + \sin a\sin b$ to rewrite the equation $r\cos(\theta - \alpha) = d$ as follows:

$$r(\cos\theta\cos\alpha + \sin\theta\sin\alpha) = d$$
$$r\cos\theta\cos\alpha + r\sin\theta\sin\alpha = d$$

We now substitute $r\cos\theta = x$ and $r\sin\theta = y$ to obtain: $x\cos\alpha + y\sin\alpha = d$. Dividing by $\cos\alpha$, transferring sides and simplifying yields

$$x + y\tan\alpha = \frac{d}{\cos\alpha}$$
$$y\tan\alpha = -x + \frac{d}{\cos\alpha}$$
$$y = -\frac{x}{\tan\alpha} + \frac{d}{\tan\alpha\cos\alpha}$$

so

$$y = (-\cot\alpha)\, x + \frac{d}{\sin\alpha}$$

This equation of the line implies that $\mathcal{L}$ has slope $m = -\cot\alpha$ and y -intercept $\frac{d}{\sin\alpha}$.

In Exercises 41–44, find an equation in polar coordinates of the line $\mathcal{L}$ with the given description.

41. The point on $\mathcal{L}$ closest to the origin has polar coordinates $\left(2, \frac{\pi}{9}\right)$.

SOLUTION In Example 5, it is shown that the polar equation of the line where (r, α) is the point on the line closest to the origin is $r = d\sec(\theta - \alpha)$. Setting $(d, \alpha) = \left(2, \frac{\pi}{9}\right)$ we obtain the following equation of the line:

$$r = 2\sec\left(\theta - \frac{\pi}{9}\right).$$

42. The point on $\mathcal{L}$ closest to the origin has rectangular coordinates $(-2, 2)$.

SOLUTION We first convert the rectangular coordinates $(-2, 2)$ to polar coordinates (d, α). This point is in the second quadrant so $\frac{\pi}{2} < \alpha < \pi$. Hence,

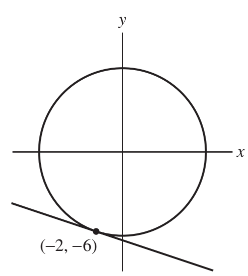
$$\left.\begin{aligned} d &= \sqrt{(-2)^2 + 2^2} = \sqrt{8} = 2\sqrt{2} \\ \alpha &= \tan^{-1}\left(\frac{2}{-2}\right) = \tan^{-1}(-1) = \pi - \frac{\pi}{4} = \frac{3\pi}{4} \end{aligned}\right. \quad \Rightarrow \quad (d, \alpha) = \left(2\sqrt{2}, \frac{3\pi}{4}\right).$$

Substituting $d = 2\sqrt{2}$ and $\alpha = \frac{3\pi}{4}$ in the equation $r = d\sec(\theta - \alpha)$ gives us

$$r = 2\sqrt{2}\sec\left(\theta - \frac{3\pi}{4}\right).$$

43. $\mathcal{L}$ is tangent to the circle $r = 2\sqrt{10}$ at the point with rectangular coordinates $(-2, -6)$.

SOLUTION



Since $\mathcal{L}$ is tangent to the circle at the point $(-2, -6)$, this is the point on $\mathcal{L}$ closest to the center of the circle which is at the origin. Therefore, we may use the polar coordinates (d, α) of this point in the equation of the line:

$$r = d\sec(\theta - \alpha) \tag{1}$$

We thus must convert the coordinates $(-2, -6)$ to polar coordinates. This point is in the third quadrant so $\pi < \alpha < \frac{3\pi}{2}$. We get

$$d = \sqrt{(-2)^2 + (-6)^2} = \sqrt{40} = 2\sqrt{10}$$

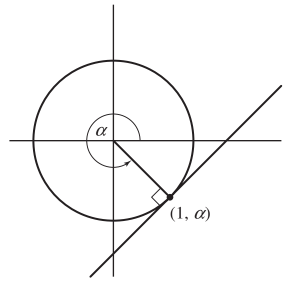
$$\alpha = \tan^{-1}\left(\frac{-6}{-2}\right) = \tan^{-1} 3 \approx \pi + 1.25 \approx 4.39$$

Substituting in (1) yields the following equation of the line:

$$r = 2\sqrt{10}\sec(\theta - 4.39).$$

44. $\mathcal{L}$ has slope 3 and is tangent to the unit circle in the fourth quadrant.

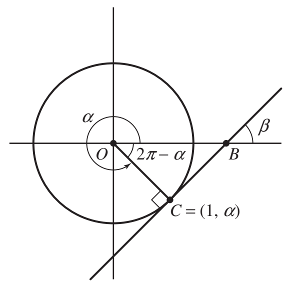
SOLUTION We denote the point of tangency by $P_0 = (1, \alpha)$ (in polar coordinates).



Since $\mathcal{L}$ is the tangent line to the circle at P_0, P_0 is the point on $\mathcal{L}$ closest to the center of the circle at the origin. Thus, the polar equation of $\mathcal{L}$ is

$$r = \sec(\theta - \alpha) \tag{1}$$

We now must find α. Let β be the given angle shown in the figure.



By the given information, $\tan\beta = 3$. Also, since the point of tangency is in the fourth quadrant, β must be an acute angle. Hence

$$\tan\beta = 3,\ 0 < \beta < \frac{\pi}{2} \Rightarrow \beta = 1.25 \text{ rad.}$$

Now, since $\frac{3\pi}{2} < \alpha < 2\pi$, we have for the triangle OBC

$$(2\pi - \alpha) + \frac{\pi}{2} + 1.25 = \pi \Rightarrow \alpha = \frac{3\pi}{2} + 1.25 = 5.96 \text{ rad.}$$

Substituting into (1) we obtain the following polar equation of the tangent line:

$$r = \sec(\theta - 5.96).$$

45. Show that every line that does not pass through the origin has a polar equation of the form

$$r = \frac{b}{\sin\theta - a\cos\theta}$$

where $b \neq 0$.

SOLUTION Write the equation of the line in rectangular coordinates as $y = ax + b$. Since the line does not pass through the origin, we have $b \neq 0$. Substitute for y and x to convert to polar coordinates, and simplify:

$$\begin{aligned} y &= ax + b \\ r\sin\theta &= ar\cos\theta + b \\ r(\sin\theta - a\cos\theta) &= b \\ r &= \frac{b}{\sin\theta - a\cos\theta} \end{aligned}$$

46. By the Law of Cosines, the distance d between two points (Figure 22) with polar coordinates (r, θ) and (r_0, θ_0) is

$$d^2 = r^2 + r_0^2 - 2rr_0\cos(\theta - \theta_0)$$

Use this distance formula to show that

$$r^2 - 10r\cos\left(\theta - \frac{\pi}{4}\right) = 56$$

is the equation of the circle of radius 9 whose center has polar coordinates $\left(5, \frac{\pi}{4}\right)$.

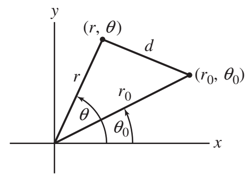


FIGURE 22

SOLUTION The distance d between a point (r, θ) on the circle and the center $(r_0, \theta_0) = \left(5, \frac{\pi}{4}\right)$ is the radius 9. Setting $d = 9$, $r_0 = 5$ and $\theta_0 = \frac{\pi}{4}$ in the distance formula we get

$$d^2 = r^2 + r_0^2 - 2rr_0 \cos(\theta - \theta_0)$$
$$9^2 = r^2 + 5^2 - 2 \cdot r \cdot 5 \cos\left(\theta - \frac{\pi}{4}\right)$$

Transferring sides we get

$$r^2 - 10r \cos\left(\theta - \frac{\pi}{4}\right) = 56.$$

47. For $a > 0$, a **lemniscate curve** is the set of points P such that the product of the distances from P to $(a, 0)$ and $(-a, 0)$ is a^2. Show that the equation of the lemniscate is

$$(x^2 + y^2)^2 = 2a^2(x^2 - y^2)$$

Then find the equation in polar coordinates. To obtain the simplest form of the equation, use the identity $\cos 2\theta = \cos^2\theta - \sin^2\theta$. Plot the lemniscate for $a = 2$ if you have a computer algebra system.

SOLUTION We compute the distances d_1 and d_2 of $P(x, y)$ from the points $(a, 0)$ and $(-a, 0)$ respectively. We obtain:

$$d_1 = \sqrt{(x-a)^2 + (y-0)^2} = \sqrt{(x-a)^2 + y^2}$$
$$d_2 = \sqrt{(x+a)^2 + (y-0)^2} = \sqrt{(x+a)^2 + y^2}$$

For the points $P(x, y)$ on the lemniscate we have $d_1 d_2 = a^2$. That is,

$$\begin{aligned}
a^2 &= \sqrt{(x-a)^2 + y^2}\sqrt{(x+a)^2 + y^2} = \sqrt{\left[(x-a)^2 + y^2\right]\left[(x+a)^2 + y^2\right]} \\
&= \sqrt{(x-a)^2(x+a)^2 + y^2(x-a)^2 + y^2(x+a)^2 + y^4} \\
&= \sqrt{(x^2 - a^2)^2 + y^2\left[(x-a)^2 + (x+a)^2\right] + y^4} \\
&= \sqrt{x^4 - 2a^2x^2 + a^4 + y^2\left(x^2 - 2xa + a^2 + x^2 + 2xa + a^2\right) + y^4} \\
&= \sqrt{x^4 - 2a^2x^2 + a^4 + 2y^2x^2 + 2y^2a^2 + y^4} \\
&= \sqrt{x^4 + 2x^2y^2 + y^4 + 2a^2(y^2 - x^2) + a^4} \\
&= \sqrt{(x^2 + y^2)^2 + 2a^2(y^2 - x^2) + a^4}.
\end{aligned}$$

Squaring both sides and simplifying yields

$$a^4 = (x^2 + y^2)^2 + 2a^2(y^2 - x^2) + a^4$$
$$0 = (x^2 + y^2)^2 + 2a^2(y^2 - x^2)$$

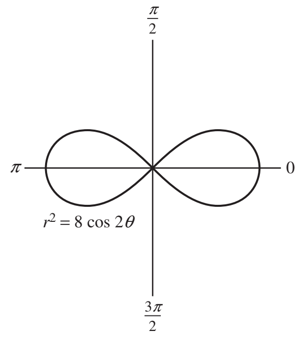
so

$$(x^2 + y^2)^2 = 2a^2(x^2 - y^2)$$

We now find the equation in polar coordinates. We substitute $x = r\cos\theta$, $y = r\sin\theta$ and $x^2 + y^2 = r^2$ into the equation of the lemniscate. This gives

$$(r^2)^2 = 2a^2(r^2\cos^2\theta - r^2\sin^2\theta) = 2a^2r^2(\cos^2\theta - \sin^2\theta) = 2a^2r^2\cos 2\theta$$
$$r^4 = 2a^2r^2\cos 2\theta$$

$r = 0$ is a solution, hence the origin is on the curve. For $r \neq 0$ we divide the equation by r^2 to obtain $r^2 = 2a^2 \cos 2\theta$. This curve also includes the origin ($r = 0$ is obtained for $\theta = \frac{\pi}{4}$ for example), hence this is the polar equation of the lemniscate. Setting $a = 2$ we get $r^2 = 8 \cos 2\theta$.



48. Let c be a fixed constant. Explain the relationship between the graphs of:

(a) $y = f(x + c)$ and $y = f(x)$ (rectangular)

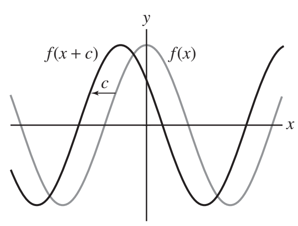
(b) $r = f(\theta + c)$ and $r = f(\theta)$ (polar)

(c) $y = f(x) + c$ and $y = f(x)$ (rectangular)

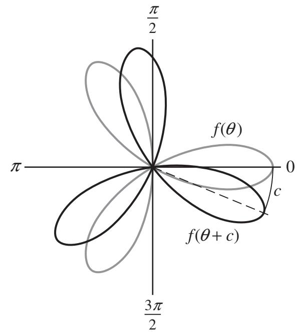
(d) $r = f(\theta) + c$ and $r = f(\theta)$ (polar)

SOLUTION

(a) For $c > 0$, $y = f(x + c)$ shifts the graph of $y = f(x)$ by c units to the left. If $c < 0$, the result is a shift to the right. It is a horizontal translation.

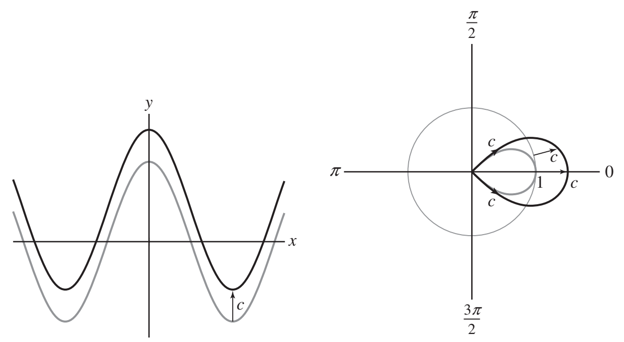


(b) As in part (a), the graph of $r = f(\theta + c)$ is a shift of the graph of $r = f(\theta)$ by c units in θ. Thus, the graph in polar coordinates is rotated by angle c as shown in the following figure:



(c) $y = f(x) + c$ shifts the graph vertically upward by c units if $c > 0$, and downward by $(-c)$ units if $c < 0$. It is a vertical translation.

(d) The graph of $r = f(\theta) + c$ is a shift of the graph of $r = f(\theta)$ by c units in r. In the corresponding graph, in polar coordinates, each point with $f(\theta) > 0$ moves on the ray connecting it to the origin c units away from the origin if $c > 0$ and $(-c)$ units toward the origin if $c < 0$, and vice-versa for $f(\theta) < 0$.



$c > 0$

49. The Derivative in Polar Coordinates Show that a polar curve $r = f(\theta)$ has parametric equations

$$x = f(\theta)\cos\theta, \qquad y = f(\theta)\sin\theta$$

Then apply Theorem 2 of Section 11.1 to prove

$$\frac{dy}{dx} = \frac{f(\theta)\cos\theta + f'(\theta)\sin\theta}{-f(\theta)\sin\theta + f'(\theta)\cos\theta} \tag{2}$$

where $f'(\theta) = df/d\theta$.

SOLUTION Multiplying both sides of the given equation by $\cos\theta$ yields $r\cos\theta = f(\theta)\cos\theta$; multiplying both sides by $\sin\theta$ yields $r\sin\theta = f(\theta)\sin\theta$. The left-hand sides of these two equations are the x and y coordinates in rectangular coordinates, so for any θ we have $x = f(\theta)\cos\theta$ and $y = f(\theta)\sin\theta$, showing that the parametric equations are as claimed. Now, by the formula for the derivative we have

$$\frac{dy}{dx} = \frac{y'(\theta)}{x'(\theta)} \tag{1}$$

We differentiate the functions $x = f(\theta)\cos\theta$ and $y = f(\theta)\sin\theta$ using the Product Rule for differentiation. This gives

$$y'(\theta) = f'(\theta)\sin\theta + f(\theta)\cos\theta$$
$$x'(\theta) = f'(\theta)\cos\theta - f(\theta)\sin\theta$$

Substituting in (1) gives

$$\frac{dy}{dx} = \frac{f'(\theta)\sin\theta + f(\theta)\cos\theta}{f'(\theta)\cos\theta - f(\theta)\sin\theta} = \frac{f(\theta)\cos\theta + f'(\theta)\sin\theta}{-f(\theta)\sin\theta + f'(\theta)\cos\theta}.$$

50. Use Eq. (2) to find the slope of the tangent line to $r = \sin\theta$ at $\theta = \frac{\pi}{3}$.

SOLUTION We have $f(\theta) = \sin\theta$, $f'(\theta) = \cos\theta$ and, by Eq. (2), the slope of the tangent line is

$$\frac{dy}{dx} = \frac{f(\theta)\cos\theta + f'(\theta)\sin\theta}{-f(\theta)\sin\theta + f'(\theta)\cos\theta} = \frac{\sin\theta\cos\theta + \cos\theta\sin\theta}{-\sin^2\theta + \cos^2\theta} = \frac{\sin 2\theta}{\cos 2\theta}$$

Evaluating at $\theta = \frac{\pi}{3}$ gives

$$\frac{dy}{dx} = \frac{\sin\frac{2\pi}{3}}{\cos\frac{2\pi}{3}} = \frac{\sqrt{3}2}{-1/2} = -\sqrt{3}$$

Thus the slope of the tangent line to $r = \sin\theta$ at $\theta = \frac{\pi}{3}$ is $-\sqrt{3}$.

51. Use Eq. (2) to find the slope of the tangent line to $r = \theta$ at $\theta = \frac{\pi}{2}$ and $\theta = \pi$.

SOLUTION In the given curve we have $r = f(\theta) = \theta$. Using Eq. (2) we obtain the following derivative, which is the slope of the tangent line at (r, θ).

$$\frac{dy}{dx} = \frac{f(\theta)\cos\theta + f'(\theta)\sin\theta}{-f(\theta)\sin\theta + f'(\theta)\cos\theta} = \frac{\theta\cos\theta + 1\cdot\sin\theta}{-\theta\sin\theta + 1\cdot\cos\theta} \tag{1}$$

The slope, m, of the tangent line at $\theta = \frac{\pi}{2}$ and $\theta = \pi$ is obtained by substituting these values in (1). We get ($\theta = \frac{\pi}{2}$):

$$m = \frac{\frac{\pi}{2}\cos\frac{\pi}{2} + \sin\frac{\pi}{2}}{-\frac{\pi}{2}\sin\frac{\pi}{2} + \cos\frac{\pi}{2}} = \frac{\frac{\pi}{2}\cdot 0 + 1}{-\frac{\pi}{2}\cdot 1 + 0} = \frac{1}{-\frac{\pi}{2}} = -\frac{2}{\pi}.$$

$(\theta = \pi)$:

$$m = \frac{\pi\cos\pi + \sin\pi}{-\pi\sin\pi + \cos\pi} = \frac{-\pi}{-1} = \pi.$$

52. Find the equation in rectangular coordinates of the tangent line to $r = 4\cos 3\theta$ at $\theta = \frac{\pi}{6}$.

SOLUTION We have $f(\theta) = 4\cos 3\theta$. By Eq. (2),

$$m = \frac{4\cos 3\theta\cos\theta - 12\sin 3\theta\sin\theta}{-4\cos 3\theta\sin\theta - 12\sin 3\theta\cos\theta}.$$

Setting $\theta = \frac{\pi}{6}$ yields

$$m = \frac{4\cos\left(\frac{\pi}{2}\right)\cos\left(\frac{\pi}{6}\right) - 12\sin\left(\frac{\pi}{2}\right)\sin\left(\frac{\pi}{6}\right)}{-4\cos\left(\frac{\pi}{2}\right)\sin\left(\frac{\pi}{6}\right) - 12\sin\left(\frac{\pi}{2}\right)\cos\left(\frac{\pi}{6}\right)} = \frac{-12\sin\frac{\pi}{6}}{-12\cos\frac{\pi}{6}} = \tan\frac{\pi}{6} = \frac{1}{\sqrt{3}}.$$

We identify the point of tangency. For $\theta = \frac{\pi}{6}$ we have $r = 4\cos\frac{3\pi}{6} = 4\cos\frac{\pi}{2} = 0$. The point of tangency is the origin. The tangent line is the line through the origin with slope $\frac{1}{\sqrt{3}}$. This is the line $y = \frac{x}{\sqrt{3}}$.

53. Find the polar coordinates of the points on the lemniscate $r^2 = \cos 2t$ in Figure 23 where the tangent line is horizontal.

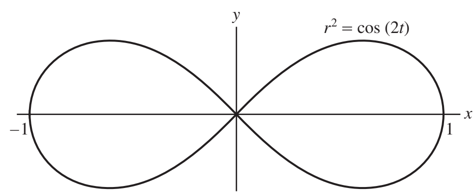


FIGURE 23

SOLUTION This curve is defined for $-\frac{\pi}{2} \le 2t \le \frac{\pi}{2}$ (where $\cos 2t \ge 0$), so for $-\frac{\pi}{4} \le t \le \frac{\pi}{4}$. For each θ in that range, there are two values of r satisfying the equation ($\pm\sqrt{\cos 2t}$). By symmetry, we need only calculate the coordinates of the points corresponding to the positive square root (i.e. to the right of the y axis). Then the equation becomes $r = \sqrt{\cos 2t}$. Now, by Eq. (2), with $f(t) = \sqrt{\cos(2t)}$ and $f'(t) = -\sin(2t)(\cos(2t))^{-1/2}$, we have

$$\frac{dy}{dx} = \frac{f(t)\cos t + f'(t)\sin t}{-f(t)\sin t + f'(t)\cos t} = \frac{\cos t\sqrt{\cos(2t)} - \sin(2t)\sin t(\cos(2t))^{-1/2}}{-\sin t\sqrt{\cos(2t)} - \sin(2t)\cos t(\cos(2t))^{-1/2}}$$

The tangent line is horizontal when this derivative is zero, which occurs when the numerator of the fraction is zero and the denominator is not. Multiply top and bottom of the fraction by $\sqrt{\cos(2t)}$, and use the identities $\cos 2t = \cos^2 t - \sin^2 t$, $\sin 2t = 2\sin t\cos t$ to get

$$-\frac{\cos t\cos 2t - \sin t\sin 2t}{\sin t\cos 2t + \cos t\sin 2t} = -\frac{\cos t(\cos^2 t - 3\sin^2 t)}{\sin t\cos 2t + \cos t\sin 2t}$$

The numerator is zero when $\cos t = 0$, so when $t = \frac{\pi}{2}$ or $t = \frac{3\pi}{2}$, or when $\tan t = \pm\frac{1}{\sqrt{3}}$, so when $t = \pm\frac{\pi}{6}$ or $t = \pm\frac{5\pi}{6}$. Of these possibilities, only $t = \pm\frac{\pi}{6}$ lie in the range $-\frac{\pi}{4} \le t \le \frac{\pi}{4}$. Note that the denominator is nonzero for $t = \pm\frac{\pi}{6}$, so these are the two values of t for which the tangent line is horizontal. The corresponding values of r are solutions to

$$r^2 = \cos\left(2\cdot\frac{\pi}{6}\right) = \cos\left(\frac{\pi}{3}\right) = \frac{1}{2}$$
$$r^2 = \cos\left(2\cdot\frac{-\pi}{6}\right) = \cos\left(-\frac{\pi}{3}\right) = \frac{1}{2}$$

Finally, the four points are $(r, t) =$

$$\left(\frac{1}{\sqrt{2}}, \frac{\pi}{6}\right), \qquad \left(-\frac{1}{\sqrt{2}}, \frac{\pi}{6}\right), \qquad \left(\frac{1}{\sqrt{2}}, -\frac{pi}{6}\right), \qquad \left(-\frac{1}{\sqrt{2}}, -\frac{\pi}{6}\right)$$

If desired, we can change the second and fourth points by adding π to the angle and making r positive, to get

$$\left(\frac{1}{\sqrt{2}}, \frac{\pi}{6}\right), \qquad \left(\frac{1}{\sqrt{2}}, \frac{7\pi}{6}\right), \qquad \left(\frac{1}{\sqrt{2}}, -\frac{pi}{6}\right), \qquad \left(\frac{1}{\sqrt{2}}, \frac{5\pi}{6}\right)$$

54. Find the polar coordinates of the points on the cardioid $r = 1 + \cos\theta$ where the tangent line is horizontal (see Figure 24).

SOLUTION Use Eq. (2) with $f(\theta) = 1 + \cos\theta$ and $f'(\theta) = -\sin\theta$. Then

$$\frac{dy}{dx} = \frac{f(\theta)\cos\theta + f'(\theta)\sin\theta}{-f(\theta)\sin\theta + f'(\theta)\cos\theta} = \frac{\cos\theta + \cos^2\theta - \sin^2\theta}{-\sin\theta - \cos\theta\sin\theta - \sin\theta\cos\theta} = -\frac{\cos\theta + \cos 2\theta}{\sin\theta + \sin 2\theta}$$

The tangent line is horizontal when the numerator is zero but the denominator is not. The numerator is zero when $\cos\theta + \cos 2\theta = 0$. But

$$\cos\theta + \cos 2\theta = \cos\theta + 2\cos^2\theta - 1 = \left(\cos\theta - \frac{1}{2}\right)(\cos\theta + 1)$$

So for $0 \le \theta < 2\pi$, the numerator is zero when $\theta = \pi$ and when $\theta = \pm\frac{\pi}{3}$. For the latter two points, the denominator is nonzero, so the tangent is horizontal at the points

$$(r, \theta) = \left(\frac{3}{2}, \frac{\pi}{3}\right), \qquad \left(\frac{3}{2}, -\frac{\pi}{3}\right) = \left(\frac{3}{2}, \frac{5\pi}{3}\right)$$

When $\theta = \pi$, both numerator and denominator vanish. However, using L'Hôpital's Rule, we have

$$-\lim_{\theta\to\pi} \frac{\cos\theta + \cos 2\theta}{\sin\theta + \sin 2\theta} = -\lim_{\theta\to\pi} \frac{-\sin\theta - 2\sin 2\theta}{\cos\theta + 2\cos 2\theta} = 0$$

so that the tangent is defined at $\theta = \pi$, and it is horizontal. Thus the tangent is also horizontal at the point

$$(r, \theta) = (0, \pi)$$

55. Use Eq. (2) to show that for $r = \sin\theta + \cos\theta$,

$$\frac{dy}{dx} = \frac{\cos 2\theta + \sin 2\theta}{\cos 2\theta - \sin 2\theta}$$

Then calculate the slopes of the tangent lines at points A, B, C in Figure 19.

SOLUTION In Exercise 49 we proved that for a polar curve $r = f(\theta)$ the following formula holds:

$$\frac{dy}{dx} = \frac{f(\theta)\cos\theta + f'(\theta)\sin\theta}{-f(\theta)\sin\theta + f'(\theta)\cos\theta} \tag{1}$$

For the given circle we have $r = f(\theta) = \sin\theta + \cos\theta$, hence $f'(\theta) = \cos\theta - \sin\theta$. Substituting in (1) we have

$$\begin{aligned}\frac{dy}{dx} &= \frac{(\sin\theta + \cos\theta)\cos\theta + (\cos\theta - \sin\theta)\sin\theta}{-(\sin\theta + \cos\theta)\sin\theta + (\cos\theta - \sin\theta)\cos\theta} = \frac{\sin\theta\cos\theta + \cos^2\theta + \cos\theta\sin\theta - \sin^2\theta}{-\sin^2\theta - \cos\theta\sin\theta + \cos^2\theta - \sin\theta\cos\theta} \\ &= \frac{\cos^2\theta - \sin^2\theta + 2\sin\theta\cos\theta}{\cos^2\theta - \sin^2\theta - 2\sin\theta\cos\theta}\end{aligned}$$

We use the identities $\cos^2\theta - \sin^2\theta = \cos 2\theta$ and $2\sin\theta\cos\theta = \sin 2\theta$ to obtain

$$\frac{dy}{dx} = \frac{\cos 2\theta + \sin 2\theta}{\cos 2\theta - \sin 2\theta} \tag{2}$$

The derivative $\frac{dy}{dx}$ is the slope of the tangent line at (r, θ). The slopes of the tangent lines at the points with polar coordinates $A = \left(1, \frac{\pi}{2}\right)$ $B = \left(0, \frac{3\pi}{4}\right)$ $C = (1, 0)$ are computed by substituting the values of θ in (2). This gives

$$\begin{aligned}\left.\frac{dy}{dx}\right|_A &= \frac{\cos\left(2\cdot\frac{\pi}{2}\right) + \sin\left(2\cdot\frac{\pi}{2}\right)}{\cos\left(2\cdot\frac{\pi}{2}\right) - \sin\left(2\cdot\frac{\pi}{2}\right)} = \frac{\cos\pi + \sin\pi}{\cos\pi - \sin\pi} = \frac{-1+0}{-1-0} = 1 \\ \left.\frac{dy}{dx}\right|_B &= \frac{\cos\left(2\cdot\frac{3\pi}{4}\right) + \sin\left(2\cdot\frac{3\pi}{4}\right)}{\cos\left(2\cdot\frac{3\pi}{4}\right) - \sin\left(2\cdot\frac{3\pi}{4}\right)} = \frac{\cos\frac{3\pi}{2} + \sin\frac{3\pi}{2}}{\cos\frac{3\pi}{2} - \sin\frac{3\pi}{2}} = \frac{0-1}{0+1} = -1 \\ \left.\frac{dy}{dx}\right|_C &= \frac{\cos(2\cdot 0) + \sin(2\cdot 0)}{\cos(2\cdot 0) - \sin(2\cdot 0)} = \frac{\cos 0 + \sin 0}{\cos 0 - \sin 0} = \frac{1+0}{1-0} = 1\end{aligned}$$

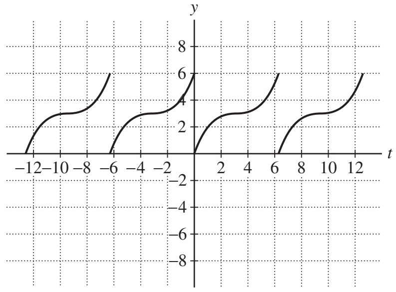
Further Insights and Challenges

56. Let $f(x)$ be a periodic function of period 2π—that is, $f(x) = f(x + 2\pi)$. Explain how this periodicity is reflected in the graph of:

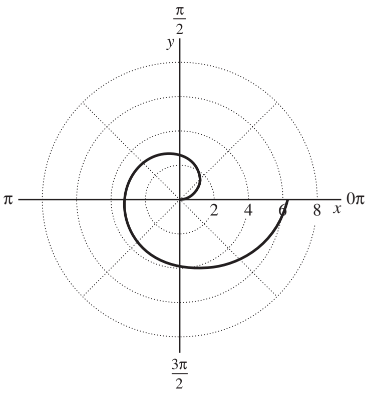
(a) $y = f(x)$ in rectangular coordinates
(b) $r = f(\theta)$ in polar coordinates

SOLUTION

(a) The graph of $y = f(x)$ on an interval of length 2π repeats itself on successive intervals of length 2π. For instance:

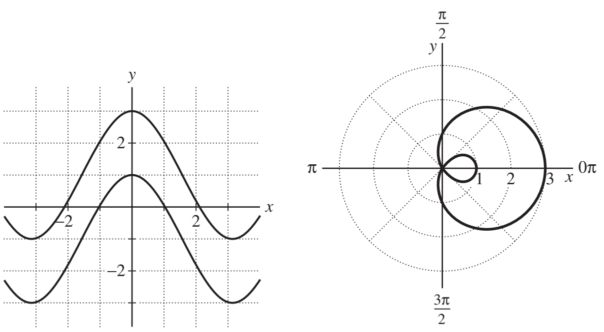


(b) Shown below is the graph of the function above, this time drawn in polar coordinates. The graphs of the various branches repeat themselves and are drawn one on the top of the other.



57. GU Use a graphing utility to convince yourself that the polar equations $r = f_1(\theta) = 2\cos\theta - 1$ and $r = f_2(\theta) = 2\cos\theta + 1$ have the same graph. Then explain why. *Hint:* Show that the points $(f_1(\theta + \pi), \theta + \pi)$ and $(f_2(\theta), \theta)$ coincide.

SOLUTION The graphs of $r = 2\cos\theta - 1$ and $r = 2\cos\theta + 1$ in the xy -plane coincide as shown in the graph obtained using a CAS.



Recall that (r, θ) and $(-r, \theta + \pi)$ represent the same point. Replacing θ by $\theta + \pi$ and r by $(-r)$ in $r = 2\cos\theta - 1$ we obtain

$$-r = 2\cos(\theta + \pi) - 1$$
$$-r = -2\cos\theta - 1$$
$$r = 2\cos\theta + 1$$

Thus, the two equations define the same graph. (One could also convert both equations to rectangular coordinates and note that they come out identical.)

58. CAS We investigate how the shape of the limaçon curve $r = b + \cos\theta$ depends on the constant b (see Figure 24).

(a) Argue as in Exercise 57 to show that the constants b and $-b$ yield the same curve.

(b) Plot the limaçon for $b = 0, 0.2, 0.5, 0.8, 1$ and describe how the curve changes.

(c) Plot the limaçon for $b = 1.2, 1.5, 1.8, 2, 2.4$ and describe how the curve changes.

(d) Use Eq. (2) to show that

$$\frac{dy}{dx} = -\left(\frac{b\cos\theta + \cos 2\theta}{b + 2\cos\theta}\right)\csc\theta$$

(e) Find the points where the tangent line is vertical. Note that there are three cases: $0 \le b < 2$, $b = 1$, and $b > 2$. Do the plots constructed in (b) and (c) reflect your results?

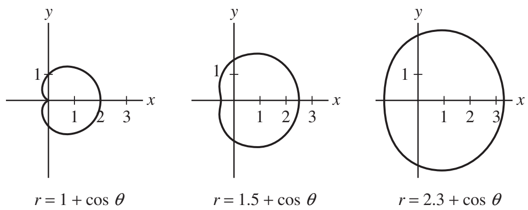


FIGURE 24

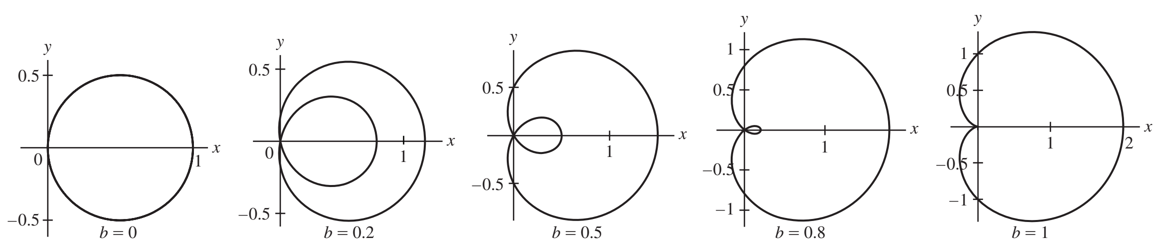
SOLUTION

(a) If (r, θ) is on the curve $r = -b + \cos\theta$, then so is $(-r, \theta + \pi)$ since they represent the same point. Thus

$$-r = -b + \cos(\theta + \pi)$$
$$-r = -b - \cos\theta$$
$$r = b + \cos\theta$$

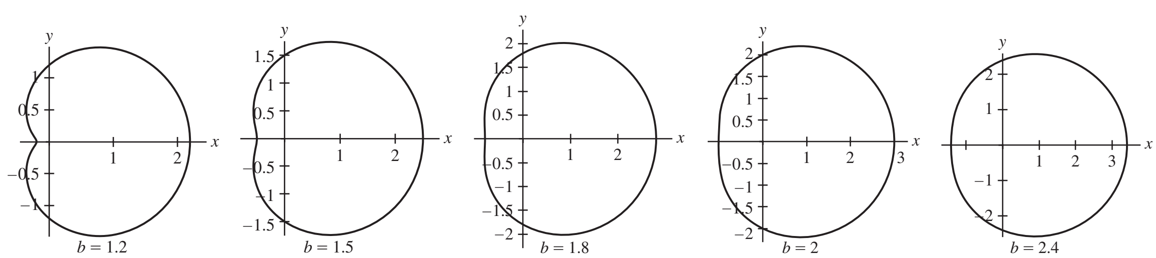
Thus the same set of points lie on the graph of both equations, so they define the same curve.

(b)



For $0 < b < 1$, there is a "loop" inside the curve. For $b = 0$, the curve is a circle, although actually for $0 \le \theta \le 2\pi$ the circle is traversed twice, so in fact the loop is as large as the circle and overlays it. When $b = 1$, the loop is pinched to a point.

(c)



For b between 1 and 2, the pinch at $b = 1$ smooths out into a concavity in the curve, which decreases in size. By $b = 2$ it appears to be gone; further increases in b push the left-hand section of the curve out, making it more convex.

(d) By Eq. (2), with $f(\theta) = b + \cos\theta$ and $f'(\theta) = -\sin\theta$, we have (using the double-angle identities for sin and cos)

$$\frac{dy}{dx} = \frac{f(\theta)\cos\theta + f'(\theta)\sin\theta}{-f(\theta)\sin\theta + f'(\theta)\cos\theta} = \frac{(b + \cos\theta)\cos\theta - \sin^2\theta}{-(b + \cos\theta)\sin\theta - \sin\theta\cos\theta} = \frac{b\cos\theta + \cos 2\theta}{-b\sin\theta - 2\sin\theta\cos\theta}$$

$$= -\frac{b\cos\theta + \cos 2\theta}{\sin\theta(b + 2\cos\theta)} = -\left(\frac{b\cos\theta + \cos 2\theta}{b + 2\cos\theta}\right)\csc\theta$$

(e) From part **(d)**, the tangent line is vertical when either $\csc\theta$ is undefined or when $b + 2\cos\theta = 0$ (as long as the numerator $b\cos\theta + \cos 2\theta \neq 0$). Consider first the case when $\csc\theta$ is undefined, so that $\theta = 0$ or $\theta = \pi$. If $\theta = 0$, the numerator of the fraction is $b + 1 \neq 0$ and the denominator is $b + 2 \neq 0$, so that the tangent is vertical here.

$$\text{For any } b, \text{ the limaçon has a vertical tangent at } (b + \cos 0, 0) = (b + 1, 0)$$

If $\theta = \pi$, the numerator of the fraction is $1 - b$ and the denominator is $b + 2 \neq 0$. As long as $b \neq 1$, the numerator does not vanish and we have found a point of vertical tangency. If $b = 1$, then by L'Hôpital's Rule,

$$-\lim_{\theta\to\pi}\left(\frac{b\cos\theta + \cos 2\theta}{b + 2\cos\theta}\right)\csc\theta = -\lim_{\theta\to\pi}\left(\frac{b\cos\theta + \cos 2\theta}{(b + 2\cos\theta)\sin\theta}\right) = \lim_{\theta\to\pi}\frac{\sin t + \sin 2t}{2\cos^2 t - 2\sin^2 t + \cos t} = 0$$

so that the tangent is not vertical here. Thus

$$\text{If } b \neq 1, \text{ the limaçon has a vertical tangent at } (b + \cos\pi, \pi) = (b - 1, \pi)$$

Next consider the possibility that $b + 2\cos\theta = 0$; this happens when $\cos\theta = -\frac{b}{2}$. First assume that $0 \le b < 2$. This equation holds for two values of θ: $\cos^{-1}\left(-\frac{b}{2}\right)$ and $-\cos^{-1}\left(-\frac{b}{2}\right)$. Neither of these angles is 0 or π, so that $\csc\theta$ is defined. Additionally, the numerator is

$$b\cos\theta + \cos 2\theta = b\cos\theta + 2\cos^2\theta - 1 = -\frac{b^2}{2} + 2\cdot\frac{b^2}{4} - 1 = -1$$

so that the numerator does not vanish. Thus

$$\text{For } 0 \le b < 2, \text{ the limaçon has a vertical tangent at } \left(\frac{b}{2}, \cos^{-1}\left(-\frac{b}{2}\right)\right) \text{ and } \left(\frac{b}{2}, -\cos^{-1}\left(-\frac{b}{2}\right)\right)$$

Next assume that $b = 2$; then $\cos\theta = -1$ holds for $\theta = \pi$; we have considered that case above. Finally assume that $b > 2$; then $\cos\theta = -\frac{b}{2}$ has no solutions. Thus, in summary, vertical tangents of the limaçon occur as follows:

$$\begin{aligned}
0 \le b < 2, b \neq 1: &\quad \left(\frac{b}{2}, \cos^{-1}\left(-\frac{b}{2}\right)\right), \left(\frac{b}{2}, -\cos^{-1}\left(-\frac{b}{2}\right)\right), (b - 1, \pi), (b + 1, 0)\\
b = 1: &\quad \left(\frac{b}{2}, \cos^{-1}\left(-\frac{b}{2}\right)\right), \left(\frac{b}{2}, -\cos^{-1}\left(-\frac{b}{2}\right)\right), (b + 1, 0)\\
b \ge 2: &\quad (b + 1, 0), (b - 1, \pi)
\end{aligned}$$

These do correspond to the figures in parts **(b)** and **(c)**.

11.4 Area and Arc Length in Polar Coordinates

Preliminary Questions

1. Polar coordinates are suited to finding the area (choose one):

(a) Under a curve between $x = a$ and $x = b$.

(b) Bounded by a curve and two rays through the origin.

SOLUTION Polar coordinates are best suited to finding the area bounded by a curve and two rays through the origin. The formula for the area in polar coordinates gives the area of this region.

2. Is the formula for area in polar coordinates valid if $f(\theta)$ takes negative values?

SOLUTION The formula for the area

$$\frac{1}{2}\int_\alpha^\beta f(\theta)^2\,d\theta$$

always gives the actual (positive) area, even if $f(\theta)$ takes on negative values.

3. The horizontal line $y = 1$ has polar equation $r = \csc\theta$. Which area is represented by the integral $\frac{1}{2}\int_{\pi/6}^{\pi/2} \csc^2\theta\, d\theta$ (Figure 12)?

(a) $\square ABCD$ **(b)** $\triangle ABC$ **(c)** $\triangle ACD$

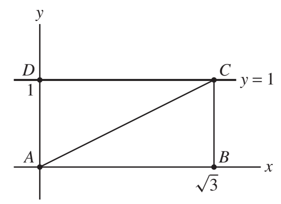


FIGURE 12

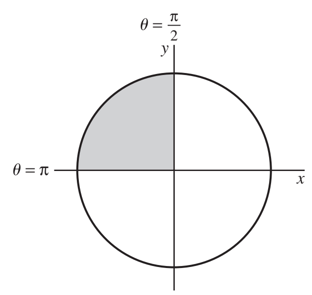
SOLUTION This integral represents an area taken from $\theta = \pi/6$ to $\theta = \pi/2$, which can only be the triangle $\triangle ACD$, as seen in part (c).

Exercises

1. Sketch the area bounded by the circle $r = 5$ and the rays $\theta = \frac{\pi}{2}$ and $\theta = \pi$, and compute its area as an integral in polar coordinates.

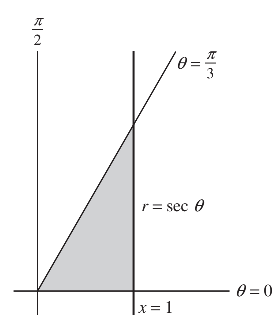
SOLUTION The region bounded by the circle $r = 5$ and the rays $\theta = \frac{\pi}{2}$ and $\theta = \pi$ is the shaded region in the figure. The area of the region is given by the following integral:

$$\frac{1}{2}\int_{\pi/2}^{\pi} r^2\, d\theta = \frac{1}{2}\int_{\pi/2}^{\pi} 5^2\, d\theta = \frac{25}{2}\left(\pi - \frac{\pi}{2}\right) = \frac{25\pi}{4}$$



2. Sketch the region bounded by the line $r = \sec\theta$ and the rays $\theta = 0$ and $\theta = \frac{\pi}{3}$. Compute its area in two ways: as an integral in polar coordinates and using geometry.

SOLUTION The region bounded by the line $r = \sec\theta$ and the rays $\theta = 0$ and $\theta = \frac{\pi}{3}$ is shown here:

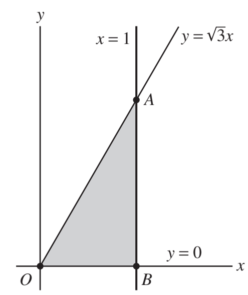


Using the area in polar coordinates, the area of the region is given by the following integral:

$$A = \frac{1}{2}\int_0^{\pi/3} r^2\, d\theta = \frac{1}{2}\int_0^{\pi/3} \sec^2\theta\, d\theta = \frac{1}{2}\tan\theta\Big|_0^{\pi/3} = \frac{1}{2}\left(\tan\frac{\pi}{3} - \tan 0\right) = \frac{\sqrt{3}}{2}$$

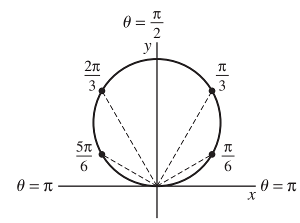
We now compute the area using the formula for the area of a triangle. The equations of the lines $\theta = \frac{\pi}{3}$, $\theta = 0$, and $r = \sec\theta$ in rectangular coordinates are $y = \sqrt{3}x$, $y = 0$ and $x = 1$ respectively (see Example 5 in Section 12.3 for the equation of the line $r = \sec\theta$). Denoting the vertices of the triangle by O, A, B (see figure) we have $O = (0, 0)$, $A = \left(1, \sqrt{3}\right)$ and $B = (1, 0)$. The area of the triangle is thus

$$A = \frac{OB \cdot AB}{2} = \frac{1 \cdot \sqrt{3}}{2} = \frac{\sqrt{3}}{2}.$$



3. Calculate the area of the circle $r = 4\sin\theta$ as an integral in polar coordinates (see Figure 4). Be careful to choose the correct limits of integration.

SOLUTION The equation $r = 4\sin\theta$ defines a circle of radius 2 tangent to the x-axis at the origin as shown in the figure:



The circle is traced as θ varies from 0 to π. We use the area in polar coordinates and the identity

$$\sin^2\theta = \frac{1}{2}(1 - \cos 2\theta)$$

to obtain the following area:

$$A = \frac{1}{2}\int_0^{\pi} r^2\, d\theta = \frac{1}{2}\int_0^{\pi} (4\sin\theta)^2\, d\theta = 8\int_0^{\pi} \sin^2\theta\, d\theta = 4\int_0^{\pi} (1 - \cos 2\theta)\, d\theta = 4\left[\theta - \frac{\sin 2\theta}{2}\right]_0^{\pi}$$
$$= 4\left(\left(\pi - \frac{\sin 2\pi}{2}\right) - 0\right) = 4\pi.$$

4. Find the area of the shaded triangle in Figure 13 as an integral in polar coordinates. Then find the rectangular coordinates of P and Q and compute the area via geometry.

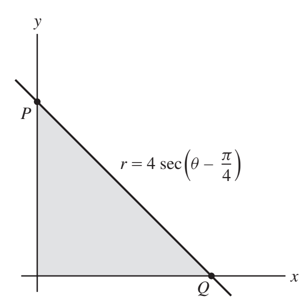


FIGURE 13

SOLUTION The boundary of the region is traced as θ varies from 0 to $\frac{\pi}{2}$, so the area is

$$\frac{1}{2}\int_0^{\pi/2} r^2\, d\theta = \frac{1}{2}\int_0^{\pi/2} 16\sec^2\left(\theta - \frac{\pi}{4}\right) d\theta = 8\tan\left(\theta - \frac{\pi}{4}\right)\Big|_0^{\pi/2} = 8(1 + 1) = 16$$

5. Find the area of the shaded region in Figure 14. Note that θ varies from 0 to $\frac{\pi}{2}$.

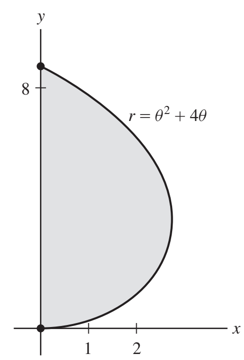

FIGURE 14

SOLUTION Since θ varies from 0 to $\frac{\pi}{2}$, the area is

$$\frac{1}{2}\int_0^{\pi/2} r^2\,d\theta = \frac{1}{2}\int_0^{\pi/2} (\theta^2 + 4\theta)^2\,d\theta = \frac{1}{2}\int_0^{\pi/2} \theta^4 + 8\theta^3 + 16\theta^2\,d\theta$$
$$= \frac{1}{2}\left(\frac{1}{5}\theta^5 + 2\theta^4 + \frac{16}{3}\theta^3\right)\Big|_0^{\pi/2} = \frac{\pi^5}{320} + \frac{\pi^4}{16} + \frac{\pi^2}{3}$$

6. Which interval of θ-values corresponds to the the shaded region in Figure 15? Find the area of the region.

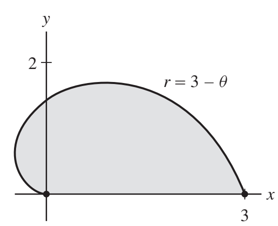

FIGURE 15

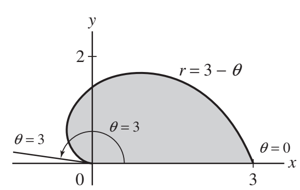
SOLUTION We first find the interval of θ. At the origin $r = 0$, so $\theta = 3$. At the endpoint on the x-axis, $\theta = 0$. Thus, θ varies from 0 to 3.



Using the area in polar coordinates we obtain

$$A = \frac{1}{2}\int_0^3 r^2\,d\theta = \frac{1}{2}\int_0^3 (3-\theta)^2\,d\theta = -\frac{(3-\theta)^3}{6}\Big|_0^3 = 4.5.$$

7. Find the total area enclosed by the cardioid in Figure 16.

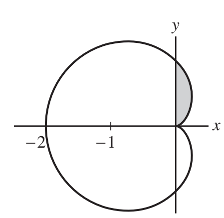


FIGURE 16 The cardioid $r = 1 - \cos\theta$.

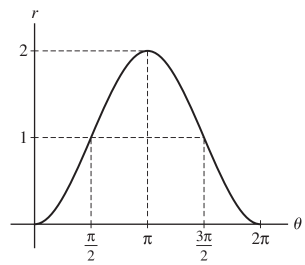
SOLUTION We graph $r = 1 - \cos\theta$ in r and θ (cartesian, not polar, this time):



We see that as θ varies from 0 to π, the radius r increases from 0 to 2, so we get the upper half of the cardioid (the lower half is obtained as θ varies from π to 2π and consequently r decreases from 2 to 0). Since the cardioid is symmetric with respect to the x-axis we may compute the upper area and double the result. Using

$$\cos^2\theta = \frac{\cos 2\theta + 1}{2}$$

we get

$$\begin{aligned} A &= 2\cdot\frac{1}{2}\int_0^{\pi} r^2\,d\theta = \int_0^{\pi}(1-\cos\theta)^2\,d\theta = \int_0^{\pi}\left(1 - 2\cos\theta + \cos^2\theta\right)d\theta \\ &= \int_0^{\pi}\left(1 - 2\cos\theta + \frac{\cos 2\theta + 1}{2}\right)d\theta = \int_0^{\pi}\left(\frac{3}{2} - 2\cos\theta + \frac{1}{2}\cos 2\theta\right)d\theta \\ &= \frac{3}{2}\theta - 2\sin\theta + \frac{1}{4}\sin 2\theta\Big|_0^{\pi} = \frac{3\pi}{2} \end{aligned}$$

The total area enclosed by the cardioid is $A = \frac{3\pi}{2}$.

8. Find the area of the shaded region in Figure 16.

SOLUTION The shaded region is traced as θ varies from 0 to $\frac{\pi}{2}$. Using the formula for the area in polar coordinates we get:

$$\begin{aligned} A &= \frac{1}{2}\int_0^{\pi/2} r^2\,d\theta = \frac{1}{2}\int_0^{\pi/2}(1-\cos\theta)^2\,d\theta = \frac{1}{2}\int_0^{\pi/2}\left(1 - 2\cos\theta + \cos^2\theta\right)d\theta \\ &= \frac{1}{2}\int_0^{\pi/2}\left(1 - 2\cos\theta + \frac{\cos 2\theta + 1}{2}\right)d\theta = \frac{1}{2}\int_0^{\pi/2}\left(\frac{3}{2} - 2\cos\theta + \frac{1}{2}\cos 2\theta\right)d\theta \\ &= \frac{1}{2}\left(\frac{3\theta}{2} - 2\sin\theta + \frac{1}{4}\sin 2\theta\right)\Big|_0^{\pi/2} = \frac{1}{2}\left(\left(\frac{3}{2}\cdot\frac{\pi}{2} - 2\sin\frac{\pi}{2} + \frac{1}{4}\sin\pi\right) - 0\right) \\ &= \frac{1}{2}\left(\frac{3\pi}{4} - 2\right) = \frac{3\pi}{8} - 1 \approx 0.18 \end{aligned}$$

9. Find the area of one leaf of the "four-petaled rose" $r = \sin 2\theta$ (Figure 17). Then prove that the total area of the rose is equal to one-half the area of the circumscribed circle.

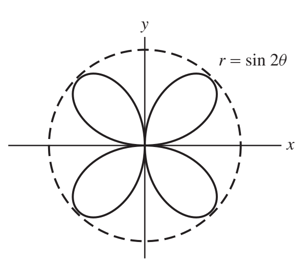


FIGURE 17 Four-petaled rose $r = \sin 2\theta$.

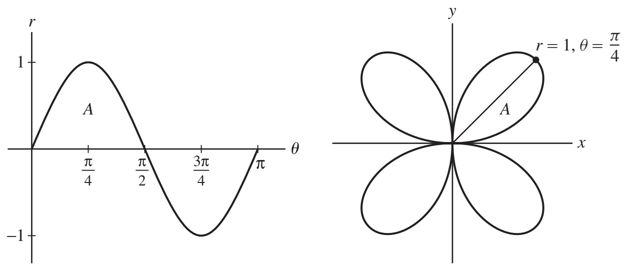
SOLUTION We consider the graph of $r = \sin 2\theta$ in cartesian and in polar coordinates:



We see that as θ varies from 0 to $\frac{\pi}{4}$ the radius r is increasing from 0 to 1, and when θ varies from $\frac{\pi}{4}$ to $\frac{\pi}{2}$, r is decreasing back to zero. Hence, the leaf in the first quadrant is traced as θ varies from 0 to $\frac{\pi}{2}$. The area of the leaf (the four leaves have equal areas) is thus

$$A = \frac{1}{2}\int_0^{\pi/2} r^2\, d\theta = \frac{1}{2}\int_0^{\pi/2} \sin^2 2\theta\, d\theta.$$

Using the identity

$$\sin^2 2\theta = \frac{1-\cos 4\theta}{2}$$

we get

$$A = \frac{1}{2}\int_0^{\pi/2}\left(\frac{1}{2} - \frac{\cos 4\theta}{2}\right) d\theta = \frac{1}{2}\left(\frac{\theta}{2} - \frac{\sin 4\theta}{8}\right)\bigg|_0^{\pi/2} = \frac{1}{2}\left(\left(\frac{\pi}{4} - \frac{\sin 2\pi}{8}\right) - 0\right) = \frac{\pi}{8}$$

The area of one leaf is $A = \frac{\pi}{8} \approx 0.39$. It follows that the area of the entire rose is $\frac{\pi}{2}$. Since the "radius" of the rose (the point where $\theta = \frac{\pi}{4}$) is 1, and the circumscribed circle is tangent there, the circumscribed circle has radius 1 and thus area π. Hence the area of the rose is half that of the circumscribed circle.

10. Find the area enclosed by one loop of the lemniscate with equation $r^2 = \cos 2\theta$ (Figure 18). Choose your limits of integration carefully.

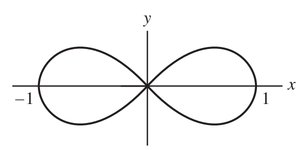


FIGURE 18 The lemniscate $r^2 = \cos 2\theta$.

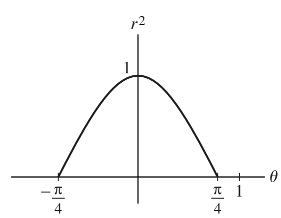
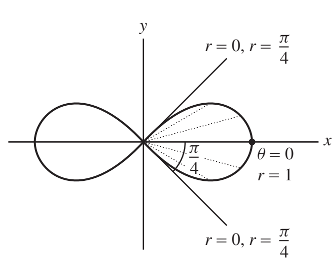
SOLUTION We sketch the graph of $r^2 = \cos 2\theta$ in the $\left(r^2, \theta\right)$ plane; for $-\frac{\pi}{4} \le \theta \le \frac{\pi}{4}$:



We see that as θ varies from $-\frac{\pi}{4}$ to 0, r^2 increases from 0 to 1, hence r also increases from 0 to 1. Then, as θ varies from 0 to $\frac{\pi}{4}$, r^2, so r decreases from 1 to 0. This gives the right-hand loop of the lemniscate.

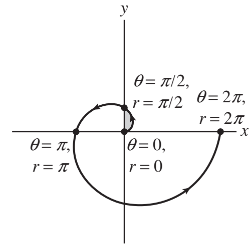


Therefore, the area enclosed by the right-hand loop is:

$$\frac{1}{2}\int_{-\pi/4}^{\pi/4} r^2\,d\theta = \frac{1}{2}\int_{-\pi/4}^{\pi/4}\cos 2\theta\,d\theta = \frac{1}{2}\frac{\sin 2\theta}{2}\bigg|_{-\pi/4}^{\pi/4} = \frac{1}{4}\left(\sin\frac{\pi}{2} - \sin\left(-\frac{\pi}{2}\right)\right) = \frac{1}{2}$$

11. Sketch the spiral $r=\theta$ for $0\le\theta\le 2\pi$ and find the area bounded by the curve and the first quadrant.

SOLUTION The spiral $r=\theta$ for $0\le\theta\le 2\pi$ is shown in the following figure in the xy-plane:



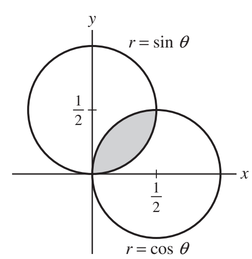
The spiral $r=\theta$

We must compute the area of the shaded region. This region is traced as θ varies from 0 to $\frac{\pi}{2}$. Using the formula for the area in polar coordinates we get

$$A = \frac{1}{2}\int_0^{\pi/2} r^2\,d\theta = \frac{1}{2}\int_0^{\pi/2}\theta^2\,d\theta = \frac{1}{2}\frac{\theta^3}{3}\bigg|_0^{\pi/2} = \frac{1}{6}\left(\frac{\pi}{2}\right)^3 = \frac{\pi^3}{48}$$

12. Find the area of the intersection of the circles $r=\sin\theta$ and $r=\cos\theta$.

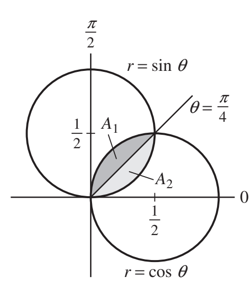
SOLUTION The region of intersection between the two circles is shown in the following figure:



We first find the value of θ at the point of intersection (besides the origin) of the two circles, by solving the following equation for $0\le a\le\frac{\pi}{2}$:

$$\sin\theta = \cos\theta$$
$$\tan\theta = 1 \Rightarrow \theta = \frac{\pi}{4}$$

We now compute the area as the sum of the two areas A_1 and A_2, shown in the figure:



Using the formula for the area in polar coordinates we get

$$A_1 = \frac{1}{2}\int_{\pi/4}^{\pi/2}\cos^2\theta\,d\theta = \frac{1}{2}\int_{\pi/2}^{\pi/2}\left(\frac{1}{2}+\frac{1}{2}\cos 2\theta\right)d\theta = \frac{1}{4}\int_{\pi/2}^{\pi/2}(1+\cos 2\theta)\,d\theta$$
$$= \frac{1}{4}\left(\theta+\frac{\sin 2\theta}{2}\right)\bigg|_{\pi/2}^{\pi/2} = \frac{1}{4}\left(\left(\frac{\pi}{2}+\frac{\sin\pi}{2}\right)-\left(\frac{\pi}{4}+\frac{\sin\frac{\pi}{2}}{2}\right)\right) = \frac{1}{4}\left(\frac{\pi}{2}-\frac{\pi}{4}-\frac{1}{2}\right) = \frac{\pi}{16}-\frac{1}{8}$$

$$A_2 = \frac{1}{2}\int_0^{\pi/4} \sin^2\theta\,d\theta = \frac{1}{2}\int_0^{\pi/4}\left(\frac{1}{2} - \frac{1}{2}\cos 2\theta\right)d\theta = \frac{1}{4}\int_0^{\pi/4}(1-\cos 2\theta)\,d\theta$$

$$= \frac{1}{4}\left(\theta - \frac{\sin 2\theta}{2}\right)\Big|_0^{\pi/4} = \frac{1}{4}\left(\left(\frac{\pi}{4} - \frac{\sin\frac{\pi}{2}}{2}\right) - 0\right) = \frac{\pi}{16} - \frac{1}{8}$$

Notice that $A_2 = A_1$ as shown in the figure due to symmetry. The total area enclosed by the two circles is the sum

$$A = A_1 + A_2 = \left(\frac{\pi}{16} - \frac{1}{8}\right) + \left(\frac{\pi}{16} - \frac{1}{8}\right) = \frac{\pi}{8} - \frac{1}{4} \approx 0.14.$$

13. Find the area of region A in Figure 19.

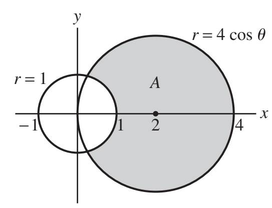


FIGURE 19

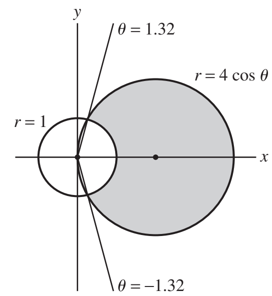
SOLUTION We first find the values of θ at the points of intersection of the two circles, by solving the following equation for $-\frac{\pi}{2} \le x \le \frac{\pi}{2}$:

$$4\cos\theta = 1 \Rightarrow \cos\theta = \frac{1}{4} \Rightarrow \theta_1 = \cos^{-1}\left(\frac{1}{4}\right)$$



We now compute the area using the formula for the area between two curves:

$$A = \frac{1}{2}\int_{-\theta_1}^{\theta_1}\left((4\cos\theta)^2 - 1^2\right)d\theta = \frac{1}{2}\int_{-\theta_1}^{\theta_1}\left(16\cos^2\theta - 1\right)d\theta$$

Using the identity $\cos^2\theta = \frac{\cos 2\theta + 1}{2}$ we get

$$A = \frac{1}{2}\int_{-\theta_1}^{\theta_1}\left(\frac{16(\cos 2\theta + 1)}{2} - 1\right)d\theta = \frac{1}{2}\int_{-\theta_1}^{\theta_1}(8\cos 2\theta + 7)\,d\theta = \frac{1}{2}(4\sin 2\theta + 7\theta)\Big|_{-\theta_1}^{\theta_1}$$

$$= 4\sin 2\theta_1 + 7\theta_1 = 8\sin\theta_1\cos\theta_1 + 7\theta_1 = 8\sqrt{1-\cos^2\theta_1}\cos\theta_1 + 7\theta_1$$

Using the fact that $\cos\theta_1 = \frac{1}{4}$ we get

$$A = \frac{\sqrt{15}}{2} + 7\cos^{-1}\left(\frac{1}{4}\right) \approx 11.163$$

14. Find the area of the shaded region in Figure 20, enclosed by the circle $r = \frac{1}{2}$ and a petal of the curve $r = \cos 3\theta$. *Hint:* Compute the area of both the petal and the region inside the petal and outside the circle.

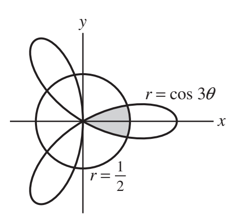


FIGURE 20

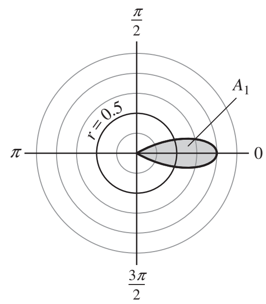
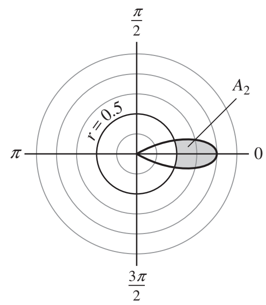
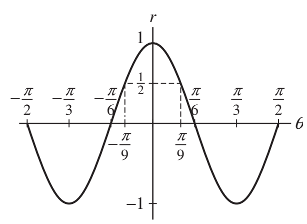
SOLUTION We compute the area A of the given region as the difference between the area A_1 of the leaf, shown here:



The area, A_2, of the region inside the leaf and outside the circle, shown here:



Computing A_1: To determine the limits of integration we use the following graph of $r = \cos 3\theta$:



$r = \cos 3\theta$

As θ varies from $-\frac{\pi}{6}$ to 0, r increases from 0 to 1. Then, as θ varies from 0 to $\frac{\pi}{6}$, r decreases from 1 back to zero. Hence the leaf is traced as θ varies from $-\frac{\pi}{6}$ to $\frac{\pi}{6}$. We use the formula for the area in polar coordinates to obtain

$$A_1 = \frac{1}{2}\int_{-\pi/6}^{\pi/6} \cos^2 3\theta \, d\theta = \frac{1}{2}\int_{-\pi/6}^{\pi/6} \left(\frac{1}{2} + \frac{1}{2}\cos 6\theta\right) d\theta = \frac{1}{4}\int_{-\pi/6}^{\pi/6} (1 + \cos 6\theta) \, d\theta$$
$$= \frac{1}{4}\left(\theta + \frac{\sin 6\theta}{6}\right)\Big|_{-\pi/6}^{\pi/6} = \frac{1}{4}\left(\left(\frac{\pi}{6} + \frac{\sin \pi}{6}\right) - \left(-\frac{\pi}{6} + \frac{\sin(-\pi)}{6}\right)\right) = \frac{1}{4}\cdot\frac{2\pi}{6} = \frac{\pi}{12}$$

Computing A_2: The two curves intersect at the points where $\cos 3\theta = \frac{1}{2}$, that is, $\theta = \pm\frac{\pi}{9}$ (see the graph of $r = \cos 3\theta$ in the $r\theta$-plane). Using the formula for the area between two curves we get

$$A_2 = \frac{1}{2}\int_{-\pi/9}^{\pi/9} \left(\cos^2 3\theta - \left(\frac{1}{2}\right)^2\right) d\theta = \frac{1}{2}\int_{-\pi/9}^{\pi/9} \left(\frac{1}{2} + \frac{1}{2}\cos 6\theta - \frac{1}{4}\right) d\theta$$
$$= \frac{1}{8}\int_{-\pi/9}^{\pi/9} (1 + 2\cos 6\theta) \, d\theta = \frac{1}{8}\left(\theta + \frac{\sin 6\theta}{3}\right)\Big|_{-\pi/9}^{\pi/9}$$
$$= \frac{1}{8}\left(\left(\frac{\pi}{9} + \frac{\sin\frac{6\pi}{9}}{3}\right) - \left(-\frac{\pi}{9} + \frac{\sin\left(-\frac{6\pi}{9}\right)}{3}\right)\right) = \frac{1}{4}\left(\frac{\pi}{9} + \frac{\sqrt{3}}{6}\right) = \frac{\pi}{36} + \frac{\sqrt{3}}{24}$$

The required area is the difference between A_1 and A_2, that is,

$$A = A_1 - A_2 = \frac{\pi}{12} - \left(\frac{\pi}{36} + \frac{\sqrt{3}}{24}\right) = \frac{\pi}{18} - \frac{\sqrt{3}}{24} \approx 0.102.$$

15. Find the area of the inner loop of the limaçon with polar equation $r = 2\cos\theta - 1$ (Figure 21).

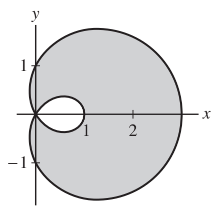


FIGURE 21 The limaçon $r = 2\cos\theta - 1$.

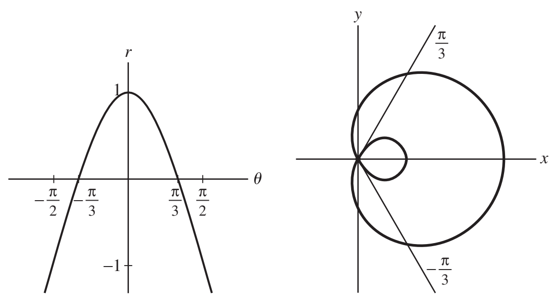
SOLUTION We consider the graph of $r = 2\cos\theta - 1$ in cartesian and in polar, for $-\frac{\pi}{2} \le x \le \frac{\pi}{2}$:



$r = 2\cos\theta - 1$

As θ varies from $-\frac{\pi}{3}$ to 0, r increases from 0 to 1. As θ varies from 0 to $\frac{\pi}{3}$, r decreases from 1 back to 0. Hence, the inner loop of the limaçon is traced as θ varies from $-\frac{\pi}{3}$ to $\frac{\pi}{3}$. The area of the shaded region is thus

$$A = \frac{1}{2}\int_{-\pi/3}^{\pi/3} r^2\,d\theta = \frac{1}{2}\int_{-\pi/3}^{\pi/3} (2\cos\theta - 1)^2\,d\theta = \frac{1}{2}\int_{-\pi/3}^{\pi/3} \left(4\cos^2\theta - 4\cos\theta + 1\right)\,d\theta$$

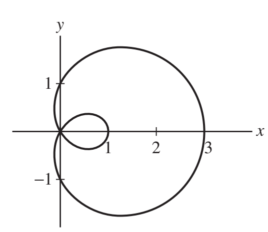
$$= \frac{1}{2}\int_{-\pi/3}^{\pi/3} (2\left(\cos 2\theta + 1\right) - 4\cos\theta + 1)\,d\theta = \frac{1}{2}\int_{-\pi/3}^{\pi/3} (2\cos 2\theta - 4\cos\theta + 3)\,d\theta$$

$$= \frac{1}{2}\left(\sin 2\theta - 4\sin\theta + 3\theta\right)\Big|_{-\pi/3}^{\pi/3} = \frac{1}{2}\left(\left(\sin\frac{2\pi}{3} - 4\sin\frac{\pi}{3} + \pi\right) - \left(\sin\left(-\frac{2\pi}{3}\right) - 4\sin\left(-\frac{\pi}{3}\right) - \pi\right)\right)$$

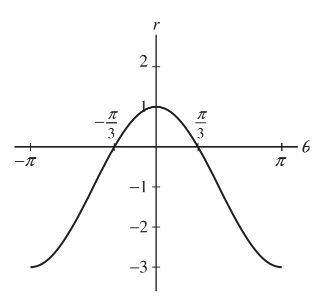
$$= \frac{\sqrt{3}}{2} - \frac{4\sqrt{3}}{2} + \pi = \pi - \frac{3\sqrt{3}}{2} \approx 0.54$$

16. Find the area of the shaded region in Figure 21 between the inner and outer loop of the limaçon $r = 2\cos\theta - 1$.

SOLUTION The region is shown in the figure below.

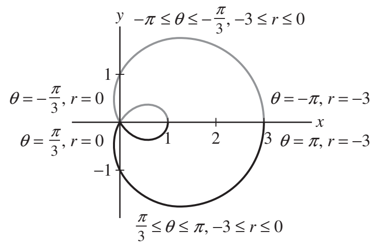


We use the following graph.



Graph of $r = 2\cos\theta - 1$

As θ varies from $\frac{\pi}{3}$ to π, r is negative and $|r|$ increases from 0 to 3. This gives the outer loop of the limaçon which is in the lower half plane. Similarly, the outer loop which is in the upper half plane is traced for $-\pi \le \theta \le -\frac{\pi}{3}$.



Using symmetry with respect to the x-axis, we obtain the following for the area of the outer loop:

$$A = 2 \cdot \frac{1}{2}\int_{\pi/3}^{\pi} r^2\,d\theta = \int_{\pi/3}^{\pi} (2\cos\theta - 1)^2\,d\theta = \int_{\pi/3}^{\pi}\left(4\cos^2\theta - 4\cos\theta + 1\right)\,d\theta$$

$$= \int_{\pi/3}^{\pi} (2\,(1+\cos 2\theta) - 4\cos\theta + 1)\;d\theta = \int_{\pi/3}^{\pi} (2\cos 2\theta - 4\cos\theta + 3)\;d\theta = \sin 2\theta - 4\sin\theta + 3\theta\Big|_{\pi/3}^{\pi}$$

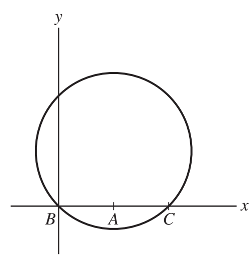
$$= (\sin 2\pi - 4\sin\pi + 3\pi) - \left(\sin\frac{2\pi}{3} - 4\sin\frac{\pi}{3} + \pi\right) = 3\pi - \left(\frac{\sqrt{3}}{2} - 2\sqrt{3} + \pi\right) = 2\pi + \frac{3\sqrt{3}}{2}$$

Finally, to find the area of the region between the inner and outer loop of the limaçon, we subtract the area of the inner loop, obtained in the previous exercise, from the area of the outer loop:

$$\left(2\pi + \frac{3\sqrt{3}}{2}\right) - \left(\pi - \frac{3\sqrt{3}}{2}\right) = \pi + 3\sqrt{3}$$

17. Find the area of the part of the circle $r = \sin\theta + \cos\theta$ in the fourth quadrant (see Exercise 26 in Section 11.3).

SOLUTION The value of θ corresponding to the point B is the solution of $r = \sin\theta + \cos\theta = 0$ for $-\pi \le \theta \le \pi$.



That is,

$$\sin\theta + \cos\theta = 0 \Rightarrow \sin\theta = -\cos\theta \Rightarrow \tan\theta = -1 \Rightarrow \theta = -\frac{\pi}{4}$$

At the point C, we have $\theta = 0$. The part of the circle in the fourth quadrant is traced if θ varies between $-\frac{\pi}{4}$ and 0. This leads to the following area:

$$A = \frac{1}{2}\int_{-\pi/4}^{0} r^2\,d\theta = \frac{1}{2}\int_{-\pi/4}^{0} (\sin\theta + \cos\theta)^2\,d\theta = \frac{1}{2}\int_{-\pi/4}^{0}\left(\sin^2\theta + 2\sin\theta\cos\theta + \cos^2\theta\right)\,d\theta$$

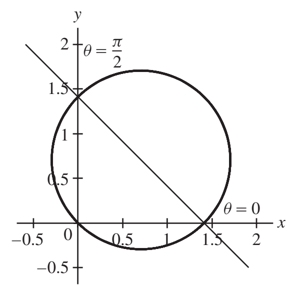
Using the identities $\sin^2\theta + \cos^2\theta = 1$ and $2\sin\theta\cos\theta = \sin 2\theta$ we get:

$$A = \frac{1}{2}\int_{-\pi/4}^{0} (1 + \sin 2\theta)\;d\theta = \frac{1}{2}\left(\theta - \frac{\cos 2\theta}{2}\right)\Big|_{-\pi/4}^{0}$$

$$= \frac{1}{2}\left(\left(0 - \frac{1}{2}\right) - \left(-\frac{\pi}{4} - \frac{\cos\left(\frac{-\pi}{2}\right)}{2}\right)\right) = \frac{1}{2}\left(\frac{\pi}{4} - \frac{1}{2}\right) = \frac{\pi}{8} - \frac{1}{4} \approx 0.14.$$

18. Find the area of the region inside the circle $r = 2\sin\left(\theta + \frac{\pi}{4}\right)$ and above the line $r = \sec\left(\theta - \frac{\pi}{4}\right)$.

SOLUTION The line $r = \sec\left(\theta - \frac{\pi}{4}\right)$ intersects the circle $r = 2\sin\left(\theta + \frac{\pi}{4}\right)$ when $\theta = 0$ and $\theta = 2\pi$.



Thus the area of the region inside the circle and above the line is

$$\begin{aligned}\frac{1}{2}\int_0^{\pi/2}\left(\left(2\sin\left(\theta+\frac{\pi}{4}\right)\right)^2 - \left(\sec\left(\theta-\frac{\pi}{4}\right)\right)^2\right)d\theta &= \frac{1}{2}\int_0^{\pi/2} 4\sin^2\left(\theta+\frac{\pi}{4}\right) - \sec^2\left(\theta-\frac{\pi}{4}\right)d\theta \\ &= \frac{1}{2}\left(2t - 2\sin\left(t+\frac{\pi}{4}\right)\cos\left(t+\frac{\pi}{4}\right) - \tan\left(t-\frac{\pi}{4}\right)\right)\Big|_0^{\pi/2} \\ &= \frac{1}{2}\left(\pi - 2\sin\left(\frac{3\pi}{4}\right)\cos\left(\frac{3\pi}{4}\right) - \tan\left(\frac{\pi}{4}\right) - \left(-2\sin\left(\frac{\pi}{4}\right)\cos\left(\frac{\pi}{4}\right) - \tan\left(-\frac{\pi}{4}\right)\right)\right) \\ &= \frac{1}{2}(\pi + 1 - 1 + 1 - 1) = \frac{\pi}{2}\end{aligned}$$

19. Find the area between the two curves in Figure 22(A).

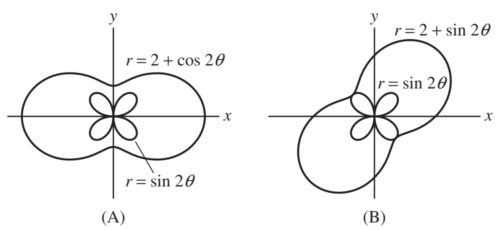


FIGURE 22

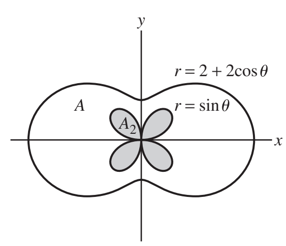
SOLUTION We compute the area A between the two curves as the difference between the area A_1 of the region enclosed in the outer curve $r = 2 + \cos 2\theta$ and the area A_2 of the region enclosed in the inner curve $r = \sin 2\theta$. That is,

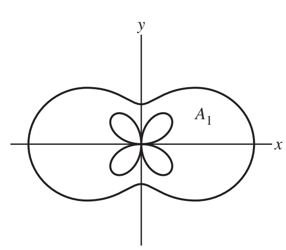
$$A = A_1 - A_2.$$



In Exercise 9 we showed that $A_2 = \frac{\pi}{2}$, hence,

$$A = A_1 - \frac{\pi}{2} \tag{1}$$

We compute the area A_1.



Using symmetry, the area is four times the area enclosed in the first quadrant. That is,

$$A_1 = 4 \cdot \frac{1}{2}\int_0^{\pi/2} r^2\,d\theta = 2\int_0^{\pi/2} (2+\cos 2\theta)^2\,d\theta = 2\int_0^{\pi/2}\left(4+4\cos 2\theta+\cos^2 2\theta\right)d\theta$$

Using the identity $\cos^2 2\theta = \frac{1}{2}\cos 4\theta + \frac{1}{2}$ we get

$$A_1 = 2\int_0^{\pi/2}\left(4+4\cos 2\theta+\frac{1}{2}\cos 4\theta+\frac{1}{2}\right)d\theta = 2\int_0^{\pi/2}\left(\frac{9}{2}+\frac{1}{2}\cos 4\theta+4\cos 2\theta\right)d\theta$$

$$= 2\left(\frac{9\theta}{2}+\frac{\sin 4\theta}{8}+2\sin 2\theta\right)\Big|_0^{\pi/2} = 2\left(\left(\frac{9\pi}{4}+\frac{\sin 2\pi}{8}+2\sin\pi\right)-0\right) = \frac{9\pi}{2} \qquad (2)$$

Combining (1) and (2) we obtain

$$A = \frac{9\pi}{2} - \frac{\pi}{2} = 4\pi.$$

20. Find the area between the two curves in Figure 22(B).

SOLUTION Since

$$2+\cos 2\left(\theta-\frac{\pi}{4}\right) = 2+\cos\left(2\theta-\frac{\pi}{2}\right) = 2+\cos\left(\frac{\pi}{2}-2\theta\right) = 2+\sin 2\theta$$

it follows that the curve $r = 2+\sin 2\theta$ is obtained by rotating the curve $r = 2+\cos\theta$ by $\frac{\pi}{4}$ about the origin. Therefore the area between the curves $r = 2+\sin 2\theta$ and $r = \sin 2\theta$ is the same as the area between the curves $r = 2+\cos\theta$ and $r = \sin 2\theta$ computed in Exercise 19. That is, $A = 4\pi$. (Notice that if the inner curve remains inside the rotated curve, the area between the curves is not changed).

21. Find the area inside both curves in Figure 23.

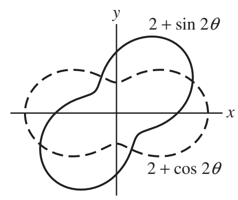


FIGURE 23

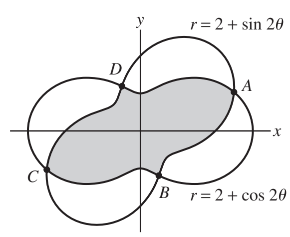
SOLUTION The area we need to find is the area of the shaded region in the figure.



We first find the values of θ at the points of intersection A, B, C, and D of the two curves, by solving the following equation for $-\pi \le \theta \le \pi$:

$$2+\cos 2\theta = 2+\sin 2\theta$$
$$\cos 2\theta = \sin 2\theta$$
$$\tan 2\theta = 1 \Rightarrow 2\theta = \frac{\pi}{4}+\pi k \Rightarrow \theta = \frac{\pi}{8}+\frac{\pi k}{2}$$

The solutions for $-\pi \le \theta \le \pi$ are

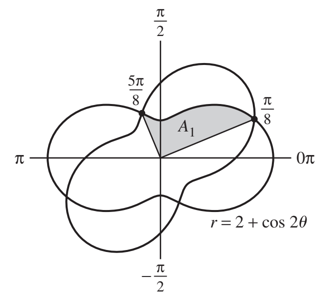
$$A:\quad \theta = \frac{\pi}{8}.$$

$$B:\quad \theta = -\frac{3\pi}{8}.$$

$$C:\quad \theta = -\frac{7\pi}{8}.$$

$$D:\quad \theta = \frac{5\pi}{8}.$$

Using symmetry, we compute the shaded area in the figure below and multiply it by 4:



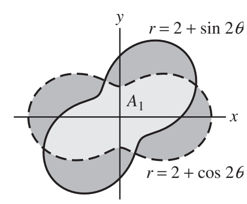
$$A = 4 \cdot A_1 = 4 \cdot \frac{1}{2} \cdot \int_{\pi/8}^{5\pi/8} (2+\cos 2\theta)^2\, d\theta = 2\int_{\pi/8}^{5\pi/8} \left(4 + 4\cos 2\theta + \cos^2 2\theta\right) d\theta$$

$$= 2\int_{\pi/8}^{5\pi/8} \left(4 + 4\cos 2\theta + \frac{1+\cos 4\theta}{2}\right) d\theta = \int_{\pi/8}^{5\pi/8} (9 + 8\cos 2\theta + \cos 4\theta)\, d\theta$$

$$= 9\theta + 4\sin 2\theta + \frac{\sin 4\theta}{4}\bigg|_{\pi/8}^{5\pi/8} = 9\left(\frac{5\pi}{8} - \frac{\pi}{8}\right) + 4\left(\sin\frac{5\pi}{4} - \sin\frac{\pi}{4}\right) + \frac{1}{4}\left(\sin\frac{5\pi}{2} - \sin\frac{\pi}{2}\right) = \frac{9\pi}{2} - 4\sqrt{2}$$

22. Find the area of the region that lies inside one but not both of the curves in Figure 23.

SOLUTION The area we need to find is the area of the shaded region in the following figure:



We denote by A_1 the area inside both curves. In Exercise 20 we showed that the curve $r = 2 + \sin 2\theta$ is obtained by rotating the curve $r = \cos 2\theta$ by $\frac{\pi}{4}$ around the origin. Hence, the areas enclosed in these curves are equal. We denote it by A_2. It follows that the area A that we need to find is

$$A = 2A_2 - 2A_1 = 2(A_2 - A_1) \tag{1}$$

In Exercise 20 we found that $A_2 = \frac{9\pi}{2}$, and in Exercise 21 we showed that $A_1 = \frac{9\pi}{2} - 4\sqrt{2}$. Substituting in (1) we obtain

$$A = 2\left(\frac{9\pi}{2} - \left(\frac{9\pi}{2} - 4\sqrt{2}\right)\right) = 8\sqrt{2} \approx 11.3.$$

23. Calculate the total length of the circle $r = 4\sin\theta$ as an integral in polar coordinates.

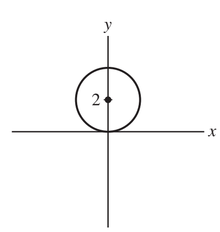
SOLUTION We use the formula for the arc length:

$$S = \int_{\alpha}^{\beta} \sqrt{f(\theta)^2 + f'(\theta)^2}\, d\theta \tag{1}$$

In this case, $f(\theta) = 4\sin\theta$ and $f'(\theta) = 4\cos\theta$, hence

$$\sqrt{f(\theta)^2 + f'(\theta)^2} = \sqrt{(4\sin\theta)^2 + (4\cos\theta)^2} = \sqrt{16} = 4$$

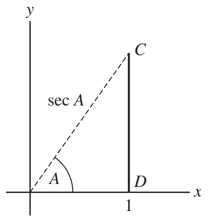
The circle is traced as θ is varied from 0 to π. Substituting $\alpha = 0$, $\beta = \pi$ in (1) yields $S = \int_0^{\pi} 4\, d\theta = 4\pi$.



The circle $r = 4\sin\theta$

24. Sketch the segment $r = \sec\theta$ for $0 \le \theta \le A$. Then compute its length in two ways: as an integral in polar coordinates and using trigonometry.

SOLUTION The line $r = \sec\theta$ has the rectangular equation $x = 1$. The segment AB for $0 \le \theta \le A$ is shown in the figure.



Using trigonometry, the length of the segment $\overline{AB}$ is

$$L = \overline{AB} = \overline{0B}\tan A = 1 \cdot \tan A = \tan A$$

Alternatively, we use the integral in polar coordinates with $f(\theta) = \sec(\theta)$ and $f'(\theta) = \tan\theta\sec\theta$. This gives

$$L = \int_0^A \sqrt{(\sec\theta)^2 + (\tan\theta\sec\theta)^2}\,d\theta = \int_0^A \sqrt{1+\tan^2\theta}\,\sec\theta\,d\theta = \int_0^A \sec^2\theta\,d\theta = \tan\theta\Big|_0^A = \tan A.$$

The two answers agree, as expected.

In Exercises 25–30, compute the length of the polar curve.

25. The length of $r = \theta^2$ for $0 \le \theta \le \pi$

SOLUTION We use the formula for the arc length. In this case $f(\theta) = \theta^2$, $f'(\theta) = 2\theta$, so we obtain

$$S = \int_0^\pi \sqrt{\left(\theta^2\right)^2 + (2\theta)^2}\,d\theta = \int_0^\pi \sqrt{\theta^4 + 4\theta^2}\,d\theta = \int_0^\pi \theta\sqrt{\theta^2+4}\,d\theta$$

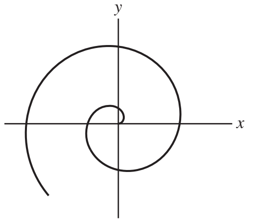
We compute the integral using the substitution $u = \theta^2 + 4$, $du = 2\theta\,d\theta$. This gives

$$S = \frac{1}{2}\int_4^{\pi^2+4} \sqrt{u}\,du = \frac{1}{2}\cdot\frac{2}{3}u^{3/2}\Big|_4^{\pi^2+4} = \frac{1}{3}\left(\left(\pi^2+4\right)^{3/2} - 4^{3/2}\right) = \frac{1}{3}\left(\left(\pi^2+4\right)^{3/2} - 8\right) \approx 14.55$$

26. The spiral $r = \theta$ for $0 \le \theta \le A$

SOLUTION We use the formula for the arc length. In this case $f(\theta) = \theta$, $f'(\theta) = 1$. Using integration formulas we get:

$$\begin{aligned} S &= \int_0^A \sqrt{\theta^2 + 1^2}\,d\theta = \int_0^A \sqrt{\theta^2+1}\,d\theta = \frac{\theta}{2}\sqrt{\theta^2+1} + \frac{1}{2}\ln\left|\theta + \sqrt{\theta^2+1}\right|\Big|_0^A \\ &= \frac{A}{2}\sqrt{A^2+1} + \frac{1}{2}\ln\left|A + \sqrt{A^2+1}\right| \end{aligned}$$



The spiral $r = \theta$

27. The equiangular spiral $r = e^\theta$ for $0 \le \theta \le 2\pi$

SOLUTION Since $f(\theta) = e^\theta$, by the formula for the arc length we have:

$$\begin{aligned} L &= \int_0^{2\pi} \sqrt{f'(\theta)^2 + f(\theta)}\,d\theta + \int_0^{2\pi} \sqrt{\left(e^\theta\right)^2 + \left(e^\theta\right)^2}\,d\theta = \int_0^{2\pi} \sqrt{2e^{2\theta}}\,d\theta \\ &= \sqrt{2}\int_0^{2\pi} e^\theta\,d\theta = \sqrt{2}e^\theta\Big|_0^{2\pi} = \sqrt{2}\left(e^{2\pi} - e^0\right) = \sqrt{2}\left(e^{2\pi} - 1\right) \approx 755.9 \end{aligned}$$

28. The inner loop of $r = 2\cos\theta - 1$ in Figure 21

SOLUTION In Exercise 15 it is shown that the inner loop of the limaçon $r = 2\cos\theta - 1$ is traced as θ varies from $-\frac{\pi}{3}$ to $\frac{\pi}{3}$. Also,

$$f(\theta) = 2\cos\theta - 1 \quad \text{and} \quad f'(\theta) = -2\sin\theta.$$

Using the integral for the arc length we obtain

$$\begin{aligned} L &= \int_{-\pi/3}^{\pi/3} \sqrt{f(\theta)^2 + f'(\theta)^2}\,d\theta = \int_{-\pi/3}^{\pi/3} \sqrt{(2\cos\theta - 1)^2 + (-2\sin\theta)^2}\,d\theta \\ &= \int_{-\pi/3}^{\pi/3} \sqrt{4\cos^2\theta - 4\cos\theta + 1 + 4\sin^2\theta}\,d\theta = \int_{-\pi/3}^{\pi/3} \sqrt{5 - 4\cos\theta}\,d\theta \end{aligned}$$

29. The cardioid $r = 1 - \cos\theta$ in Figure 16

SOLUTION In the equation of the cardioid, $f(\theta) = 1 - \cos\theta$. Using the formula for arc length in polar coordinates we have:

$$L = \int_{\alpha}^{\beta} \sqrt{f(\theta)^2 + f'(\theta)^2}\,d\theta \tag{1}$$

We compute the integrand:

$$\sqrt{f(\theta)^2 + f'(\theta)^2} = \sqrt{(1 - \cos\theta)^2 + (\sin\theta)^2} = \sqrt{1 - 2\cos\theta + \cos^2\theta + \sin^2\theta} = \sqrt{2\,(1 - \cos\theta)}$$

We identify the interval of θ. Since $-1 \le \cos\theta \le 1$, every $0 \le \theta \le 2\pi$ corresponds to a nonnegative value of r. Hence, θ varies from 0 to 2π. By (1) we obtain

$$L = \int_0^{2\pi} \sqrt{2(1 - \cos\theta)}\,d\theta$$

Now, $1 - \cos\theta = 2\sin^2(\theta/2)$, and on the interval $0 \le \theta \le \pi$, $\sin(\theta/2)$ is nonnegative, so that $\sqrt{2(1 - \cos\theta)} = \sqrt{4\sin^2(\theta/2)} = 2\sin(\theta/2)$ there. The graph is symmetric, so it suffices to compute the integral for $0 \le \theta \le \pi$, and we have

$$L = 2\int_0^{\pi} \sqrt{2(1 - \cos\theta)}\,d\theta = 2\int_0^{\pi} 2\sin(\theta/2)\,d\theta = 8\sin\frac{\theta}{2}\bigg|_0^{\pi} = 8$$

30. $r = \cos^2\theta$

SOLUTION Since $\cos\theta = \cos(-\theta)$ and $\cos^2(\pi - \theta) = \cos^2\theta$ the curve is symmetric with respect to the x and y-axis. Therefore, we may compute the length as four times the length of the part of the curve in the first quadrant. We use the formula for the arc length in polar coordinates. In this case, $f(\theta) = \cos^2\theta$, $f'(\theta) = 2\cos\theta\,(-\sin\theta)$, so we obtain

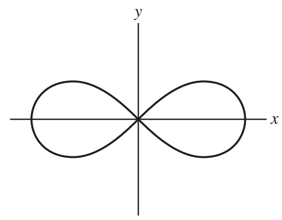
$$\begin{aligned} \sqrt{f(\theta)^2 + f'(\theta)^2} &= \sqrt{\cos^4\theta + 4\cos^2\theta\sin^2\theta} = \cos\theta\sqrt{\cos^2\theta + 4\sin^2\theta} \\ &= \cos\theta\sqrt{\cos^2\theta + \sin^2\theta + 3\sin^2\theta} = \cos\theta\sqrt{1 + 3\sin^2\theta} \end{aligned}$$

Thus,

$$L = \int_0^{\pi/2} \sqrt{f(\theta)^2 + f'(\theta)^2}\,d\theta = \int_0^{\pi/2} \cos\theta\sqrt{1 + 3\sin^2\theta}\,d\theta.$$

We compute the integral using the substitution $u = \sqrt{3}\sin\theta$ we get

$$\begin{aligned} L &= \frac{1}{\sqrt{3}}\int_0^{\sqrt{3}} \sqrt{1 + u^2}\,du = \frac{1}{\sqrt{3}}\left(\frac{u}{2}\sqrt{1 + u^2} + \frac{1}{2}\ln|u + \sqrt{1 + u^2}|\right)\bigg|_0^{\sqrt{3}} \\ &= \frac{1}{\sqrt{3}}\left(\frac{\sqrt{3}}{2}\sqrt{1 + 3} + \frac{1}{2}\ln\left(\sqrt{3} + \sqrt{1 + 3}\right) - 0\right) = 1 + \frac{1}{2\sqrt{3}}\ln\left(2 + \sqrt{3}\right) \end{aligned}$$



Graph of $r = \cos^2\theta$

Thus the total length equals $4L = 4 + \frac{2}{\sqrt{3}} \ln\left(2 + \sqrt{3}\right) \approx 5.52$.

In Exercises 31 and 32, express the length of the curve as an integral but do not evaluate it.

31. $r = (2 - \cos\theta)^{-1}, \quad 0 \le \theta \le 2\pi$

SOLUTION We have $f(\theta) = (2-\cos\theta)^{-1}$, $f'(\theta) = -(2-\cos\theta)^{-2}\sin\theta$, hence,

$$\sqrt{f^2(\theta) + f'(\theta)^2} = \sqrt{(2-\cos\theta)^{-2} + (2-\cos\theta)^{-4}\sin^2\theta} = \sqrt{(2-\cos\theta)^{-4}\left((2-\cos\theta)^2 + \sin^2\theta\right)}$$

$$= (2-\cos\theta)^{-2}\sqrt{4 - 4\cos\theta + \cos^2\theta + \sin^2\theta} = (2-\cos\theta)^{-2}\sqrt{5 - 4\cos\theta}$$

Using the integral for the arc length we get

$$L = \int_0^{2\pi} \sqrt{5 - 4\cos\theta}(2-\cos\theta)^{-2}\, d\theta.$$

32. $r = \sin^3 t, \quad 0 \le \theta \le 2\pi$

SOLUTION We have $f(t) = \sin^3 t$, $f'(t) = 3\sin^2 t\cos t$, so that

$$\sqrt{f(t)^2 + f'(t)^2} = \sqrt{\sin^6 t + 9\sin^4 t\cos^2 t} = \sin^2 t\sqrt{\sin^2 t + 9\cos^2 t}$$

$$= \sin^2 t\sqrt{\sin^2 t + \cos^2 t + 8\cos^2 t} = \sin^2 t\sqrt{1 + 8\cos^2 t}$$

Using the formula for arc length integral we get

$$L = \int_0^{2\pi} \sin^2 t\sqrt{1 + 8\cos^2 t}\, dt$$

In Exercises 33–36, use a computer algebra system to calculate the total length to two decimal places.

33. CAS The three-petal rose $r = \cos 3\theta$ in Figure 20

SOLUTION We have $f(\theta) = \cos 3\theta$, $f'(\theta) = -3\sin 3\theta$, so that

$$\sqrt{f(\theta)^2 + f'(\theta)^2} = \sqrt{\cos^2 3\theta + 9\sin^2 3\theta} = \sqrt{\cos^2 3\theta + \sin^2 3\theta + 8\sin^2 3\theta} = \sqrt{1 + 8\sin^2 3\theta}$$

Note that the curve is traversed completely for $0 \le \theta \le \pi$. Using the arc length formula and evaluating with Maple gives

$$L = \int_0^{\pi} \sqrt{f(\theta)^2 + f'(\theta)^2}\, d\theta = \int_0^{\pi} \sqrt{1 + 8\sin^2 3\theta}\, d\theta \approx 6.682446608$$

34. CAS The curve $r = 2 + \sin 2\theta$ in Figure 23

SOLUTION We have $f(\theta) = 2 + \sin 2\theta$, $f'(\theta) = 2\cos 2\theta$, so that

$$\sqrt{f(\theta)^2 + f'(\theta)^2} = \sqrt{(2 + \sin 2\theta)^2 + 4\cos^2 2\theta} = \sqrt{4 + 4\sin 2\theta + \sin^2 2\theta + 4\cos^2 2\theta}$$

$$= \sqrt{4 + 4\sin 2\theta + \sin^2 2\theta + \cos^2 2\theta + 3\cos^2 2\theta}$$

$$= \sqrt{5 + 4\sin 2\theta + 3\cos^2 2\theta}$$

The curve is traversed completely for $0 \le \theta \le 2\pi$. Using the arc length formula and evaluating with Maple gives

$$L = \int_0^{2\pi} \sqrt{f(\theta)^2 + f'(\theta)^2}\, d\theta = \int_0^{2\pi} \sqrt{f(\theta)^2 + f'(\theta)^2}\, d\theta \approx 15.40375907$$

35. CAS The curve $r = \theta \sin\theta$ in Figure 24 for $0 \le \theta \le 4\pi$

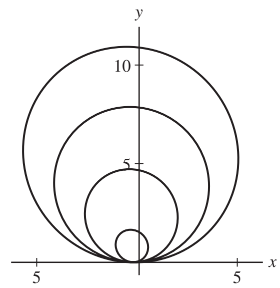


FIGURE 24 $r = \theta \sin\theta$ for $0 \le \theta \le 4\pi$.

SOLUTION We have $f(\theta) = \theta\sin\theta$, $f'(\theta) = \sin\theta + \theta\cos\theta$, so that

$$\sqrt{f(\theta)^2 + f'(\theta)^2} = \sqrt{\theta^2\sin^2\theta + (\sin\theta + \theta\cos\theta)^2} = \sqrt{\theta^2\sin^2\theta + \sin^2\theta + 2\theta\sin\theta\cos\theta + \theta^2\cos^2\theta}$$
$$= \sqrt{\theta^2 + \sin^2\theta + \theta\sin 2\theta}$$

using the identities $\sin^2\theta + \cos^2\theta = 1$ and $2\sin\theta\cos\theta = \sin 2\theta$. Thus by the arc length formula and evaluating with Maple, we have

$$L = \int_0^{4\pi} \sqrt{f(\theta)^2 + f'(\theta)^2}\,d\theta = \int_0^{4\pi} \sqrt{\theta^2 + \sin^2\theta + \theta\sin 2\theta}\,d\theta \approx 79.56423976$$

36. CAS $r = \sqrt{\theta}$, $0 \le \theta \le 4\pi$

SOLUTION We have $f(\theta) = \sqrt{\theta}$, $f'(\theta) = \frac{1}{2}\theta^{-1/2}$, so that

$$\sqrt{f(\theta)^2 + f'(\theta)^2} = \sqrt{\theta + \frac{1}{4\theta}}$$

so that by the arc length formula, evaluating with Maple, we have

$$L = \int_0^{4\pi} \sqrt{f(\theta)^2 + f'(\theta)^2}\,d\theta = \int_0^{4\pi} \sqrt{\theta + \frac{1}{4\theta}}\,d\theta \approx 30.50125041$$

Further Insights and Challenges

37. Suppose that the polar coordinates of a moving particle at time t are $(r(t), \theta(t))$. Prove that the particle's speed is equal to $\sqrt{(dr/dt)^2 + r^2(d\theta/dt)^2}$.

SOLUTION The speed of the particle in rectangular coordinates is:

$$\frac{ds}{dt} = \sqrt{x'(t)^2 + y'(t)^2} \tag{1}$$

We need to express the speed in polar coordinates. The x and y coordinates of the moving particles as functions of t are

$$x(t) = r(t)\cos\theta(t), \quad y(t) = r(t)\sin\theta(t)$$

We differentiate $x(t)$ and $y(t)$, using the Product Rule for differentiation. We obtain (omitting the independent variable t)

$$x' = r'\cos\theta - r(\sin\theta)\,\theta'$$
$$y' = r'\sin\theta - r(\cos\theta)\,\theta'$$

Hence,

$$x'^2 + y'^2 = \left(r'\cos\theta - r\theta'\sin\theta\right)^2 + \left(r'\sin\theta + r\theta'\cos\theta\right)^2$$
$$= r'^2\cos^2\theta - 2r'r\theta'\cos\theta\sin\theta + r^2\theta'^2\sin^2\theta + r'^2\sin^2\theta + 2r'r\theta'\sin^2\theta\cos\theta + r^2\theta'^2\cos^2\theta$$
$$= r'^2\left(\cos^2\theta + \sin^2\theta\right) + r^2\theta'^2\left(\sin^2\theta + \cos^2\theta\right) = r'^2 + r^2\theta'^2 \tag{2}$$

Substituting (2) into (1) we get

$$\frac{ds}{dt} = \sqrt{r'^2 + r^2\theta'^2} = \sqrt{\left(\frac{dr}{dt}\right)^2 + r^2\left(\frac{d\theta}{dt}\right)^2}$$

38. Compute the speed at time $t = 1$ of a particle whose polar coordinates at time t are $r = t, \theta = t$ (use Exercise 37). What would the speed be if the particle's rectangular coordinates were $x = t$, $y = t$? Why is the speed increasing in one case and constant in the other?

SOLUTION By Exercise 37 the speed of the particle is

$$\frac{ds}{dt} = \sqrt{\left(\frac{dr}{dt}\right)^2 + r^2\left(\frac{d\theta}{dt}\right)^2} \tag{1}$$

In this case $r = t$ and $\theta = t$ so $\frac{dr}{dt} = 1$ and $\frac{d\theta}{dt} = 1$. Substituting into (1) gives the following function of the speed:

$$\frac{ds}{dt} = \sqrt{1 + r(t)^2}$$

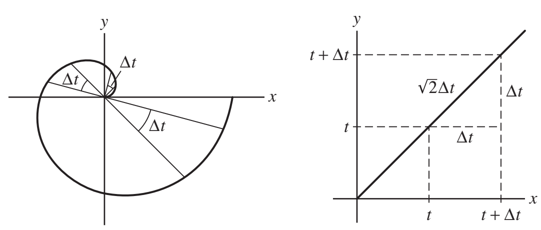
The speed expressed in rectangular coordinates is

$$\frac{ds}{dt} = \sqrt{x'(t)^2 + y'(t)^2}$$

If $x = t$ and $y = t$, then $x'(t) = 1$ and $y'(t) = 1$. So the speed of the particle at time t is

$$\frac{ds}{dt} = \sqrt{1^2 + 1^2} = \sqrt{2}$$

On the curve $x = t$, $y = t$ the particle travels the same distance $\Delta t\sqrt{2}$ for all time intervals Δt, hence, it has a constant speed. However, on the spiral $r = t, \theta = t$ the particle travels greater distances for time intervals $(t, t + \Delta t)$ as t increases, hence the speed is an increasing function of t.



$x = t, y = t$ $\qquad$ $r = t, \theta = t$

11.5 Conic Sections

Preliminary Questions

1. Which of the following equations defines an ellipse? Which does not define a conic section?

(a) $4x^2 - 9y^2 = 12$ **(b)** $-4x + 9y^2 = 0$

(c) $4y^2 + 9x^2 = 12$ **(d)** $4x^3 + 9y^3 = 12$

SOLUTION

(a) This is the equation of the hyperbola $\left(\frac{x}{\sqrt{3}}\right)^2 - \left(\frac{y}{\frac{2}{\sqrt{3}}}\right)^2 = 1$, which is a conic section.

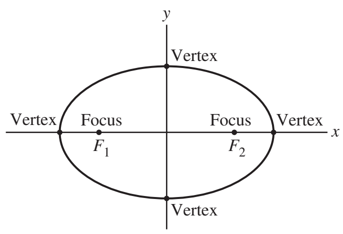
(b) The equation $-4x + 9y^2 = 0$ can be rewritten as $x = \frac{9}{4}y^2$, which defines a parabola. This is a conic section.

(c) The equation $4y^2 + 9x^2 = 12$ can be rewritten in the form $\left(\frac{y}{\sqrt{3}}\right)^2 + \left(\frac{x}{\frac{2}{\sqrt{3}}}\right)^2 = 1$, hence it is the equation of an ellipse, which is a conic section.

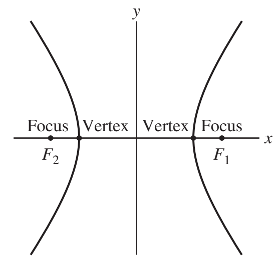
(d) This is not the equation of a conic section, since it is not an equation of degree two in x and y.

2. For which conic sections do the vertices lie between the foci?

SOLUTION If the vertices lie between the foci, the conic section is a hyperbola.



ellipse: foci between vertices

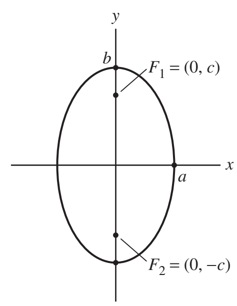


hyperbola: vertices between foci

3. What are the foci of

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1 \quad \text{if } a < b?$$

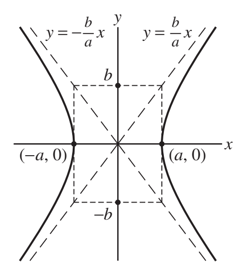
SOLUTION If $a < b$ the foci of the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$ are at the points $(0, c)$ and $(0, -c)$ on the y-axis, where $c = \sqrt{b^2 - a^2}$.



$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1; a < b$

4. What is the geometric interpretation of b/a in the equation of a hyperbola in standard position?

SOLUTION The vertices, i.e., the points where the focal axis intersects the hyperbola, are at the points $(a, 0)$ and $(-a, 0)$. The values $\pm\frac{b}{a}$ are the slopes of the two asymptotes of the hyperbola.



Hyperbola in standard position

Exercises

In Exercises 1–6, find the vertices and foci of the conic section.

1. $\left(\frac{x}{9}\right)^2 + \left(\frac{y}{4}\right)^2 = 1$

SOLUTION This is an ellipse in standard position with $a = 9$ and $b = 4$. Hence, $c = \sqrt{9^2 - 4^2} = \sqrt{65} \approx 8.06$. The foci are at $F_1 = (-8.06, 0)$ and $F_2 = (8.06, 0)$, and the vertices are $(9, 0)$, $(-9, 0)$, $(0, 4)$, $(0, -4)$.

2. $\dfrac{x^2}{9} + \dfrac{y^2}{4} = 1$

SOLUTION Writing the equation in the from $\left(\frac{x}{3}\right)^2 + \left(\frac{y}{2}\right)^2 = 1$ we get an ellipse with $a = 3$ and $b = 2$. Hence $c = \sqrt{3^2 - 2^2} = \sqrt{5} \approx 2.24$. The foci are at $F_1 = (-2.24, 0)$ and $F_2 = (2.24, 0)$ and the vertices are $(3, 0)$, $(-3, 0)$, $(0, 2)$, $(0, -2)$.

3. $\left(\frac{x}{4}\right)^2 - \left(\frac{y}{9}\right)^2 = 1$

SOLUTION This is a hyperbola in standard position with $a = 4$ and $b = 9$. Hence, $c = \sqrt{a^2 + b^2} = \sqrt{97} \approx 9.85$. The foci are at $(\pm\sqrt{97}, 0)$ and the vertices are $(\pm 2, 0)$.

4. $\frac{x^2}{4} - \frac{y^2}{9} = 36$

SOLUTION Putting this equation in standard form gives

$$\left(\frac{x}{12}\right)^2 - \left(\frac{y}{18}\right)^2 = 1$$

so this is a hyperbola in standard position with $a = 12$ and $b = 18$. Thus

$$c = \sqrt{a^2 + b^2} = 6\sqrt{13} \approx 21.633$$

The foci are at $(\pm 6\sqrt{13}, 0)$ and the vertices are at $(\pm 12, 0)$.

5. $\left(\frac{x-3}{7}\right)^2 - \left(\frac{y+1}{4}\right)^2 = 1$

SOLUTION We first consider the hyperbola $\left(\frac{x}{7}\right)^2 - \left(\frac{y}{4}\right)^2 = 1$. For this hyperbola, $a = 7$, $b = 4$ and $c = \sqrt{7^2 + 4^2} \approx 8.06$. Hence, the foci are at $(8.06, 0)$ and $(-8.06, 0)$ and the vertices are at $(7, 0)$ and $(-7, 0)$. Since the given hyperbola is obtained by translating the center of the hyperbola $\left(\frac{x}{7}\right)^2 - \left(\frac{y}{4}\right)^2 = 1$ to the point $(3, -1)$, the foci are at $F_1 = (8.06 + 3, 0 - 1) = (11.06, -1)$ and $F_2 = (-8.06 + 3, 0 - 1) = (-5.06, -1)$ and the vertices are $A = (7 + 3, 0 - 1) = (10, -1)$ and $A' = (-7 + 3, 0 - 1) = (-4, -1)$.

6. $\left(\frac{x-3}{4}\right)^2 + \left(\frac{y+1}{7}\right)^2 = 1$

SOLUTION We first consider the ellipse $\left(\frac{x}{4}\right)^2 + \left(\frac{y}{7}\right)^2 = 1$. Hence, $a = 4$ and $b = 7$ so $a < b$ and the focal axis is vertical. $c = \sqrt{7^2 - 4^2} \approx 5.74$ hence the foci are at $(0, 5.74)$ and $(0, -5.74)$. The vertices are $(4, 0)$, $(-4, 0)$, $(0, 7)$, $(0, -7)$. When we translate the ellipse so that its center is $(3, -1)$, the points above are translated so that the new vertices are $(4 + 3, 0 - 1) = (7, -1)$, $(-4 + 3, 0 - 1) = (-1, -1)$, $(0 + 3, 7 - 1) = (3, 6)$ and $(0 + 3, -7 - 1) = (3, -8)$. The new foci are at $(3, 4.74)$ and $(3, -6.74)$.

In Exercises 7–10, find the equation of the ellipse obtained by translating (as indicated) the ellipse

$$\left(\frac{x-8}{6}\right)^2 + \left(\frac{y+4}{3}\right)^2 = 1$$

7. Translated with center at the origin

SOLUTION Recall that the equation

$$\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1$$

describes an ellipse with center (h, k). Thus, for our ellipse to be located at the origin, it must have equation

$$\frac{x^2}{6^2} + \frac{y^2}{3^2} = 1$$

8. Translated with center at $(-2, -12)$

SOLUTION Recall that the equation

$$\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1$$

describes an ellipse with center (h, k). Thus, for our ellipse to have center $(-2, -12)$, it must have equation

$$\frac{(x+2)^2}{6^2} + \frac{(y+12)^2}{3^2} = 1$$

9. Translated to the right six units

SOLUTION Recall that the equation

$$\frac{(x-h)^2}{a^2}+\frac{(y-k)^2}{b^2}=1$$

describes an ellipse with center (h, k). The original ellipse has center at $(8, -4)$, so we want an ellipse with center $(14, -4)$. Thus its equation is

$$\frac{(x-14)^2}{6^2}+\frac{(y+4)^2}{3^2}=1$$

10. Translated down four units

SOLUTION Recall that the equation

$$\frac{(x-h)^2}{a^2}+\frac{(y-k)^2}{b^2}=1$$

describes an ellipse with center (h, k). The original ellipse has center at $(8, -4)$, so we want an ellipse with center $(8, -8)$. Thus its equation is

$$\frac{(x-8)^2}{6^2}+\frac{(y+8)^2}{3^2}=1$$

In Exercises 11–14, find the equation of the given ellipse.

11. Vertices $(\pm 5, 0)$ and $(0, \pm 7)$

SOLUTION Since both sets of vertices are symmetric around the origin, the center of the ellipse is at $(0, 0)$. We have $a = 5$ and $b = 7$, so the equation of the ellipse is

$$\left(\frac{x}{5}\right)^2+\left(\frac{y}{7}\right)^2=1$$

12. Foci $(\pm 6, 0)$ and focal vertices $(\pm 10, 0)$

SOLUTION The equation is $\left(\frac{x}{a}\right)^2+\left(\frac{y}{b}\right)^2=1$ with $a = 10$. The foci are $(\pm c, 0)$ with $c = 6$, so we use the relation $c=\sqrt{a^2-b^2}$ to find b:

$$b^2=a^2-c^2=10^2-6^2=64 \Rightarrow b=8$$

Therefore the equation of the ellipse is

$$\left(\frac{x}{10}\right)^2+\left(\frac{y}{8}\right)^2=1.$$

13. Foci $(0, \pm 10)$ and eccentricity $e = \frac{3}{5}$

SOLUTION Since the foci are on the y axis, this ellipse has a vertical major axis with center $(0, 0)$, so its equation is

$$\left(\frac{x}{b}\right)^2+\left(\frac{y}{a}\right)^2=1$$

We have $a=\frac{c}{e}=\frac{10}{3/5}=\frac{50}{3}$ and

$$b=\sqrt{a^2-c^2}=\sqrt{\frac{2500}{9}-100}=\frac{1}{3}\sqrt{2500-900}=\frac{40}{3}$$

Thus the equation of the ellipse is

$$\left(\frac{x}{40/3}\right)^2+\left(\frac{y}{50/3}\right)^2=1$$

14. Vertices $(4, 0)$, $(28, 0)$ and eccentricity $e = \frac{2}{3}$

SOLUTION This ellipse has a horizontal major axis with center midway between the vertices, at $(16, 0)$. Thus if the center were at $(0, 0)$, the ellipse would have vertices $(\pm 12, 0)$, so that $a = 12$ and $c = ae = 12 \cdot \frac{2}{3} = 8$. Then

$$b=\sqrt{a^2-c^2}=\sqrt{12^2-8^2}=\sqrt{80}=4\sqrt{5}$$

Finally, translating the center to (16, 0), the equation of the ellipse is

$$\left(\frac{(x-16)}{12}\right)^2 + \left(\frac{y}{4\sqrt{5}}\right)^2 = 1$$

In Exercises 15–20, find the equation of the given hyperbola.

15. Vertices $(\pm 3, 0)$ and foci $(\pm 5, 0)$

SOLUTION The equation is $\left(\frac{x}{a}\right)^2 - \left(\frac{y}{b}\right)^2 = 1$. The vertices are $(\pm a, 0)$ with $a = 3$ and the foci $(\pm c, 0)$ with $c = 5$. We use the relation $c = \sqrt{a^2 + b^2}$ to find b:

$$b = \sqrt{c^2 - a^2} = \sqrt{5^2 - 3^2} = \sqrt{16} = 4$$

Therefore, the equation of the hyperbola is

$$\left(\frac{x}{3}\right)^2 - \left(\frac{y}{4}\right)^2 = 1.$$

16. Vertices $(\pm 3, 0)$ and asymptotes $y = \pm\frac{1}{2}x$

SOLUTION The equation is $\left(\frac{x}{a}\right)^2 - \left(\frac{y}{b}\right)^2 = 1$. The vertices are $(\pm a, 0)$ with $a = 3$ and the asymptotes are $y = \pm\frac{b}{a}x$ with $\frac{b}{a} = \frac{1}{2}$. Hence, $b = \frac{a}{2} = \frac{3}{2}$ so the equation of the hyperbola is

$$\left(\frac{x}{3}\right)^2 - \left(\frac{y}{3/2}\right)^2 = 1$$

17. Foci $(\pm 4, 0)$ and eccentricity $e = 2$

SOLUTION We have $c = 4$ and $e = 2$; from $c = ae$ we get $a = 2$, and then

$$b = \sqrt{c^2 - a^2} = \sqrt{4^2 - 2^2} = 2\sqrt{3}$$

The hyperbola has center at (0, 0) and horizontal axis, so its equation is

$$\left(\frac{x}{2}\right)^2 - \left(\frac{y}{2\sqrt{3}}\right)^2 = 1$$

18. Vertices $(0, \pm 6)$ and eccentricity $e = 3$

SOLUTION The hyperbola has a vertical focal axis and center at (0, 0), so has equation

$$\left(\frac{y}{b}\right)^2 - \left(\frac{x}{a}\right)^2 = 1$$

$b = 6$ and $e = 3$ implies, since $be = c$, that $c = 18$, and

$$a = \sqrt{c^2 - b^2} = \sqrt{18^2 - 6^2} = \sqrt{288} = 12\sqrt{2}$$

Thus the equation of the hyperbola is

$$\left(\frac{y}{6}\right)^2 - \left(\frac{x}{12\sqrt{2}}\right)^2 = 1$$

19. Vertices $(-3, 0)$, $(7, 0)$ and eccentricity $e = 3$

SOLUTION The center is at $\frac{-3+7}{2} = 2$ with a horizontal focal axis, so the equation is

$$\left(\frac{x-2}{a}\right)^2 - \left(\frac{y}{b}\right)^2 = 1.$$

Then $a = 7 - 2 = 5$, and $c = ae = 5 \cdot 3 = 15$. Finally,

$$b = \sqrt{c^2 - a^2} = \sqrt{15^2 - 5^2} = 10\sqrt{2}$$

so that the equation of the hyperbola is

$$\left(\frac{x-2}{5}\right)^2 - \left(\frac{y}{10\sqrt{2}}\right)^2 = 1$$

20. Vertices $(0, -6)$, $(0, 4)$ and foci $(0, -9)$, $(0, 7)$

SOLUTION The center of the hyperbola is at $\frac{-6+4}{2} = -1$ along the y axis; we write the equation as

$$\left(\frac{y+1}{b}\right)^2 - \left(\frac{x}{a}\right)^2 = 1$$

$b = 5$ since it is the distance from the given vertex to the center, and $c = 8$ since it is the distance from the foci to the center. Then

$$a = \sqrt{c^2 - b^2} = \sqrt{64 - 25} = \sqrt{39}$$

so that the equation of the hyperbola is

$$\left(\frac{y+1}{5}\right)^2 - \left(\frac{x}{\sqrt{39}}\right)^2 = 1$$

In Exercises 21–28, find the equation of the parabola with the given properties.

21. Vertex $(0, 0)$, focus $\left(\frac{1}{12}, 0\right)$

SOLUTION Since the focus is on the x-axis rather than the y-axis, and the vertex is $(0, 0)$, the equation is $x = \frac{1}{4c}y^2$. The focus is $(0, c)$ with $c = \frac{1}{12}$, so the equation is

$$x = \frac{1}{4 \cdot \frac{1}{12}}y^2 = 3y^2$$

22. Vertex $(0, 0)$, focus $(0, 2)$

SOLUTION The vertex is at $(0, 0)$, so the equation is $y = \frac{1}{4c}x^2 = \frac{1}{8}x^2$.

23. Vertex $(0, 0)$, directrix $y = -5$

SOLUTION The equation is $y = \frac{1}{4c}x^2$. The directrix is $y = -c$ with $c = 5$, hence $y = \frac{1}{20}x^2$.

24. Vertex $(3, 4)$, directrix $y = -2$

SOLUTION If the graph were translated to the origin, the vertex would be $(0, 0)$ and the directrix would be translated down 4 units so would be $y = -6$. Then $c = 6$ so the equation is $y = \frac{1}{4c}x^2 = \frac{1}{24}x^2$. Translating back to $(3, 4)$ gives

$$y = \frac{1}{24}(x-3)^2 + 4$$

25. Focus $(0, 4)$, directrix $y = -4$

SOLUTION The focus is $(0, c)$ with $c = 4$ and the directrix is $y = -c$ with $c = 4$, hence the equation of the parabola is

$$y = \frac{1}{4c}x^2 = \frac{x^2}{16}.$$

26. Focus $(0, -4)$, directrix $y = 4$

SOLUTION The focus is at $(0, c)$ with $c = -4$ and the directrix is $y = -c$ with $c = -4$, hence the equation $y = \frac{x^2}{4c}$ of the parabola becomes $y = -\frac{x^2}{16}$. Since $c < 0$, the parabola is open downward.

27. Focus $(2, 0)$, directrix $x = -2$

SOLUTION The focus is on the x-axis rather than on the y-axis and the directrix is a vertical line rather than horizontal as in the parabola in standard position. Therefore, the equation of the parabola is obtained by interchanging x and y in $y = \frac{1}{4c}x^2$. Also, by the given information $c = 2$. Hence, $x = \frac{1}{4c}y^2 = \frac{1}{4 \cdot 2}y^2$ or $x = \frac{y^2}{8}$.

28. Focus $(-2, 0)$, vertex $(2, 0)$

SOLUTION The vertex is always midway between the focus and the directrix, so the directrix must be the vertical line $x = 6$, and $c = -2 - 2 = -4$. Since the directrix is a vertical line, the parabola is obtained by interchanging x and y in the equation for a parabola in standard position. Finally, $c = -2 - 2 = -4$ is the distance from the vertex to the focus, so the equation is

$$x - 2 = \frac{1}{4c}y^2 = -\frac{1}{16}y^2, \quad \text{so} \quad x = 2 - \frac{1}{16}y^2$$

In Exercises 29–38, find the vertices, foci, center (if an ellipse or a hyperbola), and asymptotes (if a hyperbola).

29. $x^2 + 4y^2 = 16$

SOLUTION We first divide the equation by 16 to convert it to the equation in standard form:

$$\frac{x^2}{16} + \frac{4y^2}{16} = 1 \Rightarrow \frac{x^2}{16} + \frac{y^2}{4} = 1 \Rightarrow \left(\frac{x}{4}\right)^2 + \left(\frac{y}{2}\right)^2 = 1$$

For this ellipse, $a = 4$ and $b = 2$ hence $c = \sqrt{4^2 - 2^2} = \sqrt{12} \approx 3.5$. Since $a > b$ we have:

- The vertices are at $(\pm 4, 0)$, $(0, \pm 2)$.
- The foci are $F_1 = (-3.5, 0)$ and $F_2 = (3.5, 0)$.
- The focal axis is the x-axis and the conjugate axis is the y-axis.
- The ellipse is centered at the origin.

30. $4x^2 + y^2 = 16$

SOLUTION We divide the equation by 16 to rewrite it in the standard form:

$$\frac{4x^2}{16} + \frac{y^2}{16} = 1 \Rightarrow \frac{x^2}{4} + \frac{y^2}{16} = 1 \Rightarrow \left(\frac{x}{2}\right)^2 + \left(\frac{y}{4}\right)^2 = 1$$

This is the equation of an ellipse with $a = 2$, $b = 4$. Since $a < b$ the focal axis is the y-axis. Also, $c = \sqrt{4^2 - 2^2} = \sqrt{12} \approx 3.5$. We get:

- The vertices are at $(\pm 2, 0)$, $(0, \pm 4)$.
- The foci are $(0, \pm 3.5)$.
- The focal axis is the y-axis and the conjugate axis is the x-axis.
- The center is at the origin.

31. $\left(\frac{x-3}{4}\right)^2 - \left(\frac{y+5}{7}\right)^2 = 1$

SOLUTION For this hyperbola $a = 4$ and $b = 7$ so $c = \sqrt{4^2 + 7^2} = \sqrt{65} \approx 8.06$. For the standard hyperbola $\left(\frac{x}{4}\right)^2 - \left(\frac{y}{7}\right)^2 = 1$, we have

- The vertices are $A = (4, 0)$ and $A' = (-4, 0)$.
- The foci are $F = (\sqrt{65}, 0)$ and $F' = (-\sqrt{65}, 0)$.
- The focal axis is the x-axis $y = 0$, and the conjugate axis is the y-axis $x = 0$.
- The center is at the midpoint of $\overline{FF'}$; that is, at the origin.
- The asymptotes $y = \pm\frac{b}{a}x$ are $y = \pm\frac{7}{4}x$.

The given hyperbola is a translation of the standard hyperbola, 3 units to the right and 5 units downward. Hence the following holds:

- The vertices are at $A = (7, -5)$ and $A' = (-1, -5)$.
- The foci are at $F = (3 + \sqrt{65}, -5)$ and $F' = (3 - \sqrt{65}, -5)$.
- The focal axis is $y = -5$ and the conjugate axis is $x = 3$.
- The center is at $(3, -5)$.
- The asymptotes are $y + 5 = \pm\frac{7}{4}(x - 3)$.

32. $3x^2 - 27y^2 = 12$

SOLUTION We first rewrite the equation in the standard form:

$$\frac{3x^2}{12} - \frac{27y^2}{12} = 1 \Rightarrow \frac{x^2}{4} - \frac{y^2}{\frac{4}{9}} = 1 \Rightarrow \left(\frac{x}{2}\right)^2 - \left(\frac{y}{\frac{2}{3}}\right)^2 = 1$$

This is the equation of an hyperbola in standard position. We have $a = 2$, $b = \frac{2}{3}$ and $c = \sqrt{2^2 + \left(\frac{2}{3}\right)^2} \approx 2.1$. Hence:

- The vertices are $(\pm 2, 0)$.
- The foci are $(\pm 2.1, 0)$.

- The focal axis is the x-axis and the conjugate axis is the y-axis.
- The center is at the origin.
- The asymptotes are $y = \pm\frac{b}{a}x$, that is, $y = \pm\frac{1}{3}x$.

33. $4x^2 - 3y^2 + 8x + 30y = 215$

SOLUTION Since there is no cross term, we complete the square of the terms involving x and y separately:

$$4x^2 - 3y^2 + 8x + 30y = 4\left(x^2 + 2x\right) - 3\left(y^2 - 10y\right) = 4(x+1)^2 - 4 - 3(y-5)^2 + 75 = 215$$

Hence,

$$4(x+1)^2 - 3(y-5)^2 = 144$$
$$\frac{4(x+1)^2}{144} - \frac{3(y-5)^2}{144} = 1$$
$$\left(\frac{x+1}{6}\right)^2 - \left(\frac{y-5}{\sqrt{48}}\right)^2 = 1$$

This is the equation of the hyperbola obtained by translating the hyperbola $\left(\frac{x}{6}\right)^2 - \left(\frac{y}{\sqrt{48}}\right)^2 = 1$ one unit to the left and five units upwards. Since $a = 6$, $b = \sqrt{48}$, we have $c = \sqrt{36+48} = \sqrt{84} \sim 9.2$. We obtain the following table:

	Standard position	Translated hyperbola
vertices	$(6, 0), (-6, 0)$	$(5, 5), (-7, 5)$
foci	$(\pm 9.2, 0)$	$(8.2, 5), (-10.2, 5)$
focal axis	The x-axis	$y = 5$
conjugate axis	The y-axis	$x = -1$
center	The origin	$(-1, 5)$
asymptotes	$y = \pm 1.15x$	$y = -1.15x + 3.85$ $y = 1.15x + 6.15$

34. $y = 4x^2$

SOLUTION This is the parabola in standard position $y = \frac{1}{4c}x^2$ with $c = \frac{1}{16}$. The vertex of the parabola is at the origin, the focus is $F = \left(0, \frac{1}{16}\right)$ and the axis is the y-axis.

35. $y = 4(x-4)^2$

SOLUTION By Exercise 34, the parabola $y = 4x^2$ has the vertex at the origin, the focus at $\left(0, \frac{1}{16}\right)$ and its axis is the y-axis. Our parabola is a translation of the standard parabola four units to the right. Hence its vertex is at $(4, 0)$, the focus is at $\left(4, \frac{1}{16}\right)$ and its axis is the vertical line $x = 4$.

36. $8y^2 + 6x^2 - 36x - 64y + 134 = 0$

SOLUTION We first identify the conic section. Since there is no cross term, we complete the square of the terms involving x and y terms separately:

$$\begin{aligned}8y^2 + 6x^2 - 36x - 64y + 134 &= 6\left(x^2 - 6x\right) + 8\left(y^2 - 8y\right) + 134\\ &= 6(x-3)^2 - 54 + 8(y-4)^2 - 128 + 134\\ &= 6(x-3)^2 + 8(y-4)^2 - 48\end{aligned}$$

We obtain the following equation:

$$6(x-3)^2 + 8(y-4)^2 - 48 = 0$$
$$3(x-3)^2 + 4(y-4)^2 = 24$$
$$\left(\frac{x-3}{\sqrt{8}}\right)^2 + \left(\frac{y-4}{\sqrt{6}}\right)^2 = 1$$

We identify the conic as a translation of the ellipse $\left(\frac{x}{\sqrt{8}}\right)^2 + \left(\frac{y}{\sqrt{6}}\right)^2 = 1$, so that the center is at $c = (3, 4)$. Since $a = \sqrt{8}$, $b = \sqrt{6}$ and $a > b$ the foci of the standard ellipse are $\left(-\sqrt{2}, 0\right)$ and $\left(\sqrt{2}, 0\right)$ for $\sqrt{2} = c = \sqrt{a^2 - b^2}$. Hence the foci of the translated ellipse are $\left(3-\sqrt{2},4\right)$ and $\left(3+\sqrt{2},4\right)$. The vertices $\left(\pm\sqrt{8},0\right)$ and $\left(0,\pm\sqrt{6}\right)$ of the standard ellipse are translated to the points $\left(3\pm\sqrt{8},4\right)$ and $\left(3,4\pm\sqrt{6}\right)$. The focal axis is the line $y=4$, and the conjugate axis is the line $x=3$.

37. $4x^2+25y^2-8x-10y=20$

SOLUTION Since there are no cross terms this conic section is obtained by translating a conic section in standard position. To identify the conic section we complete the square of the terms involving x and y separately:

$$\begin{aligned}4x^2+25y^2-8x-10y &= 4\left(x^2-2x\right)+25\left(y^2-\frac{2}{5}y\right)\\ &= 4(x-1)^2-4+25\left(y-\frac{1}{5}\right)^2-1\\ &= 4(x-1)^2+25\left(y-\frac{1}{5}\right)^2-5=20\end{aligned}$$

Hence,

$$\begin{aligned}4(x-1)^2+25\left(y-\frac{1}{5}\right)^2&=25\\ \frac{4}{25}(x-1)^2+\left(y-\frac{1}{5}\right)^2&=1\\ \left(\frac{x-1}{\frac{5}{2}}\right)^2+\left(y-\frac{1}{5}\right)^2&=1\end{aligned}$$

This is the equation of the ellipse obtained by translating the ellipse in standard position $\left(\frac{x}{\frac{5}{2}}\right)^2+y^2=1$ one unit to the right and $\frac{1}{5}$ unit upward. Since $a=\frac{5}{2}$, $b=1$ we have $c=\sqrt{\left(\frac{5}{2}\right)^2-1}\approx 2.3$, so we obtain the following table:

	Standard position	Translated ellipse
Vertices	$\left(\pm\frac{5}{2},0\right),(0,\pm 1)$	$\left(1\pm\frac{5}{2},\frac{1}{5}\right),\left(1,\frac{1}{5}\pm 1\right)$
Foci	$(-2.3,0),(2.3,0)$	$\left(-1.3,\frac{1}{5}\right),\left(3.3,\frac{1}{5}\right)$
Focal axis	The x-axis	$y=\frac{1}{5}$
Conjugate axis	The y-axis	$x=1$
Center	The origin	$\left(1,\frac{1}{5}\right)$

38. $16x^2+25y^2-64x-200y+64=0$

SOLUTION There is no cross term in this equation, so the conic section is obtained by translating a conic section in standard position. Complete the square in each variable:

$$\begin{aligned}-64 &= 16x^2+25y^2-64x-200y=16x^2-64x+64+25y^2-200y+400-64-400\\ &= 16(x^2-4x+4)+25(y^2-8y+16)-464=16(x-2)^2+25(y-4)^2-464\end{aligned}$$

Collecting constants gives

$$16(x-2)^2+25(y-4)^2=400$$

and dividing through by 400 gives an ellipse whose equation in standard form is so that the curve is an ellipse whose equation in standard form is

$$\left(\frac{x-2}{5}\right)^2+\left(\frac{y-4}{4}\right)^2=1$$

Thus the center of the ellipse is $(2,4)$. The focal axis is $y=4$, because $a=5$ and $b=4$ imply that the focal axis is horizontal. Thus the conjugate axis is $x=2$. $c=\sqrt{a^2-b^2}=\sqrt{25-16}=3$. Thus

- The vertices are $(2\pm 5,4)$ and $(2,4\pm 4)$, so are $(-3,4)$, $(7,4)$, $(2,0)$, and $(2,8)$.
- The foci are $(2\pm 3,4)$ so are $(5,4)$ and $(-1,4)$.

In Exercises 39–42, use the Discriminant Test to determine the type of the conic section (in each case, the equation is nondegenerate). Plot the curve if you have a computer algebra system.

39. $4x^2 + 5xy + 7y^2 = 24$

SOLUTION Here, $D = 25 - 4 \cdot 4 \cdot 7 = -87$, so the conic section is an ellipse.

40. $x^2 - 2xy + y^2 + 24x - 8 = 0$

SOLUTION Here, $D = 4 - 4 \cdot 1 \cdot 1 = 0$, giving us a parabola.

41. $2x^2 - 8xy + 3y^2 - 4 = 0$

SOLUTION Here, $D = 64 - 4 \cdot 2 \cdot 3 = 40$, giving us a hyperbola.

42. $2x^2 - 3xy + 5y^2 - 4 = 0$

SOLUTION Here, $D = 9 - 4 \cdot 2 \cdot (5) = -31$, giving us an ellipse or a circle. Since the coefficients of x^2 and y^2 are different, the curve is an ellipse.

43. Show that the "conic" $x^2 + 3y^2 - 6x + 12y + 23 = 0$ has no points.

SOLUTION Complete the square in each variable separately:

$$-23 = x^2 - 6x + 3y^2 + 12y = (x^2 - 6x + 9) + (3y^2 + 12y + 12) - 9 - 12 = (x-3)^2 + 3(y+2)^2 - 21$$

Collecting constants and reversing sides gives

$$(x-3)^2 + 3(y+2)^2 = -2$$

which has no solutions since the left-hand side is a sum of two squares so is always nonnegative.

44. For which values of a does the conic $3x^2 + 2y^2 - 16y + 12x = a$ have at least one point?

SOLUTION Complete the square in each variable:

$$a = 3x^2 + 2y^2 - 16y + 12x = 3x^2 + 12x + 12 + 2y^2 - 16y + 32 - 12 - 32 = 3(x+2)^2 + 2(x-4)^2 - 44$$

so that, collecting constants,

$$3(x+2)^2 + 2(x-4)^2 = a + 44$$

The left-hand side is a sum of two squares, so is always nonnegative, so in order for the conic (ellipse) to have at least one point, we must have $a + 44 \ge 0$, or $a \ge -44$.

45. Show that $\frac{b}{a} = \sqrt{1 - e^2}$ for a standard ellipse of eccentricity e.

SOLUTION By the definition of eccentricity:

$$e = \frac{c}{a} \tag{1}$$

For the ellipse in standard position, $c = \sqrt{a^2 - b^2}$. Substituting into (1) and simplifying yields

$$e = \frac{\sqrt{a^2 - b^2}}{a} = \sqrt{\frac{a^2 - b^2}{a^2}} = \sqrt{1 - \left(\frac{b}{a}\right)^2}$$

We square the two sides and solve for $\frac{b}{a}$:

$$e^2 = 1 - \left(\frac{b}{a}\right)^2 \Rightarrow \left(\frac{b}{a}\right)^2 = 1 - e^2 \Rightarrow \frac{b}{a} = \sqrt{1 - e^2}$$

46. Show that the eccentricity of a hyperbola in standard position is $e = \sqrt{1 + m^2}$, where $\pm m$ are the slopes of the asymptotes.

SOLUTION By the definition of eccentricity, we have:

$$e = \frac{c}{a} \tag{1}$$

For the hyperbola in standard position, $c = \sqrt{a^2 + b^2}$, by substituting in (1) we get

$$e = \frac{\sqrt{a^2 + b^2}}{a} = \sqrt{\frac{a^2 + b^2}{a^2}} = \sqrt{1 + \left(\frac{b}{a}\right)^2} \tag{2}$$

The slopes of the asymptotes are $\pm\frac{b}{a}$. Setting $m = \frac{b}{a}$ we get

$$e = \sqrt{1 + m^2}$$

47. Explain why the dots in Figure 23 lie on a parabola. Where are the focus and directrix located?

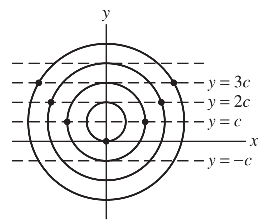


FIGURE 23

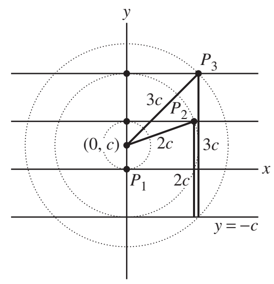
SOLUTION All the circles are centered at $(0, c)$ and the kth circle has radius kc. Hence the indicated point P_k on the kth circle has a distance kc from the point $F = (0, c)$. The point P_k also has distance kc from the line $y = -c$. That is, the indicated point on each circle is equidistant from the point $F = (0, c)$ and the line $y = -c$, hence it lies on the parabola with focus at $F = (0, c)$ and directrix $y = -c$.



48. Find the equation of the ellipse consisting of points P such that $PF_1 + PF_2 = 12$, where $F_1 = (4, 0)$ and $F_2 = (-2, 0)$.

SOLUTION This is a translation one unit to the right of an ellipse in standard position with foci $F_1 = (3, 0)$ and $F_2 = (-3, 0)$; points P on this ellipse therefore also satisfy the equation $PF_1 + PF_2 = 12$. But $PF_1 + PF_2 = 2a$ so that $a = 6$; since $(3, 0)$ is a focus, $c = 3$, so that $b = \sqrt{a^2 - c^2} = \sqrt{36 - 9} = 3\sqrt{3}$. The equation of the ellipse in standard position is therefore

$$\frac{x^2}{36} + \frac{y^2}{27} = 1$$

so that the equation of the desired ellipse is

$$\frac{(x-1)^2}{36} + \frac{y^2}{27} = 1$$

49. A **latus rectum** of a conic section is a chord through a focus parallel to the directrix. Find the area bounded by the parabola $y = x^2/(4c)$ and its latus rectum (refer to Figure 8).

SOLUTION The directrix is $y = -c$, and the focus is $(0, c)$. The chord through the focus parallel to $y = -c$ is clearly $y = c$; this line intersects the parabola when $c = x^2/(4c)$ or $4c^2 = x^2$, so when $x = \pm 2c$. The desired area is then

$$\int_{-2c}^{2c} c - \frac{1}{4c}x^2\,dx = \left(c\,x - \frac{1}{12c}x^3\right)\Big|_{-2c}^{2c}$$
$$= 2c^2 - \frac{8c^3}{12c} - \left(-2c^2 - \frac{(-2c)^3}{12c}\right) = 4c^2 - \frac{4}{3}c^2 = \frac{8}{3}c^2$$

50. Show that the tangent line at a point $P = (x_0, y_0)$ on the hyperbola $\left(\frac{x}{a}\right)^2 - \left(\frac{y}{b}\right)^2 = 1$ has equation

$$Ax - By = 1$$

where $A = \dfrac{x_0}{a^2}$ and $B = \dfrac{y_0}{b^2}$.

SOLUTION The equation of the tangent line is

$$y - y_0 = m\,(x - x_0)\,;\;\; m = \frac{dy}{dx}\Big|_{x=x_0,\,y=y_0} \tag{1}$$

To find the slope m we first implicitly differentiate the equation of the hyperbola with respect to x, which gives

$$2\left(\frac{x}{a}\right)\cdot\frac{1}{a}-2\left(\frac{y}{b}\right)\cdot\frac{1}{b}y'=0$$
$$\frac{x}{a^2}=\frac{y}{b^2}y'\Rightarrow y'=\frac{b^2}{a^2}\left(\frac{x}{y}\right)$$

We substitute $x=x_0$, $y=y_0$ to obtain the following slope of the tangent line:

$$m=\frac{b^2}{a^2}\frac{x_0}{y_0}=\frac{x_0}{a^2}\cdot\frac{b^2}{y_0}=A\cdot\frac{1}{B}=\frac{A}{B} \tag{2}$$

Substituting (2) in (1) gives

$$y-y_0=\frac{A}{B}(x-x_0)$$
$$By-By_0=Ax-Ax_0\Rightarrow Ax-By=Ax_0-By_0 \tag{3}$$

Now,

$$Ax_0-By_0=\frac{x_0}{a^2}x_0-\frac{y_0}{b^2}y_0=\frac{x_0^2}{a^2}-\frac{y_0^2}{b^2}$$

and the point (x_0, y_0) lies on the hyperbola so

$$\frac{x_0^2}{a^2}-\frac{y_0^2}{b^2}=1,$$

therefore $Ax_0-By_0=1$. Substituting in (3) we obtain $Ax-By=1$.

In Exercises 51–54, find the polar equation of the conic with the given eccentricity and directrix, and focus at the origin.

51. $e=\frac{1}{2}$, $x=3$

SOLUTION Substituting $e=\frac{1}{2}$ and $d=3$ in the polar equation of a conic section we obtain

$$r=\frac{ed}{1+e\cos\theta}=\frac{\frac{1}{2}\cdot 3}{1+\frac{1}{2}\cos\theta}=\frac{3}{2+\cos\theta}\Rightarrow r=\frac{3}{2+\cos\theta}$$

52. $e=\frac{1}{2}$, $x=-3$

SOLUTION We use the polar equation of a conic section with $e=\frac{1}{2}$ and $d=-3$ to obtain

$$r=\frac{ed}{1+e\cos\theta}=\frac{\frac{1}{2}\cdot(-3)}{1+\frac{1}{2}\cos\theta}=\frac{-3}{2+\cos\theta}\Rightarrow r=\frac{-3}{2+\cos\theta}$$

53. $e=1$, $x=4$

SOLUTION We substitute $e=1$ and $d=4$ in the polar equation of a conic section to obtain

$$r=\frac{ed}{1+e\cos\theta}=\frac{1\cdot 4}{1+1\cdot\cos\theta}=\frac{4}{1+\cos\theta}\Rightarrow r=\frac{4}{1+\cos\theta}$$

54. $e=\frac{3}{2}$, $x=-4$

SOLUTION Substituting $e=\frac{3}{2}$ and $d=-4$ in the polar equation of the conic section gives

$$r=\frac{ed}{1+e\cos\theta}=\frac{\frac{3}{2}\cdot(-4)}{1+\frac{3}{2}\cos\theta}=\frac{-12}{2+3\cos\theta}\Rightarrow r=\frac{-12}{2+3\cos\theta}$$

In Exercises 55–58, identify the type of conic, the eccentricity, and the equation of the directrix.

55. $r=\dfrac{8}{1+4\cos\theta}$

SOLUTION Matching with the polar equation $r=\frac{ed}{1+e\cos\theta}$ we get $ed=8$ and $e=4$ yielding $d=2$. Since $e>1$, the conic section is a hyperbola, having eccentricity $e=4$ and directrix $x=2$ (referring to the focus-directrix definition (11)).

56. $r = \dfrac{8}{4+\cos\theta}$

SOLUTION To identify the values of e and d we first rewrite the equation in the form $r = \frac{ed}{1+e\cos\theta}$:

$$r = \frac{8}{4+\cos\theta} = \frac{2}{1+\frac{1}{4}\cos\theta}$$

Thus, $ed = 2$ and $e = \frac{1}{4}$, yielding $d = 8$. Since $e < 1$, the conic is an ellipse, having eccentricity $e = \frac{1}{4}$ and directrix $x = 8$.

57. $r = \dfrac{8}{4+3\cos\theta}$

SOLUTION We first rewrite the equation in the form $r = \frac{ed}{1+e\cos\theta}$, obtaining

$$r = \frac{2}{1+\frac{3}{4}\cos\theta}$$

Hence, $ed = 2$ and $e = \frac{3}{4}$ yielding $d = \frac{8}{3}$. Since $e < 1$, the conic section is an ellipse, having eccentricity $e = \frac{3}{4}$ and directrix $x = \frac{8}{3}$.

58. $r = \dfrac{12}{4+3\cos\theta}$

SOLUTION We rewrite the equation in the form of the polar equation $r = \frac{ed}{1+e\cos\theta}$:

$$r = \frac{12}{4+3\cos\theta} = \frac{3}{1+\frac{3}{4}\cos\theta}$$

Hence, $ed = 3$ and $e = \frac{3}{4}$ which implies $d = 4$. Since $e < 1$, the conic section is an ellipse having eccentricity $e = \frac{3}{4}$ and directrix $x = 4$.

59. Find a polar equation for the hyperbola with focus at the origin, directrix $x = -2$, and eccentricity $e = 1.2$.

SOLUTION We substitute $d = -2$ and $e = 1.2$ in the polar equation $r = \frac{ed}{1+e\cos\theta}$ and use Exercise 40 to obtain

$$r = \frac{1.2\cdot(-2)}{1+1.2\cos\theta} = \frac{-2.4}{1+1.2\cos\theta} = \frac{-12}{5+6\cos\theta} = \frac{12}{5-6\cos\theta}$$

60. Let $\mathcal{C}$ be the ellipse $r = de/(1+e\cos\theta)$, where $e < 1$. Show that the x-coordinates of the points in Figure 24 are as follows:

Point	A	C	F_2	A'
x-coordinate	$\dfrac{de}{e+1}$	$-\dfrac{de^2}{1-e^2}$	$-\dfrac{2de^2}{1-e^2}$	$-\dfrac{de}{1-e}$

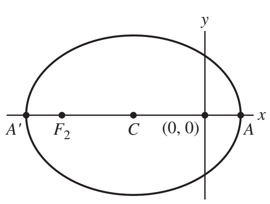


FIGURE 24

SOLUTION To find the x coordinate of A we substitute $\theta = 0$ in the polar equation $r = \frac{de}{1+e\cos\theta}$. This gives

$$x_A = r\cos 0 = r = \frac{de}{1+e\cos 0} = \frac{de}{1+e} \tag{1}$$

The point A' corresponds to $\theta = \pi$, so

$$x_{A'} = r\cos\pi = -r = -\frac{de}{1+e\cos\pi} = -\frac{de}{1-e} \tag{2}$$

The center C is the midpoint of $\overline{A'A}$. From (1) and (2) we obtain

$$x_C = \frac{x_A + x_{A'}}{2} = \frac{1}{2}\left(\frac{de}{1+e} - \frac{de}{1-e}\right) = \frac{de(1-e) - de(1+e)}{2(1+e)(1-e)} = \frac{-de^2}{1-e^2} \tag{3}$$

Finally, one focus is at the origin; the center C is the midpoint of $\overline{F_1F_2}$. Thus

$$x_C = \frac{x_{F_1} + x_{F_2}}{2} = \frac{0 + x_{F_2}}{2} = \frac{x_{F_2}}{2} \Rightarrow x_{F_2} = 2x_C$$

Using (3), we obtain

$$x_{F_2} = \frac{-2de^2}{1-e^2}$$

61. Find an equation in rectangular coordinates of the conic

$$r = \frac{16}{5 + 3\cos\theta}$$

Hint: Use the results of Exercise 60.

SOLUTION Put this equation in the form of the referenced exercise:

$$\frac{16}{5+3\cos\theta} = \frac{\frac{16}{5}}{1 + \frac{3}{5}\cos\theta} = \frac{\frac{16}{3}\cdot\frac{3}{5}}{1 + \frac{3}{5}\cos\theta}$$

so that $e = \frac{3}{5}$ and $d = \frac{16}{3}$. Then the center of the ellipse has x-coordinate

$$-\frac{de^2}{1-e^2} = -\frac{\frac{16}{3}\cdot\frac{9}{25}}{1 - \frac{9}{25}} = -\frac{16}{3}\cdot\frac{9}{25}\cdot\frac{25}{16} = -3$$

and y-coordinate 0, and A' has x-coordinate

$$-\frac{de}{1-e} = -\frac{\frac{16}{3}\cdot\frac{3}{5}}{1 - \frac{3}{5}} = -\frac{16}{3}\cdot\frac{3}{5}\cdot\frac{5}{2} = -8$$

and y-coordinate 0, so $a = -3 - (-8) = 5$, and the equation is

$$\left(\frac{x+3}{5}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$$

To find b, set $\theta = \frac{\pi}{2}$; then $r = \frac{16}{5}$. But the point corresponding to $\theta = \frac{\pi}{2}$ lies on the y-axis, so has coordinates $\left(0, \frac{16}{5}\right)$. This point is on the ellipse, so that

$$\left(\frac{0+3}{5}\right)^2 + \left(\frac{\frac{16}{5}}{b}\right)^2 = 1 \quad\Rightarrow\quad \frac{256}{25\cdot b^2} = \frac{16}{25} \quad\Rightarrow\quad \frac{256}{b^2} = 16 \quad\Rightarrow\quad b = 4$$

and the equation is

$$\left(\frac{x+3}{5}\right)^2 + \left(\frac{y}{4}\right)^2 = 1$$

62. Let $e > 1$. Show that the vertices of the hyperbola $r = \dfrac{de}{1 + e\cos\theta}$ have x-coordinates $\dfrac{ed}{e+1}$ and $\dfrac{ed}{e-1}$.

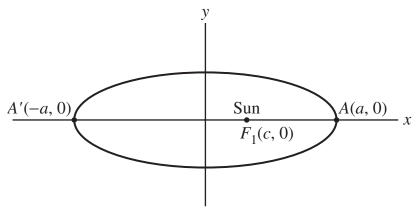
SOLUTION Since the focus is at the origin and the hyperbola is to the right (see figure), the two vertices have positive x coordinates. The corresponding values of θ at the vertices are $\theta = 0$ and $\theta = \pi$. Hence, since $e > 1$ we obtain

$$x_A = |r(0)| = \left|\frac{de}{1 + e\cos 0}\right| = \frac{de}{1+e}$$

$$x_{A'} = |r(\pi)| = \left|\frac{de}{1 + e\cos\pi}\right| = \left|\frac{de}{1-e}\right| = \frac{de}{e-1}$$

63. Kepler's First Law states that planetary orbits are ellipses with the sun at one focus. The orbit of Pluto has eccentricity $e \approx 0.25$. Its **perihelion** (closest distance to the sun) is approximately 2.7 billion miles. Find the **aphelion** (farthest distance from the sun).

SOLUTION We define an xy-coordinate system so that the orbit is an ellipse in standard position, as shown in the figure.



The aphelion is the length of $\overline{A'F_1}$, that is $a + c$. By the given data, we have

$$0.25 = e = \frac{c}{a} \Rightarrow c = 0.25a$$
$$a - c = 2.7 \Rightarrow c = a - 2.7$$

Equating the two expressions for c we get

$$0.25a = a - 2.7$$
$$0.75a = 2.7 \Rightarrow a = \frac{2.7}{0.75} = 3.6, \;\; c = 3.6 - 2.7 = 0.9$$

The aphelion is thus

$$\overline{A'F_0} = a + c = 3.6 + 0.9 = 4.5 \text{ billion miles.}$$

64. Kepler's Third Law states that the ratio $T/a^{3/2}$ is equal to a constant C for all planetary orbits around the sun, where T is the period (time for a complete orbit) and a is the semimajor axis.

(a) Compute C in units of days and kilometers, given that the semimajor axis of the earth's orbit is 150×10^6 km.

(b) Compute the period of Saturn's orbit, given that its semimajor axis is approximately 1.43×10^9 km.

(c) Saturn's orbit has eccentricity $e = 0.056$. Find the perihelion and aphelion of Saturn (see Exercise 63).

SOLUTION

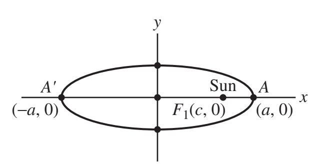
(a) By Kepler's Law, $\frac{T}{a^{3/2}} = C$. For the earth's orbit $a = 150 \times 10^6$ km and $T = 365$ days. Hence,

$$C = \frac{T}{a^{3/2}} = \frac{365}{(150 \times 10^6)^{3/2}} = \frac{365}{1837.12 \times 10^9} = 1.987 \cdot 10^{-10} \text{ days/km}$$

(b) By Kepler's Third Law and using the constant C computed in part (a) we get

$$\frac{T}{a^{3/2}} = C$$
$$\frac{T}{(1.43 \times 10^9)^{3/2}} = 1.987 \times 10^{-10}$$
$$T = (1.987 \times 10^{-10})(1.43 \times 10^9)^{3/2} = 10{,}745 \text{ days.}$$

(c) We define the xy-coordinate system so that the orbit is in standard position (see figure). (The sun is at one focus.)



The perihelion is $a - c$ and the aphelion is $a + c$. By the given information $a = 1.43 \times 10^9$ km and $e = 0.056$. Hence

$$e = \frac{c}{a} \Rightarrow 0.056 = \frac{c}{1.43 \times 10^9} \Rightarrow c = 0.08 \times 10^9 \text{ km}$$

We obtain the following solutions:

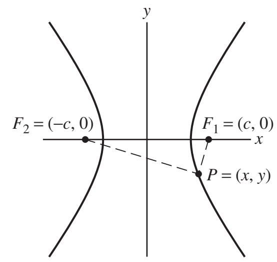
$$\text{perihelion} = a - c = 1.43 \times 10^9 - 0.08 \times 10^9 = 1.35 \times 10^9 \text{ km}$$
$$\text{aphelion} = a + c = 1.43 \times 10^9 + 0.08 \times 10^9 = 1.51 \times 10^9 \text{ km}$$

Further Insights and Challenges

65. Verify Theorem 2.

SOLUTION Let $F_1 = (c, 0)$ and $F_2 = (-c, 0)$ and let $P(x, y)$ be an arbitrary point on the hyperbola. Then for some constant a,

$$\overline{PF_1} - \overline{PF_2} = \pm 2a$$



Using the distance formula we write this as

$$\sqrt{(x-c)^2 + y^2} - \sqrt{(x+c)^2 + y^2} = \pm 2a.$$

Moving the second term to the right and squaring both sides gives

$$\sqrt{(x-c)^2 + y^2} = \sqrt{(x+c)^2 + y^2} \pm 2a$$
$$(x-c)^2 + y^2 = (x+c)^2 + y^2 \pm 4a\sqrt{(x+c)^2 + y^2} + 4a^2$$
$$(x-c)^2 - (x+c)^2 - 4a^2 = \pm 4a\sqrt{(x+c)^2 + y^2}$$
$$xc + a^2 = \pm a\sqrt{(x+c)^2 + y^2}$$

We square and simplify to obtain

$$x^2c^2 + 2xca^2 + a^4 = a^2\left((x+c)^2 + y^2\right)$$
$$= a^2x^2 + 2a^2xc + a^2c^2 + a^2y^2$$
$$\left(c^2 - a^2\right)x^2 - a^2y^2 = a^2\left(c^2 - a^2\right)$$
$$\frac{x^2}{a^2} - \frac{y^2}{c^2 - a^2} = 1$$

For $b = \sqrt{c^2 - a^2}$ (or $c = \sqrt{a^2 + b^2}$) we get

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1 \Rightarrow \left(\frac{x}{a}\right)^2 - \left(\frac{y}{b}\right)^2 = 1.$$

66. Verify Theorem 5 in the case $0 < e < 1$. *Hint:* Repeat the proof of Theorem 5, but set $c = d/(e^{-2} - 1)$.

SOLUTION We follow closely the proof of Theorem 5 in the book, which covered the case $e > 1$. This time, for $0 < e < 1$, we prove that $PF = ePD$ defines an ellipse. We choose our coordinate axes so that the focus F lies on the x-axis with coordinates $F = (c, 0)$ and so that the directrix is vertical, lying to the right of F at a distance d from F. As suggested by the hint, we set $c = \frac{d}{e^{-2}-1}$, but since we are working towards an ellipse, we will also need to let $b = \sqrt{a^2 - c^2}$ as opposed to the $\sqrt{c^2 - a^2}$ from the original proof of Theorem 5. Here's the complete list of definitions:

$$c = \frac{d}{e^{-2} - 1}, \quad a = \frac{c}{e}, \quad b = \sqrt{a^2 - c^2}$$

The directrix is the line

$$x = c + d = c + c(e^{-2} - 1) = ce^{-2} = \frac{a}{e}$$

Now, the equation

$$PF = e \cdot PD$$

for the points $P = (x, y)$, $F = (c, 0)$, and $D = (a/e, y)$ becomes

$$\sqrt{(x-c)^2 + y^2} = e \cdot \sqrt{(x-(a/e))^2}$$

Returning to the proof of Theorem 5, we see that this is the same equation that appears in the middle of the proof of the Theorem. As seen there, this equation can be transformed into

$$\frac{x^2}{a^2} - \frac{y^2}{a^2(e^2-1)} = 1$$

and this is equivalent to

$$\frac{x^2}{a^2} + \frac{y^2}{a^2(1-e^2)} = 1$$

Since $a^2(1-e^2) = a^2 - a^2e^2 = a^2 - c^2 = b^2$, then we obtain the equation of the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

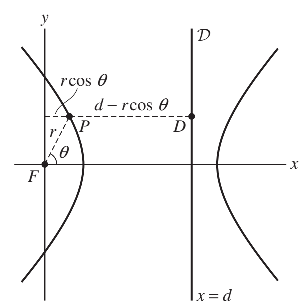
67. Verify that if $e > 1$, then Eq. (11) defines a hyperbola of eccentricity e, with its focus at the origin and directrix at $x = d$.

SOLUTION The points $P = (r, \theta)$ on the hyperbola satisfy $\overline{PF} = e\overline{PD}$, $e > 1$. Referring to the figure we see that

$$\overline{PF} = r,\ \overline{PD} = d - r\cos\theta \tag{1}$$

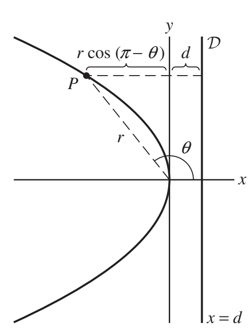
Hence

$$r = e(d - r\cos\theta)$$
$$r = ed - er\cos\theta$$
$$r(1 + e\cos\theta) = ed \Rightarrow r = \frac{ed}{1 + e\cos\theta}$$



Remark: Equality (1) holds also for $\theta > \frac{\pi}{2}$. For example, in the following figure, we have

$$\overline{PD} = d + r\cos(\pi - \theta) = d - r\cos\theta$$



Reflective Property of the Ellipse *In Exercises 68–70, we prove that the focal radii at a point on an ellipse make equal angles with the tangent line $\mathcal{L}$. Let $P = (x_0, y_0)$ be a point on the ellipse in Figure 25 with foci $F_1 = (-c, 0)$ and $F_2 = (c, 0)$, and eccentricity $e = c/a$.*

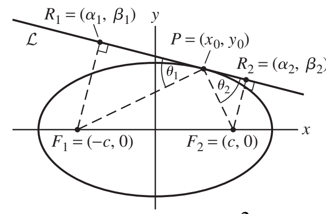


FIGURE 25 The ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$.

68. Show that the equation of the tangent line at P is $Ax + By = 1$, where $A = \dfrac{x_0}{a^2}$ and $B = \dfrac{y_0}{b^2}$.

SOLUTION The equation of the tangent line is

$$y - y_0 = m(x - x_0); \quad m = \left.\frac{dy}{dx}\right|_{x=x_0, y=y_0} \tag{1}$$

To find the slope m we implicitly differentiate the equation of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ with respect to x. We get

$$\frac{2x}{a^2} + \frac{2yy'}{b^2} = 0 \Rightarrow \frac{yy'}{b^2} = -\frac{x}{a^2} \Rightarrow y' = -\frac{b^2}{a^2}\left(\frac{x}{y}\right)$$

We substitute $x = x_0$, $y = y_0$ to obtain the following slope of the tangent line:

$$m = -\frac{b^2}{a^2}\frac{x_0}{y_0} = -\frac{x_0}{a^2} \cdot \frac{b^2}{y_0} = -\frac{A}{B}$$

Substituting in (1) and simplifying gives

$$y - y_0 = -\frac{A}{B}(x - x_0)$$
$$By - By_0 = -Ax + Ax_0$$
$$Ax + By = Ax_0 + By_0$$

Now,

$$Ax_0 + By_0 = \frac{x_0^2}{a^2} + \frac{y_0^2}{b^2},$$

so we get $Ax + By = 1$.

69. Points R_1 and R_2 in Figure 25 are defined so that $\overline{F_1R_1}$ and $\overline{F_2R_2}$ are perpendicular to the tangent line.

(a) Show, with A and B as in Exercise 68, that

$$\frac{\alpha_1 + c}{\beta_1} = \frac{\alpha_2 - c}{\beta_2} = \frac{A}{B}$$

(b) Use (a) and the distance formula to show that

$$\frac{F_1R_1}{F_2R_2} = \frac{\beta_1}{\beta_2}$$

(c) Use (a) and the equation of the tangent line in Exercise 68 to show that

$$\beta_1 = \frac{B(1 + Ac)}{A^2 + B^2}, \qquad \beta_2 = \frac{B(1 - Ac)}{A^2 + B^2}$$

SOLUTION

(a) Since $R_1 = (\alpha_1, \beta_1)$ and $R_2 = (\alpha_2, \beta_2)$ lie on the tangent line at P, that is on the line $Ax + By = 1$, we have

$$A\alpha_1 + B\beta_1 = 1 \quad \text{and} \quad A\alpha_2 + B\beta_2 = 1$$

The slope of the line R_1F_1 is $\frac{\beta_1}{\alpha_1 + c}$ and it is perpendicular to the tangent line having slope $-\frac{A}{B}$. Similarly, the slope of the line R_2F_2 is $\frac{\beta_2}{\alpha_2 - c}$ and it is also perpendicular to the tangent line. Hence,

$$\frac{\alpha_1 + c}{\beta_1} = \frac{A}{B} \quad \text{and} \quad \frac{\alpha_2 - c}{\beta_2} = \frac{A}{B}.$$

(b) Using the distance formula, we have

$$\overline{R_1F_1}^2 = (\alpha_1 + c)^2 + \beta_1^2$$

Thus,

$$\overline{R_1F_1}^2 = \beta_1^2 \left(\left(\frac{\alpha_1 + c}{\beta_1} \right)^2 + 1 \right) \tag{1}$$

By part (a), $\frac{\alpha_1+c}{\beta_1} = \frac{A}{B}$. Substituting in (1) gives

$$\overline{R_1F_1}^2 = \beta_1^2 \left(\frac{A^2}{B^2} + 1 \right) \tag{2}$$

Likewise,

$$\overline{R_2F_2}^2 = (\alpha_2 - c)^2 + {\beta_2}^2 = {\beta_2}^2 \left(\left(\frac{\alpha_2 - c}{\beta_2} \right)^2 + 1 \right) \tag{3}$$

but since $\frac{\alpha_2-c}{\beta_2} = \frac{A}{B}$, substituting in (3) gives

$$\overline{R_2F_2}^2 = \beta_2^2 \left(\frac{A^2}{B^2} + 1 \right). \tag{4}$$

Dividing, we find that

$$\frac{\overline{R_1F_1}^2}{\overline{R_2F_2}^2} = \frac{\beta_1^2}{\beta_2^2} \quad \text{so} \quad \frac{\overline{R_1F_1}}{\overline{R_2F_2}} = \frac{\beta_1}{\beta_2},$$

as desired.

(c) In part (a) we showed that

$$\begin{cases} A\alpha_1 + B\beta_1 = 1 \\ \dfrac{\beta_1}{\alpha_1 + c} = \dfrac{B}{A} \end{cases}$$

Eliminating α_1 and solving for β_1 gives

$$\beta_1 = \frac{B(1 + Ac)}{A^2 + B^2}. \tag{5}$$

Similarly, we have

$$\begin{cases} A\alpha_2 + B\beta_2 = 1 \\ \dfrac{\beta_2}{\alpha_2 - c} = \dfrac{B}{A} \end{cases}$$

Eliminating α_2 and solving for β_2 yields

$$\beta_2 = \frac{B\,(1 - Ac)}{A^2 + B^2} \tag{6}$$

70. (a) Prove that $PF_1 = a + x_0e$ and $PF_2 = a - x_0e$. *Hint:* Show that $PF_1{}^2 - PF_2{}^2 = 4x_0c$. Then use the defining property $PF_1 + PF_2 = 2a$ and the relation $e = c/a$.

(b) Verify that $\dfrac{F_1R_1}{PF_1} = \dfrac{F_2R_2}{PF_2}$.

(c) Show that $\sin\theta_1 = \sin\theta_2$. Conclude that $\theta_1 = \theta_2$.

SOLUTION

(a) Using the distance formula we have

$$\overline{PF_1}^2 = (x_0 + c)^2 + y^2; \quad \overline{PF_2}^2 = (x_0 - c)^2 + y^2$$

Hence,

$$\overline{PF_1}^2 - \overline{PF_2}^2 = (x_0 + c)^2 + y^2 - (x_0 - c)^2 - y^2$$

$$= (x_0 + c)^2 - (x_0 - c)^2$$
$$= x_0{}^2 + 2x_0c + c^2 - x_0{}^2 + 2x_0c - c^2 = 4x_0c$$

That is, $\overline{PF_1}^2 - \overline{PF_2}^2 = 4x_0c$. Now use the identity $u^2 - v^2 = (u - v)(u + v)$ to write this as

$$\left(\overline{PF_1} - \overline{PF_2}\right)\left(\overline{PF_1} + \overline{PF_2}\right) = 4x_0c \tag{1}$$

Since P lies on the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$ we have

$$\overline{PF_1} + \overline{PF_2} = 2a \tag{2}$$

Substituting in (1) gives

$$\left(\overline{PF_1} - \overline{PF_2}\right) \cdot 2a = 4x_0c$$

We divide by a and use the eccentricity $e = \frac{c}{a}$ to obtain

$$\overline{PF_1} - \overline{PF_2} = 2x_0e$$

Solve this equation together with equation (2) to see that

$$\overline{PF_1} = a + x_0e, \qquad \overline{PF_2} = a - x_0e$$

(b) Substituting the expression for β_1 from Eq. (5) in Exercise 69 into Eq. (2) in Exercise 69 yields

$$\overline{R_1F_1}^2 = \frac{B^2(1 + Ac)^2}{(A^2 + B^2)^2}\left(\frac{A^2}{B^2} + 1\right) = \frac{B^2(1 + Ac)^2(A^2 + B^2)}{(A^2 + B^2)^2B^2} = \frac{(1 + Ac)^2}{A^2 + B^2}$$

and similarly, substituting the expression for β_2 from Eq. (6) in Exercise 69 into Eq. (4) in Exercise 69 yields

$$\overline{R_2F_2}^2 = \frac{B^2(1 - Ac)^2}{(A^2 + B^2)^2}\left(\frac{A^2}{B^2} + 1\right) = \frac{B^2(1 - Ac)^2(A^2 + B^2)}{(A^2 + B^2)^2B^2} = \frac{(1 - Ac)^2}{A^2 + B^2}$$

Taking square roots and dividing these two formulas gives

$$\frac{\overline{R_1F_1}}{\overline{R_2F_2}} = \frac{\frac{1+Ac}{\sqrt{A^2+B^2}}}{\frac{1-Ac}{\sqrt{A^2+B^2}}} = \frac{1 + Ac}{1 - Ac}$$

Substitute $c = ea$ and $A = \frac{x_0}{a^2}$ (from Exercise 68) to get

$$\frac{\overline{R_1F_1}}{\overline{R_2F_2}} = \frac{1 + \frac{x_0ea}{a^2}}{1 - \frac{x_0ea}{a^2}} = \frac{1 + \frac{x_0e}{a}}{1 - \frac{x_0e}{a}} = \frac{a + x_0e}{a - x_0e}$$

But part (a) showed that $\overline{PF_1} = a + x_0e$ and $\overline{PF_2} = a - x_0e$, so that

$$\frac{\overline{R_1F_1}}{\overline{R_2F_2}} = \frac{\overline{PF_1}}{\overline{PF_2}} \qquad \Rightarrow \qquad \frac{\overline{R_1F_1}}{\overline{PF_1}} = \frac{\overline{R_2F_2}}{\overline{PF_2}}$$

(c) Since $\frac{\overline{R_1F_1}}{\overline{PF_1}} = \sin\theta_1$ and $\frac{\overline{R_2F_2}}{\overline{PF_2}} = \sin\theta_2$, we get $\sin\theta_1 = \sin\theta_2$, which implies that $\theta_1 = \theta_2$ since the two angles are acute.

71. Here is another proof of the Reflective Property.

(a) Figure 25 suggests that $\mathcal{L}$ is the unique line that intersects the ellipse only in the point P. Assuming this, prove that $QF_1 + QF_2 > PF_1 + PF_2$ for all points Q on the tangent line other than P.

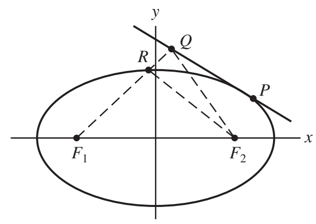
(b) Use the Principle of Least Distance (Example 6 in Section 4.7) to prove that $\theta_1 = \theta_2$.

SOLUTION

(a) Consider a point $Q \neq P$ on the line $\mathcal{L}$ (see figure). Since $\mathcal{L}$ intersects the ellipse in only one point, the remainder of the line lies outside the ellipse, so that QR does not have zero length, and F_2QR is a triangle. Thus

$$QF_1 + QF_2 = QR + RF_1 + QF_2 = RF_1 + (QR + QF_2) > RF_1 + RF_2$$

since the sum of lengths of two sides of a triangle exceeds the length of the third side. But since point R lies on the ellipse, $RF_2 + RF_2 = PF_1 + PF_2$, and we are done.



(b) Consider a beam of light traveling from F_1 to F_2 by reflection off of the line $\mathcal{L}$. By the principle of least distance, the light takes the shortest path, which by part (a) is the path through P. By Example 6 in Section 4.7, this shortest path has the property that the angle of incidence (θ_1) is equal to the angle of reflection (θ_2).

72. Show that the length QR in Figure 26 is independent of the point P.

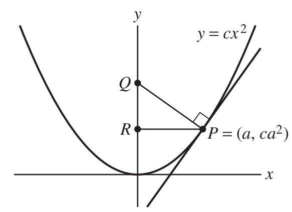


FIGURE 26

SOLUTION We find the slope m of the tangent line at $P = \left(a, ca^2\right)$:

$$m = (cx^2)'\Big|_{x=a} = 2cx\Big|_{x=a} = 2ca$$

The slope of the perpendicular line PQ is, thus, $-\frac{1}{2ca}$, and the equation of this line is

$$y - ca^2 = -\frac{1}{2ca}(x-a) \Rightarrow y = -\frac{x}{2ac} + ca^2 + \frac{1}{2c}$$

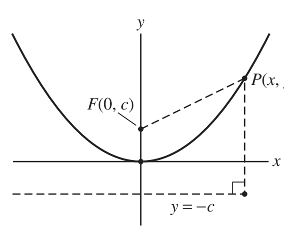
The y-intercept of the line PQ is $y = ca^2 + \frac{1}{2c}$. We now find the length $\overline{QR}$, by computing the distance between the points $Q(0, ca^2 + \frac{1}{2c})$ and $P(0, ca^2)$. This gives

$$\overline{QR} = ca^2 + \frac{1}{2c} - ca^2 = \frac{1}{2c}$$

Indeed, the length $\overline{QR}$ is independent of a, i.e. it is independent of the point P.

73. Show that $y = x^2/4c$ is the equation of a parabola with directrix $y = -c$, focus $(0, c)$, and the vertex at the origin, as stated in Theorem 3.

SOLUTION The points $P = (x, y)$ on the parabola are equidistant from $F = (0, c)$ and the line $y = -c$.



That is, by the distance formula, we have

$$\overline{PF} = \overline{PD}$$
$$\sqrt{x^2 + (y-c)^2} = |y + c|$$

Squaring and simplifying yields

$$x^2 + (y-c)^2 = (y+c)^2$$
$$x^2 + y^2 - 2yc + c^2 = y^2 + 2yc + c^2$$
$$x^2 - 2yc = 2yc$$

$$x^2 = 4yc \Rightarrow y = \frac{x^2}{4c}$$

Thus, we showed that the points that are equidistant from the focus $F = (0, c)$ and the directrix $y = -c$ satisfy the equation $y = \frac{x^2}{4c}$.

74. Consider two ellipses in standard position:

$$E_1: \quad \left(\frac{x}{a_1}\right)^2 + \left(\frac{y}{b_1}\right)^2 = 1$$

$$E_2: \quad \left(\frac{x}{a_2}\right)^2 + \left(\frac{y}{b_2}\right)^2 = 1$$

We say that E_1 is similar to E_2 under scaling if there exists a factor $r > 0$ such that for all (x, y) on E_1, the point (rx, ry) lies on E_2. Show that E_1 and E_2 are similar under scaling if and only if they have the same eccentricity. Show that any two circles are similar under scaling.

SOLUTION If E_1 and E_2 are similar under scaling, then since $(a_1, 0)$ and $(0, b_1)$ are points on the first ellipse, the scaled points $(ra_1, 0)$ and $(0, rb_1)$ must be on the second ellipse. This implies that $(ra_1/a_2)^2 + (0/b_2)^2 = 1$ and that $(0/a_1)^2 + (rb_1/b_2)^2 = 1$, which means that $ra_1 \pm a_2$ and $rb_1 = \pm b_2$. But, since r, a_1, and a_2 are all positive, then this implies that $a_2 = ra_1$ and $b_2 = rb_1$, and so

$$c_2 = \sqrt{a_2^2 - b_2^2} = r\sqrt{a_1^2 - b_1^2} = rc_1.$$

Thus,

$$e_2 = \frac{c_2}{a_2} = \frac{r_1 c_1}{r_1 a_1} = \frac{c_1}{a_1} = e_1$$

and so the two ellipses have the same eccentricity. On the other hand, if the two ellipses have the same eccentricity, then

$$\sqrt{1 - \frac{b_2^2}{a_2^2}} = \frac{c_2}{a_2} = e_2 = e_1 = \frac{c_1}{a_1} = \sqrt{1 - \frac{b_1^2}{a_1^2}}$$

which implies

$$\sqrt{1 - \frac{b_2^2}{a_2^2}} = \sqrt{1 - \frac{b_1^2}{a_1^2}}$$

and this implies that $b_2/a_2 = \pm b_1/a_1$ and so $b_2/a_2 = b_1/a_1$ (recall that all constants are positive). Define $r = b_2/b_1$. Then, $b_2 = rb_1$, but since $b_2/a_2 = b_1/a_1$ we get that $a_2 = ra_1$ as well. Thus, for the point (x, y) on the first ellipse, we have that

$$\left(\frac{x}{a_1}\right)^2 + \left(\frac{y}{b_1}\right)^2 = 1$$

If we put the scaled point (rx, ry) into the second ellipse, we get

$$\left(\frac{rx}{a_2}\right)^2 + \left(\frac{ry}{b_2}\right)^2 = \left(\frac{rx}{ra_1}\right)^2 + \left(\frac{ry}{rb_1}\right)^2 = \left(\frac{x}{a_1}\right)^2 + \left(\frac{y}{b_1}\right)^2 = 1$$

which implies that E_2 is a scaled version of E_1. Since all circles have eccentricity 0, then they are all similar under scaling.

75. Derive Eqs. (13) and (14) in the text as follows. Write the coordinates of P with respect to the rotated axes in Figure 21 in polar form $x' = r\cos\alpha$, $y' = r\sin\alpha$. Explain why P has polar coordinates $(r, \alpha + \theta)$ with respect to the standard x and y-axes and derive Eqs. (13) and (14) using the addition formulas for cosine and sine.

SOLUTION If the polar coordinates of P with respect to the rotated axes are (r, α), then the line from the origin to P has length r and makes an angle of α with the rotated x-axis (the x'-axis). Since the x'-axis makes an angle of θ with the x-axis, it follows that the line from the origin to P makes an angle of $\alpha + \theta$ with the x-axis, so that the polar coordinates of P with respect to the standard axes are $(r, \alpha + \theta)$. Write (x', y') for the rectangular coordinates of P with respect to the rotated axes and (x, y) for the rectangular coordinates of P with respect to the standard axes. Then

$$x = r\cos(\alpha + \theta) = (r\cos\alpha)\cos\theta - (r\sin\alpha)\sin\theta = x'\cos\theta - y'\sin\theta$$

$$y = r\sin(\alpha + \theta) = r\sin\alpha\cos\theta + r\cos\alpha\sin\theta = (r\cos\alpha)\sin\theta + (r\sin\alpha)\cos\theta = x'\sin\theta + y'\cos\theta$$

76. If we rewrite the general equation of degree 2 (Eq. 12) in terms of variables x' and y' that are related to x and y by Eqs. (13) and (14), we obtain a new equation of degree 2 in x' and y' of the same form but with different coefficients:

$$a'x^2 + b'xy + c'y^2 + d'x + e'y + f' = 0$$

(a) Show that $b' = b\cos 2\theta + (c-a)\sin 2\theta$.
(b) Show that if $b \neq 0$, then we obtain $b' = 0$ for

$$\theta = \frac{1}{2}\cot^{-1}\frac{a-c}{b}$$

This proves that it is always possible to eliminate the cross term bxy by rotating the axes through a suitable angle.

SOLUTION

(a) If we plug in $x = x'\cos\theta - y'\sin\theta$ and $y = x'\sin\theta + y'\cos\theta$ into the equation $ax^2 + bxy + cy^2 + dx + ey + f = 0$, we will get a very ugly mess. Fortunately, we only care about the $x'y'$ term, so we really only need to look at the $ax^2 + bxy + cy^2$ part of the formula. In fact, we only need to pull out those terms which have an $x'y'$ in them. Thus

$$\begin{aligned} ax^2 &\quad \text{becomes} \quad a(x'\cos\theta - y'\sin\theta)^2 = -2ax'y'\cos\theta\sin\theta + \dots \\ bxy &\quad \text{becomes} \quad b(x'\cos\theta - y'\sin\theta)(x'\sin\theta + y'\cos\theta) = bx'y'(\cos^2\theta - \sin^2\theta) + \dots \\ cy^2 &\quad \text{becomes} \quad c(x'\sin\theta + y'\cos\theta)^2 = 2cx'y'\cos\theta\sin\theta + \dots \end{aligned}$$

so that

$$ax^2 + bxy + cy^2 = ((c-a)2\sin\theta\cos\theta + b(\cos^2\theta - \sin^2\theta))x'y' + \cdots = ((c-a)\sin 2\theta + b\cos 2\theta)x'y' + \dots$$

and thus b', the coefficient of $x'y'$, is $b\cos 2\theta + (c-a)\sin 2\theta$, as desired.
(b) Setting $b' = 0$, we get $0 = b\cos 2\theta + (c-a)\sin 2\theta$, so $b\cos 2\theta = (a-c)\sin 2\theta$, so $\cot 2\theta = \frac{a-c}{b}$, giving us $2\theta = \cot^{-1}\frac{a-c}{b}$, and thus $\theta = \frac{1}{2}\cot^{-1}\frac{a-c}{b}$.

CHAPTER REVIEW EXERCISES

1. Which of the following curves pass through the point $(1, 4)$?

(a) $c(t) = (t^2, t+3)$
(b) $c(t) = (t^2, t-3)$
(c) $c(t) = (t^2, 3-t)$
(d) $c(t) = (t-3, t^2)$

SOLUTION To check whether it passes through the point $(1, 4)$, we solve the equations $c(t) = (1, 4)$ for the given curves.

(a) Comparing the second coordinate of the curve and the point yields:

$$\begin{aligned} t + 3 &= 4 \\ t &= 1 \end{aligned}$$

We substitute $t = 1$ in the first coordinate, to obtain

$$t^2 = 1^2 = 1$$

Hence the curve passes through $(1, 4)$.

(b) Comparing the second coordinate of the curve and the point yields:

$$\begin{aligned} t - 3 &= 4 \\ t &= 7 \end{aligned}$$

We substitute $t = 7$ in the first coordinate to obtain

$$t^2 = 7^2 = 49 \neq 1$$

Hence the curve does not pass through $(1, 4)$.

(c) Comparing the second coordinate of the curve and the point yields

$$\begin{aligned} 3 - t &= 4 \\ t &= -1 \end{aligned}$$

We substitute $t = -1$ in the first coordinate, to obtain

$$t^2 = (-1)^2 = 1$$

Hence the curve passes through $(1, 4)$.

(d) Comparing the first coordinate of the curve and the point yields

$$\begin{aligned} t - 3 &= 1 \\ t &= 4 \end{aligned}$$

We substitute $t = 4$ in the second coordinate, to obtain:

$$t^2 = 4^2 = 16 \neq 4$$

Hence the curve does not pass through $(1, 4)$.

2. Find parametric equations for the line through $P = (2, 5)$ perpendicular to the line $y = 4x - 3$.

SOLUTION The line perpendicular to $y = 4x - 3$ at $P = (2, 5)$ is the line of slope $-\frac{1}{4}$ passing through P. This line has the equation

$$y - 5 = -\frac{1}{4}(x - 2)$$

A bit of calculation shows that the parametric equations of the line are

$$c(t) = \left(2 + t, 5 - \frac{1}{4}t\right)$$

or

$$\begin{aligned} x &= 2 + t \\ y &= 5 - \frac{1}{4}t \end{aligned}$$

3. Find parametric equations for the circle of radius 2 with center $(1, 1)$. Use the equations to find the points of intersection of the circle with the x- and y-axes.

SOLUTION Using the standard technique for parametric equations of curves, we obtain

$$c(t) = (1 + 2\cos t, 1 + 2\sin t)$$

We compare the x coordinate of $c(t)$ to 0:

$$\begin{aligned} 1 + 2\cos t &= 0 \\ \cos t &= -\frac{1}{2} \\ t &= \pm\frac{2\pi}{3} \end{aligned}$$

Substituting in the y coordinate yields

$$1 + 2\sin\left(\pm\frac{2\pi}{3}\right) = 1 \pm 2\frac{\sqrt{3}}{2} = 1 \pm \sqrt{3}$$

Hence, the intersection points with the y-axis are $(0, 1 \pm \sqrt{3})$. We compare the y coordinate of $c(t)$ to 0:

$$\begin{aligned} 1 + 2\sin t &= 0 \\ \sin t &= -\frac{1}{2} \\ t &= -\frac{\pi}{6} \quad \text{or} \quad \frac{7}{6}\pi \end{aligned}$$

Substituting in the x coordinates yields

$$\begin{aligned} 1 + 2\cos\left(-\frac{\pi}{6}\right) &= 1 + 2\frac{\sqrt{3}}{2} = 1 + \sqrt{3} \\ 1 + 2\cos\left(\frac{7}{6}\pi\right) &= 1 - 2\cos\left(\frac{\pi}{6}\right) = 1 - 2\frac{\sqrt{3}}{2} = 1 - \sqrt{3} \end{aligned}$$

Hence, the intersection points with the x-axis are $(1 \pm \sqrt{3}, 0)$.

4. Find a parametrization $c(t)$ of the line $y = 5 - 2x$ such that $c(0) = (2, 1)$.

SOLUTION The line is passing through $P = (0, 5)$ with slope -2, hence (by one of the examples in section 12.1) it has the parametrization

$$c(t) = (t, 5 - 2t)$$

This parametrization does not satisfy $c(0) = (2, 1)$. We replace the parameter t by a parameter s, so that $t = s + \beta$, to obtain another parametrization for the line:

$$c^*(s) = (s + \beta, 5 - 2(s + \beta)) = (s + \beta, 5 - 2\beta - 2s) \tag{1}$$

We require that $c^*(0) = (2, 1)$. That is,

$$c^*(0) = (\beta, 5 - 2\beta) = (2, 1)$$

or

$$\begin{aligned} \beta &= 2 \\ 5 - 2\beta &= 1 \end{aligned} \quad \Rightarrow \quad \beta = 2$$

Substituting in (1) gives the parametrization

$$c^*(s) = (s + 2, 1 - 2s)$$

5. Find a parametrization $c(\theta)$ of the unit circle such that $c(0) = (-1, 0)$.

SOLUTION The unit circle has the parametrization

$$c(t) = (\cos t, \sin t)$$

This parametrization does not satisfy $c(0) = (-1, 0)$. We replace the parameter t by a parameter θ so that $t = \theta + \alpha$, to obtain another parametrization for the circle:

$$c^*(\theta) = (\cos(\theta + \alpha), \sin(\theta + \alpha)) \tag{1}$$

We need that $c^*(0) = (1, 0)$, that is,

$$c^*(0) = (\cos\alpha, \sin\alpha) = (-1, 0)$$

Hence

$$\begin{aligned} \cos\alpha &= -1 \\ \sin\alpha &= 0 \end{aligned} \quad \Rightarrow \quad \alpha = \pi$$

Substituting in (1) we obtain the following parametrization:

$$c^*(\theta) = (\cos(\theta + \pi), \sin(\theta + \pi))$$

6. Find a path $c(t)$ that traces the parabolic arc $y = x^2$ from $(0, 0)$ to $(3, 9)$ for $0 \le t \le 1$.

SOLUTION The second coordinates of the points on the parabolic arc are the square of the first coordinates. Therefore the points on the arc have the form:

$$c(t) = (\alpha t, \alpha^2 t^2) \tag{1}$$

We need that $c(1) = (3, 9)$. That is,

$$c(1) = (\alpha, \alpha^2) = (3, 9) \Rightarrow \alpha = 3$$

Substituting in (1) gives the following parametrization:

$$c(t) = (3t, 9t^2)$$

7. Find a path $c(t)$ that traces the line $y = 2x + 1$ from $(1, 3)$ to $(3, 7)$ for $0 \le t \le 1$.

SOLUTION Solution 1: By one of the examples in section 12.1, the line through $P = (1, 3)$ with slope 2 has the parametrization

$$c(t) = (1 + t, 3 + 2t)$$

But this parametrization does not satisfy $c(1) = (3, 7)$. We replace the parameter t by a parameter s so that $t = \alpha s + \beta$. We get

$$c^*(s) = (1 + \alpha s + \beta, 3 + 2(\alpha s + \beta)) = (\alpha s + \beta + 1, 2\alpha s + 2\beta + 3)$$

We need that $c^*(0) = (1, 3)$ and $c^*(1) = (3, 7)$. Hence,

$$c^*(0) = (1 + \beta, 3 + 2\beta) = (1, 3)$$
$$c^*(1) = (\alpha + \beta + 1, 2\alpha + 2\beta + 3) = (3, 7)$$

We obtain the equations

$$\begin{aligned} 1 + \beta &= 1 \\ 3 + 2\beta &= 3 \\ \alpha + \beta + 1 &= 3 \\ 2\alpha + 2\beta + 3 &= 7 \end{aligned} \quad \Rightarrow \quad \beta = 0, \alpha = 2$$

Substituting in (1) gives

$$c^*(s) = (2s + 1, 4s + 3)$$

Solution 2: The segment from $(1, 3)$ to $(3, 7)$ has the following vector parametrization:

$$(1 - t)\langle 1, 3\rangle + t\langle 3, 7\rangle = \langle 1 - t + 3t, 3(1 - t) + 7t\rangle = \langle 1 + 2t, 3 + 4t\rangle$$

The parametrization is thus

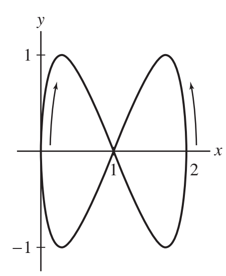
$$c(t) = (1 + 2t, 3 + 4t)$$

8. Sketch the graph $c(t) = (1 + \cos t, \sin 2t)$ for $0 \le t \le 2\pi$ and draw arrows specifying the direction of motion.

SOLUTION From $x = 1 + \cos t$ we have $x - 1 = \cos t$. We substitute this in the y coordinate to obtain

$$y = \sin 2t = 2 \sin t \cos t = \pm 2\sqrt{\sin^2 t} \cos t = \pm 2\sqrt{1 - \cos^2 t} \cos t = \pm 2\sqrt{1 - (x - 1)^2}(x - 1)$$

We can see that the graph is symmetric with respect to the x-axis, hence we plot the function $y = 2\sqrt{1 - (x - 1)^2}(x - 1)$ and reflect it with respect to the x-axis. When $t = 0$ we have $c(0) = (2, 0)$. when t increases near 0, $\cos t$ is decreasing and $\sin 2t$ is increasing, hence the general direction at the point $(2, 0)$ is upwards and left. As t approaches $\pi/2$, the x-coordinate decreases to 1 and the y-coordinate to 0. Likewise, as t moves from $\pi/2$ to π, the x-coordinate moves to 0 while the y-coordinate falls to -1 and then rises to 0. The resulting graph is seen here in the corresponding figure.



Plot of Exercise 8

In Exercises 9–12, express the parametric curve in the form $y = f(x)$.

9. $c(t) = (4t - 3, 10 - t)$

SOLUTION We use the given equation to express t in terms of x.

$$\begin{aligned} x &= 4t - 3 \\ 4t &= x + 3 \\ t &= \frac{x + 3}{4} \end{aligned}$$

Substituting in the equation of y yields

$$y = 10 - t = 10 - \frac{x + 3}{4} = -\frac{x}{4} + \frac{37}{4}$$

That is,

$$y = -\frac{x}{4} + \frac{37}{4}$$

10. $c(t) = (t^3 + 1, t^2 - 4)$

SOLUTION The parametric equations are $x = t^3 + 1$ and $y = t^2 - 4$. We express t in terms of x:

$$\begin{aligned} x &= t^3 + 1 \\ t^3 &= x - 1 \\ t &= (x-1)^{1/3} \end{aligned}$$

Substituting in the equation of y yields

$$y = t^2 - 4 = (x-1)^{2/3} - 4$$

That is,

$$y = (x-1)^{2/3} - 4$$

11. $c(t) = \left(3 - \frac{2}{t}, t^3 + \frac{1}{t}\right)$

SOLUTION We use the given equation to express t in terms of x:

$$\begin{aligned} x &= 3 - \frac{2}{t} \\ \frac{2}{t} &= 3 - x \\ t &= \frac{2}{3-x} \end{aligned}$$

Substituting in the equation of y yields

$$y = \left(\frac{2}{3-x}\right)^3 + \frac{1}{2/(3-x)} = \frac{8}{(3-x)^3} + \frac{3-x}{2}$$

12. $x = \tan t, \quad y = \sec t$

SOLUTION We use the trigonometric identity

$$1 + \tan^2 t = \sec^2 t$$

Substituting the parametric equations $x = \tan t$ and $y = \sec t$ we obtain

$$1 + x^2 = y^2 \quad \text{or} \quad y = \pm\sqrt{x^2+1}$$

In Exercises 13–16, calculate dy/dx at the point indicated.

13. $c(t) = (t^3 + t, t^2 - 1), \quad t = 3$

SOLUTION The parametric equations are $x = t^3 + t$ and $y = t^2 - 1$. We use the theorem on the slope of the tangent line to find $\frac{dy}{dx}$:

$$\frac{dy}{dx} = \frac{\frac{dy}{dt}}{\frac{dx}{dt}} = \frac{2t}{3t^2+1}$$

We now substitute $t = 3$ to obtain

$$\left.\frac{dy}{dx}\right|_{t=3} = \frac{2 \cdot 3}{3 \cdot 3^2 + 1} = \frac{3}{14}$$

14. $c(\theta) = (\tan^2\theta, \cos\theta), \quad \theta = \frac{\pi}{4}$

SOLUTION The parametric equations are $x = \tan^2\theta$, $y = \cos\theta$. We use the theorem on the slope of the tangent line to find $\frac{dy}{dx}$:

$$\frac{dy}{dx} = \frac{\frac{dy}{d\theta}}{\frac{dx}{d\theta}} = \frac{-\sin\theta}{2\tan\theta\sec^2\theta} = -\frac{\cos^3\theta}{2}$$

We now substitute $\theta = \frac{\pi}{4}$ to obtain

$$\left.\frac{dy}{dx}\right|_{\theta=\pi/4} = -\frac{\cos^3\frac{\pi}{4}}{2} = -\frac{1}{4\sqrt{2}}$$

15. $c(t) = (e^t - 1, \sin t), \quad t = 20$

SOLUTION We use the theorem for the slope of the tangent line to find $\frac{dy}{dx}$:

$$\frac{dy}{dx} = \frac{\frac{dy}{dt}}{\frac{dx}{dt}} = \frac{(\sin t)'}{(e^t - 1)'} = \frac{\cos t}{e^t}$$

We now substitute $t = 20$:

$$\left.\frac{dy}{dx}\right|_{t=0} = \frac{\cos 20}{e^{20}}$$

16. $c(t) = (\ln t, 3t^2 - t), \quad P = (0, 2)$

SOLUTION The parametric equations are $x = \ln t$, $y = 3t^2 - t$. We use the theorem for the slope of the tangent line to find $\frac{dy}{dx}$:

$$\frac{dy}{dx} = \frac{\frac{dy}{dt}}{\frac{dx}{dt}} = \frac{6t - 1}{\frac{1}{t}} = 6t^2 - t \tag{1}$$

We now must identify the value of t corresponding to the point $P = (0, 2)$ on the curve. We solve the following equations:

$$\begin{aligned} \ln t &= 0 \\ 3t^2 - t &= 2 \end{aligned} \quad \Rightarrow \quad t = 1$$

Substituting $t = 1$ in (1) we obtain

$$\left.\frac{dy}{dx}\right|_{P} = 6 \cdot 1^2 - 1 = 5$$

17. CAS Find the point on the cycloid $c(t) = (t - \sin t, 1 - \cos t)$ where the tangent line has slope $\frac{1}{2}$.

SOLUTION Since $x = t - \sin t$ and $y = 1 - \cos t$, the theorem on the slope of the tangent line gives

$$\frac{dy}{dx} = \frac{\frac{dy}{dt}}{\frac{dx}{dt}} = \frac{\sin t}{1 - \cos t}$$

The points where the tangent line has slope $\frac{1}{2}$ are those where $\frac{dy}{dx} = \frac{1}{2}$. We solve for t:

$$\begin{aligned} \frac{dy}{dx} &= \frac{1}{2} \\ \frac{\sin t}{1 - \cos t} &= \frac{1}{2} \\ 2\sin t &= 1 - \cos t \end{aligned} \tag{1}$$

We let $u = \sin t$. Then $\cos t = \pm\sqrt{1 - \sin^2 t} = \pm\sqrt{1 - u^2}$. Hence

$$2u = 1 \pm \sqrt{1 - u^2}$$

We transfer sides and square to obtain

$$\pm\sqrt{1 - u^2} = 2u - 1$$

$$\begin{aligned} 1-u^2 &= 4u^2-4u+1 \\ 5u^2-4u &= u(5u-4)=0 \\ u=0,\ u &= \frac{4}{5} \end{aligned}$$

We find t by the relation $u=\sin t$:

$$\begin{aligned} u=0: &\quad \sin t = 0 \Rightarrow t=0, t=\pi \\ u=\frac{4}{5}: &\quad \sin t = \frac{4}{5} \Rightarrow t\approx 0.93, t\approx 2.21 \end{aligned}$$

These correspond to the points $(0,1)$, $(\pi,2)$, $(0.13,0.40)$, and $(1.41,1.60)$, respectively, for $0<t<2\pi$.

18. Find the points on $(t+\sin t, t-2\sin t)$ where the tangent is vertical or horizontal.

SOLUTION We use the theorem for the slope of the tangent line to find $\frac{dy}{dx}$:

$$\frac{dy}{dx}=\frac{\frac{dy}{dt}}{\frac{dx}{dt}}=\frac{1-2\cos t}{1+\cos t}$$

We find the values of t for which the denominator is zero. We ignore the numerator, since when $1+\cos t=0$, $1-2\cos t=3\neq 0$.

$$\begin{aligned} 1+\cos t &= 0 \\ \cos t &= -1 \\ t &= \pi+2\pi k \quad \text{where } k\in\mathbb{Z} \end{aligned}$$

We now find the values of t for which the numerator is 0:

$$\begin{aligned} 1-2\cos t &= 0 \\ 1 &= 2\cos t \\ \frac{1}{2} &= \cos t \\ t &= \pm\frac{\pi}{3}+2\pi k \quad \text{where } k\in\mathbb{Z} \end{aligned}$$

Note that the denominator is not zero at these points. Thus, we have vertical tangents at $t=\pi+2\pi k$ and horizontal tangents at $t=\pm\pi/3+2\pi k$.

19. Find the equation of the Bézier curve with control points

$$P_0=(-1,-1),\quad P_1=(-1,1),\quad P_2=(1,1),\quad P_3(1,-1)$$

SOLUTION We substitute the given points in the appropriate formulas in the text to find the parametric equations of the Bézier curve. We obtain

$$\begin{aligned} x(t) &= -(1-t)^3-3t(1-t)^2+t^2(1-t)+t^3 \\ &= -(1-3t+3t^2-t^3)-(3t-6t^2+3t^3)+(t^2-t^3)+t^3 \\ &= (-2t^3+4t^2-1) \\ y(t) &= -(1-t)^3+3t(1-t)^2+t^2(1-t)-t^3 \\ &= -(1-3t+3t^2-t^3)+(3t-6t^2+3t^3)+(t^2-t^3)-t^3 \\ &= (2t^3-8t^2+6t-1) \end{aligned}$$

20. Find the speed at $t=\frac{\pi}{4}$ of a particle whose position at time t seconds is $c(t)=(\sin 4t, \cos 3t)$.

SOLUTION We use the parametric definition to find the speed. We obtain

$$\frac{ds}{dt}=\sqrt{((\sin 4t)')^2+((\cos 3t)')^2}=\sqrt{(4\cos 4t)^2+(-3\sin 3t)^2}=\sqrt{16\cos^2 4t+9\sin^2 3t}$$

At time $t=\frac{\pi}{4}$ the speed is

$$\left.\frac{ds}{dt}\right|_{t=\pi/4}=\sqrt{16\cos^2\pi+9\sin^2\frac{3\pi}{4}}=\sqrt{16+9\cdot\frac{1}{2}}=\sqrt{20.5}\approx 4.53$$

21. Find the speed (as a function of t) of a particle whose position at time t seconds is $c(t) = (\sin t + t, \cos t + t)$. What is the particle's maximal speed?

SOLUTION We use the parametric definition to find the speed. We obtain

$$\frac{ds}{dt} = \sqrt{((\sin t + t)')^2 + ((\cos t + t)')^2} = \sqrt{(\cos t + 1)^2 + (1 - \sin t)^2}$$
$$= \sqrt{\cos^2 t + 2\cos t + 1 + 1 - 2\sin t + \sin^2 t} = \sqrt{3 + 2(\cos t - \sin t)}$$

We now differentiate the speed function to find its maximum:

$$\frac{d^2 s}{dt^2} = \left(\sqrt{3 + 2(\cos t - \sin t)}\right)' = \frac{-\sin t - \cos t}{\sqrt{3 + 2(\cos t - \sin t)}}$$

We equate the derivative to zero, to obtain the maximum point:

$$\begin{aligned}
\frac{d^2 s}{dt^2} &= 0 \\
\frac{-\sin t - \cos t}{\sqrt{3 + 2(\cos t - \sin t)}} &= 0 \\
-\sin t - \cos t &= 0 \\
-\sin t &= \cos t \\
\sin(-t) &= \cos(-t) \\
-t &= \frac{\pi}{4} + \pi k \\
t &= -\frac{\pi}{4} + \pi k
\end{aligned}$$

Substituting t in the function of speed we obtain the value of the maximal speed:

$$\sqrt{3 + 2\left(\cos -\frac{\pi}{4} - \sin -\frac{\pi}{4}\right)} = \sqrt{3 + 2\left(\frac{\sqrt{2}}{2} - \left(-\frac{\sqrt{2}}{2}\right)\right)} = \sqrt{3 + 2\sqrt{2}}$$

22. Find the length of $(3e^t - 3, 4e^t + 7)$ for $0 \le t \le 1$.

SOLUTION We use the formula for arc length, to obtain

$$s = \int_0^1 \sqrt{((3e^t - 3)')^2 + ((4e^t + 7)')^2}\, dt = \int_0^1 \sqrt{(3e^t)^2 + (4e^t)^2}\, dt$$
$$= \int_0^1 \sqrt{9e^{2t} + 16e^{2t}}\, dt = \int_0^1 \sqrt{25e^{2t}}\, dt = \int_0^1 5e^t\, dt = 5e^t\Big|_0^1 = 5(e - 1)$$

In Exercises 23 and 24, let $c(t) = (e^{-t}\cos t, e^{-t}\sin t)$.

23. Show that $c(t)$ for $0 \le t < \infty$ has finite length and calculate its value.

SOLUTION We use the formula for arc length, to obtain:

$$\begin{aligned}
s &= \int_0^\infty \sqrt{((e^{-t}\cos t)')^2 + ((e^{-t}\sin t)')^2} dt \\
&= \int_0^\infty \sqrt{(-e^{-t}\cos t - e^{-t}\sin t)^2 + (-e^{-t}\sin t + e^{-t}\cos t)^2} dt \\
&= \int_0^\infty \sqrt{e^{-2t}(\cos t + \sin t)^2 + e^{-2t}(\cos t - \sin t)^2} dt \\
&= \int_0^\infty e^{-t}\sqrt{\cos^2 t + 2\sin t\cos t + \sin^2 t + \cos^2 t - 2\sin t\cos t + \sin^2 t}\, dt \\
&= \int_0^\infty e^{-t}\sqrt{2} dt = \sqrt{2}(-e^{-t})\Big|_0^\infty = -\sqrt{2}\left(\lim_{t\to\infty} e^{-t} - e^0\right) \\
&= -\sqrt{2}(0 - 1) = \sqrt{2}
\end{aligned}$$

24. Find the first positive value of t_0 such that the tangent line to $c(t_0)$ is vertical, and calculate the speed at $t = t_0$.

SOLUTION The curve has a vertical tangent where $\lim_{t\to t_0}\left|\frac{dy}{dx}\right| = \infty$. We first find $\frac{dy}{dx}$ using the theorem for the slope of a tangent line:

$$\frac{dy}{dx} = \frac{\frac{dy}{dt}}{\frac{dx}{dt}} = \frac{(e^{-t}\sin t)'}{(e^{-t}\cos t)'} = \frac{-e^{-t}\sin t + e^{-t}\cos t}{-e^{-t}\cos t - e^{-t}\sin t}$$
$$= -\frac{\cos t - \sin t}{\cos t + \sin t} = \frac{\sin t - \cos t}{\sin t + \cos t}$$

We now search for t_0 such that $\lim_{t\to t_0}\left|\frac{dy}{dx}\right| = \infty$. In our case, this happens when the denominator is 0, but the numerator is not, thus:

$$\sin t_0 + \cos t_0 = 0$$
$$\cos t_0 = -\sin t_0$$
$$\cos -t_0 = \sin -t_0$$
$$-t_0 = \frac{\pi}{4} - \pi$$
$$t_0 = \frac{3}{4}\pi$$

We now use the formula for the speed, to find the speed at t_0.

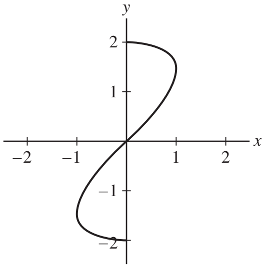
$$\frac{ds}{dt} = \sqrt{((e^{-t}\sin t)')^2 + ((e^{-t}\cos t)')^2}$$
$$= \sqrt{(-e^{-t}\cos t - e^{-t}\sin t)^2 + (-e^{-t}\sin t + e^{-t}\cos t)^2}$$
$$= \sqrt{e^{-2t}(\cos t + \sin t)^2 + e^{-2t}(\cos t - \sin t)^2}$$
$$= e^{-t}\sqrt{\cos^2 t + 2\sin t\cos t + \sin^2 t + \cos^2 t - 2\sin t\cos t + \sin^2 t} = e^{-t}\sqrt{2}$$

Next we substitute $t = \frac{3}{4}\pi$, to obtain

$$e^{-t_0}\sqrt{2} = e^{-3\pi/4}\sqrt{2}$$

25. CAS Plot $c(t) = (\sin 2t, 2\cos t)$ for $0 \le t \le \pi$. Express the length of the curve as a definite integral, and approximate it using a computer algebra system.

SOLUTION We use a CAS to plot the curve. The resulting graph is shown here.



Plot of the curve $(\sin 2t, 2\cos t)$

To calculate the arc length we use the formula for the arc length to obtain

$$s = \int_0^{\pi} \sqrt{(2\cos 2t)^2 + (-2\sin t)^2}\,dt = 2\int_0^{\pi} \sqrt{\cos^2 2t + \sin^2 t}\,dt$$

We use a CAS to obtain $s = 6.0972$.

26. Convert the points $(x, y) = (1, -3), (3, -1)$ from rectangular to polar coordinates.

SOLUTION We convert the given points from cartesian coordinates to polar coordinates. For the first point we have

$$r = \sqrt{x^2 + y^2} = \sqrt{1^2 + (-3)^2} = \sqrt{10}$$
$$\theta = \arctan \frac{y}{x} = \arctan -3 = 5.034$$

For the second point we have

$$r = \sqrt{x^2 + y^2} = \sqrt{3^2 + (-1)^2} = \sqrt{10}$$
$$\theta = \arctan \frac{y}{x} = \arctan \frac{-1}{3} = -0.321,\ 5.961$$

27. Convert the points $(r, \theta) = \left(1, \frac{\pi}{6}\right), \left(3, \frac{5\pi}{4}\right)$ from polar to rectangular coordinates.

SOLUTION We convert the points from polar coordinates to cartesian coordinates. For the first point we have

$$x = r\cos\theta = 1 \cdot \cos\frac{\pi}{6} = \frac{\sqrt{3}}{2}$$
$$y = r\sin\theta = 1 \cdot \sin\frac{\pi}{6} = \frac{1}{2}$$

For the second point we have

$$x = r\cos\theta = 3\cos\frac{5\pi}{4} = -\frac{3\sqrt{2}}{2}$$
$$y = r\sin\theta = 3\sin\frac{5\pi}{4} = -\frac{3\sqrt{2}}{2}$$

28. Write $(x + y)^2 = xy + 6$ as an equation in polar coordinates.

SOLUTION We use the formula for converting from cartesian coordinates to polar coordinates to substitute r and θ for x and y:

$$\begin{aligned}
(x+y)^2 &= xy + 6 \\
x^2 + 2xy + y^2 &= xy + 6 \\
x^2 + y^2 &= -xy + 6 \\
r^2 &= -(r\cos\theta)(r\sin\theta) + 6 \\
r^2 &= -r^2\cos\theta\sin\theta + 6 \\
r^2(1 + \sin\theta\cos\theta) &= 6 \\
r^2 &= \frac{6}{1 + \sin\theta\cos\theta} \\
r^2 &= \frac{6}{1 + \frac{\sin 2\theta}{2}} \\
r^2 &= \frac{12}{2 + \sin 2\theta}
\end{aligned}$$

29. Write $r = \dfrac{2\cos\theta}{\cos\theta - \sin\theta}$ as an equation in rectangular coordinates.

SOLUTION We use the formula for converting from polar coordinates to cartesian coordinates to substitute x and y for r and θ:

$$\begin{aligned}
r &= \frac{2\cos\theta}{\cos\theta - \sin\theta} \\
\sqrt{x^2 + y^2} &= \frac{2r\cos\theta}{r\cos\theta - r\sin\theta} \\
\sqrt{x^2 + y^2} &= \frac{2x}{x - y}
\end{aligned}$$

30. Show that $r = \dfrac{4}{7\cos\theta - \sin\theta}$ is the polar equation of a line.

SOLUTION We use the formula for converting from polar coordinates to cartesian coordinates to substitute x and y for r and θ:

$$\begin{aligned} r &= \frac{4}{7\cos\theta - \sin\theta} \\ 1 &= \frac{4}{7r\cos\theta - r\sin\theta} \\ 1 &= \frac{4}{7x - y} \\ 7x - y &= 4 \\ y &= 7x - 4 \end{aligned}$$

We obtained a linear function. Since the original equation in polar coordinates represents the same curve, it represents a straight line as well.

31. GU Convert the equation

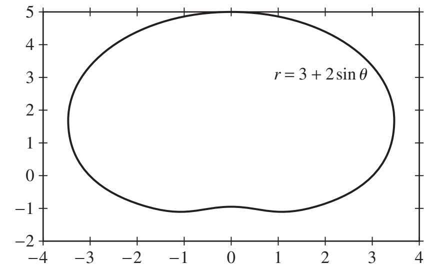
$$9(x^2 + y^2) = (x^2 + y^2 - 2y)^2$$

to polar coordinates, and plot it with a graphing utility.

SOLUTION We use the formula for converting from cartesian coordinates to polar coordinates to substitute r and θ for x and y:

$$\begin{aligned} 9(x^2 + y^2) &= (x^2 + y^2 - 2y)^2 \\ 9r^2 &= (r^2 - 2r\sin\theta)^2 \\ 3r &= r^2 - 2r\sin\theta \\ 3 &= r - 2\sin\theta \\ r &= 3 + 2\sin\theta \end{aligned}$$

The plot of $r = 3 + 2\sin\theta$ is shown here:



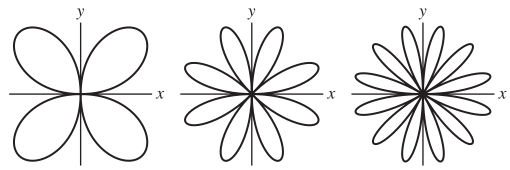
Plot of $r = 3 + 2\sin\theta$

32. Calculate the area of the circle $r = 3\sin\theta$ bounded by the rays $\theta = \frac{\pi}{3}$ and $\theta = \frac{2\pi}{3}$.

SOLUTION We use the formula for area in polar coordinates to obtain

$$\begin{aligned} A &= \frac{1}{2}\int_{\pi/3}^{2\pi/3} (3\sin\theta)^2\,d\theta = \frac{9}{2}\int_{\pi/3}^{2\pi/3} \sin^2\theta\,d\theta = \frac{9}{4}\int_{\pi/3}^{2\pi/3} (1 - \cos 2\theta)\,d\theta = \frac{9}{4}\left(\theta - \frac{\sin 2\theta}{2}\Big|_{\pi/3}^{2\pi/3}\right) \\ &= \frac{9}{4}\left(\frac{\pi}{3} - \frac{1}{2}\left(\sin\frac{4\pi}{3} - \sin\frac{2\pi}{3}\right)\right) = \frac{9}{4}\left(\frac{\pi}{3} - \frac{1}{2}\left(-\frac{\sqrt{3}}{2} - \frac{\sqrt{3}}{2}\right)\right) = \frac{9}{4}\left(\frac{\pi}{3} + \frac{\sqrt{3}}{2}\right) \end{aligned}$$

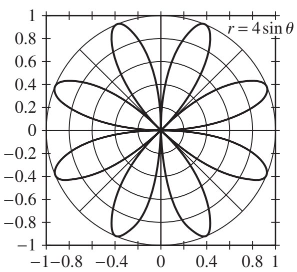
33. Calculate the area of one petal of $r = \sin 4\theta$ (see Figure 1).



$n = 2$ (4 petals) $n = 4$ (8 petals) $n = 6$ (12 petals)

FIGURE 1 Plot of $r = \sin(n\theta)$.

SOLUTION We use a CAS to generate the plot, as shown here.



Plot of $r = \sin 4\theta$

We can see that one leaf lies between the rays $\theta = 0$ and $\theta = \dfrac{\theta}{4}$. We now use the formula for area in polar coordinates to obtain

$$A = \frac{1}{2}\int_0^{\pi/4} \sin^2 4\theta \, d\theta = \frac{1}{4}\int_0^{\pi/4} (1 - \cos 8\theta)\, d\theta = \frac{1}{4}\left(\theta - \frac{\sin 8\theta}{8}\Big|_0^{\pi/4}\right)$$

$$= \frac{\pi}{16} - \frac{1}{32}(\sin 2\pi - \sin 0) = \frac{\pi}{16}$$

34. The equation $r = \sin(n\theta)$, where $n \geq 2$ is even, is a "rose" of $2n$ petals (Figure 1). Compute the total area of the flower, and show that it does not depend on n.

SOLUTION We calculate the total area of the flower, that is, the area between the rays $\theta = 0$ and $\theta = 2\pi$, using the formula for area in polar coordinates:

$$A = \frac{1}{2}\int_0^{2\pi} \sin^2 2n\theta \, d\theta = \frac{1}{4}\int_0^{2\pi} (1 - \cos 4n\theta)\, d\theta = \frac{1}{4}\left(\theta - \frac{\sin 4n\theta}{4n}\Big|_0^{2\pi}\right)$$

$$= \frac{\pi}{2} - \frac{1}{16n}(\sin 8n\pi - \sin 0) = \frac{\pi}{2}$$

Since the area is $\dfrac{\pi}{2}$ for every $n \in \mathbb{Z}$, the area is independent of n.

35. Calculate the total area enclosed by the curve $r^2 = \cos\theta e^{\sin\theta}$ (Figure 2).

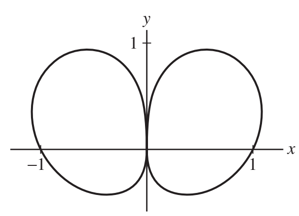


FIGURE 2 Graph of $r^2 = \cos\theta e^{\sin\theta}$.

SOLUTION Note that this is defined only for θ between $-\pi/2$ and $\pi/2$. We use the formula for area in polar coordinates to obtain:

$$A = \frac{1}{2}\int_{-\pi/2}^{\pi/2} r^2 \, d\theta = \frac{1}{2}\int_{-\pi/2}^{\pi/2} \cos\theta e^{\sin\theta}\, d\theta$$

We evaluate the integral by making the substitution $x = \sin\theta\, dx = \cos\theta\, d\theta$:

$$A = \frac{1}{2}\int_{-\pi/2}^{\pi/2} \cos\theta e^{\sin\theta} d\theta = \frac{1}{2}e^x\Big|_{-1}^{1} = \frac{1}{2}\left(e - e^{-1}\right)$$

36. Find the shaded area in Figure 3.

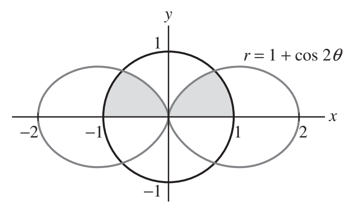

FIGURE 3

SOLUTION We first find the points of intersection between the unit circle and the function.

$$\begin{aligned}1 &= 1 + \cos 2\theta\\ \cos 2\theta &= 0\\ 2\theta &= \frac{\pi}{2} + \pi n\\ \theta &= \frac{\pi}{4} + \frac{\pi}{2}n\end{aligned}$$

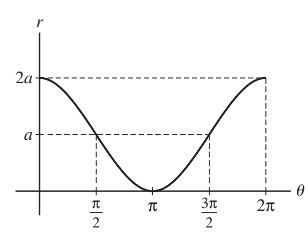
We now find the area of the shaded figure in the first quadrant. This has two parts. The first, from 0 to $\pi/4$, is just an octant of the unit circle, and thus has area $\pi/8$. The second, from $\pi/4$ to $\pi/2$, is found as follows:

$$\begin{aligned}A &= \frac{1}{2}\int_{\pi/4}^{\pi/2} (1+\cos 2\theta)^2\, d\theta = \frac{1}{2}\int_{\pi/4}^{\pi/2} 1 + 2\cos 2\theta + \cos^2 2\theta\, d\theta = \frac{1}{2}\int_{\pi/4}^{\pi/2} \frac{3}{2} + 2\cos 2\theta + \frac{1}{2}\cos 4\theta\, d\theta\\ &= \frac{1}{2}\left(\frac{3\theta}{2} + \sin 2\theta + \frac{1}{8}\sin 4\theta\right)\Big|_{\pi/4}^{\pi/2} = \frac{1}{2}\left(\frac{3\pi}{8} - 1\right)\end{aligned}$$

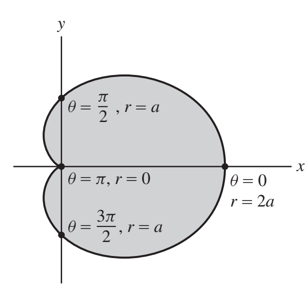
The total area in the first quadrant is thus $\frac{5\pi}{16} - \frac{1}{2}$; multiply by 2 to get the total area of $\frac{5\pi}{8} - 1$.

37. Find the area enclosed by the cardioid $r = a(1 + \cos\theta)$, where $a > 0$.

SOLUTION The graph of $r = a\,(1 + \cos\theta)$ in the $r\theta$-plane for $0 \le \theta \le 2\pi$ and the cardioid in the xy-plane are shown in the following figures:



$r = a\,(1 + \cos\theta)$



The cardioid $r = a\,(1 + \cos\theta)$, $a > 0$

As θ varies from 0 to π the radius r decreases from $2a$ to 0, and this gives the upper part of the cardioid.

The lower part is traced as θ varies from π to 2π and consequently r increases from 0 back to $2a$. We compute the area enclosed by the upper part of the cardioid and the x-axis, using the following integral (we use the identity $\cos^2\theta = \frac{1}{2} + \frac{1}{2}\cos 2\theta$):

$$\begin{aligned}\frac{1}{2}\int_0^{\pi} r^2\, d\theta &= \frac{1}{2}\int_0^{\pi} a^2(1+\cos\theta)^2\, d\theta = \frac{a^2}{2}\int_0^{\pi}\left(1 + 2\cos\theta + \cos^2\theta\right) d\theta\\ &= \frac{a^2}{2}\int_0^{\pi}\left(1 + 2\cos\theta + \frac{1}{2} + \frac{1}{2}\cos 2\theta\right) d\theta = \frac{a^2}{2}\int_0^{\pi}\left(\frac{3}{2} + 2\cos\theta + \frac{1}{2}\cos 2\theta\right) d\theta\\ &= \frac{a^2}{2}\left[\frac{3\theta}{2} + 2\sin\theta + \frac{1}{4}\sin 2\theta\right]\Big|_0^{\pi} = \frac{a^2}{2}\left[\frac{3\pi}{2} + 2\sin\pi + \frac{1}{4}\sin 2\pi - 0\right] = \frac{3\pi a^2}{4}\end{aligned}$$

Using symmetry, the total area A enclosed by the cardioid is

$$A = 2 \cdot \frac{3\pi a^2}{4} = \frac{3\pi a^2}{2}$$

38. Calculate the length of the curve with polar equation $r = \theta$ in Figure 4.

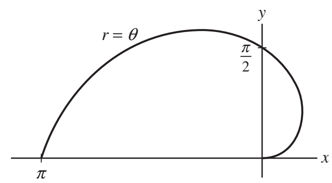


FIGURE 4

SOLUTION The interval of θ values is $0 \le \theta \le \pi$. We use the formula for the arc length in polar coordinates, with $r = f(\theta) = \theta$. We get

$$S = \int_0^{\pi} \sqrt{f(\theta)^2 + f'(\theta)^2}\, d\theta = \int_0^{\pi} \sqrt{\theta^2 + \left(\theta'\right)^2}\, d\theta = \int_0^{\pi} \sqrt{\theta^2 + 1}\, d\theta$$
$$= \frac{\theta}{2}\sqrt{\theta^2+1} + \frac{1}{2}\ln\left|\theta + \sqrt{\theta^2+1}\right|\Bigg|_{\theta=0}^{\pi} = \frac{\pi}{2}\sqrt{\pi^2+1} + \frac{1}{2}\ln\left(\pi + \sqrt{\pi^2+1}\right)$$

39. CAS Figure 5 shows the graph of $r = e^{0.5\theta}\sin\theta$ for $0 \le \theta \le 2\pi$. Use a computer algebra system to approximate the difference in length between the outer and inner loops.

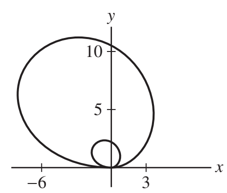

FIGURE 5

SOLUTION We note that the inner loop is the curve for $\theta \in [0, \pi]$, and the outer loop is the curve for $\theta \in [\pi, 2\pi]$. We express the length of these loops using the formula for the arc length. The length of the inner loop is

$$s_1 = \int_0^{\pi} \sqrt{(e^{0.5\theta}\sin\theta)^2 + ((e^{0.5\theta}\sin\theta)')^2} d\theta = \int_0^{\pi} \sqrt{e^{\theta}\sin^2\theta + \left(\frac{e^{0.5\theta}\sin\theta}{2} + e^{0.5\theta}\cos\theta\right)^2}\, d\theta$$

and the length of the outer loop is

$$s_2 = \int_{\pi}^{2\pi} \sqrt{e^{\theta}\sin^2\theta + \left(\frac{e^{0.5\theta}\sin\theta}{2} + e^{0.5\theta}\cos\theta\right)^2}\, d\theta$$

We now use the CAS to calculate the arc length of each of the loops. We obtain that the length of the inner loop is 7.5087 and the length of the outer loop is 36.121, hence the outer one is 4.81 times longer than the inner one.

40. Show that $r = f_1(\theta)$ and $r = f_2(\theta)$ define the same curves in polar coordinates if $f_1(\theta) = -f_2(\theta + \pi)$. Use this to show that the following define the same conic section:

$$r = \frac{de}{1 - e\cos\theta}, \qquad r = \frac{-de}{1 + e\cos\theta}$$

SOLUTION Suppose (r, θ) lies on the curve $r = f_2(\theta)$. Since (r, θ) and $(-r, \theta + \pi)$ define the same point in polar coordinates, we have $-r = f_2(\theta + \pi) = -f_1(\theta)$, so that $r = f_1(\theta)$, Thus (r, θ) lies on f_1 as well. Conversely, suppose (r, θ) lies on $r = f_1(\theta)$. Since (r, θ) and $(-r, \theta - \pi)$ define the same point in polar coordinates, we have $-r = f_1(\theta - \pi) = -f_2(\theta - \pi + \pi) = -f_2(\theta)$ so that $r = f_2(\theta)$ and (r, θ) lies on f_2 as well. Thus the two equations define exactly the same set of points.

Now set

$$f_1(\theta) = \frac{de}{1 - e\cos\theta} \qquad f_2(\theta) = -\frac{de}{1 + e\cos\theta}$$

and consider the polar equations $r = f_1(\theta)$ and $r = f_2(\theta)$. We have

$$-f_2(\theta + \pi) = -\frac{-de}{1 + e\cos(\theta + \pi)} = \frac{de}{1 - e\cos\theta} = f_1(\theta)$$

so that by the above, the two equations define the same conic section.

In Exercises 41–44, identify the conic section. Find the vertices and foci.

41. $\left(\frac{x}{3}\right)^2 + \left(\frac{y}{2}\right)^2 = 1$

SOLUTION This is an ellipse in standard position. Its foci are $(\pm\sqrt{3^2 - 2^2}, 0) = (\pm\sqrt{5}, 0)$ and its vertices are $(\pm 3, 0)$, $(0, \pm 2)$.

42. $x^2 - 2y^2 = 4$

SOLUTION We divide the equation by 4 to obtain

$$\left(\frac{x}{2}\right)^2 - \left(\frac{y}{\sqrt{2}}\right)^2 = 1$$

This is a hyperbola in standard position, its foci are $\left(\pm\sqrt{2^2 + \sqrt{2}^2}, 0\right) = (\pm\sqrt{6}, 0)$, and its vertices are $(\pm 2, 0)$.

43. $\left(2x + \frac{1}{2}y\right)^2 = 4 - (x - y)^2$

SOLUTION We simplify the equation:

$$\begin{aligned}
\left(2x + \frac{1}{2}y\right)^2 &= 4 - (x - y)^2 \\
4x^2 + 2xy + \frac{1}{4}y^2 &= 4 - x^2 + 2xy - y^2 \\
5x^2 + \frac{5}{4}y^2 &= 4 \\
\frac{5x^2}{4} + \frac{5y^2}{16} &= 1 \\
\left(\frac{x}{\frac{2}{\sqrt{5}}}\right)^2 + \left(\frac{y}{\frac{4}{\sqrt{5}}}\right)^2 &= 1
\end{aligned}$$

This is an ellipse in standard position, with foci $\left(0, \pm\sqrt{\left(\frac{4}{\sqrt{5}}\right)^2 - \left(\frac{2}{\sqrt{5}}\right)^2}\right) = \left(0, \pm\sqrt{\frac{12}{5}}\right)$ and vertices $\left(\pm\frac{2}{\sqrt{5}}, 0\right)$, $\left(0, \pm\frac{4}{\sqrt{5}}\right)$.

44. $(y - 3)^2 = 2x^2 - 1$

SOLUTION We simplify the equation:

$$\begin{aligned}
(y - 3)^2 &= 2x^2 - 1 \\
2x^2 - (y - 3)^2 &= 1 \\
\left(\frac{x}{\frac{1}{\sqrt{2}}}\right)^2 - (y - 3)^2 &= 1
\end{aligned}$$

This is a hyperbola shifted 3 units on the y-axis. Therefore, its foci are $\left(\pm\sqrt{\left(\frac{1}{\sqrt{2}}\right)^2 + 1}, 3\right) = \left(\pm\sqrt{\frac{3}{2}}, 3\right)$ and its vertices are $\left(\pm\frac{1}{\sqrt{2}}, 3\right)$.

In Exercises 45–50, find the equation of the conic section indicated.

45. Ellipse with vertices $(\pm 8, 0)$ and foci $(\pm\sqrt{3}, 0)$

SOLUTION Since the foci of the desired ellipse are on the x-axis, we conclude that $a > b$. We are given that the points $(\pm 8, 0)$ are vertices of the ellipse, and since they are on the x-axis, $a = 8$. We are given that the foci are $(\pm\sqrt{3}, 0)$ and we have shown that $a > b$, hence we have that $\sqrt{a^2 - b^2} = \sqrt{3}$. Solving for b yields

$$\sqrt{a^2 - b^2} = \sqrt{3}$$
$$a^2 - b^2 = 3$$
$$8^2 - b^2 = 3$$
$$b^2 = 61$$
$$b = \sqrt{61}$$

Next we use a and b to construct the equation of the ellipse:

$$\left(\frac{x}{8}\right)^2 + \left(\frac{y}{\sqrt{61}}\right)^2 = 1.$$

46. Ellipse with foci $(\pm 8, 0)$, eccentricity $\frac{1}{8}$

SOLUTION If the foci are on the x-axis, then $a > b$, and $c = \sqrt{a^2 - b^2}$. We are given that $e = \frac{1}{8}$, and $c = 8$. Substituting and solving for a and b yields

$$e = \frac{c}{a}$$
$$c = \sqrt{a^2 - b^2}$$
$$\frac{1}{8} = \frac{8}{a}$$
$$64 = a$$
$$8 = \sqrt{64^2 - b^2}$$
$$64 = 64^2 - b^2$$
$$b^2 = 64 \cdot 63$$
$$b = 8\sqrt{63}$$

We use a and b to construct the equation of the ellipse:

$$\left(\frac{x}{64}\right)^2 + \left(\frac{y}{8\sqrt{63}}\right)^2 = 1.$$

47. Hyperbola with vertices $(\pm 8, 0)$, asymptotes $y = \pm \frac{3}{4}x$

SOLUTION Since the asymptotes of the hyperbola are $y = \pm \frac{3}{4}x$, and the equation of the asymptotes for a general hyperbola in standard position is $y = \pm \frac{b}{a}x$, we conclude that $\frac{b}{a} = \frac{3}{4}$. We are given that the vertices are $(\pm 8, 0)$, thus $a = 8$. We substitute and solve for b:

$$\frac{b}{a} = \frac{3}{4}$$
$$\frac{b}{8} = \frac{3}{4}$$
$$b = 6$$

Next we use a and b to construct the equation of the hyperbola:

$$\left(\frac{x}{8}\right)^2 - \left(\frac{y}{6}\right)^2 = 1.$$

48. Hyperbola with foci $(2, 0)$ and $(10, 0)$, eccentricity $e = 4$

SOLUTION Since the foci lie on the x axis, the x is the focal axis. The center of the hyperbola is midway between the foci, so lies at $(6, 0)$, and $c = 4$. Then $c = ae$ gives $a = 1$; then $b = \sqrt{c^2 - a^2} = \sqrt{15}$, so that the equation of the hyperbola is

$$(x - 6)^2 - \left(\frac{y}{\sqrt{15}}\right)^2 = 1$$

49. Parabola with focus $(8, 0)$, directrix $x = -8$

SOLUTION This is similar to the usual equation of a parabola, but we must use y as x, and x as y, to obtain

$$x = \frac{1}{32}y^2.$$

50. Parabola with vertex $(4, -1)$, directrix $x = 15$

SOLUTION The directrix is a vertical line and the vertex is $(4, -1)$, so the equation is of the form

$$x - 4 = \frac{1}{4c}(y + 1)^2$$

The directrix is to the right of the vertex; the distance from the directrix to the vertex is -11, so $c = -11$ and the equation is

$$x = 4 - \frac{1}{44}(y + 1)^2$$

51. Find the asymptotes of the hyperbola $3x^2 + 6x - y^2 - 10y = 1$.

SOLUTION We complete the squares and simplify:

$$\begin{aligned} 3x^2 + 6x - y^2 - 10y &= 1 \\ 3(x^2 + 2x) - (y^2 + 10y) &= 1 \\ 3(x^2 + 2x + 1 - 1) - (y^2 + 10y + 25 - 25) &= 1 \\ 3(x + 1)^2 - 3 - (y + 5)^2 + 25 &= 1 \\ 3(x + 1)^2 - (y + 5)^2 &= -21 \\ \left(\frac{y + 5}{\sqrt{21}}\right)^2 - \left(\frac{x + 1}{\sqrt{7}}\right)^2 &= 1 \end{aligned}$$

We obtained a hyperbola with focal axis that is parallel to the y-axis, and is shifted -5 units on the y-axis, and -1 units in the x-axis. Therefore, the asymptotes are

$$x + 1 = \pm\frac{\sqrt{7}}{\sqrt{21}}(y + 5) \quad \text{or} \quad y + 5 = \pm\sqrt{3}(x + 1).$$

52. Show that the "conic section" with equation $x^2 - 4x + y^2 + 5 = 0$ has no points.

SOLUTION We complete the squares in the given equation:

$$\begin{aligned} x^2 - 4x + 4y^2 + 5 &= 0 \\ x^2 - 4x + 4 - 4 + 4y^2 + 5 &= 0 \\ (x - 2)^2 + 4y^2 &= -1 \end{aligned}$$

Since $(x - 2)^2 \geq 0$ and $y^2 \geq 0$, there is no point satisfying the equation, hence it cannot represent a conic section.

53. Show that the relation $\frac{dy}{dx} = (e^2 - 1)\frac{x}{y}$ holds on a standard ellipse or hyperbola of eccentricity e.

SOLUTION We differentiate the equations of the standard ellipse and the hyperbola with respect to x:

Ellipse:	Hyperbola:
$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$	$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$
$\frac{2x}{a^2} + \frac{2y}{b^2}\frac{dy}{dx} = 0$	$\frac{2x}{a^2} - \frac{2y}{b^2}\frac{dy}{dx} = 0$
$\frac{dy}{dx} = -\frac{b^2}{a^2}\frac{x}{y}$	$\frac{dy}{dx} = \frac{b^2}{a^2}\frac{x}{y}$

The eccentricity of the ellipse is $e = \frac{\sqrt{a^2 - b^2}}{a}$, hence $e^2a^2 = a^2 - b^2$ or $e^2 = 1 - \frac{b^2}{a^2}$ yielding $\frac{b^2}{a^2} = 1 - e^2$.

The eccentricity of the hyperbola is $e = \frac{\sqrt{a^2+b^2}}{a}$, hence $e^2a^2 = a^2 + b^2$ or $e^2 = 1 + \frac{b^2}{a^2}$, giving $\frac{b^2}{a^2} = e^2 - 1$. Combining with the expressions for $\frac{dy}{dx}$ we get:

Ellipse: $$\frac{dy}{dx} = -(1-e^2)\frac{x}{y} = (e^2-1)\frac{x}{y}$$

Hyperbola: $$\frac{dy}{dx} = (e^2-1)\frac{x}{y}$$

We, thus, proved that the relation $\frac{dy}{dx} = (e^2 - 1)\frac{x}{y}$ holds on a standard ellipse or hyperbola of eccentricity e.

54. The orbit of Jupiter is an ellipse with the sun at a focus. Find the eccentricity of the orbit if the perihelion (closest distance to the sun) equals 740×10^6 km and the aphelion (farthest distance from the sun) equals 816×10^6 km.

SOLUTION For the sake of simplicity, we treat all numbers in units of 10^6 km. By Kepler's First Law we conclude that the sun is at one of the foci of the ellipse. Therefore, the closest and farthest points to the sun are vertices. Moreover, they are the vertices on the x-axis, hence we conclude that the distance between the two vertices is

$$2a = 740 + 816 = 1556$$

Since the distance between each focus and the vertex that is closest to it is the same distance, and since $a = 778$, we conclude that the distance between the foci is

$$c = a - 740 = 38$$

We substitute this in the formula for the eccentricity to obtain:

$$e = \frac{c}{a} = 0.0488.$$

55. Refer to Figure 25 in Section 11.5. Prove that the product of the perpendicular distances F_1R_1 and F_2R_2 from the foci to a tangent line of an ellipse is equal to the square b^2 of the semiminor axes.

SOLUTION We first consider the ellipse in standard position:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

The equation of the tangent line at $P = (x_0, y_0)$ is

$$\frac{x_0x}{a^2} + \frac{y_0y}{b^2} = 1$$

or

$$b^2x_0x + a^2y_0y - a^2b^2 = 0$$

The distances of the foci $F_1 = (c, 0)$ and $F_2 = (-c, 0)$ from the tangent line are

$$\overline{F_1R_1} = \frac{|b^2x_0c - a^2b^2|}{\sqrt{b^4x_0^2 + a^4y_0^2}}; \quad \overline{F_2R_2} = \frac{|b^2x_0c + a^2b^2|}{\sqrt{b^4x_0^2 + a^4y_0^2}}$$

We compute the product of the distances:

$$\overline{F_1R_1} \cdot \overline{F_2R_2} = \left|\frac{\left(b^2x_0c - a^2b^2\right)\left(b^2x_0c + a^2b^2\right)}{b^4x_0^2 + a^4y_0^2}\right| = \left|\frac{b^4x_0^2c^2 - a^4b^4}{b^4x_0^2 + a^4y_0^2}\right| \tag{1}$$

The point $P = (x_0, y_0)$ lies on the ellipse, hence:

$$\frac{x_0^2}{a^2} + \frac{y_0^2}{b^2} = 1 \Rightarrow a^4y_0^2 = a^4b^2 - a^2b^2x_0^2$$

We substitute in (1) to obtain (notice that $b^2 - a^2 = -c^2$)

$$\begin{aligned}\overline{F_1R_1} \cdot \overline{F_2R_2} &= \frac{|b^4x_0^2c^2 - a^4b^4|}{|b^4x_0^2 + a^4b^2 - a^2b^2x_0^2|} = \frac{|b^4x_0^2c^2 - a^4b^4|}{|b^2(b^2 - a^2)x_0^2 + a^4b^2|} \\ &= \frac{|b^4x_0^2c^2 - a^4b^4|}{|-b^2x_0^2c^2 + a^4b^2|} = \frac{|b^2(x_0^2c^2 - a^4)|}{|-(x_0^2c^2 - a^4)|} = |-b^2| = b^2\end{aligned}$$

The product $\overline{F_1R_1} \cdot \overline{F_2R_2}$ remains unchanged if we translate the standard ellipse.

12 VECTOR GEOMETRY

12.1 Vectors in the Plane (LT Section 13.1)

Preliminary Questions

1. Answer true or false. Every nonzero vector is:

(a) Equivalent to a vector based at the origin.

(b) Equivalent to a unit vector based at the origin.

(c) Parallel to a vector based at the origin.

(d) Parallel to a unit vector based at the origin.

SOLUTION

(a) This statement is true. Translating the vector so that it is based on the origin, we get an equivalent vector based at the origin.

(b) Equivalent vectors have equal lengths, hence vectors that are not unit vectors, are not equivalent to a unit vector.

(c) This statement is true. A vector based at the origin such that the line through this vector is parallel to the line through the given vector, is parallel to the given vector.

(d) Since parallel vectors do not necessarily have equal lengths, the statement is true by the same reasoning as in (c).

2. What is the length of $-3\mathbf{a}$ if $\|\mathbf{a}\| = 5$?

SOLUTION Using properties of the length we get

$$\|-3\mathbf{a}\| = |-3|\|\mathbf{a}\| = 3\|\mathbf{a}\| = 3 \cdot 5 = 15$$

3. Suppose that $\mathbf{v}$ has components $\langle 3, 1\rangle$. How, if at all, do the components change if you translate $\mathbf{v}$ horizontally two units to the left?

SOLUTION Translating $\mathbf{v} = \langle 3, 1\rangle$ yields an equivalent vector, hence the components are not changed.

4. What are the components of the zero vector based at $P = (3, 5)$?

SOLUTION The components of the zero vector are always $\langle 0, 0\rangle$, no matter where it is based.

5. True or false?

(a) The vectors $\mathbf{v}$ and $-2\mathbf{v}$ are parallel.

(b) The vectors $\mathbf{v}$ and $-2\mathbf{v}$ point in the same direction.

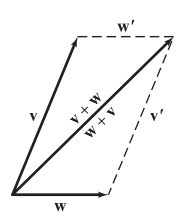
SOLUTION

(a) The lines through $\mathbf{v}$ and $-2\mathbf{v}$ are parallel, therefore these vectors are parallel.

(b) The vector $-2\mathbf{v}$ is a scalar multiple of $\mathbf{v}$, where the scalar is negative. Therefore $-2\mathbf{v}$ points in the opposite direction as $\mathbf{v}$.

6. Explain the commutativity of vector addition in terms of the Parallelogram Law.

SOLUTION To determine the vector $\mathbf{v} + \mathbf{w}$, we translate $\mathbf{w}$ to the equivalent vector $\mathbf{w}'$ whose tail coincides with the head of $\mathbf{v}$. The vector $\mathbf{v} + \mathbf{w}$ is the vector pointing from the tail of $\mathbf{v}$ to the head of $\mathbf{w}'$.



To determine the vector $\mathbf{w} + \mathbf{v}$, we translate $\mathbf{v}$ to the equivalent vector $\mathbf{v}'$ whose tail coincides with the head of $\mathbf{w}$. Then $\mathbf{w} + \mathbf{v}$ is the vector pointing from the tail of $\mathbf{w}$ to the head of $\mathbf{v}'$. In either case, the resulting vector is the vector with the tail at the basepoint of $\mathbf{v}$ and $\mathbf{w}$, and head at the opposite vertex of the parallelogram. Therefore $\mathbf{v} + \mathbf{w} = \mathbf{w} + \mathbf{v}$.

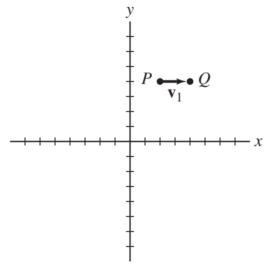
Exercises

1. Sketch the vectors $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3, \mathbf{v}_4$ with tail P and head Q, and compute their lengths. Are any two of these vectors equivalent?

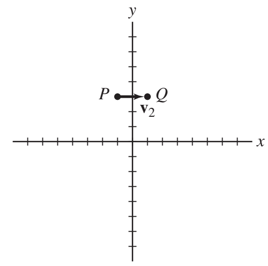
	$\mathbf{v}_1$	$\mathbf{v}_2$	$\mathbf{v}_3$	$\mathbf{v}_4$
P	$(2, 4)$	$(-1, 3)$	$(-1, 3)$	$(4, 1)$
Q	$(4, 4)$	$(1, 3)$	$(2, 4)$	$(6, 3)$

SOLUTION Using the definitions we obtain the following answers:

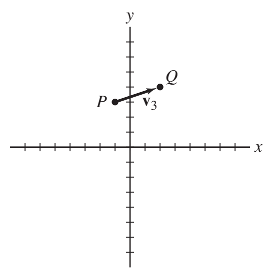
$$\mathbf{v}_1 = \overrightarrow{PQ} = \langle 4-2, 4-4\rangle = \langle 2, 0\rangle$$
$$\|\mathbf{v}_1\| = \sqrt{2^2+0^2} = 2$$



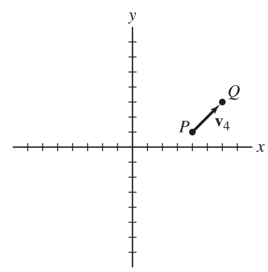
$$\mathbf{v}_2 = \langle 1-(-1), 3-3\rangle = \langle 2, 0\rangle$$
$$\|\mathbf{v}_2\| = \sqrt{2^2+0^2} = 2$$



$$\mathbf{v}_3 = \langle 2-(-1), 4-3\rangle = \langle 3, 1\rangle$$
$$\|\mathbf{v}_3\| = \sqrt{3^2+1^2} = \sqrt{10}$$



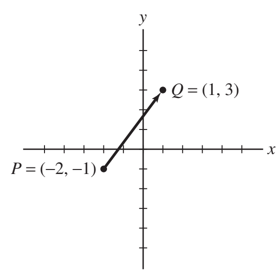
$$\mathbf{v}_4 = \langle 6-4, 3-1\rangle = \langle 2, 2\rangle$$
$$\|\mathbf{v}_4\| = \sqrt{2^2+2^2} = \sqrt{8} = 2\sqrt{2}$$



$\mathbf{v}_1$ and $\mathbf{v}_2$ are parallel and have the same length, hence they are equivalent.

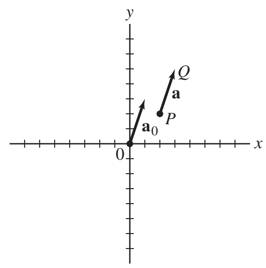
2. Sketch the vector $\mathbf{b} = \langle 3, 4\rangle$ based at $P = (-2, -1)$.

SOLUTION The vector $\mathbf{b} = \langle 3, 4\rangle$ based at P has terminal point Q, located 3 units to the right and 4 units up from P. Therefore $Q = (-2+3, -1+4) = (1, 3)$. The vector equivalent to $\mathbf{b}$ is PQ shown in the figure.



3. What is the terminal point of the vector $\mathbf{a} = \langle 1, 3\rangle$ based at $P = (2, 2)$? Sketch $\mathbf{a}$ and the vector $\mathbf{a}_0$ based at the origin and equivalent to $\mathbf{a}$.

SOLUTION The terminal point Q of the vector $\mathbf{a}$ is located 1 unit to the right and 3 units up from $P = (2, 2)$. Therefore, $Q = (2+1, 2+3) = (3, 5)$. The vector $\mathbf{a}_0$ equivalent to $\mathbf{a}$ based at the origin is shown in the figure, along with the vector $\mathbf{a}$.

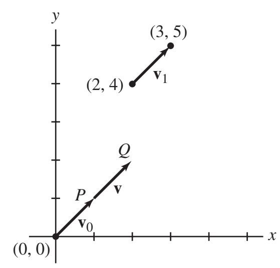


4. Let $\mathbf{v} = \overrightarrow{PQ}$, where $P = (1, 1)$ and $Q = (2, 2)$. What is the head of the vector $\mathbf{v}'$ equivalent to $\mathbf{v}$ based at $(2, 4)$? What is the head of the vector $\mathbf{v}_0$ equivalent to $\mathbf{v}$ based at the origin? Sketch $\mathbf{v}$, $\mathbf{v}_0$, and $\mathbf{v}'$.

SOLUTION We first find the components of $\mathbf{v}$:

$$\mathbf{v} = \overrightarrow{PQ} = \langle 1, 1\rangle$$

Since $\mathbf{v}'$ is equivalent to $\mathbf{v}$, the two vectors have the same components, hence the head of $\mathbf{v}'$ is located one unit to the right and one unit up from $(2, 4)$. This is the point $(3, 5)$. The head of $\mathbf{v}_0$ is located one unit to the right and one unit up from the origin; that is, the head is at the point $(1, 1)$.



In Exercises 5–8, find the components of $\overrightarrow{PQ}$.

5. $P = (3, 2), \quad Q = (2, 7)$

SOLUTION Using the definition of the components of a vector we have $\overrightarrow{PQ} = \langle 2 - 3, 7 - 2\rangle = \langle -1, 5\rangle$.

6. $P = (1, -4), \quad Q = (3, 5)$

SOLUTION The components of $\overrightarrow{PQ}$ are $\overrightarrow{PQ} = \langle 3 - 1, 5 - (-4)\rangle = \langle 2, 9\rangle$.

7. $P = (3, 5), \quad Q = (1, -4)$

SOLUTION By the definition of the components of a vector, we obtain $\overrightarrow{PQ} = \langle 1 - 3, -4 - 5\rangle = \langle -2, -9\rangle$.

8. $P = (0, 2), \quad Q = (5, 0)$

SOLUTION The components of the vector $\overrightarrow{PQ}$ are $\overrightarrow{PQ} = \langle 5 - 0, 0 - 2\rangle = \langle 5, -2\rangle$.

In Exercises 9–14, calculate.

9. $\langle 2, 1\rangle + \langle 3, 4\rangle$

SOLUTION Using vector algebra we have $\langle 2, 1\rangle + \langle 3, 4\rangle = \langle 2 + 3, 1 + 4\rangle = \langle 5, 5\rangle$.

10. $\langle -4, 6\rangle - \langle 3, -2\rangle$

SOLUTION $\langle -4, 6\rangle - \langle 3, -2\rangle = \langle -4 - 3, 6 - (-2)\rangle = \langle -7, 8\rangle$

11. $5\,\langle 6, 2\rangle$

SOLUTION $5\langle 6, 2\rangle = \langle 5 \cdot 6, 5 \cdot 2\rangle = \langle 30, 10\rangle$

12. $4(\langle 1, 1\rangle + \langle 3, 2\rangle)$

SOLUTION Using vector algebra we obtain

$$4\,(\langle 1, 1\rangle + \langle 3, 2\rangle) = 4\langle 1 + 3, 1 + 2\rangle = 4\langle 4, 3\rangle = \langle 4 \cdot 4, 4 \cdot 3\rangle = \langle 16, 12\rangle$$

13. $\left\langle -\frac{1}{2}, \frac{5}{3}\right\rangle + \left\langle 3, \frac{10}{3}\right\rangle$

SOLUTION The vector sum is $\left\langle -\dfrac{1}{2}, \dfrac{5}{3}\right\rangle + \left\langle 3, \dfrac{10}{3}\right\rangle = \left\langle -\dfrac{1}{2} + 3, \dfrac{5}{3} + \dfrac{10}{3}\right\rangle = \left\langle \dfrac{5}{2}, 5\right\rangle$.

14. $\langle \ln 2, e \rangle + \langle \ln 3, \pi \rangle$

SOLUTION The vector sum is $\langle \ln 2, e \rangle + \langle \ln 3, \pi \rangle = \langle \ln 2 + \ln 3, e + \pi \rangle = \langle \ln 6, e + \pi \rangle$.

15. Which of the vectors (A)–(C) in Figure 21 is equivalent to $\mathbf{v} - \mathbf{w}$?

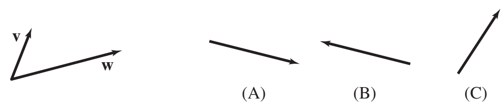


FIGURE 21

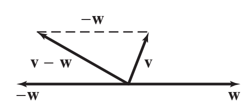
SOLUTION The vector $-\mathbf{w}$ has the same length as $\mathbf{w}$ but points in the opposite direction. The sum $\mathbf{v} + (-\mathbf{w})$, which is the difference $\mathbf{v} - \mathbf{w}$, is obtained by the parallelogram law. This vector is the vector shown in (b).



16. Sketch $\mathbf{v} + \mathbf{w}$ and $\mathbf{v} - \mathbf{w}$ for the vectors in Figure 22.

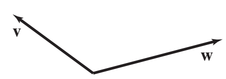


FIGURE 22

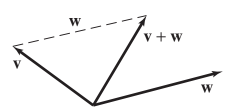
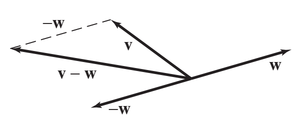
SOLUTION The vector $\mathbf{v} + \mathbf{w}$ is obtained by the parallelogram law:



Since $\mathbf{v} - \mathbf{w} = \mathbf{v} + (-\mathbf{w})$, we first sketch the vector $-\mathbf{w}$, which has the same length as $\mathbf{w}$ but points to the opposite direction. Then we add $-\mathbf{w}$ to $\mathbf{v}$ using the parallelogram law. This gives:



17. Sketch $2\mathbf{v}$, $-\mathbf{w}$, $\mathbf{v} + \mathbf{w}$, and $2\mathbf{v} - \mathbf{w}$ for the vectors in Figure 23.

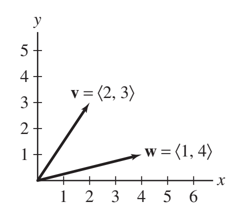


FIGURE 23

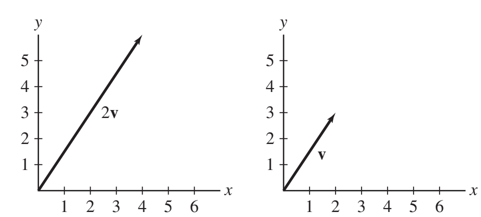
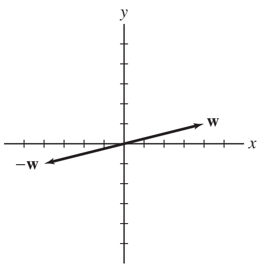
SOLUTION The scalar multiple $2\mathbf{v}$ points in the same direction as $\mathbf{v}$ and its length is twice the length of $\mathbf{v}$. It is the vector $2\mathbf{v} = \langle 4, 6 \rangle$.



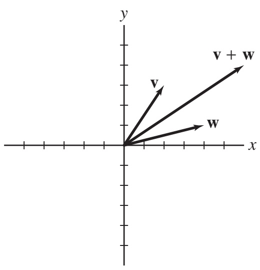
$-\mathbf{w}$ has the same length as $\mathbf{w}$ but points to the opposite direction. It is the vector $-\mathbf{w} = \langle -4, -1 \rangle$.



The vector sum $\mathbf{v} + \mathbf{w}$ is the vector:

$$\mathbf{v} + \mathbf{w} = \langle 2, 3\rangle + \langle 4, 1\rangle = \langle 6, 4\rangle.$$

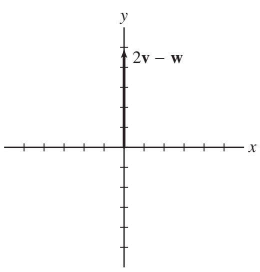
This vector is shown in the following figure:



The vector $2\mathbf{v} - \mathbf{w}$ is

$$2\mathbf{v} - \mathbf{w} = 2\langle 2, 3\rangle - \langle 4, 1\rangle = \langle 4, 6\rangle - \langle 4, 1\rangle = \langle 0, 5\rangle$$

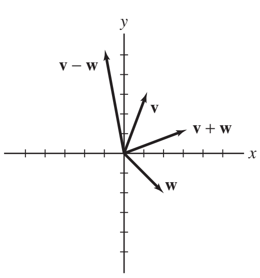
It is shown next:



18. Sketch $\mathbf{v} = \langle 1, 3\rangle$, $\mathbf{w} = \langle 2, -2\rangle$, $\mathbf{v} + \mathbf{w}$, $\mathbf{v} - \mathbf{w}$.

SOLUTION We compute the sum $\mathbf{v} + \mathbf{w}$ and the difference $\mathbf{v} - \mathbf{w}$ and then sketch the vectors. This gives:

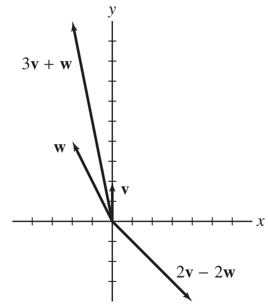
$$\mathbf{v} + \mathbf{w} = \langle 1, 3\rangle + \langle 2, -2\rangle = \langle 1 + 2, 3 - 2\rangle = \langle 3, 1\rangle$$
$$\mathbf{v} - \mathbf{w} = \langle 1, 3\rangle - \langle 2, -2\rangle = \langle 1 - 2, 3 + 2\rangle = \langle -1, 5\rangle$$



19. Sketch $\mathbf{v} = \langle 0, 2\rangle$, $\mathbf{w} = \langle -2, 4\rangle$, $3\mathbf{v} + \mathbf{w}$, $2\mathbf{v} - 2\mathbf{w}$.

SOLUTION We compute the vectors and then sketch them:

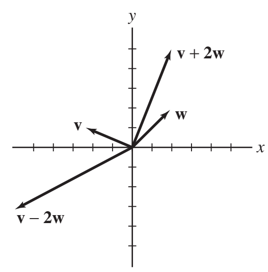
$$3\mathbf{v} + \mathbf{w} = 3\langle 0, 2\rangle + \langle -2, 4\rangle = \langle 0, 6\rangle + \langle -2, 4\rangle = \langle -2, 10\rangle$$
$$2\mathbf{v} - 2\mathbf{w} = 2\langle 0, 2\rangle - 2\langle -2, 4\rangle = \langle 0, 4\rangle - \langle -4, 8\rangle = \langle 4, -4\rangle$$



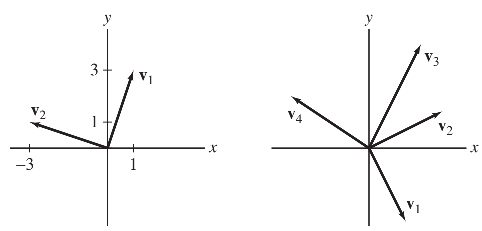
20. Sketch $\mathbf{v} = \langle -2, 1\rangle$, $\mathbf{w} = \langle 2, 2\rangle$, $\mathbf{v} + 2\mathbf{w}$, $\mathbf{v} - 2\mathbf{w}$.

SOLUTION We compute the linear combinations $\mathbf{v} + 2\mathbf{w}$ and $\mathbf{v} - 2\mathbf{w}$ and then sketch the vectors:

$$\mathbf{v} + 2\mathbf{w} = \langle -2, 1\rangle + 2\langle 2, 2\rangle = \langle -2, 1\rangle + \langle 4, 4\rangle = \langle 2, 5\rangle$$
$$\mathbf{v} - 2\mathbf{w} = \langle -2, 1\rangle - 2\langle 2, 2\rangle = \langle -2, 1\rangle - \langle 4, 4\rangle = \langle -6, -3\rangle$$



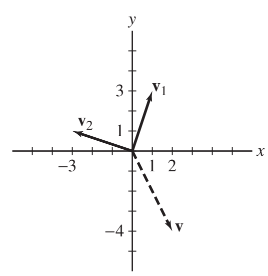
21. Sketch the vector $\mathbf{v}$ such that $\mathbf{v} + \mathbf{v}_1 + \mathbf{v}_2 = \mathbf{0}$ for $\mathbf{v}_1$ and $\mathbf{v}_2$ in Figure 24(A).



(A) (B)

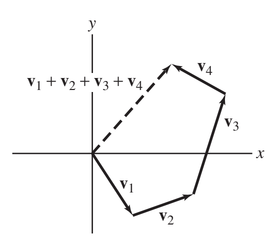
FIGURE 24

SOLUTION Since $\mathbf{v} + \mathbf{v}_1 + \mathbf{v}_2 = 0$, we have that $\mathbf{v} = -\mathbf{v}_1 - \mathbf{v}_2$, and since $\mathbf{v}_1 = \langle 1, 3\rangle$ and $\mathbf{v}_2 = \langle -3, 1\rangle$, then $\mathbf{v} = -\mathbf{v}_1 - \mathbf{v}_2 = \langle 2, -4\rangle$, as seen in this picture.



22. Sketch the vector sum $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3 + \mathbf{v}_4$ in Figure 24(B).

SOLUTION If we place the vectors $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3, \mathbf{v}_4$ tip to tail, as shown in the following figure, it is easy to sketch in the sum $\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3 + \mathbf{v}_4$, as shown.



23. Let $\mathbf{v} = \overrightarrow{PQ}$, where $P = (-2, 5)$, $Q = (1, -2)$. Which of the following vectors with the given tails and heads are equivalent to $\mathbf{v}$?

(a) $(-3, 3)$, $(0, 4)$ **(b)** $(0, 0)$, $(3, -7)$
(c) $(-1, 2)$, $(2, -5)$ **(d)** $(4, -5)$, $(1, 4)$

SOLUTION Two vectors are equivalent if they have the same components. We thus compute the vectors and check whether this condition is satisfied.

$$\mathbf{v} = \overrightarrow{PQ} = \langle 1 - (-2), -2 - 5 \rangle = \langle 3, -7 \rangle$$

(a) $\langle 0 - (-3), 4 - 3 \rangle = \langle 3, 1 \rangle$ **(b)** $\langle 3 - 0, -7 - 0 \rangle = \langle 3, -7 \rangle$
(c) $\langle 2 - (-1), -5 - 2 \rangle = \langle 3, -7 \rangle$ **(d)** $\langle 1 - 4, 4 - (-5) \rangle = \langle -3, 9 \rangle$

We see that the vectors in (b) and (c) are equivalent to $\mathbf{v}$.

24. Which of the following vectors are parallel to $\mathbf{v} = \langle 6, 9 \rangle$ and which point in the same direction?

(a) $\langle 12, 18 \rangle$ **(b)** $\langle 3, 2 \rangle$ **(c)** $\langle 2, 3 \rangle$
(d) $\langle -6, -9 \rangle$ **(e)** $\langle -24, -27 \rangle$ **(f)** $\langle -24, -36 \rangle$

SOLUTION Two vectors are parallel if they are scalar multiples of each other. The vectors point in the same direction if the multiplying scalar is positive. We use this to obtain the following conclusions:

(a) $\langle 12, 18 \rangle = 2\langle 6, 9 \rangle = 2\mathbf{v} \Rightarrow$ both vectors point in the same direction.
(b) $\langle 3, 2 \rangle$ is not a scalar multiple of $\mathbf{v}$, hence the vectors are not parallel.
(c) $\langle 2, 3 \rangle = \frac{1}{3}\langle 6, 9 \rangle = \frac{1}{3}\mathbf{v} \Rightarrow$ both vectors point in the same direction.
(d) $\langle -6, -9 \rangle = -\langle 6, 9 \rangle = -\mathbf{v} \Rightarrow$ parallel to $\mathbf{v}$ and points in the opposite direction.
(e) $\langle -24, -27 \rangle$ is not a scalar multiple of $\mathbf{v}$, hence the vectors are not parallel.
(f) $\langle -24, -36 \rangle = -4\langle 6, 9 \rangle = -4\mathbf{v} \Rightarrow$ parallel to $\mathbf{v}$ and points in the opposite direction.

In Exercises 25–28, sketch the vectors $\overrightarrow{AB}$ and $\overrightarrow{PQ}$, and determine whether they are equivalent.

25. $A = (1, 1)$, $B = (3, 7)$, $P = (4, -1)$, $Q = (6, 5)$

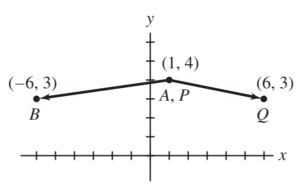
SOLUTION We compute the vectors and check whether they have the same components:

$$\begin{aligned} \overrightarrow{AB} &= \langle 3 - 1, 7 - 1 \rangle = \langle 2, 6 \rangle \\ \overrightarrow{PQ} &= \langle 6 - 4, 5 - (-1) \rangle = \langle 2, 6 \rangle \end{aligned} \quad \Rightarrow \quad \text{The vectors are equivalent.}$$

26. $A = (1, 4)$, $B = (-6, 3)$, $P = (1, 4)$, $Q = (6, 3)$

SOLUTION We compute $\overrightarrow{AB}$ and $\overrightarrow{PQ}$ and see if they have the same components:

$$\begin{aligned} \overrightarrow{AB} &= \langle -6 - 1, 3 - 4 \rangle = \langle -7, -1 \rangle \\ \overrightarrow{PQ} &= \langle 6 - 1, 3 - 4 \rangle = \langle 5, -1 \rangle \end{aligned} \quad \Rightarrow \quad \text{The vectors are not equivalent.}$$



27. $A = (-3, 2)$, $B = (0, 0)$, $P = (0, 0)$, $Q = (3, -2)$

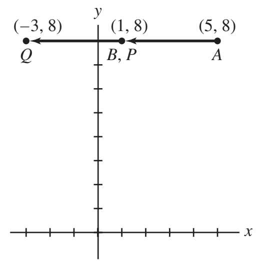
SOLUTION We compute the vectors $\overrightarrow{AB}$ and $\overrightarrow{PQ}$:

$$\begin{aligned} \overrightarrow{AB} &= \langle 0 - (-3), 0 - 2 \rangle = \langle 3, -2 \rangle \\ \overrightarrow{PQ} &= \langle 3 - 0, -2 - 0 \rangle = \langle 3, -2 \rangle \end{aligned} \quad \Rightarrow \quad \text{The vectors are equivalent.}$$

28. $A = (5, 8)$, $B = (1, 8)$, $P = (1, 8)$, $Q = (-3, 8)$

SOLUTION Computing $\overrightarrow{AB}$ and $\overrightarrow{PQ}$ gives:

$$\begin{aligned} \overrightarrow{AB} &= \langle 1 - 5, 8 - 8 \rangle = \langle -4, 0 \rangle \\ \overrightarrow{PQ} &= \langle -3 - 1, 8 - 8 \rangle = \langle -4, 0 \rangle \end{aligned} \quad \Rightarrow \quad \text{The vectors are equivalent.}$$



In Exercises 29–32, are $\overrightarrow{AB}$ and $\overrightarrow{PQ}$ parallel? And if so, do they point in the same direction?

29. $A = (1, 1), \quad B = (3, 4), \quad P = (1, 1), \quad Q = (7, 10)$

SOLUTION We compute the vectors $\overrightarrow{AB}$ and $\overrightarrow{PQ}$:

$$\overrightarrow{AB} = \langle 3 - 1, 4 - 1 \rangle = \langle 2, 3 \rangle$$
$$\overrightarrow{PQ} = \langle 7 - 1, 10 - 1 \rangle = \langle 6, 9 \rangle$$

Since $\overrightarrow{AB} = \frac{1}{3}\langle 6, 9 \rangle$, the vectors are parallel and point in the same direction.

30. $A = (-3, 2), \quad B = (0, 0), \quad P = (0, 0), \quad Q = (3, 2)$

SOLUTION We compute the two vectors:

$$\overrightarrow{AB} = \langle 0 - (-3), 0 - 2 \rangle = \langle 3, -2 \rangle$$
$$\overrightarrow{PQ} = \langle 3 - 0, 2 - 0 \rangle = \langle 3, 2 \rangle$$

The vectors are not scalar multiples of each other, hence they are not parallel.

31. $A = (2, 2), \quad B = (-6, 3), \quad P = (9, 5), \quad Q = (17, 4)$

SOLUTION We compute the vectors $\overrightarrow{AB}$ and $\overrightarrow{PQ}$:

$$\overrightarrow{AB} = \langle -6 - 2, 3 - 2 \rangle = \langle -8, 1 \rangle$$
$$\overrightarrow{PQ} = \langle 17 - 9, 4 - 5 \rangle = \langle 8, -1 \rangle$$

Since $\overrightarrow{AB} = -\overrightarrow{PQ}$, the vectors are parallel and point in opposite directions.

32. $A = (5, 8), \quad B = (2, 2), \quad P = (2, 2), \quad Q = (-3, 8)$

SOLUTION Computing $\overrightarrow{AB}$ and $\overrightarrow{PQ}$ gives:

$$\overrightarrow{AB} = \langle 2 - 5, 2 - 8 \rangle = \langle -3 - 6 \rangle$$
$$\overrightarrow{PQ} = \langle -3 - 2, 8 - 2 \rangle = \langle -5, 6 \rangle$$

The vectors are not scalar multiples of each other, hence they are not parallel.

In Exercises 33–36, let $R = (-2, 7)$. Calculate the following.

33. The length of $\overrightarrow{OR}$

SOLUTION Since $\overrightarrow{OR} = \langle -2, 7 \rangle$, the length of the vector is $\|\overrightarrow{OR}\| = \sqrt{(-2)^2 + 7^2} = \sqrt{53}$.

34. The components of $\mathbf{u} = \overrightarrow{PR}$, where $P = (1, 2)$

SOLUTION We compute the components of the vector to obtain:

$$\mathbf{u} = \overrightarrow{PR} = \langle -2 - 1, 7 - 2 \rangle = \langle -3, 5 \rangle$$

35. The point P such that $\overrightarrow{PR}$ has components $\langle -2, 7 \rangle$

SOLUTION Denoting $P = (x_0, y_0)$ we have:

$$\overrightarrow{PR} = \langle -2 - x_0, 7 - y_0 \rangle = \langle -2, 7 \rangle$$

Equating corresponding components yields:

$$\begin{aligned} -2 - x_0 &= -2 \\ 7 - y_0 &= 7 \end{aligned} \quad \Rightarrow \quad x_0 = 0,\ y_0 = 0 \quad \Rightarrow \quad P = (0, 0)$$

36. The point Q such that $\overrightarrow{RQ}$ has components $\langle 8, -3\rangle$

SOLUTION We denote $Q = (x_0, y_0)$ and have:

$$\overrightarrow{RQ} = \langle x_0 - (-2), y_0 - 7\rangle = \langle x_0 + 2, y_0 - 7\rangle = \langle 8, -3\rangle$$

Equating the corresponding components of the two vectors yields:

$$\begin{array}{l} x_0 + 2 = 8 \\ y_0 - 7 = -3 \end{array} \quad \Rightarrow \quad x_0 = 6, \; y_0 = 4 \quad \Rightarrow \quad Q = (6, 4)$$

In Exercises 37–42, find the given vector.

37. Unit vector $\mathbf{e_v}$ where $\mathbf{v} = \langle 3, 4\rangle$

SOLUTION The unit vector $\mathbf{e_v}$ is the following vector:

$$\mathbf{e_v} = \frac{1}{\|\mathbf{v}\|}\mathbf{v}$$

We find the length of $\mathbf{v} = \langle 3, 4\rangle$:

$$\|\mathbf{v}\| = \sqrt{3^2 + 4^2} = \sqrt{25} = 5$$

Thus

$$\mathbf{e_v} = \frac{1}{5}\langle 3, 4\rangle = \left\langle \frac{3}{5}, \frac{4}{5}\right\rangle.$$

38. Unit vector $\mathbf{e_w}$ where $\mathbf{w} = \langle 24, 7\rangle$

SOLUTION The unit vector $\mathbf{e_w}$ is the following vector:

$$\mathbf{e_w} = \frac{1}{\|\mathbf{w}\|}\mathbf{w}$$

We find the length of $\mathbf{w} = \langle 24, 7\rangle$:

$$\|\mathbf{w}\| = \sqrt{24^2 + 7^2} = \sqrt{625} = 25$$

Thus

$$\mathbf{e_w} = \frac{1}{25}\langle 24, 7\rangle = \left\langle \frac{24}{25}, \frac{7}{25}\right\rangle.$$

39. Vector of length 4 in the direction of $\mathbf{u} = \langle -1, -1\rangle$

SOLUTION Since $\|u\| = \sqrt{(-1)^2 + (-1)^2} = \sqrt{2}$, the unit vector in the direction of $\mathbf{u}$ is $\mathbf{e_u} = \left\langle -\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right\rangle$. We multiply $\mathbf{e_u}$ by 4 to obtain the desired vector:

$$4\mathbf{e_u} = 4\left\langle -\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right\rangle = \left\langle -2\sqrt{2}, -2\sqrt{2}\right\rangle$$

40. Unit vector in the direction opposite to $\mathbf{v} = \langle -2, 4\rangle$

SOLUTION We first compute the unit vector $\mathbf{e_v}$ in the direction of $\mathbf{v}$ and then multiply by -1 to obtain a unit vector in the opposite direction. This gives:

$$\mathbf{e_v} = \frac{1}{\|\mathbf{v}\|}\mathbf{v} = \frac{1}{\sqrt{(-2)^2 + 4^2}}\langle -2, 4\rangle = \frac{1}{\sqrt{20}}\langle -2, 4\rangle = \left\langle -\frac{2}{2\sqrt{5}}, \frac{4}{2\sqrt{5}}\right\rangle = \left\langle -\frac{1}{\sqrt{5}}, \frac{2}{\sqrt{5}}\right\rangle$$

The desired vector is thus

$$-\mathbf{e_v} = -\left\langle -\frac{1}{\sqrt{5}}, \frac{2}{\sqrt{5}}\right\rangle = \left\langle \frac{1}{\sqrt{5}}, -\frac{2}{\sqrt{5}}\right\rangle.$$

41. Unit vector $\mathbf{e}$ making an angle of $\frac{4\pi}{7}$ with the x-axis

SOLUTION The unit vector $\mathbf{e}$ is the following vector:

$$\mathbf{e} = \left\langle \cos\frac{4\pi}{7}, \sin\frac{4\pi}{7}\right\rangle = \langle -0.22, 0.97\rangle.$$

42. Vector **v** of length 2 making an angle of 30° with the x-axis

SOLUTION The desired vector is

$$\mathbf{v} = 2\langle \cos 30^\circ, \sin 30^\circ \rangle = 2\left\langle \frac{\sqrt{3}}{2}, \frac{1}{2} \right\rangle = \left\langle \sqrt{3}, 1 \right\rangle.$$

43. Find all scalars λ such that $\lambda\langle 2, 3\rangle$ has length 1.

SOLUTION We have:

$$\|\lambda\langle 2, 3\rangle\| = |\lambda|\|\langle 2, 3\rangle\| = |\lambda|\sqrt{2^2+3^2} = |\lambda|\sqrt{13}$$

The scalar λ must satisfy

$$\begin{aligned} |\lambda|\sqrt{13} &= 1 \\ |\lambda| &= \frac{1}{\sqrt{13}} \end{aligned} \quad\Rightarrow\quad \lambda_1 = \frac{1}{\sqrt{13}},\ \lambda_2 = -\frac{1}{\sqrt{13}}$$

44. Find a vector **v** satisfying $3\mathbf{v} + \langle 5, 20\rangle = \langle 11, 17\rangle$.

SOLUTION Write $\mathbf{v} = \langle x, y\rangle$ to get the equation $3\langle x, y\rangle + \langle 5, 20\rangle = \langle 11, 17\rangle$, which gives us $3x + 5 = 11$ (and thus $x = 2$) and also $3y + 20 = 17$ (and so $y = -1$). Thus, $\mathbf{v} = \langle 2, -1\rangle$.

45. What are the coordinates of the point P in the parallelogram in Figure 25(A)?

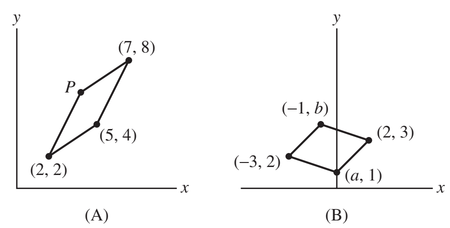


FIGURE 25

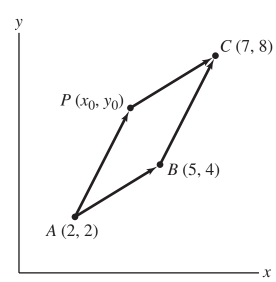
SOLUTION We denote by A, B, C the points in the figure.



Let $P = (x_0, y_0)$. We compute the following vectors:

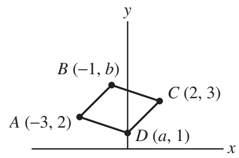
$$\overrightarrow{PC} = \langle 7 - x_0, 8 - y_0\rangle$$
$$\overrightarrow{AB} = \langle 5 - 2, 4 - 2\rangle = \langle 3, 2\rangle$$

The vectors $\overrightarrow{PC}$ and $\overrightarrow{AB}$ are equivalent, hence they have the same components. That is:

$$\begin{aligned} 7 - x_0 &= 3 \\ 8 - y_0 &= 2 \end{aligned} \quad\Rightarrow\quad x_0 = 4,\ y_0 = 6 \quad\Rightarrow\quad P = (4, 6)$$

46. What are the coordinates a and b in the parallelogram in Figure 25(B)?

SOLUTION We denote the points in the figure by A, B, C and D.



We compute the following vectors:

$$\overrightarrow{AB} = \langle -1 - (-3), b - 2 \rangle = \langle 2, b - 2 \rangle$$
$$\overrightarrow{DC} = \langle 2 - a, 3 - 1 \rangle = \langle 2 - a, 2 \rangle$$

Since $\overrightarrow{AB} = \overrightarrow{DC}$, the two vectors have the same components. That is,

$$\begin{aligned} 2 &= 2 - a \\ b - 2 &= 2 \end{aligned} \quad \Rightarrow \quad \begin{aligned} a &= 0 \\ b &= 4 \end{aligned}$$

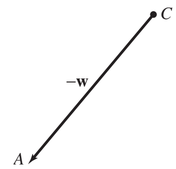
47. Let $\mathbf{v} = \overrightarrow{AB}$ and $\mathbf{w} = \overrightarrow{AC}$, where A, B, C are three distinct points in the plane. Match (a)–(d) with (i)–(iv). (*Hint:* Draw a picture.)

(a) $-\mathbf{w}$ **(b)** $-\mathbf{v}$ **(c)** $\mathbf{w} - \mathbf{v}$ **(d)** $\mathbf{v} - \mathbf{w}$

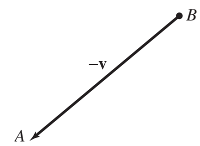
(i) $\overrightarrow{CB}$ **(ii)** $\overrightarrow{CA}$ **(iii)** $\overrightarrow{BC}$ **(iv)** $\overrightarrow{BA}$

SOLUTION

(a) $-\mathbf{w}$ has the same length as $\mathbf{w}$ and points in the opposite direction. Hence: $-\mathbf{w} = \overrightarrow{CA}$.



(b) $-\mathbf{v}$ has the same length as $\mathbf{v}$ and points in the opposite direction. Hence: $-\mathbf{v} = \overrightarrow{BA}$.

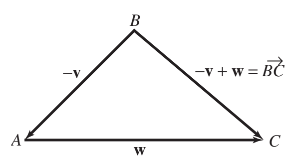


(c) By the parallelogram law we have:

$$\overrightarrow{BC} = \overrightarrow{BA} + \overrightarrow{AC} = -\mathbf{v} + \mathbf{w} = \mathbf{w} - \mathbf{v}$$

That is,

$$\mathbf{w} - \mathbf{v} = \overrightarrow{BC}$$

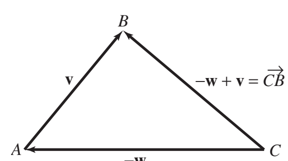


(d) By the parallelogram law we have:

$$\overrightarrow{CB} = \overrightarrow{CA} + \overrightarrow{AB} = -\mathbf{w} + \mathbf{v} = \mathbf{v} - \mathbf{w}$$

That is,

$$\mathbf{v} - \mathbf{w} = \overrightarrow{CB}.$$



48. Find the components and length of the following vectors:

(a) $4\mathbf{i} + 3\mathbf{j}$ **(b)** $2\mathbf{i} - 3\mathbf{j}$ **(c)** $\mathbf{i} + \mathbf{j}$ **(d)** $\mathbf{i} - 3\mathbf{j}$

SOLUTION

(a) Since $\mathbf{i} = \langle 1, 0 \rangle$ and $\mathbf{j} = \langle 0, 1 \rangle$, using vector algebra we have:

$$4\mathbf{i} + 3\mathbf{j} = 4\langle 1, 0 \rangle + 3\langle 0, 1 \rangle = \langle 4, 0 \rangle + \langle 0, 3 \rangle = \langle 4 + 0, 0 + 3 \rangle = \langle 4, 3 \rangle$$

The length of the vector is:

$$\|4\mathbf{i}+3\mathbf{j}\| = \sqrt{4^2+3^2} = 5$$

(b) We use vector algebra and the definition of the standard basis vector to compute the components of the vector $2\mathbf{i}-3\mathbf{j}$:

$$2\mathbf{i}-3\mathbf{j} = 2\langle 1,0\rangle - 3\langle 0,1\rangle = \langle 2,0\rangle - \langle 0,3\rangle = \langle 2-0, 0-3\rangle = \langle 2,-3\rangle$$

The length of this vector is:

$$\|2\mathbf{i}-3\mathbf{j}\| = \sqrt{2^2+(-3)^2} = \sqrt{13}$$

(c) We find the components of the vector $\mathbf{i}+\mathbf{j}$:

$$\mathbf{i}+\mathbf{j} = \langle 1,0\rangle + \langle 0,1\rangle = \langle 1+0, 0+1\rangle = \langle 1,1\rangle$$

The length of this vector is:

$$\|\mathbf{i}+\mathbf{j}\| = \sqrt{1^2+1^2} = \sqrt{2}$$

(d) We find the components of the vector $\mathbf{i}-3\mathbf{j}$, using vector algebra:

$$\mathbf{i}-3\mathbf{j} = \langle 1,0\rangle - 3\langle 0,1\rangle = \langle 1,0\rangle - \langle 0,3\rangle = \langle 1-0, 0-3\rangle = \langle 1,-3\rangle$$

The length of this vector is

$$\|\mathbf{i}-3\mathbf{j}\| = \sqrt{1^2+(-3)^2} = \sqrt{10}$$

In Exercises 49–52, calculate the linear combination.

49. $3\mathbf{j}+(9\mathbf{i}+4\mathbf{j})$

SOLUTION We have:

$$3\mathbf{j}+(9\mathbf{i}+4\mathbf{j}) = 3\langle 0,1\rangle + 9\langle 1,0\rangle + 4\langle 0,1\rangle = \langle 9,7\rangle$$

50. $-\frac{3}{2}\mathbf{i}+5\left(\frac{1}{2}\mathbf{j}-\frac{1}{2}\mathbf{i}\right)$

SOLUTION We have:

$$-\frac{3}{2}\mathbf{i}+5\left(\frac{1}{2}\mathbf{j}-\frac{1}{2}\mathbf{i}\right) = -\frac{3}{2}\langle 1,0\rangle + 5\left(\frac{1}{2}\langle 0,1\rangle - \frac{1}{2}\langle 1,0\rangle\right) = \left\langle -4, \frac{5}{2}\right\rangle$$

51. $(3\mathbf{i}+\mathbf{j})-6\mathbf{j}+2(\mathbf{j}-4\mathbf{i})$

SOLUTION We have:

$$(3\mathbf{i}+\mathbf{j})-6\mathbf{j}+2(\mathbf{j}-4\mathbf{i}) = (\langle 3,0\rangle + \langle 0,1\rangle) - \langle 0,6\rangle + 2(\langle 0,1\rangle - \langle 4,0\rangle) = \langle -5,-3\rangle$$

52. $3(3\mathbf{i}-4\mathbf{j})+5(\mathbf{i}+4\mathbf{j})$

SOLUTION We have:

$$3(3\mathbf{i}-4\mathbf{j})+5(\mathbf{i}+4\mathbf{j}) = 3(\langle 3,0\rangle - \langle 0,4\rangle) + 5(\langle 1,0\rangle + \langle 0,4\rangle) = \langle 14,8\rangle$$

53. For each of the position vectors $\mathbf{u}$ with endpoints A, B, and C in Figure 26, indicate with a diagram the multiples $r\mathbf{v}$ and $s\mathbf{w}$ such that $\mathbf{u} = r\mathbf{v}+s\mathbf{w}$. A sample is shown for $\mathbf{u} = \overrightarrow{OQ}$.

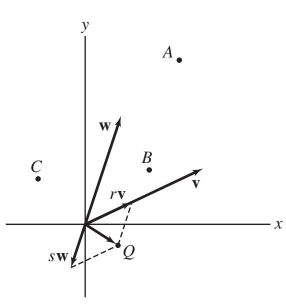


FIGURE 26

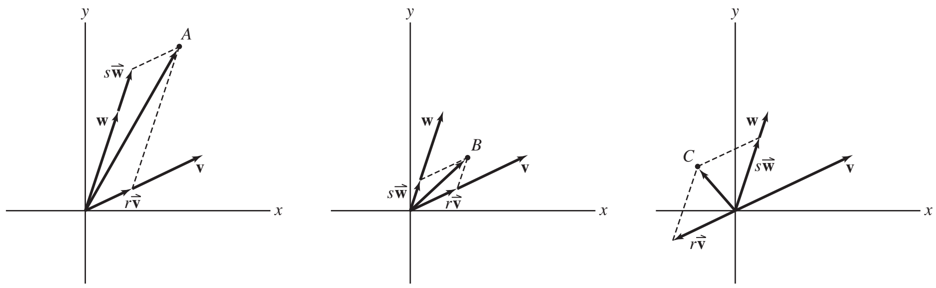
SOLUTION See the following three figures:



54. Sketch the parallelogram spanned by $\mathbf{v} = \langle 1, 4 \rangle$ and $\mathbf{w} = \langle 5, 2 \rangle$. Add the vector $\mathbf{u} = \langle 2, 3 \rangle$ to the sketch and express $\mathbf{u}$ as a linear combination of $\mathbf{v}$ and $\mathbf{w}$.

SOLUTION We have

$$\mathbf{u} = \langle 2, 3 \rangle = r\mathbf{v} + s\mathbf{w} = r\langle 1, 4 \rangle + s\langle 5, 2 \rangle$$

which becomes the two equations

$$2 = r + 5s$$
$$3 = 4r + 2s$$

Solving the first equation for r gives

$$r = 2 - 5s$$

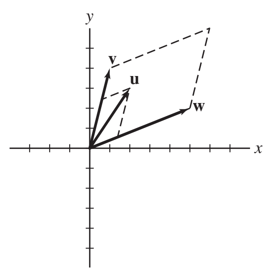
and substituting that into the first equation gives

$$3 = 4(2 - 5s) + 2s = 8 - 18s$$

So $18s = 5$, so $s = 5/18$, and thus $r = 11/18$. In other words,

$$\mathbf{u} = \langle 2, 3 \rangle = \frac{11}{18}\langle 1, 4 \rangle + \frac{5}{18}\langle 5, 2 \rangle$$

as seen in this picture:



In Exercises 55 and 56, express $\mathbf{u}$ *as a linear combination* $\mathbf{u} = r\mathbf{v} + s\mathbf{w}$. *Then sketch* $\mathbf{u}, \mathbf{v}, \mathbf{w}$, *and the parallelogram formed by* $r\mathbf{v}$ *and* $s\mathbf{w}$.

55. $\mathbf{u} = \langle 3, -1 \rangle$; $\mathbf{v} = \langle 2, 1 \rangle, \mathbf{w} = \langle 1, 3 \rangle$

SOLUTION We have

$$\mathbf{u} = \langle 3, -1 \rangle = r\mathbf{v} + s\mathbf{w} = r\langle 2, 1 \rangle + s\langle 1, 3 \rangle$$

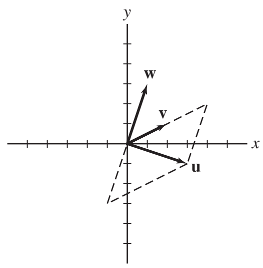
which becomes the two equations

$$3 = 2r + s$$
$$-1 = r + 3s$$

Solving the second equation for r gives $r = -1 - 3s$, and substituting that into the first equation gives $3 = 2(-1 - 3s) + s = -2 - 6s + s$, so $5 = -5s$, so $s = -1$, and thus $r = 2$. In other words,

$$\mathbf{u} = \langle 3, -1 \rangle = 2\langle 2, 1 \rangle - 1\langle 1, 3 \rangle$$

as seen in this sketch:



56. $\mathbf{u} = \langle 6, -2 \rangle$; $\mathbf{v} = \langle 1, 1 \rangle$, $\mathbf{w} = \langle 1, -1 \rangle$

SOLUTION We have

$$\mathbf{u} = \langle 6, -2 \rangle = r\mathbf{v} + s\mathbf{w} = r\langle 1, 1 \rangle + s\langle 1, -1 \rangle$$

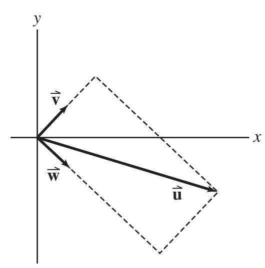
which becomes the two equations

$$6 = r + s$$
$$-2 = r - s$$

Adding gives $4 = 2r$, so $r = 2$ and thus $s = 4$. In other words,

$$\mathbf{u} = \langle 6, -2 \rangle = 2\langle 1, 1 \rangle + 4\langle 1, -1 \rangle$$

as seen in this sketch:



57. Calculate the magnitude of the force on cables 1 and 2 in Figure 27.

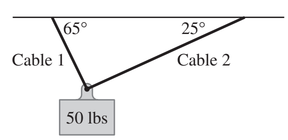


FIGURE 27

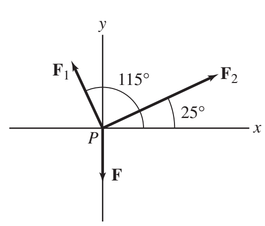
SOLUTION The three forces acting on the point P are:

- The force $\mathbf{F}$ of magnitude 50 lb that acts vertically downward.
- The forces $\mathbf{F}_1$ and $\mathbf{F}_2$ that act through cables 1 and 2 respectively.



Since the point P is not in motion we have

$$\mathbf{F}_1 + \mathbf{F}_2 + \mathbf{F} = 0 \tag{1}$$

We compute the forces. Letting $\|\mathbf{F}_1\| = f_1$ and $\|\mathbf{F}_2\| = f_2$ we have:

$$\mathbf{F}_1 = f_1\langle \cos 115^\circ, \sin 115^\circ \rangle = f_1\langle -0.423, 0.906 \rangle$$
$$\mathbf{F}_2 = f_2\langle \cos 25^\circ, \sin 25^\circ \rangle = f_2\langle 0.906, 0.423 \rangle$$
$$\mathbf{F} = \langle 0, -50 \rangle$$

Substituting the forces in (1) gives

$$f_1\langle -0.423, 0.906\rangle + f_2\langle 0.906, 0.423\rangle + \langle 0, -50\rangle = \langle 0, 0\rangle$$
$$\langle -0.423 f_1 + 0.906 f_2, 0.906 f_1 + 0.423 f_2 - 50\rangle = \langle 0, 0\rangle$$

We equate corresponding components and get

$$-0.423 f_1 + 0.906 f_2 = 0$$
$$0.906 f_1 + 0.423 f_2 - 50 = 0$$

By the first equation, $f_2 = 0.467 f_1$. Substituting in the second equation and solving for f_1 yields

$$0.906 f_1 + 0.423 \cdot 0.467 f_1 - 50 = 0$$
$$1.104 f_1 = 50 \quad \Rightarrow \quad f_1 = 45.29, \; f_2 = 0.467 f_1 = 21.15$$

We conclude that the magnitude of the force on cable 1 is $f_1 = 45.29$ lb and the magnitude of the force on cable 2 is $f_2 = 21.15$ lb.

58. Determine the magnitude of the forces $\mathbf{F}_1$ and $\mathbf{F}_2$ in Figure 28, assuming that there is no net force on the object.

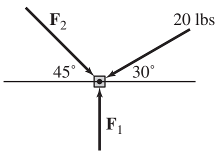


FIGURE 28

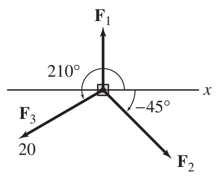
SOLUTION We denote $\|\mathbf{F}_1\| = f_1$ and $\|\mathbf{F}_2\| = f_2$. It is convenient (but not necessary) to redraw the vectors as being centered at the object, giving us the following figure.



Since there is no net force on the object, we have

$$\mathbf{F}_1 + \mathbf{F}_2 + \mathbf{F}_3 = 0 \tag{1}$$

We find the forces:

$$\mathbf{F}_1 = f_1\langle 0, 1\rangle = \langle 0, f_1\rangle$$
$$\mathbf{F}_2 = f_2\langle \cos(-45^\circ), \sin(-45^\circ)\rangle = f_2\left\langle \frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right\rangle = \langle 0.707 f_2, -0.707 f_2\rangle$$
$$\mathbf{F}_3 = 20\langle \cos 210^\circ, \sin 210^\circ\rangle = \langle -17.32, -10\rangle$$

We substitute the forces in (1):

$$\langle 0, f_1\rangle + \langle 0.707 f_2, -0.707 f_2\rangle + \langle -17.32, -10\rangle = \langle 0, 0\rangle$$
$$\langle 0.707 f_2 - 17.32, f_1 - 0.707 f_2 - 10\rangle = \langle 0, 0\rangle$$

Equating corresponding components we obtain

$$0.707 f_2 - 17.32 = 0$$
$$f_1 - 0.707 f_2 - 10 = 0$$

The first equation gives $f_2 = 24.5$. Substituting in the second equation and solving for f_1 gives

$$f_1 - 0.707 \cdot 24.5 - 10 = 0 \Rightarrow f_1 = 27.32$$

The magnitude of the forces $\mathbf{F}_1$ and $\mathbf{F}_2$ are $f_1 = 27.32$ lb and $f_2 = 24.5$ lb respectively.

59. A plane flying due east at 200 km/h encounters a 40-km/h wind blowing in the north-east direction. The resultant velocity of the plane is the vector sum $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2$, where $\mathbf{v}_1$ is the velocity vector of the plane and $\mathbf{v}_2$ is the velocity vector of the wind (Figure 29). The angle between $\mathbf{v}_1$ and $\mathbf{v}_2$ is $\frac{\pi}{4}$. Determine the resultant *speed* of the plane (the length of the vector $\mathbf{v}$).

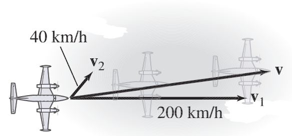


FIGURE 29

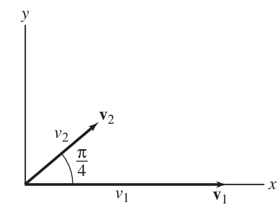
SOLUTION The resultant speed of the plane is the length of the sum vector $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2$. We place the xy-coordinate system as shown in the figure, and compute the components of the vectors $\mathbf{v}_1$ and $\mathbf{v}_2$. This gives

$$\mathbf{v}_1 = \langle v_1, 0 \rangle$$

$$\mathbf{v}_2 = \left\langle v_2 \cos\frac{\pi}{4}, v_2 \sin\frac{\pi}{4} \right\rangle = \left\langle v_2 \cdot \frac{\sqrt{2}}{2}, v_2 \cdot \frac{\sqrt{2}}{2} \right\rangle$$



We now compute the sum $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2$:

$$\mathbf{v} = \langle v_1, 0 \rangle + \left\langle \frac{\sqrt{2}v_2}{2}, \frac{\sqrt{2}v_2}{2} \right\rangle = \left\langle \frac{\sqrt{2}}{2}v_2 + v_1, \frac{\sqrt{2}}{2}v_2 \right\rangle$$

The resultant speed is the length of $\mathbf{v}$, that is,

$$v = \|\mathbf{v}\| = \sqrt{\left(\frac{\sqrt{2}v_2}{2}\right)^2 + \left(v_1 + \frac{\sqrt{2}v_2}{2}\right)^2} = \sqrt{\frac{v_2^2}{2} + v_1^2 + 2 \cdot \frac{\sqrt{2}}{2}v_2 v_1 + \frac{v_2^2}{2}} = \sqrt{v_1^2 + v_2^2 + \sqrt{2}v_1 v_2}$$

Finally, we substitute the given information $v_1 = 200$ and $v_2 = 40$ in the equation above, to obtain

$$v = \sqrt{200^2 + 40^2 + \sqrt{2} \cdot 200 \cdot 40} \approx 230 \text{ km/hr}$$

Further Insights and Challenges

In Exercises 60–62, refer to Figure 30, which shows a robotic arm consisting of two segments of lengths L_1 and L_2.

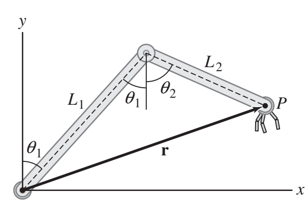


FIGURE 30

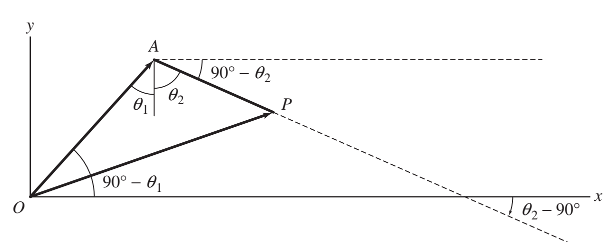
60. Find the components of the vector $\mathbf{r} = \overrightarrow{OP}$ in terms of θ_1 and θ_2.

SOLUTION We denote by A the point in the figure.



By the parallelogram law we have

$$\mathbf{r} = \overrightarrow{OA} + \overrightarrow{AP} \tag{1}$$

We find the vectors $\overrightarrow{OA}$ and $\overrightarrow{AP}$:

- The vector $\overrightarrow{OA}$ has length L_1 and it makes an angle of $90^\circ - \theta_1$ with the x-axis.
- The vector $\overrightarrow{AP}$ has length L_2 and it makes an angle of $-(90^\circ - \theta_2) = \theta_2 - 90^\circ$ with the x-axis.

Hence,

$$\overrightarrow{OA} = L_1 \left\langle \cos(90^\circ - \theta_1), \sin(90^\circ - \theta_1) \right\rangle = L_1 \langle \sin\theta_1, \cos\theta_1 \rangle = \langle L_1 \sin\theta_1, L_1 \cos\theta_1 \rangle$$

$$\overrightarrow{AP} = L_2 \left\langle \cos(\theta_2 - 90^\circ), \sin(\theta_2 - 90^\circ) \right\rangle = L_2 \langle \sin\theta_2, -\cos\theta_2 \rangle = \langle L_2 \sin\theta_2, -L_2 \cos\theta_2 \rangle$$

Substituting into (1) we obtain

$$\mathbf{r} = \langle L_1 \sin\theta_1, L_1 \cos\theta_1 \rangle + \langle L_2 \sin\theta_2 - L_2 \cos\theta_2 \rangle$$
$$\mathbf{r} = \langle L_1 \sin\theta_1 + L_2 \sin\theta_2, L_1 \cos\theta_1 - L_2 \cos\theta_2 \rangle$$

Thus, the x component of $\mathbf{r}$ is $L_1 \sin\theta_1 + L_2 \sin\theta_2$ and the y component is $L_1 \cos\theta_1 - L_2 \cos\theta_2$.

61. Let $L_1 = 5$ and $L_2 = 3$. Find $\mathbf{r}$ for $\theta_1 = \frac{\pi}{3}$, $\theta_2 = \frac{\pi}{4}$.

SOLUTION In Exercise 60 we showed that

$$\mathbf{r} = \langle L_1 \sin\theta_1 + L_2 \sin\theta_2, L_1 \cos\theta_1 - L_2 \cos\theta_2 \rangle$$

Substituting the given information we obtain

$$\mathbf{r} = \left\langle 5 \sin\frac{\pi}{3} + 3 \sin\frac{\pi}{4}, 5 \cos\frac{\pi}{3} - 3 \cos\frac{\pi}{4} \right\rangle = \left\langle \frac{5\sqrt{3}}{2} + \frac{3\sqrt{2}}{2}, \frac{5}{2} - \frac{3\sqrt{2}}{2} \right\rangle \approx \langle 6.45, 0.38 \rangle$$

62. Let $L_1 = 5$ and $L_2 = 3$. Show that the set of points reachable by the robotic arm with $\theta_1 = \theta_2$ is an ellipse.

SOLUTION Substituting $L_1 = 5$, $L_2 = 3$, and $\theta_1 = \theta_2 = \theta$ in the formula for $\mathbf{r}$ obtained in Exercise 60 we get

$$\begin{aligned} \mathbf{r} &= \langle L_1 \sin\theta_1 + L_2 \sin\theta_2, L_1 \cos\theta_1 - L_2 \cos\theta_2 \rangle \\ &= \langle 5\sin\theta + 3\sin\theta, 5\cos\theta - 3\cos\theta \rangle = \langle 8\sin\theta, 2\cos\theta \rangle \end{aligned}$$

Thus, the x and y components of $\mathbf{r}$ are

$$x = 8\sin\theta, \; y = 2\cos\theta$$

so $\frac{x}{8} = \sin\theta$, $\frac{y}{2} = \cos\theta$. Using the identity $\sin^2\theta + \cos^2\theta = 1$ we get

$$\left(\frac{x}{8}\right)^2 + \left(\frac{y}{2}\right)^2 = 1,$$

which is the formula of an ellipse.

63. Use vectors to prove that the diagonals $\overline{AC}$ and $\overline{BD}$ of a parallelogram bisect each other (Figure 31). *Hint:* Observe that the midpoint of $\overline{BD}$ is the terminal point of $\mathbf{w} + \frac{1}{2}(\mathbf{v} - \mathbf{w})$.

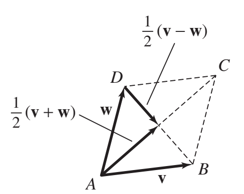


FIGURE 31

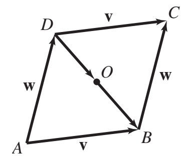
SOLUTION We denote by O the midpoint of $\overline{BD}$. Hence,

$$\overrightarrow{DO} = \frac{1}{2}\overrightarrow{DB}$$



Using the Parallelogram Law we have

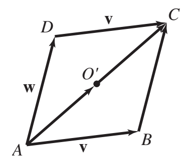
$$\overrightarrow{AO} = \overrightarrow{AD} + \overrightarrow{DO} = \overrightarrow{AD} + \frac{1}{2}\overrightarrow{DB}$$

Since $\overrightarrow{AD} = \mathbf{w}$ and $\overrightarrow{DB} = \mathbf{v} - \mathbf{w}$ we get

$$\overrightarrow{AO} = \mathbf{w} + \frac{1}{2}(\mathbf{v} - \mathbf{w}) = \frac{\mathbf{w} + \mathbf{v}}{2} \tag{1}$$

On the other hand, $\overrightarrow{AC} = \overrightarrow{AD} + \overrightarrow{DC} = \mathbf{w} + \mathbf{v}$, hence the midpoint O' of the diagonal $\overline{AC}$ is the terminal point of $\frac{\mathbf{w}+\mathbf{v}}{2}$. That is,

$$\overrightarrow{AO'} = \frac{\mathbf{w} + \mathbf{v}}{2} \tag{2}$$



We combine (1) and (2) to conclude that O and O' are the same point. That is, the diagonal $\overline{AC}$ and $\overline{BD}$ bisect each other.

64. Use vectors to prove that the segments joining the midpoints of opposite sides of a quadrilateral bisect each other (Figure 32). *Hint:* Show that the midpoints of these segments are the terminal points of

$$\frac{1}{4}(2\mathbf{u} + \mathbf{v} + \mathbf{z}) \quad \text{and} \quad \frac{1}{4}(2\mathbf{v} + \mathbf{w} + \mathbf{u})$$

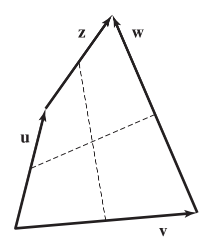


FIGURE 32

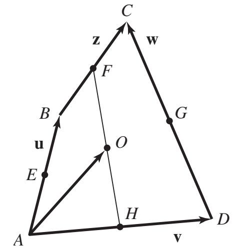
SOLUTION We denote by A, B, C, D the corresponding points in the figure and by E, F, G, H the midpoints of the sides $\overline{AB}$, $\overline{BC}$, $\overline{CD}$ and $\overline{AD}$, respectively. Also, O is the midpoint of $\overline{FH}$ and O' is the midpoint of $\overline{EG}$.



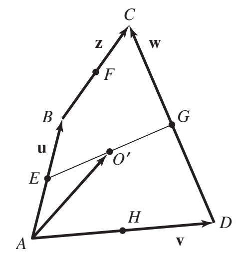
We must show that O and O' are the same point. Using the Parallelogram Law we have

$$\overrightarrow{AO} = \overrightarrow{AH} + \overrightarrow{HO} = \frac{1}{2}\mathbf{v} + \frac{1}{2}\overrightarrow{HF}$$

$$\overrightarrow{HF} = \overrightarrow{HA} + \overrightarrow{AB} + \overrightarrow{BF} = -\frac{1}{2}\mathbf{v} + \mathbf{u} + \frac{1}{2}\mathbf{z}$$

Hence,

$$\overrightarrow{AO} = \frac{1}{2}\mathbf{v} + \frac{1}{2}\left(-\frac{1}{2}\mathbf{v} + \mathbf{u} + \frac{1}{2}\mathbf{z}\right) = \frac{1}{4}\mathbf{v} + \frac{1}{2}\mathbf{u} + \frac{1}{4}\mathbf{z} = \frac{1}{4}(2\mathbf{u} + \mathbf{v} + \mathbf{z}) \tag{1}$$



Similarly,

$$\overrightarrow{AO'} = \overrightarrow{AD} + \overrightarrow{DG} + \overrightarrow{GO'} = \mathbf{v} + \frac{1}{2}\mathbf{w} + \frac{1}{2}\overrightarrow{GE}$$

$$\overrightarrow{GE} = \overrightarrow{GD} + \overrightarrow{DA} + \overrightarrow{AE} = -\frac{1}{2}\mathbf{w} - \mathbf{v} + \frac{1}{2}\mathbf{u}$$

Hence,

$$\overrightarrow{AO'} = \mathbf{v} + \frac{1}{2}\mathbf{w} + \frac{1}{2}\left(-\frac{1}{2}\mathbf{w} - \mathbf{v} + \frac{1}{2}\mathbf{u}\right) = \frac{1}{2}\mathbf{v} + \frac{1}{4}\mathbf{w} + \frac{1}{4}\mathbf{u} = \frac{1}{4}(2\mathbf{v} + \mathbf{w} + \mathbf{u}) \tag{2}$$

To show that $\overrightarrow{AO} = \overrightarrow{AO'}$ we must express $\mathbf{z}$ in terms of $\mathbf{u}$, $\mathbf{v}$ and $\mathbf{w}$. We have

$$\mathbf{v} + \mathbf{w} - \mathbf{z} - \mathbf{u} = 0 \Rightarrow \mathbf{z} = \mathbf{v} + \mathbf{w} - \mathbf{u}$$

Substituting into (1) we get

$$\overrightarrow{AO} = \frac{1}{4}(2\mathbf{u} + \mathbf{v} + (\mathbf{v} + \mathbf{w} - \mathbf{u})) = \frac{1}{4}(2\mathbf{v} + \mathbf{w} + \mathbf{u}) \tag{3}$$

By (2) and (3) we conclude that $\overrightarrow{AO} = \overrightarrow{AO'}$. It means that the points O and O' are the same point, in other words, the segment $\overline{FH}$ and $\overline{EG}$ bisect each other.

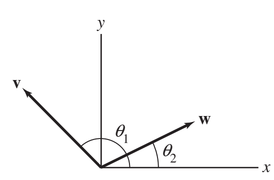
65. Prove that two vectors $\mathbf{v} = \langle a, b\rangle$ and $\mathbf{w} = \langle c, d\rangle$ are perpendicular if and only if

$$ac + bd = 0$$

SOLUTION Suppose that the vectors $\mathbf{v}$ and $\mathbf{w}$ make angles θ_1 and θ_2, which are not $\frac{\pi}{2}$ or $\frac{3\pi}{2}$, respectively, with the positive x-axis. Then their components satisfy

$$\begin{aligned} a &= \|\mathbf{v}\|\cos\theta_1 \\ b &= \|\mathbf{v}\|\sin\theta_1 \end{aligned} \quad \Rightarrow \quad \frac{b}{a} = \frac{\sin\theta_1}{\cos\theta_1} = \tan\theta_1$$

$$\begin{aligned} c &= \|\mathbf{w}\|\cos\theta_2 \\ d &= \|\mathbf{w}\|\sin\theta_2 \end{aligned} \quad \Rightarrow \quad \frac{d}{c} = \frac{\sin\theta_2}{\cos\theta_2} = \tan\theta_2$$



That is, the vectors $\mathbf{v}$ and $\mathbf{w}$ are on the lines with slopes $\frac{b}{a}$ and $\frac{d}{c}$, respectively. The lines are perpendicular if and only if their slopes satisfy

$$\frac{b}{a} \cdot \frac{d}{c} = -1 \quad \Rightarrow \quad bd = -ac \quad \Rightarrow \quad ac + bd = 0$$

We now consider the case where one of the vectors, say $\mathbf{v}$, is perpendicular to the x-axis. In this case $a = 0$, and the vectors are perpendicular if and only if $\mathbf{w}$ is parallel to the x-axis, that is, $d = 0$. So $ac + bd = 0 \cdot c + b \cdot 0 = 0$.

12.2 Vectors in Three Dimensions (LT Section 13.2)

Preliminary Questions

1. What is the terminal point of the vector $\mathbf{v} = \langle 3, 2, 1\rangle$ based at the point $P = (1, 1, 1)$?

SOLUTION We denote the terminal point by $Q = (a, b, c)$. Then by the definition of components of a vector, we have

$$\langle 3, 2, 1\rangle = \langle a - 1, b - 1, c - 1\rangle$$

Equivalent vectors have equal components respectively, thus,

$$\begin{aligned} 3 &= a - 1 & & a = 4 \\ 2 &= b - 1 & \Rightarrow \quad & b = 3 \\ 1 &= c - 1 & & c = 2 \end{aligned}$$

The terminal point of $\mathbf{v}$ is thus $Q = (4, 3, 2)$.

2. What are the components of the vector $\mathbf{v} = \langle 3, 2, 1\rangle$ based at the point $P = (1, 1, 1)$?

SOLUTION The component of $\mathbf{v} = \langle 3, 2, 1\rangle$ are $\langle 3, 2, 1\rangle$ regardless of the base point. The component of $\mathbf{v}$ and the base point $P = (1, 1, 1)$ determine the head $Q = (a, b, c)$ of the vector, as found in the previous exercise.

3. If $\mathbf{v} = -3\mathbf{w}$, then (choose the correct answer):

(a) $\mathbf{v}$ and $\mathbf{w}$ are parallel.

(b) $\mathbf{v}$ and $\mathbf{w}$ point in the same direction.

SOLUTION The vectors $\mathbf{v}$ and $\mathbf{w}$ lie on parallel lines, hence these vectors are parallel. Since $\mathbf{v}$ is a scalar multiple of $\mathbf{w}$ by a negative scalar, $\mathbf{v}$ and $\mathbf{w}$ point in opposite directions. Thus, (a) is correct and (b) is not.

4. Which of the following is a direction vector for the line through $P = (3, 2, 1)$ and $Q = (1, 1, 1)$?

(a) $\langle 3, 2, 1\rangle$ **(b)** $\langle 1, 1, 1\rangle$ **(c)** $\langle 2, 1, 0\rangle$

SOLUTION Any vector that is parallel to the vector $\overrightarrow{PQ}$ is a direction vector for the line through P and Q. We compute the vector $\overrightarrow{PQ}$:

$$\overrightarrow{PQ} = \langle 1 - 3, 1 - 2, 1 - 1\rangle = \langle -2, -1, 0\rangle.$$

The vectors $\langle 3, 2, 1\rangle$ and $\langle 1, 1, 1\rangle$ are not constant multiples of $\overrightarrow{PQ}$, hence they are not parallel to $\overrightarrow{PQ}$. However $\langle 2, 1, 0\rangle = -1\langle -2, -1, 0\rangle = -\overrightarrow{PQ}$, hence the vector $\langle 2, 1, 0\rangle$ is parallel to $\overrightarrow{PQ}$. Therefore, the vector $\langle 2, 1, 0\rangle$ is a direction vector for the line through P and Q.

5. How many different direction vectors does a line have?

SOLUTION All the vectors that are parallel to a line are also direction vectors for that line. Therefore, there are infinitely many direction vectors for a line.

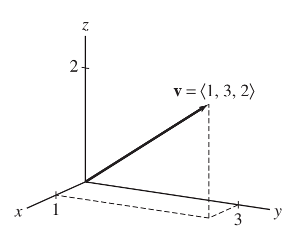
6. True or false? If $\mathbf{v}$ is a direction vector for a line $\mathcal{L}$, then $-\mathbf{v}$ is also a direction vector for $\mathcal{L}$.

SOLUTION True. Every vector that is parallel to $\mathbf{v}$ is a direction vector for the line L. Since $-\mathbf{v}$ is parallel to $\mathbf{v}$, it is also a direction vector for L.

Exercises

1. Sketch the vector $\mathbf{v} = \langle 1, 3, 2\rangle$ and compute its length.

SOLUTION The vector $\mathbf{v} = \langle 1, 3, 2\rangle$ is shown in the following figure:



The length of $\mathbf{v}$ is

$$\|\mathbf{v}\| = \sqrt{1^2 + 3^2 + 2^2} = \sqrt{14}$$

2. Let $\mathbf{v} = \overrightarrow{P_0Q_0}$, where $P_0 = (1, -2, 5)$ and $Q_0 = (0, 1, -4)$. Which of the following vectors (with tail P and head Q) are equivalent to $\mathbf{v}$?

	$\mathbf{v}_1$	$\mathbf{v}_2$	$\mathbf{v}_3$	$\mathbf{v}_4$
P	$(1, 2, 4)$	$(1, 5, 4)$	$(0, 0, 0)$	$(2, 4, 5)$
Q	$(0, 5, -5)$	$(0, -8, 13)$	$(-1, 3, -9)$	$(1, 7, 4)$

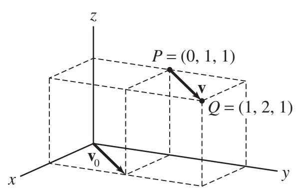
SOLUTION We compute the vectors $\mathbf{v}$, $\mathbf{v}_1$, $\mathbf{v}_2$, $\mathbf{v}_3$ and $\mathbf{v}_4$:

$$\begin{aligned}\mathbf{v} = \overrightarrow{P_0Q_0} &= \langle 0-1, 1-(-2), -4-5\rangle = \langle -1, 3, -9\rangle \\ \mathbf{v}_1 &= \langle 0-1, 5-2, -5-4\rangle = \langle -1, 3, -9\rangle \\ \mathbf{v}_2 &= \langle 0-1, -8-5, 13-4\rangle = \langle -1, -13, 9\rangle \\ \mathbf{v}_3 &= \langle -1-0, 3-0, -9-0\rangle = \langle -1, 3, -9\rangle \\ \mathbf{v}_4 &= \langle 1-2, 7-4, 4-5\rangle = \langle -1, 3, -1\rangle\end{aligned}$$

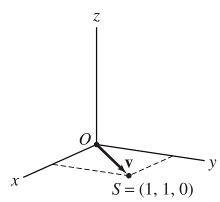
The vectors $\mathbf{v}_1$ and $\mathbf{v}_3$ are equivalent to $\mathbf{v}$.

3. Sketch the vector $\mathbf{v} = \langle 1, 1, 0\rangle$ based at $P = (0, 1, 1)$. Describe this vector in the form $\overrightarrow{PQ}$ for some point Q, and sketch the vector $\mathbf{v}_0$ based at the origin equivalent to $\mathbf{v}$.

SOLUTION The vector $\mathbf{v} = \langle 1, 1, 0\rangle$ based at $P = (0, 1, 1)$ is shown in the figure:



The head Q of the vector $\mathbf{v} = \overrightarrow{PQ}$ is at the point $Q = (0+1, 1+1, 1+0) = (1, 2, 1)$.



The vector $\mathbf{v}_0$ based at the origin and equivalent to $\mathbf{v}$ is

$$v_0 = \langle 1, 1, 0\rangle = \overrightarrow{OS}, \text{ where } S = (1, 1, 0).$$

4. Determine whether the coordinate systems (A)–(C) in Figure 17 satisfy the right-hand rule.

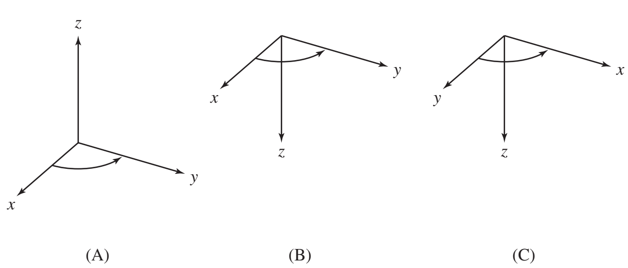


FIGURE 17

SOLUTION The coordinate systems (A) and (C) satisfy the right-hand rule, since when the right hand is positioned so that the fingers curl from the positive x-axis toward the positive y-axis, the thumb points in the positive z-direction. Similarly, system (B) does not satisfy the right-hand rule.

In Exercises 5–8, find the components of the vector $\overrightarrow{PQ}$.

5. $P = (1, 0, 1)$, $\quad Q = (2, 1, 0)$

SOLUTION By the definition of the vector components we have

$$\overrightarrow{PQ} = \langle 2-1, 1-0, 0-1\rangle = \langle 1, 1, -1\rangle$$

6. $P = (-3, -4, 2)$, $Q = (1, -4, 3)$

SOLUTION The components of the vector $\overrightarrow{PQ}$ are

$$\overrightarrow{PQ} = \langle 1 - (-3), -4 - (-4), 3 - 2 \rangle = \langle 4, 0, 1 \rangle$$

7. $P = (4, 6, 0)$, $Q = \left(-\frac{1}{2}, \frac{9}{2}, 1\right)$

SOLUTION Using the definition of vector components we have

$$\overrightarrow{PQ} = \left\langle -\frac{1}{2} - 4, \frac{9}{2} - 6, 1 - 0 \right\rangle = \left\langle -\frac{9}{2}, -\frac{3}{2}, 1 \right\rangle$$

8. $P = \left(-\frac{1}{2}, \frac{9}{2}, 1\right)$, $Q = (4, 6, 0)$

SOLUTION The components of the vector with the head at $Q = (4, 6, 0)$ and tail at $P = \left(-\frac{1}{2}, \frac{9}{2}, 1\right)$ are

$$\overrightarrow{PQ} = \left\langle 4 - \left(-\frac{1}{2}\right), 6 - \frac{9}{2}, 0 - 1 \right\rangle = \left\langle \frac{9}{2}, \frac{3}{2}, -1 \right\rangle.$$

In Exercises 9–12, let $R = (1, 4, 3)$.

9. Calculate the length of $\overrightarrow{OR}$.

SOLUTION The length of $\overrightarrow{OR}$ is the distance from $R = (1, 4, 3)$ to the origin. That is,

$$\|\overrightarrow{OR}\| = \sqrt{(1-0)^2 + (4-0)^2 + (3-0)^2} = \sqrt{26} \approx 5.1.$$

10. Find the point Q such that $\mathbf{v} = \overrightarrow{RQ}$ has components $\langle 4, 1, 1 \rangle$, and sketch $\mathbf{v}$.

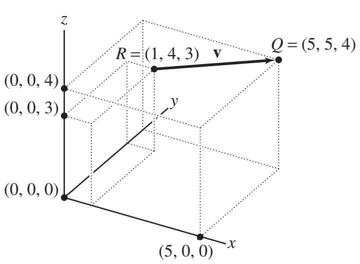
SOLUTION Denoting $Q = (x_0, y_0, z_0)$ we have

$$\overrightarrow{RQ} = \langle x_0 - 1, y_0 - 4, z_0 - 3 \rangle = \langle 4, 1, 1 \rangle$$

Equating corresponding components, we get

$$\begin{aligned} x_0 - 1 &= 4 \\ y_0 - 4 &= 1 \quad \Rightarrow \quad x_0 = 5,\ y_0 = 5,\ z_0 = 4 \\ z_0 - 3 &= 1 \end{aligned}$$

The point Q is, thus, $Q = (5, 5, 4)$.



11. Find the point P such that $\mathbf{w} = \overrightarrow{PR}$ has components $\langle 3, -2, 3 \rangle$, and sketch $\mathbf{w}$.

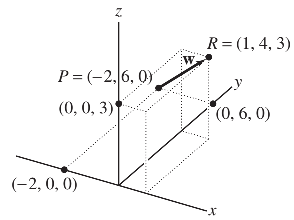
SOLUTION Denoting $P = (x_0, y_0, z_0)$ we get

$$\overrightarrow{PR} = \langle 1 - x_0, 4 - y_0, 3 - z_0 \rangle = \langle 3, -2, 3 \rangle$$

Equating corresponding components gives

$$\begin{aligned} 1 - x_0 &= 3 \\ 4 - y_0 &= -2 \quad \Rightarrow \quad x_0 = -2,\ y_0 = 6,\ z_0 = 0 \\ 3 - z_0 &= 3 \end{aligned}$$

The point P is, thus, $P = (-2, 6, 0)$.



12. Find the components of $\mathbf{u} = \overrightarrow{PR}$, where $P = (1, 2, 2)$.

SOLUTION The components of $\mathbf{u} = \overrightarrow{PR}$ where $P = (1, 2, 2)$ and $R = (1, 4, 3)$ are

$$\mathbf{u} = \overrightarrow{PR} = \langle 1 - 1, 4 - 2, 3 - 2 \rangle = \langle 0, 2, 1 \rangle$$

13. Let $\mathbf{v} = \langle 4, 8, 12 \rangle$. Which of the following vectors is parallel to $\mathbf{v}$? Which point in the same direction?

(a) $\langle 2, 4, 6 \rangle$ **(b)** $\langle -1, -2, 3 \rangle$

(c) $\langle -7, -14, -21 \rangle$ **(d)** $\langle 6, 10, 14 \rangle$

SOLUTION A vector is parallel to $\mathbf{v}$ if it is a scalar multiple of $\mathbf{v}$. It points in the same direction if the multiplying scalar is positive. Using these properties we obtain the following answer:

(a) $\langle 2, 4, 6 \rangle = \frac{1}{2}\mathbf{v} \Rightarrow$ The vectors are parallel and point in the same direction.

(b) $\langle -1, -2, 3 \rangle$ is not a scalar multiple of $\mathbf{v}$, hence these vectors are not parallel.

(c) $\langle -7, -14, -21 \rangle = -\frac{7}{4}\mathbf{v} \Rightarrow$ The vectors are parallel but point in opposite directions.

(d) $\langle 6, 10, 14 \rangle$ is not a constant multiple of $\mathbf{v}$, hence these vectors are not parallel.

In Exercises 14–17, determine whether $\overrightarrow{AB}$ is equivalent to $\overrightarrow{PQ}$.

14. $A = (1, 1, 1)$ $B = (3, 3, 3)$
$P = (1, 4, 5)$ $Q = (3, 6, 7)$

SOLUTION Two vectors are equivalent if one is a translation of the other, that is, if they have the same components. We compute $\overrightarrow{AB}$ and $\overrightarrow{PQ}$:

$$\left.\begin{aligned}\overrightarrow{AB} &= \langle 3 - 1, 3 - 1, 3 - 1 \rangle = \langle 2, 2, 2 \rangle \\ \overrightarrow{PQ} &= \langle 3 - 1, 6 - 4, 7 - 5 \rangle = \langle 2, 2, 2 \rangle\end{aligned}\right. \quad \Rightarrow \quad \text{The vectors are equivalent.}$$

15. $A = (1, 4, 1)$ $B = (-2, 2, 0)$
$P = (2, 5, 7)$ $Q = (-3, 2, 1)$

SOLUTION We compute the two vectors:

$$\overrightarrow{AB} = \langle -2 - 1, 2 - 4, 0 - 1 \rangle = \langle -3, -2, -1 \rangle$$

$$\overrightarrow{PQ} = \langle -3 - 2, 2 - 5, 1 - 7 \rangle = \langle -5, -3, -6 \rangle$$

The components of $\overrightarrow{AB}$ and $\overrightarrow{PQ}$ are not equal, hence they are not a translate of each other, that is, the vectors are not equivalent.

16. $A = (0, 0, 0)$ $B = (-4, 2, 3)$
$P = (4, -2, -3)$ $Q = (0, 0, 0)$

SOLUTION We compute $\overrightarrow{AB}$ and $\overrightarrow{PQ}$:

$$\left.\begin{aligned}\overrightarrow{AB} &= \langle -4 - 0, 2 - 0, 3 - 0 \rangle = \langle -4, 2, 3 \rangle \\ \overrightarrow{PQ} &= \langle 0 - 4, 0 - (-2), 0 - (-3) \rangle = \langle -4, 2, 3 \rangle\end{aligned}\right. \quad \Rightarrow \quad \text{The vectors are equivalent.}$$

17. $A = (1, 1, 0)$ $B = (3, 3, 5)$
$P = (2, -9, 7)$ $Q = (4, -7, 13)$

SOLUTION The vectors $\overrightarrow{AB}$ and $\overrightarrow{PQ}$ are the following vectors:

$$\overrightarrow{AB} = \langle 3 - 1, 3 - 1, 5 - 0 \rangle = \langle 2, 2, 5 \rangle$$

$$\overrightarrow{PQ} = \langle 4 - 2, -7 - (-9), 13 - 7 \rangle = \langle 2, 2, 6 \rangle$$

The z-coordinates of the vectors are not equal, hence the vectors are not equivalent.

In Exercises 18–23, calculate the linear combinations.

18. $5\langle 2, 2, -3\rangle + 3\langle 1, 7, 2\rangle$

SOLUTION Using vector algebra we get

$$5\langle 2, 2, -3\rangle + 3\langle 1, 7, 2\rangle = \langle 10, 10, -15\rangle + \langle 3, 21, 6\rangle = \langle 13, 31, -9\rangle.$$

19. $-2\langle 8, 11, 3\rangle + 4\langle 2, 1, 1\rangle$

SOLUTION Using the operations of vector addition and scalar multiplication we have

$$-2\langle 8, 11, 3\rangle + 4\langle 2, 1, 1\rangle = \langle -16, -22, -6\rangle + \langle 8, 4, 4\rangle = \langle -8, -18, -2\rangle.$$

20. $6(4\mathbf{j} + 2\mathbf{k}) - 3(2\mathbf{i} + 7\mathbf{k})$

SOLUTION Using vector algebra, we have

$$6(4\mathbf{j} + 2\mathbf{k}) - 3(2\mathbf{i} + 7\mathbf{k}) = (24\mathbf{j} + 12\mathbf{k}) - (6\mathbf{i} + 21\mathbf{k}) = -6\mathbf{i} + 24\mathbf{j} - 9\mathbf{k}.$$

21. $\frac{1}{2}\langle 4, -2, 8\rangle - \frac{1}{3}\langle 12, 3, 3\rangle$

SOLUTION Using the operations on vectors we have

$$\frac{1}{2}\langle 4, -2, 8\rangle - \frac{1}{3}\langle 12, 3, 3\rangle = \langle 2, -1, 4\rangle - \langle 4, 1, 1\rangle = \langle -2, -2, 3\rangle.$$

22. $5(\mathbf{i} + 2\mathbf{j}) - 3(2\mathbf{j} + \mathbf{k}) + 7(2\mathbf{k} - \mathbf{i})$

SOLUTION Using the operations on vectors we have

$$5(\mathbf{i} + 2\mathbf{j}) - 3(2\mathbf{j} + \mathbf{k}) + 7(2\mathbf{k} - \mathbf{i}) = 5\mathbf{i} + 10\mathbf{j} - 6\mathbf{j} - 3\mathbf{k} + 14\mathbf{k} - 7\mathbf{i} = -2\mathbf{i} + 4\mathbf{j} + 11\mathbf{k}.$$

23. $4\langle 6, -1, 1\rangle - 2\langle 1, 0, -1\rangle + 3\langle -2, 1, 1\rangle$

SOLUTION Using the operations of vector addition and scalar multiplication we have

$$\begin{aligned} 4\langle 6, -1, 1\rangle - 2\langle 1, 0, -1\rangle + 3\langle -2, 1, 1\rangle &= \langle 24, -4, 4\rangle + \langle -2, 0, 2\rangle + \langle -6, 3, 3\rangle \\ &= \langle 16, -1, 9\rangle. \end{aligned}$$

In Exercises 24–27, find the given vector.

24. $\mathbf{e_v}$, where $\mathbf{v} = \langle 1, 1, 2\rangle$

SOLUTION $\mathbf{e_v}$ is the vector

$$\mathbf{e_v} = \frac{1}{\|\mathbf{v}\|}\mathbf{v}$$

We find the length of $\mathbf{v}$:

$$\|\mathbf{v}\| = \sqrt{1^2 + 1^2 + 2^2} = \sqrt{6}$$

Hence,

$$\mathbf{e_v} = \frac{1}{\sqrt{6}}\langle 1, 1, 2\rangle = \left\langle \frac{1}{\sqrt{6}}, \frac{1}{\sqrt{6}}, \frac{2}{\sqrt{6}} \right\rangle$$

25. $\mathbf{e_w}$, where $\mathbf{w} = \langle 4, -2, -1\rangle$

SOLUTION We first find the length of $\mathbf{w}$:

$$\|\mathbf{w}\| = \sqrt{4^2 + (-2)^2 + 1^2} = \sqrt{21}$$

Hence,

$$\mathbf{e_w} = \frac{1}{\|\mathbf{w}\|}\mathbf{w} = \left\langle \frac{4}{\sqrt{21}}, \frac{-2}{\sqrt{21}}, \frac{-1}{\sqrt{21}} \right\rangle$$

26. Unit vector in the direction of $\mathbf{u} = \langle 1, 0, 7 \rangle$

SOLUTION A unit vector in the direction of $\mathbf{u} = \langle 1, 0, 7 \rangle$ is the vector

$$\mathbf{e_u} = \frac{1}{\|\mathbf{u}\|}\mathbf{u}$$

We compute the length of $\mathbf{u}$:

$$\|\mathbf{u}\| = \sqrt{1^2 + 0^2 + 7^2} = \sqrt{50} = 5\sqrt{2}$$

Hence,

$$\mathbf{e_u} = \frac{1}{5\sqrt{2}}\langle 1, 0, 7 \rangle = \left\langle \frac{1}{5\sqrt{2}}, 0, \frac{7}{5\sqrt{2}} \right\rangle$$

27. Unit vector in the direction opposite to $\mathbf{v} = \langle -4, 4, 2 \rangle$

SOLUTION A unit vector in the direction opposite to $\mathbf{v} = \langle -4, 4, 2 \rangle$ is the following vector:

$$-\mathbf{e_v} = -\frac{1}{\|\mathbf{v}\|}\mathbf{v}$$

We compute the length of $\mathbf{v}$:

$$\|\mathbf{v}\| = \sqrt{(-4)^2 + 4^2 + 2^2} = 6$$

The desired vector is, thus,

$$-\mathbf{e_v} = -\frac{1}{6}\langle -4, 4, 2 \rangle = \left\langle \frac{-4}{-6}, \frac{4}{-6}, \frac{2}{-6} \right\rangle = \left\langle \frac{2}{3}, -\frac{2}{3}, -\frac{1}{3} \right\rangle$$

28. Sketch the following vectors, and find their components and lengths.

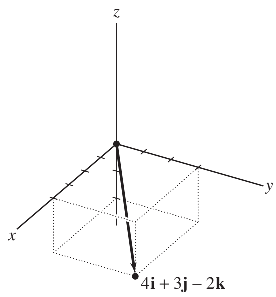
(a) $4\mathbf{i} + 3\mathbf{j} - 2\mathbf{k}$ **(b)** $\mathbf{i} + \mathbf{j} + \mathbf{k}$

(c) $4\mathbf{j} + 3\mathbf{k}$ **(d)** $12\mathbf{i} + 8\mathbf{j} - \mathbf{k}$

SOLUTION By the definition of the standard basis vectors in R^3 and the definition of vector length, we obtain the following answers:

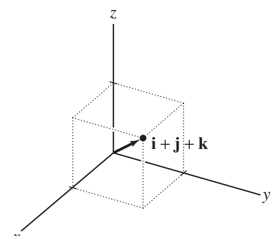
(a) $4\mathbf{i} + 3\mathbf{j} - 2\mathbf{k} = \langle 4, 3, -2 \rangle$

$\|4\mathbf{i} + 3\mathbf{j} - 2\mathbf{k}\| = \sqrt{4^2 + 3^2 + (-2)^2} = \sqrt{29}$



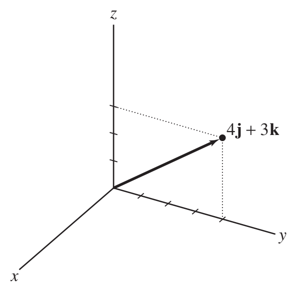
(b) $\mathbf{i} + \mathbf{j} + \mathbf{k} = \langle 1, 1, 1 \rangle$

$\|\mathbf{i} + \mathbf{j} + \mathbf{k}\| = \sqrt{1^2 + 1^2 + 1^2} = \sqrt{3}$



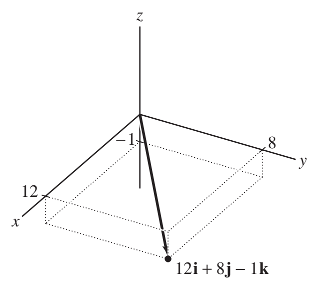
(c) $4\mathbf{j} + 3\mathbf{k} = \langle 0, 4, 3 \rangle$

$\|4\mathbf{j} + 3\mathbf{k}\| = \sqrt{0^2 + 4^2 + 3^2} = 5$



(d) $12\mathbf{i} + 8\mathbf{j} - \mathbf{k} = \langle 12, 8, -1 \rangle$

$\|12\mathbf{i} + 8\mathbf{j} - \mathbf{k}\| = \sqrt{12^2 + 8^2 + (-1)^2} = \sqrt{209}$



In Exercises 29–36, find a vector parametrization for the line with the given description.

29. Passes through $P = (1, 2, -8)$, direction vector $\mathbf{v} = \langle 2, 1, 3 \rangle$

SOLUTION The vector parametrization for the line is

$$\mathbf{r}(t) = \overrightarrow{OP} + t\mathbf{v}$$

Inserting the given data we get

$$\mathbf{r}(t) = \langle 1, 2, -8 \rangle + t\langle 2, 1, 3 \rangle = \langle 1 + 2t, 2 + t, -8 + 3t \rangle$$

30. Passes through $P = (4, 0, 8)$, direction vector $\mathbf{v} = \langle 1, 0, 1 \rangle$

SOLUTION A vector parametrization of the line is

$$\mathbf{r}(t) = \overrightarrow{OP} + t\mathbf{v} = \langle 4, 0, 8 \rangle + t\langle 1, 0, 1 \rangle = \langle 4 + t, 0, 8 + t \rangle$$

31. Passes through $P = (4, 0, 8)$, direction vector $\mathbf{v} = 7\mathbf{i} + 4\mathbf{k}$

SOLUTION Since $\mathbf{v} = 7\mathbf{i} + 4\mathbf{k} = \langle 7, 0, 4 \rangle$ we obtain the following parametrization:

$$\mathbf{r}(t) = \overrightarrow{OP} + t\mathbf{v} = \langle 4, 0, 8 \rangle + t\langle 7, 0, 4 \rangle = \langle 4 + 7t, 0, 8 + 4t \rangle$$

32. Passes through O, direction vector $\mathbf{v} = \langle 3, -1, -4 \rangle$

SOLUTION Since $\mathbf{v} = \langle 3, -1, -4 \rangle$ and $P = O$, we obtain the following parametrization:

$$\mathbf{r}(t) = \overrightarrow{OP} + t\mathbf{v} = \langle 0, 0, 0 \rangle + t\langle 3, -1, -4 \rangle = \langle 3t, -t, -4t \rangle$$

33. Passes through $(1, 1, 1)$ and $(3, -5, 2)$

SOLUTION We use the equation of the line through two points P and Q:

$$\mathbf{r}(t) = (1 - t)\overrightarrow{OP} + t\overrightarrow{OQ}$$

Since $\overrightarrow{OP} = \langle 1, 1, 1 \rangle$ and $\overrightarrow{OQ} = \langle 3, -5, 2 \rangle$ we obtain

$$\mathbf{r}(t) = (1 - t)\langle 1, 1, 1 \rangle + t\langle 3, -5, 2 \rangle = \langle 1 - t, 1 - t, 1 - t \rangle + \langle 3t, -5t, 2t \rangle = \langle 1 + 2t, 1 - 6t, 1 + t \rangle$$

34. Passes through $(-2, 0, -2)$ and $(4, 3, 7)$

SOLUTION Using the equation of the line through two points P and Q, with $\overrightarrow{OP} = \langle -2, 0, -2 \rangle$ and $\overrightarrow{OQ} = \langle 4, 3, 7 \rangle$ we obtain

$$\begin{aligned}\mathbf{r}(t) &= (1 - t)\overrightarrow{OP} + t\overrightarrow{OQ} = (1 - t)\langle -2, 0, -2 \rangle + t\langle 4, 3, 7 \rangle \\ &= \langle -2(1 - t), 0, -2(1 - t) \rangle + \langle 4t, 3t, 7t \rangle = \langle -2 + 6t, 3t, -2 + 9t \rangle\end{aligned}$$

35. Passes through O and $(4, 1, 1)$

SOLUTION By the equation of the line through two points we get

$$\mathbf{r}(t) = (1-t)\langle 0, 0, 0\rangle + t\langle 4, 1, 1\rangle = \langle 0, 0, 0\rangle + \langle 4t, t, t\rangle = \langle 4t, t, t\rangle$$

36. Passes through $(1, 1, 1)$ parallel to the line through $(2, 0, -1)$ and $(4, 1, 3)$

SOLUTION The direction vector is $\mathbf{v} = \langle 4-2, 1-0, 3-(-1)\rangle = \langle 2, 1, 4\rangle$. Hence, using the equation of a line we obtain

$$\mathbf{r}(t) = \langle 1, 1, 1\rangle + t\langle 2, 1, 4\rangle = \langle 1+2t, 1+t, 1+4t\rangle$$

In Exercises 37–40, find parametric equations for the lines with the given description.

37. Perpendicular to the xy-plane, passes through the origin

SOLUTION A direction vector for the line is a vector parallel to the z-axis, for instance, we may choose $\mathbf{v} = \langle 0, 0, 1\rangle$. The line passes through the origin $(0, 0, 0)$, hence we obtain the following parametrization:

$$\mathbf{r}(t) = \langle 0, 0, 0\rangle + t\langle 0, 0, 1\rangle = \langle 0, 0, t\rangle$$

or $x = 0$, $y = 0$, $z = t$.

38. Perpendicular to the yz-plane, passes through $(0, 0, 2)$

SOLUTION The direction vector is parallel to the x-axis. We may choose $\mathbf{v} = \langle 1, 0, 0\rangle$. Also $\overrightarrow{OP_0} = \langle 0, 0, 2\rangle$ so we obtain

$$\mathbf{r}(t) = \overrightarrow{OP_0} + t\mathbf{v} = \langle 0, 0, 2\rangle + t\langle 1, 0, 0\rangle = \langle t, 0, 2\rangle$$

or $x = t$, $y = 0$, $z = 2$.

39. Parallel to the line through $(1, 1, 0)$ and $(0, -1, -2)$, passes through $(0, 0, 4)$

SOLUTION The direction vector is $\mathbf{v} = \langle 0-1, -1-1, -2-0\rangle = \langle -1, -2, -2\rangle$. Hence, using the equation of a line we obtain

$$\mathbf{r}(t) = \langle 0, 0, 4\rangle + t\langle -1, -2, -2\rangle = \langle -t, -2t, 4-2t\rangle$$

40. Passes through $(1, -1, 0)$ and $(0, -1, 2)$

SOLUTION Using the equation of the line through two points P and Q, with $\overrightarrow{OP} = \langle 1, -1, 0\rangle$ and $\overrightarrow{OQ} = \langle 0, -1, 2\rangle$ we obtain

$$\begin{aligned}\mathbf{r}(t) &= (1-t)\overrightarrow{OP} + t\overrightarrow{OQ} = (1-t)\langle 1, -1, 0\rangle + t\langle 0, -1, 2\rangle \\ &= \langle (1-t), -(1-t), 0\rangle + \langle 0, -t, 2t\rangle = \langle 1-t, -1, 2t\rangle\end{aligned}$$

41. Which of the following is a parametrization of the line through $P = (4, 9, 8)$ perpendicular to the xz-plane (Figure 18)?

(a) $\mathbf{r}(t) = \langle 4, 9, 8\rangle + t\langle 1, 0, 1\rangle$
(b) $\mathbf{r}(t) = \langle 4, 9, 8\rangle + t\langle 0, 0, 1\rangle$
(c) $\mathbf{r}(t) = \langle 4, 9, 8\rangle + t\langle 0, 1, 0\rangle$
(d) $\mathbf{r}(t) = \langle 4, 9, 8\rangle + t\langle 1, 1, 0\rangle$

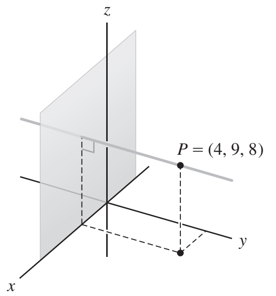


FIGURE 18

SOLUTION Since the direction vector must be perpendicular to the xz-plane, then the direction vector for the line must be parallel to $\mathbf{j}$, which is only satisfied by solution (c).

42. Find a parametrization of the line through $P = (4, 9, 8)$ perpendicular to the yz-plane.

SOLUTION The direction vector is parallel to the x-axis. We may choose $\mathbf{v} = \langle 1, 0, 0\rangle$. Also $\overrightarrow{OP} = \langle 4, 9, 8\rangle$ so we obtain

$$\mathbf{r}(t) = \overrightarrow{OP} + t\mathbf{v} = \langle 4, 9, 8\rangle + t\langle 1, 0, 0\rangle = \langle 4+t, 9, 8\rangle$$

or $x = 4+t$, $y = 9$, $z = 8$.

In Exercises 43–46, let $P = (2, 1, -1)$ *and* $Q = (4, 7, 7)$*. Find the coordinates of each of the following.*

43. The midpoint of $\overline{PQ}$

SOLUTION We first parametrize the line through $P = (2, 1, -1)$ and $Q = (4, 7, 7)$:

$$\mathbf{r}(t) = (1-t)\langle 2, 1, -1\rangle + t\langle 4, 7, 7\rangle = \langle 2+2t, 1+6t, -1+8t\rangle$$

The midpoint of $\overline{PQ}$ occurs at $t = \frac{1}{2}$, that is,

$$\text{midpoint} = \mathbf{r}\left(\frac{1}{2}\right) = \left\langle 2 + 2\cdot\frac{1}{2}, 1 + 6\cdot\frac{1}{2}, -1 + 8\cdot\frac{1}{2}\right\rangle = \langle 3, 4, 3\rangle$$

The midpoint of $\overline{PQ}$ is the terminal point of the vector $\mathbf{r}(t)$, that is, $(3, 4, 3)$. (One could also use the midpoint formula to arrive at the same solution.)

44. The point on $\overline{PQ}$ lying two-thirds of the way from P to Q

SOLUTION We first parametrize the line through $P = (2, 1, -1)$ and $Q = (4, 7, 7)$:

$$\mathbf{r}(t) = (1-t)\langle 2, 1, -1\rangle + t\langle 4, 7, 7\rangle = \langle 2+2t, 1+6t, -1+8t\rangle$$

The point on $\overline{PQ}$ lying two-thirds of the way from P to Q is at $t = \frac{2}{3}$. That is,

$$\mathbf{r}\left(\frac{2}{3}\right) = \left\langle 2 + 2\cdot\frac{2}{3}, 1 + 6\cdot\frac{2}{3}, -1 + 8\cdot\frac{2}{3}\right\rangle = \left\langle \frac{10}{3}, 5, \frac{13}{3}\right\rangle$$

The desired point is the head of the vector $\mathbf{r}(\frac{2}{3})$ which is $\left\langle \frac{10}{3}, 5, \frac{13}{3}\right\rangle$.

45. The point R such that Q is the midpoint of $\overline{PR}$

SOLUTION We denote $R = (x_0, y_0, z_0)$. By the formula for the midpoint of a segment we have

$$\langle 4, 7, 7\rangle = \left\langle \frac{2+x_0}{2}, \frac{1+y_0}{2}, \frac{-1+z_0}{2}\right\rangle$$

Equating corresponding components we get

$$\begin{aligned} 4 &= \frac{2+x_0}{2} \\ 7 &= \frac{1+y_0}{2} \\ 7 &= \frac{-1+z_0}{2} \end{aligned} \quad \Rightarrow \quad x_0 = 6,\ y_0 = 13,\ z_0 = 15 \quad \Rightarrow \quad R = (6, 13, 15)$$

46. The two points on the line through $\overline{PQ}$ whose distance from P is twice its distance from Q

SOLUTION In Exercise 44 we showed that the parametric equation of the line through P and Q is

$$\mathbf{r}(t) = \langle 2+2t, 1+6t, -1+8t\rangle \tag{1}$$

Hence an arbitrary point R on the line is $R = (2+2t, 1+6t, -1+8t)$. We must find the points R on the line satisfying

$$\|\overrightarrow{PR}\| = 2\|\overrightarrow{QR}\| \tag{2}$$

We compute the lengths of the vectors:

$$\begin{aligned} \|\overrightarrow{PR}\| &= \|\langle 2t, 6t, 8t\rangle\| = |t|\sqrt{2^2+6^2+8^2} = \sqrt{104}|t| \\ \|\overrightarrow{QR}\| &= \|\langle -2+2t, -6+6t, -8+8t\rangle\| = \|(-1+t)\langle 2, 6, 8\rangle\| \\ &= |-1+t|\sqrt{2^2+6^2+8^2} = |-1+t|\sqrt{104} \end{aligned}$$

Substituting in (2) and solving for t gives $\sqrt{104}|t| = 2\sqrt{104}|-1+t|$ and so $|t| = 2|t-1|$. Thus, either $t = 2(t-1)$ (and so $t = 2$) or $t = -2(t-1)$ (and so $t = \frac{2}{3}$). We now compute $\mathbf{r}(t)$ for these values of t. Using (1) we get

$$\begin{aligned} \mathbf{r}(2) &= \langle 2+2\cdot 2, 1+6\cdot 2, -1+8\cdot 2\rangle = \langle 6, 13, 15\rangle \\ \mathbf{r}\left(\frac{2}{3}\right) &= \left\langle 2+2\cdot\frac{2}{3}, 1+6\cdot\frac{2}{3}, -1+8\cdot\frac{2}{3}\right\rangle = \left\langle \frac{10}{3}, 5, \frac{13}{3}\right\rangle \end{aligned}$$

The desired points are the terminal points on these vectors. That is, $(6, 13, 15)$ and $\left(\frac{10}{3}, 5, \frac{13}{3}\right)$.

47. Show that $\mathbf{r}_1(t)$ and $\mathbf{r}_2(t)$ define the same line, where

$$\mathbf{r}_1(t) = \langle 3, -1, 4\rangle + t\langle 8, 12, -6\rangle$$
$$\mathbf{r}_2(t) = \langle 11, 11, -2\rangle + t\langle 4, 6, -3\rangle$$

Hint: Show that $\mathbf{r}_2$ passes through $(3, -1, 4)$ and that the direction vectors for $\mathbf{r}_1$ and $\mathbf{r}_2$ are parallel.

SOLUTION We observe first that the direction vectors of $\mathbf{r}_1(t)$ and $\mathbf{r}_2(t)$ are multiples of each other:

$$\langle 8, 12, -6\rangle = 2\langle 4, 6, -3\rangle$$

Therefore $\mathbf{r}_1(t)$ and $\mathbf{r}_2(t)$ are parallel. To show they coincide, it suffices to prove that they share a point in common, so we verify that $\mathbf{r}_1(0) = \langle 3, -1, 4\rangle$ lies on $\mathbf{r}_2(t)$ by solving for t:

$$\begin{aligned}\langle 3, -1, 4\rangle &= \langle 11, 11, -2\rangle + t\langle 4, 6, -3\rangle\\ \langle 3, -1, 4\rangle - \langle 11, 11, -2\rangle &= t\langle 4, 6, -3\rangle\\ \langle -8, -12, 6\rangle &= t\langle 4, 6, -3\rangle\end{aligned}$$

This equation is satisfied for $t = -2$, so $\mathbf{r}_1$ and $\mathbf{r}_2$ coincide.

48. Show that $\mathbf{r}_1(t)$ and $\mathbf{r}_2(t)$ define the same line, where

$$\mathbf{r}_1(t) = t\langle 2, 1, 3\rangle, \qquad \mathbf{r}_2(t) = \langle -6, -3, -9\rangle + t\langle 8, 4, 12\rangle$$

SOLUTION Note that $\mathbf{r}_1(-3) = \mathbf{r}_2(0)$ and $\mathbf{r}_1(0) = \mathbf{r}_2(3/4)$. Since both lines go through these two distinct points, then they must be the same line. (One could also solve this problem by showing that they share a point and have parallel direction vectors.)

49. Find two different vector parametrizations of the line through $P = (5, 5, 2)$ with direction vector $\mathbf{v} = \langle 0, -2, 1\rangle$.

SOLUTION Two different parameterizations are

$$\mathbf{r}_1(t) = \langle 5, 5, 2\rangle + t\langle 0, -2, 1\rangle$$
$$\mathbf{r}_2(t) = \langle 5, 5, 2\rangle + t\langle 0, -20, 10\rangle$$

50. Find the point of intersection of the lines $\mathbf{r}(t) = \langle 1, 0, 0\rangle + t\langle -3, 1, 0\rangle$ and $\mathbf{s}(t) = \langle 0, 1, 1\rangle + t\langle 2, 0, 1\rangle$.

SOLUTION The two lines intersect if there exist parameter values t_1 and t_2 such that

$$\begin{aligned}\langle 1, 0, 0\rangle + t_1\langle -3, 1, 0\rangle &= \langle 0, 1, 1\rangle + t_2\langle 2, 0, 1\rangle\\ \langle 1, 0, 0\rangle + \langle -3t_1, t_1, 0\rangle &= \langle 0, 1, 1\rangle + \langle 2t_2, 0, t_2\rangle\\ \langle 1 - 3t_1, t_1, 0\rangle &= \langle 2t_2, 1, 1 + t_2\rangle\end{aligned}$$

We obtain the following equations for the components of the two vectors:

$$1 - 3t_1 = 2t_2 \tag{1}$$
$$t_1 = 1 \tag{2}$$
$$0 = 1 + t_2 \tag{3}$$

The third equation yields $t_2 = -1$ and the second yields $t_1 = 1$. We now must check whether these values satisfy the first equation:

$$\begin{aligned}1 - 3t_1 &= 1 - 3 = -2\\ 2t_2 &= 2 \cdot (-1) = -2\end{aligned} \quad \Rightarrow \quad 1 - 3t_1 = 2t_2 \quad \text{for} \quad t_1 = 1,\ t_2 = -1$$

Therefore, $t_1 = 1$ and $t_2 = -1$ are solutions of the equations in (1)–(3). To find the point of intersection of the given lines we first set one of the solutions t_1 or t_2 in the equation of corresponding line. Setting $t_1 = 1$ in $\langle 1, 0, 0\rangle + t\langle -3, 1, 0\rangle$ yields

$$\langle 1, 0, 0\rangle + 1 \cdot \langle -3, 1, 0\rangle = \langle -2, 1, 0\rangle$$

The head $(-2, 1, 0)$ is the required point.

51. Show that the lines $\mathbf{r}_1(t) = \langle -1, 2, 2\rangle + t\,\langle 4, -2, 1\rangle$ and $\mathbf{r}_2(t) = \langle 0, 1, 1\rangle + t\,\langle 2, 0, 1\rangle$ do not intersect.

SOLUTION The two lines intersect if there exist parameter values t_1 and t_2 such that

$$\begin{aligned}\langle -1, 2, 2\rangle + t_1\langle 4, -2, 1\rangle &= \langle 0, 1, 1\rangle + t_2\langle 2, 0, 1\rangle\\ \langle -1 + 4t_1, 2 - 2t_1, 2 + t_1\rangle &= \langle 2t_2, 1, 1 + t_2\rangle\end{aligned}$$

Equating corresponding components yields

$$\begin{aligned}-1 + 4t_1 &= 2t_2\\ 2 - 2t_1 &= 1\\ 2 + t_1 &= 1 + t_2\end{aligned}$$

The second equation implies $t_1 = \frac{1}{2}$. Substituting into the first and third equations we get

$$\begin{aligned}-1 + 4\cdot\frac{1}{2} = 2t_2 \quad &\Rightarrow \quad t_2 = \frac{1}{2}\\ 2 + \frac{1}{2} = 1 + t_2 \quad &\Rightarrow \quad t_2 = \frac{3}{2}\end{aligned}$$

We conclude that the equations do not have solutions, which means that the two lines do not intersect.

52. Determine whether the lines $\mathbf{r}_1(t) = \langle 2, 1, 1\rangle + t\,\langle -4, 0, 1\rangle$ and $\mathbf{r}_2(s) = \langle -4, 1, 5\rangle + s\,\langle 2, 1, -2\rangle$ intersect, and if so, find the point of intersection.

SOLUTION The lines intersect if there exist parameter values t and s such that

$$\begin{aligned}\langle 2, 1, 1\rangle + t\langle -4, 0, 1\rangle &= \langle -4, 1, 5\rangle + s\langle 2, 1, -2\rangle\\ \langle 2 - 4t, 1, 1 + t\rangle &= \langle -4 + 2s, 1 + s, 5 - 2s\rangle\end{aligned}$$

We equate corresponding components to obtain

$$\begin{aligned}2 - 4t &= -4 + 2s\\ 1 &= 1 + s\\ 1 + t &= 5 - 2s\end{aligned}$$

The second equation implies $s = 0$. Substituting in the first and third equations we get

$$\begin{aligned}2 - 4t = -4 + 2\cdot 0 \quad &\Rightarrow \quad t = \frac{3}{2}\\ 1 + t = 5 - 2\cdot 0 \quad &\Rightarrow \quad t = 4\end{aligned}$$

We conclude that the equations do not have solutions, that is, the lines do not intersect.

53. Determine whether the lines $\mathbf{r}_1(t) = \langle 0, 1, 1\rangle + t\,\langle 1, 1, 2\rangle$ and $\mathbf{r}_2(s) = \langle 2, 0, 3\rangle + s\,\langle 1, 4, 4\rangle$ intersect, and if so, find the point of intersection.

SOLUTION The lines intersect if there exist parameter values t and s such that

$$\begin{aligned}\langle 0, 1, 1\rangle + t\langle 1, 1, 2\rangle &= \langle 2, 0, 3\rangle + s\langle 1, 4, 4\rangle\\ \langle t, 1 + t, 1 + 2t\rangle &= \langle 2 + s, 4s, 3 + 4s\rangle \qquad (1)\end{aligned}$$

Equating corresponding components we get

$$\begin{aligned}t &= 2 + s\\ 1 + t &= 4s\\ 1 + 2t &= 3 + 4s\end{aligned}$$

Substituting t from the first equation into the second equation we get

$$\begin{aligned}1 + 2 + s &= 4s\\ 3s &= 3\end{aligned} \quad \Rightarrow \quad s = 1,\ t = 2 + s = 3$$

We now check whether $s = 1$, $t = 3$ satisfy the third equation:

$$\begin{aligned}1 + 2\cdot 3 &= 3 + 4\cdot 1\\ 7 &= 7\end{aligned}$$

We conclude that $s = 1$, $t = 3$ is the solution of (1), hence the two lines intersect. To find the point of intersection we substitute $s = 1$ in the right-hand side of (1) to obtain

$$\langle 2 + 1, 4 \cdot 1, 3 + 4 \cdot 1 \rangle = \langle 3, 4, 7 \rangle$$

The point of intersection is the terminal point of this vector, that is, (3, 4, 7).

54. Find the intersection of the lines $\mathbf{r}_1(t) = \langle -1, 1 \rangle + t\,\langle 2, 4 \rangle$ and $\mathbf{r}_2(s) = \langle 2, 1 \rangle + s\,\langle -1, 6 \rangle$ in $\mathbf{R}^2$.

SOLUTION We must find the parameter values t and s such that

$$\begin{aligned} \langle -1, 1 \rangle + t\langle 2, 4 \rangle &= \langle 2, 1 \rangle + s\langle -1, 6 \rangle \\ \langle -1 + 2t, 1 + 4t \rangle &= \langle 2 - s, 1 + 6s \rangle \end{aligned} \tag{1}$$

Equating corresponding components we get

$$\begin{aligned} -1 + 2t &= 2 - s \\ 1 + 4t &= 1 + 6s \end{aligned}$$

The first equation implies $s = 3 - 2t$. We substitute in the second equation:

$$\begin{aligned} 1 + 4t &= 1 + 6(3 - 2t) \\ 1 + 4t &= 19 - 12t \\ 16t &= 18 \end{aligned} \quad \Rightarrow \quad t = \frac{9}{8},\ s = 3 - 2 \cdot \frac{9}{8} = \frac{3}{4}$$

To find the point of intersection we substitute $s = \frac{3}{4}$ in the right-hand side of (1). This gives

$$\left\langle 2 - \frac{3}{4}, 1 + 6 \cdot \frac{3}{4} \right\rangle = \left\langle \frac{5}{4}, \frac{11}{2} \right\rangle.$$

The point of intersection is the terminal point of this vector which is $\left(\frac{5}{4}, \frac{11}{2}\right)$.

55. Find the components of the vector $\mathbf{v}$ whose tail and head are the midpoints of segments $\overline{AC}$ and $\overline{BC}$ in Figure 19.

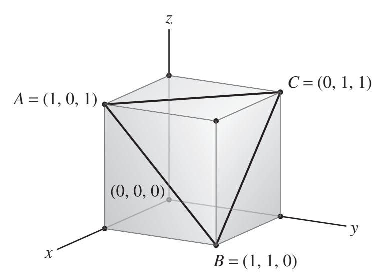

FIGURE 19

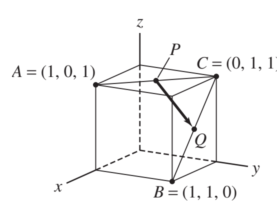
SOLUTION We denote by P and Q the midpoints of the segments $\overline{AC}$ and $\overline{BC}$ respectively. Thus,

$$\mathbf{v} = \overrightarrow{PQ} \tag{1}$$



We use the formula for the midpoint of a segment to find the coordinates of the points P and Q. This gives

$$P = \left(\frac{1+0}{2}, \frac{0+1}{2}, \frac{1+1}{2} \right) = \left(\frac{1}{2}, \frac{1}{2}, 1 \right)$$

$$Q = \left(\frac{1+0}{2}, \frac{1+1}{2}, \frac{0+1}{2} \right) = \left(\frac{1}{2}, 1, \frac{1}{2} \right)$$

Substituting in (1) yields the following vector:

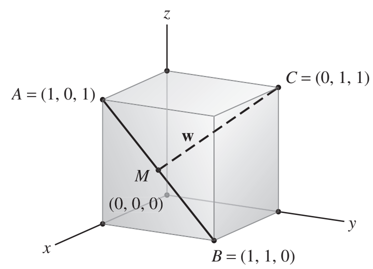
$$\mathbf{v} = \overrightarrow{PQ} = \left\langle \frac{1}{2} - \frac{1}{2}, 1 - \frac{1}{2}, \frac{1}{2} - 1 \right\rangle = \left\langle 0, \frac{1}{2}, -\frac{1}{2} \right\rangle.$$

56. Find the components of the vector **w** whose tail is C and head is the midpoint of $\overline{AB}$ in Figure 19.

SOLUTION We denote the midpoint of $\overline{AB}$ by $M = (a, b, c)$. To find the coordinates of M we first parametrize the line through $A = (1, 0, 1)$ and $B = (1, 1, 0)$:

$$\mathbf{r}(t) = (1-t)\langle 1, 0, 1\rangle + t\langle 1, 1, 0\rangle = \langle 1-t, 0, 1-t\rangle + \langle t, t, 0\rangle = \langle 1, t, 1-t\rangle$$

The midpoint of $\overline{AB}$ occurs at $t = \frac{1}{2}$, hence the vector $\overline{OM}$ is $\langle 1, \frac{1}{2}, \frac{1}{2}\rangle$.



The point M is the terminal point of $\overline{OM}$, that is, $M = \left(1, \frac{1}{2}, \frac{1}{2}\right)$. We now find the vector $\mathbf{w} = \overline{CM}$:

$$\mathbf{w} = \left\langle 1-0, \frac{1}{2}-1, \frac{1}{2}-1\right\rangle = \left\langle 1, -\frac{1}{2}, -\frac{1}{2}\right\rangle.$$

Further Insights and Challenges

In Exercises 57–63, we consider the equations of a line in ***symmetric form****, when $a \neq 0$, $b \neq 0$, $c \neq 0$.*

$$\frac{x-x_0}{a} = \frac{y-y_0}{b} = \frac{z-z_0}{c} \qquad \boxed{12}$$

57. Let $\mathcal{L}$ be the line through $P_0 = (x_0, y_0, c_0)$ with direction vector $\mathbf{v} = \langle a, b, c\rangle$. Show that $\mathcal{L}$ is defined by the symmetric Eq. (12). *Hint:* Use the vector parametrization to show that every point on $\mathcal{L}$ satisfies Eq. (12).

SOLUTION $\mathcal{L}$ is given by vector parametrization

$$\mathbf{r}(t) = \langle x_0, y_0, z_0\rangle + t\,\langle a, b, c\rangle$$

which gives us the equations

$$x = x_0 + at$$
$$y = y_0 + bt$$
$$z = z_0 + ct.$$

Solving for t gives

$$t = \frac{x-x_0}{a}$$
$$t = \frac{y-y_0}{b}$$
$$t = \frac{z-z_0}{c}$$

Setting each equation equal to the other gives Eq. (12).

58. Find the symmetric equations of the line through $P_0 = (-2, 3, 3)$ with direction vector $\mathbf{v} = \langle 2, 4, 3\rangle$.

SOLUTION Using $(x_0, y_0, z_0) = (-2, 3, 3)$ and $\langle a, b, c\rangle = \langle 2, 4, 3\rangle$ in Eq. (12) gives

$$\frac{x+2}{2} = \frac{y-3}{4} = \frac{z-3}{3}$$

59. Find the symmetric equations of the line through $P = (1, 1, 2)$ and $Q = (-2, 4, 0)$.

SOLUTION This line has direction vector $\overrightarrow{PQ} = \langle -3, 3, -2\rangle$. Using $(x_0, y_0, z_0) = P = (1, 1, 2)$ and $\langle a, b, c\rangle = \overrightarrow{PQ} = \langle -3, 3, -2\rangle$ in Eq. (12) gives

$$\frac{x-1}{-3} = \frac{y-1}{3} = \frac{z-2}{-2}$$

60. Find the symmetric equations of the line

$$x = 3 + 2t, \quad y = 4 - 9t, \quad z = 12t$$

SOLUTION If we solve each equation fot t, we get:

$$t = \frac{x-3}{2}, \quad t = \frac{4-y}{9}, \quad t = \frac{z}{12}$$

When we set these equations equal to each other, we get:

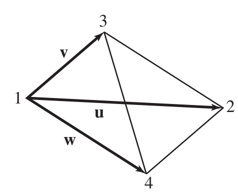
$$\frac{x-3}{2} = \frac{4-y}{9} = \frac{z}{12}$$

61. Find a vector parametrization for the line

$$\frac{x-5}{9} = \frac{y+3}{7} = z - 10$$

SOLUTION Using $(x_0, y_0, z_0) = (5, -3, 10)$ and $\langle a, b, c\rangle = \langle 9, 7, 1\rangle$ gives

$$\mathbf{r}(t) = \langle 5, -3, 10\rangle + t\,\langle 9, 7, 1\rangle$$



62. Find a vector parametrization for the line $\frac{x}{2} = \frac{y}{7} = \frac{z}{8}$.

SOLUTION If we let t equal these three terms, as follows:

$$t = \frac{x}{2} = \frac{y}{7} = \frac{z}{8}$$

then we can break it up into three equations:

$$t = \frac{x}{2}, \quad t = \frac{y}{7}, \quad t = \frac{z}{8}$$

and solving for x, y, and z gives us:

$$x = 2t, \quad y = 7t, \quad z = 8t$$

and writing this in vector form gives us

$$\mathbf{r}(t) = t\,\langle 2, 7, 8\rangle$$

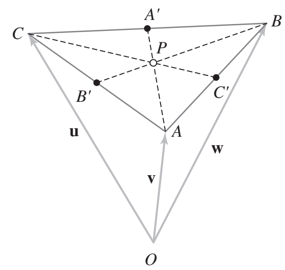
63. Show that the line in the plane through (x_0, y_0) of slope m has symmetric equations

$$x - x_0 = \frac{y - y_0}{m}$$

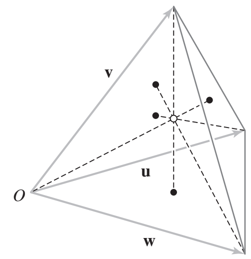
SOLUTION The line through (x_0, y_0) of slope m has equation $y - y_0 = m(x - x_0)$, which becomes $x - x_0 = \frac{1}{m}(y - y_0)$, which becomes

$$\frac{x - x_0}{1} = \frac{y - y_0}{m}$$

64. A median of a triangle is a segment joining a vertex to the midpoint of the opposite side. Referring to Figure 20(A), prove that three medians of triangle ABC intersect at the terminal point P of the vector $\frac{1}{3}(\mathbf{u} + \mathbf{v} + \mathbf{w})$. The point P is the *centroid* of the triangle. *Hint:* Show, by parametrizing the segment $\overline{AA'}$, that P lies two-thirds of the way from A to A'. It will follow similarly that P lies on the other two medians.



(A)



(B)

FIGURE 20

SOLUTION We denote the vertices of the triangle by A, B, C as shown in Figure 20(A). Hence,

$$\overrightarrow{OA'} = \overrightarrow{OB} + \overrightarrow{BA'} = \mathbf{w} + \frac{1}{2}(\mathbf{u} - \mathbf{w}) = \frac{1}{2}(\mathbf{u} + \mathbf{w})$$

$$\overrightarrow{OA} = \mathbf{v}$$

Thus, the line through the points A and A' has the parametrization

$$t\mathbf{v} + (1 - t)\frac{\mathbf{u} + \mathbf{w}}{2} \tag{1}$$

Similarly, the line through B and B' has the parametrization

$$t\mathbf{w} + (1 - t)\frac{\mathbf{v} + \mathbf{u}}{2} \tag{2}$$

And the line through C and C' has the parametrization

$$t\mathbf{u} + (1 - t)\frac{\mathbf{v} + \mathbf{w}}{2} \tag{3}$$

Now, setting $t = \frac{1}{3}$ in (1), (2) and (3) yields $\frac{1}{3}(\mathbf{u} + \mathbf{v} + \mathbf{w})$. We conclude that the terminal point of this vector lies on each one of the lines, hence it is their point of intersection.

65. A median of a tetrahedron is a segment joining a vertex to the centroid of the opposite face. The tetrahedron in Figure 20(B) has vertices at the origin and at the terminal points of vectors $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$. Show that the medians intersect at the terminal point of $\frac{1}{4}(\mathbf{u} + \mathbf{v} + \mathbf{w})$.

SOLUTION We first find vectors from the origin to the centroids of the four faces (labelled 1,2,3,4 after their opposite vertices, also labelled 1,2,3,4). Now, by the previous problem (Exercise 64), a vector from the origin (vertex 1) to the centroid of the opposite face (face 1) is $\frac{1}{3}(\mathbf{u} + \mathbf{v} + \mathbf{w})$. As for face 2, a vector from vertex 2 to the centroid of face 2 is $\frac{1}{3}(-\mathbf{u} + (\mathbf{v} - \mathbf{u}) + (\mathbf{w} - \mathbf{u}))$, but since vertex 2 is at the head of vector $\mathbf{u}$, then a vector from the origin to the centroid of face 2 is $\mathbf{u} + \frac{1}{3}(-\mathbf{u} + (\mathbf{v} - \mathbf{u}) + (\mathbf{w} - \mathbf{u})) = \frac{1}{3}(\mathbf{v} + \mathbf{w})$. Similarly, a vector from the origin to the centroid of face 3 is $\mathbf{v} + \frac{1}{3}(-\mathbf{v} + (\mathbf{u} - \mathbf{v}) + (\mathbf{w} - \mathbf{v})) = \frac{1}{3}(\mathbf{u} + \mathbf{w})$, and from the origin to the centroid of face 4 is $\frac{1}{3}(\mathbf{u} + \mathbf{v})$.

We now find the paramentric equations of four lines $\ell_1, \dots, \ell_4$, each from vertex i to the centroid of the (opposite) face i.

$$\ell_1(t) = t\mathbf{0} + (1 - t)\frac{1}{3}(\mathbf{u} + \mathbf{v} + \mathbf{w})$$

$$\ell_2(t) = t\mathbf{u} + (1 - t)\frac{1}{3}(\mathbf{v} + \mathbf{w})$$

$$\ell_3(t) = t\mathbf{v} + (1 - t)\frac{1}{3}(\mathbf{u} + \mathbf{w})$$

$$\ell_4(t) = t\mathbf{w} + (1 - t)\frac{1}{3}(\mathbf{u} + \mathbf{v})$$

By substituting $t = 1/4$ into each line, we find that they all intersect in the same point:

$$\ell_1(1/4) = 1/4\mathbf{0} + (1 - 1/4)\frac{1}{3}(\mathbf{u} + \mathbf{v} + \mathbf{w}) = 1/4(\mathbf{u} + \mathbf{v} + \mathbf{w})$$

$$\ell_2(1/4) = 1/4\mathbf{u} + (1 - 1/4)\frac{1}{3}(\mathbf{v} + \mathbf{w}) = 1/4(\mathbf{u} + \mathbf{v} + \mathbf{w})$$

$$\ell_3(1/4) = 1/4\mathbf{v} + (1 - 1/4)\frac{1}{3}(\mathbf{u} + \mathbf{w}) = 1/4(\mathbf{u} + \mathbf{v} + \mathbf{w})$$

$$\ell_4(1/4) = 1/4\mathbf{w} + (1 - 1/4)\frac{1}{3}(\mathbf{u} + \mathbf{v}) = 1/4(\mathbf{u} + \mathbf{v} + \mathbf{w})$$

We conclude that all four lines intersect at the terminal point of the vector $1/4(\mathbf{u} + \mathbf{v} + \mathbf{w})$, as desired.

12.3 Dot Product and the Angle between Two Vectors (LT Section 13.3)

Preliminary Questions

1. Is the dot product of two vectors a scalar or a vector?

SOLUTION The dot product of two vectors is the sum of products of scalars, hence it is a scalar.

2. What can you say about the angle between **a** and **b** if $\mathbf{a} \cdot \mathbf{b} < 0$?

SOLUTION Since the cosine of the angle between **a** and **b** satisfies $\cos\theta = \frac{\mathbf{a}\cdot\mathbf{b}}{\|\mathbf{a}\|\|\mathbf{b}\|}$, also $\cos\theta < 0$. By definition $0 \le \theta \le \pi$, but since $\cos\theta < 0$ then θ is in $(\pi/2, \pi]$. In other words, the angle between **a** and **b** is obtuse.

3. Which property of dot products allows us to conclude that if **v** is orthogonal to both **u** and **w**, then **v** is orthogonal to $\mathbf{u} + \mathbf{w}$?

SOLUTION One property is that two vectors are orthogonal if and only if the dot product of the two vectors is zero. The second property is the Distributive Law. Since **v** is orthogonal to **u** and **w**, we have $\mathbf{v} \cdot \mathbf{u} = 0$ and $\mathbf{v} \cdot \mathbf{w} = 0$. Therefore,

$$\mathbf{v} \cdot (\mathbf{u} + \mathbf{w}) = \mathbf{v} \cdot \mathbf{u} + \mathbf{v} \cdot \mathbf{w} = 0 + 0 = 0$$

We conclude that **v** is orthogonal to $\mathbf{u} + \mathbf{w}$.

4. Which is the projection of **v** along **v**: (a) **v** or (b) $\mathbf{e_v}$?

SOLUTION The projection of **v** along itself is **v**, since

$$\mathbf{v}_{||} = \left(\frac{\mathbf{v} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right)\mathbf{v} = \mathbf{v}$$

Also, the projection of **v** along $\mathbf{e_v}$ is the same answer, **v**, because

$$\mathbf{v}_{||} = \left(\frac{\mathbf{v} \cdot \mathbf{e_v}}{\mathbf{e_v} \cdot \mathbf{e_v}}\right)\mathbf{e_v} = \|\mathbf{v}\|\mathbf{e_v} = \mathbf{v}$$

5. Let $\mathbf{u}_{||}$ be the projection of **u** along **v**. Which of the following is the projection **u** along the vector $2\mathbf{v}$ and which is the projection of $2\mathbf{u}$ along **v**?

(a) $\frac{1}{2}\mathbf{u}_{||}$ **(b)** $\mathbf{u}_{||}$ **(c)** $2\mathbf{u}_{||}$

SOLUTION Since $\mathbf{u}_{||}$ is the projection of **u** along **v**, we have,

$$\mathbf{u}_{||} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right)\mathbf{v}$$

The projection of **u** along the vector $2\mathbf{v}$ is

$$\left(\frac{\mathbf{u} \cdot 2\mathbf{v}}{2\mathbf{v} \cdot 2\mathbf{v}}\right)2\mathbf{v} = \left(\frac{2\mathbf{u} \cdot \mathbf{v}}{4\mathbf{v} \cdot \mathbf{v}}\right)2\mathbf{v} = \left(\frac{4\mathbf{u} \cdot \mathbf{v}}{4\mathbf{v} \cdot \mathbf{v}}\right)\mathbf{v} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right)\mathbf{v} = \mathbf{u}_{||}$$

That is, $u_{||}$ is the projection of **u** along $2\mathbf{v}$, so our answer is (b) for the first part. Notice that the projection of **u** along **v** is the projection of **u** along the unit vector $\mathbf{e_v}$, hence it depends on the direction of **v** rather than on the length of **v**. Therefore, the projection of **u** along **v** and along $2\mathbf{v}$ is the same vector.

On the other hand, the projection of $2\mathbf{u}$ along **v** is as follows:

$$\left(\frac{2\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right)\mathbf{v} = 2\left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right)\mathbf{v} = 2\mathbf{u}_{||}$$

giving us answer (c) for the second part.

6. Which of the following is equal to $\cos\theta$, where θ is the angle between **u** and **v**?

(a) $\mathbf{u} \cdot \mathbf{v}$ **(b)** $\mathbf{u} \cdot \mathbf{e_v}$ **(c)** $\mathbf{e_u} \cdot \mathbf{e_v}$

SOLUTION By the Theorems on the Dot Product and the Angle Between Vectors, we have

$$\cos\theta = \frac{\mathbf{u} \cdot \mathbf{v}}{\|\mathbf{u}\|\|\mathbf{v}\|} = \frac{\mathbf{u}}{\|\mathbf{u}\|} \cdot \frac{\mathbf{v}}{\|\mathbf{v}\|} = \mathbf{e_u} \cdot \mathbf{e_v}$$

The correct answer is (c).

Exercises

In Exercises 1–12, compute the dot product.

1. $\langle 1, 2, 1\rangle \cdot \langle 4, 3, 5\rangle$

SOLUTION Using the definition of the dot product we obtain

$$\langle 1, 2, 1\rangle \cdot \langle 4, 3, 5\rangle = 1 \cdot 4 + 2 \cdot 3 + 1 \cdot 5 = 15$$

2. $\langle 3, -2, 2\rangle \cdot \langle 1, 0, 1\rangle$

SOLUTION By the definition of the dot product we have

$$\langle 3, -2, 2\rangle \cdot \langle 1, 0, 1\rangle = 3 \cdot 1 + (-2) \cdot 0 + 2 \cdot 1 = 5$$

3. $\langle 0, 1, 0\rangle \cdot \langle 7, 41, -3\rangle$

SOLUTION The dot product is

$$\langle 0, 1, 0\rangle \cdot \langle 7, 41, -3\rangle = 0 \cdot 7 + 1 \cdot 41 + 0 \cdot (-3) = 41$$

4. $\langle 1, 1, 1\rangle \cdot \langle 6, 4, 2\rangle$

SOLUTION We multiply corresponding components and add to obtain

$$\langle 1, 1, 1\rangle \cdot \langle 6, 4, 2\rangle = 1 \cdot 6 + 1 \cdot 4 + 1 \cdot 2 = 12$$

5. $\langle 3, 1\rangle \cdot \langle 4, -7\rangle$

SOLUTION The dot product of the two vectors is the following scalar:

$$\langle 3, 1\rangle \cdot \langle 4, -7\rangle = 3 \cdot 4 + 1 \cdot (-7) = 5$$

6. $\left\langle \frac{1}{6}, \frac{1}{2}\right\rangle \cdot \left\langle 3, \frac{1}{2}\right\rangle$

SOLUTION The dot product is

$$\left\langle \frac{1}{6}, \frac{1}{2}\right\rangle \cdot \left\langle 3, \frac{1}{2}\right\rangle = \frac{1}{6} \cdot 3 + \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{2} + \frac{1}{4} = \frac{3}{4}$$

7. $\mathbf{k} \cdot \mathbf{j}$

SOLUTION By the orthogonality of $\mathbf{j}$ and $\mathbf{k}$, we have $\mathbf{k} \cdot \mathbf{j} = 0$

8. $\mathbf{k} \cdot \mathbf{k}$

SOLUTION Since $\mathbf{k}$ has length 1, we have $\mathbf{k} \cdot \mathbf{k} = 1$

9. $(\mathbf{i} + \mathbf{j}) \cdot (\mathbf{j} + \mathbf{k})$

SOLUTION By the distributive law and the orthogonality of $\mathbf{i}$, $\mathbf{j}$ and $\mathbf{k}$ we have

$$(\mathbf{i} + \mathbf{j}) \cdot (\mathbf{j} + \mathbf{k}) = \mathbf{i} \cdot \mathbf{j} + \mathbf{i} \cdot \mathbf{k} + \mathbf{j} \cdot \mathbf{j} + \mathbf{j} \cdot \mathbf{k} = 0 + 0 + 1 + 0 = 1$$

10. $(3\mathbf{j} + 2\mathbf{k}) \cdot (\mathbf{i} - 4\mathbf{k})$

SOLUTION By the distributive law and the orthogonality of $\mathbf{i}$, $\mathbf{j}$ and $\mathbf{k}$ we have

$$(3\mathbf{j} + 2\mathbf{k}) \cdot (\mathbf{i} - 4\mathbf{k}) = 3\mathbf{j} \cdot \mathbf{i} - 12\mathbf{j} \cdot \mathbf{k} + 2\mathbf{k} \cdot \mathbf{i} - 8\mathbf{k} \cdot \mathbf{k} = 0 - 0 + 0 - 8\|\mathbf{k}\|^2 = -8 \cdot 1^2 = -8$$

11. $(\mathbf{i} + \mathbf{j} + \mathbf{k}) \cdot (3\mathbf{i} + 2\mathbf{j} - 5\mathbf{k})$

SOLUTION We use properties of the dot product to obtain

$$\begin{aligned}(\mathbf{i} + \mathbf{j} + \mathbf{k}) \cdot (3\mathbf{i} + 2\mathbf{j} - 5\mathbf{k}) &= 3\mathbf{i} \cdot \mathbf{i} + 2\mathbf{i} \cdot \mathbf{j} - 5\mathbf{i} \cdot \mathbf{k} + 3\mathbf{j} \cdot \mathbf{i} + 2\mathbf{j} \cdot \mathbf{j} - 5\mathbf{j} \cdot \mathbf{k} + 3\mathbf{k} \cdot \mathbf{i} + 2\mathbf{k} \cdot \mathbf{j} - 5\mathbf{k} \cdot \mathbf{k} \\ &= 3\|\mathbf{i}\|^2 + 2\|\mathbf{j}\|^2 - 5\|\mathbf{k}\|^2 = 3 \cdot 1 + 2 \cdot 1 - 5 \cdot 1 = 0\end{aligned}$$

12. $(-\mathbf{k}) \cdot (\mathbf{i} - 2\mathbf{j} + 7\mathbf{k})$

SOLUTION Using the distributive law we have

$$(-\mathbf{k}) \cdot (\mathbf{i} - 2\mathbf{j} + 7\mathbf{k}) = -\mathbf{k} \cdot \mathbf{i} + 2\mathbf{k} \cdot \mathbf{j} - 7\mathbf{k} \cdot \mathbf{k} = 0 + 0 - 7\|\mathbf{k}\|^2 = -7 \cdot 1^2 = -7$$

In Exercises 13–18, determine whether the two vectors are orthogonal and, if not, whether the angle between them is acute or obtuse.

13. $\langle 1, 1, 1\rangle, \quad \langle 1, -2, -2\rangle$

SOLUTION We compute the dot product of the two vectors:

$$\langle 1, 1, 1\rangle \cdot \langle 1, -2, -2\rangle = 1 \cdot 1 + 1 \cdot (-2) + 1 \cdot (-2) = -3$$

Since the dot product is negative, the angle between the vectors is obtuse.

14. $\langle 0, 2, 4\rangle, \quad \langle -5, 0, 0\rangle$

SOLUTION Computing the dot product gives

$$\langle 0, 2, 4\rangle \cdot \langle -5, 0, 0\rangle = 0 \cdot (-5) + 2 \cdot 0 + 4 \cdot 0 = 0$$

The dot product is zero, hence the vectors are orthogonal.

15. $\langle 1, 2, 1\rangle, \quad \langle 7, -3, -1\rangle$

SOLUTION We compute the dot product:

$$\langle 1, 2, 1\rangle \cdot \langle 7, -3, -1\rangle = 1 \cdot 7 + 2 \cdot (-3) + 1 \cdot (-1) = 0$$

The dot product is zero, hence the vectors are orthogonal.

16. $\langle 0, 2, 4\rangle, \quad \langle 3, 1, 0\rangle$

SOLUTION We find the dot product of the two vectors:

$$\langle 0, 2, 4\rangle \cdot \langle 3, 1, 0\rangle = 0 \cdot 3 + 2 \cdot 1 + 4 \cdot 0 = 2$$

The dot product is positive, hence the angle between the vectors is acute.

17. $\left\langle \frac{12}{5}, -\frac{4}{5}\right\rangle, \quad \left\langle \frac{1}{2}, -\frac{7}{4}\right\rangle$

SOLUTION We find the dot product of the two vectors:

$$\left\langle \frac{12}{5}, -\frac{4}{5}\right\rangle \cdot \left\langle \frac{1}{2}, -\frac{7}{4}\right\rangle = \frac{12}{5} \cdot \frac{1}{2} + \left(-\frac{4}{5}\right) \cdot \left(-\frac{7}{4}\right) = \frac{12}{10} + \frac{28}{20} = \frac{13}{5}$$

The dot product is positive, hence the angle between the vectors is acute.

18. $\langle 12, 6\rangle, \quad \langle 2, -4\rangle$

SOLUTION Since $\langle 12, 6\rangle \cdot \langle 2, -4\rangle = 12 \cdot 2 + 6 \cdot (-4) = 0$, the vectors are orthogonal.

In Exercises 19–22, find the cosine of the angle between the vectors.

19. $\langle 0, 3, 1\rangle, \quad \langle 4, 0, 0\rangle$

SOLUTION Since $\langle 0, 3, 1\rangle \cdot \langle 4, 0, 0\rangle = 0 \cdot 4 + 3 \cdot 0 + 1 \cdot 0 = 0$, the vectors are orthogonal, that is, the angle between them is $\theta = 90^\circ$ and $\cos\theta = 0$.

20. $\langle 1, 1, 1\rangle, \quad \langle 2, -1, 2\rangle$

SOLUTION We write $\mathbf{v} = \langle 1, 1, 1\rangle$ and $\mathbf{w} = \langle 2, -1, 2\rangle$ and use the formula for the cosine of the angle between $\mathbf{u}$ and $\mathbf{v}$:

$$\cos\theta = \frac{\mathbf{v} \cdot \mathbf{w}}{\|\mathbf{v}\| \|\mathbf{w}\|}$$

We compute the values in this formula:

$$\|\mathbf{v}\| = \sqrt{1^2 + 1^2 + 1^2} = \sqrt{3}$$
$$\|\mathbf{w}\| = \sqrt{2^2 + (-1)^2 + 2^2} = 3$$
$$\mathbf{v} \cdot \mathbf{w} = \langle 1, 1, 1 \rangle \cdot \langle 2, -1, 2 \rangle = 1 \cdot 2 + 1 \cdot (-1) + 1 \cdot 2 = 3$$

Hence,

$$\cos\theta = \frac{3}{3\sqrt{3}} = \frac{1}{\sqrt{3}}.$$

21. $\mathbf{i} + \mathbf{j}, \quad \mathbf{j} + 2\mathbf{k}$

SOLUTION We use the formula for the cosine of the angle between two vectors. Let $\mathbf{v} = \mathbf{i} + \mathbf{j}$ and $\mathbf{w} = \mathbf{j} + 2\mathbf{k}$. We compute the following values:

$$\|\mathbf{v}\| = \|\mathbf{i} + \mathbf{j}\| = \sqrt{1^2 + 1^2} = \sqrt{2}$$
$$\|\mathbf{w}\| = \|\mathbf{j} + 2\mathbf{k}\| = \sqrt{1^2 + 2^2} = \sqrt{5}$$
$$\mathbf{v} \cdot \mathbf{w} = (\mathbf{i} + \mathbf{j}) \cdot (\mathbf{j} + 2\mathbf{k}) = \mathbf{i} \cdot \mathbf{j} + 2\mathbf{i} \cdot \mathbf{k} + \mathbf{j} \cdot \mathbf{j} + 2\mathbf{j} \cdot \mathbf{k} = \|\mathbf{j}\|^2 = 1$$

Hence,

$$\cos\theta = \frac{\mathbf{v} \cdot \mathbf{w}}{\|\mathbf{v}\|\|\mathbf{w}\|} = \frac{1}{\sqrt{2}\sqrt{5}} = \frac{1}{\sqrt{10}}.$$

22. $3\mathbf{i} + \mathbf{k}, \quad \mathbf{i} + \mathbf{j} + \mathbf{k}$

SOLUTION We write $\mathbf{v} = 3\mathbf{i} + \mathbf{k}$, $\mathbf{w} = \mathbf{i} + \mathbf{j} + \mathbf{k}$. To use the formula for the cosine of the angle θ between two vectors we need to compute the following values:

$$\|\mathbf{v}\| = \sqrt{3^2 + 1^2} = \sqrt{10}$$
$$\|\mathbf{w}\| = \sqrt{1^2 + 1^2 + 1^2} = \sqrt{3}$$
$$\mathbf{v} \cdot \mathbf{w} = (3\mathbf{i} + \mathbf{k}) \cdot (\mathbf{i} + \mathbf{j} + \mathbf{k}) = (3\mathbf{i} + 0\mathbf{j} + \mathbf{k}) \cdot (\mathbf{i} + \mathbf{j} + \mathbf{k}) = 3 \cdot 1 + 0 \cdot 1 + 1 \cdot 1 = 4$$

Hence,

$$\cos\theta = \frac{\mathbf{v} \cdot \mathbf{w}}{\|\mathbf{v}\|\|\mathbf{w}\|} = \frac{4}{\sqrt{10}\sqrt{3}} = \frac{4}{\sqrt{30}}$$

In Exercises 23–28, find the angle between the vectors. Use a calculator if necessary.

23. $\langle 2, \sqrt{2} \rangle, \quad \langle 1 + \sqrt{2}, 1 - \sqrt{2} \rangle$

SOLUTION We write $\mathbf{v} = \left\langle 2, \sqrt{2} \right\rangle$ and $\mathbf{w} = \left\langle 2, \sqrt{2} \right\rangle$. To use the formula for the cosine of the angle θ between two vectors we need to compute the following values:

$$\|\mathbf{v}\| = \sqrt{4 + 2} = \sqrt{6}$$
$$\|\mathbf{w}\| = \sqrt{(1 + \sqrt{2})^2 + (1 - \sqrt{2})^2} = \sqrt{6}$$
$$\mathbf{v} \cdot \mathbf{w} = 2 + 2\sqrt{2} + \sqrt{2} - 2 = 3\sqrt{2}$$

Hence,

$$\cos\theta = \frac{\mathbf{v} \cdot \mathbf{w}}{\|\mathbf{v}\|\|\mathbf{w}\|} = \frac{3\sqrt{2}}{\sqrt{6}\sqrt{6}} = \frac{\sqrt{2}}{2}$$

and so,

$$\theta = \cos^{-1}\frac{\sqrt{2}}{2} = \pi/4$$

24. $\langle 5, \sqrt{3}\rangle, \quad \langle \sqrt{3}, 2\rangle$

SOLUTION We denote $\mathbf{v} = \left\langle 5, \sqrt{3}\right\rangle$ and $\mathbf{w} = \left\langle \sqrt{3}, 2\right\rangle$. To use the formula for the cosine of the angle θ between two vectors we need to compute the following values:

$$\|\mathbf{v}\| = \sqrt{25+3} = \sqrt{28}$$
$$\|\mathbf{w}\| = \sqrt{3+4} = \sqrt{7}$$
$$\mathbf{v}\cdot\mathbf{w} = 5\cdot\sqrt{3} + \sqrt{3}\cdot 2 = 7\sqrt{3}$$

Hence,

$$\cos\theta = \frac{\mathbf{v}\cdot\mathbf{w}}{\|\mathbf{v}\|\|\mathbf{w}\|} = \frac{7\sqrt{3}}{\sqrt{28}\sqrt{7}} = \frac{\sqrt{3}}{2}$$

and so,

$$\theta = \cos^{-1}\frac{\sqrt{3}}{2} = \pi/6$$

25. $\langle 1, 1, 1\rangle, \quad \langle 1, 0, 1\rangle$

SOLUTION We denote $\mathbf{v} = \langle 1, 1, 1\rangle$ and $\mathbf{w} = \langle 1, 0, 1\rangle$. To use the formula for the cosine of the angle θ between two vectors we need to compute the following values:

$$\|\mathbf{v}\| = \sqrt{1^2+1^2+1^2} = \sqrt{3}$$
$$\|\mathbf{w}\| = \sqrt{1^2+0^2+1^2} = \sqrt{2}$$
$$\mathbf{v}\cdot\mathbf{w} = 1+0+1 = 2$$

Hence,

$$\cos\theta = \frac{\mathbf{v}\cdot\mathbf{w}}{\|\mathbf{v}\|\|\mathbf{w}\|} = \frac{2}{\sqrt{3}\sqrt{2}} = \frac{\sqrt{6}}{3}$$

and so,

$$\theta = \cos^{-1}\frac{\sqrt{6}}{3} \approx 0.615$$

26. $\langle 3, 1, 1\rangle, \quad \langle 2, -4, 2\rangle$

SOLUTION We denote $\mathbf{v} = \langle 3, 1, 1\rangle$ and $\mathbf{w} = \langle 2, -4, 2\rangle$. To use the formula for the cosine of the angle θ between two vectors we need to compute the following values:

$$\|\mathbf{v}\| = \sqrt{3^2+1^2+1^2} = \sqrt{11}$$
$$\|\mathbf{w}\| = \sqrt{2^2+(-4)^2+2^2} = \sqrt{24}$$
$$\mathbf{v}\cdot\mathbf{w} = 6-4+2 = 4$$

Hence,

$$\cos\theta = \frac{\mathbf{v}\cdot\mathbf{w}}{\|\mathbf{v}\|\|\mathbf{w}\|} = \frac{4}{\sqrt{11}\sqrt{24}} = \frac{2}{\sqrt{66}}$$

and so,

$$\theta = \cos^{-1}\frac{2}{\sqrt{66}} \approx 1.322$$

27. $\langle 0, 1, 1\rangle, \quad \langle 1, -1, 0\rangle$

SOLUTION We denote $\mathbf{v} = \langle 0, 1, 1\rangle$ and $\mathbf{w} = \langle 1, -1, 0\rangle$. To use the formula for the cosine of the angle θ between two vectors we need to compute the following values:

$$\|\mathbf{v}\| = \sqrt{0^2+1^2+1^2} = \sqrt{2}$$
$$\|\mathbf{w}\| = \sqrt{1^2+(-1)^2+0^2} = \sqrt{2}$$
$$\mathbf{v}\cdot\mathbf{w} = 0+(-1)+0 = -1$$

Hence,

$$\cos\theta = \frac{\mathbf{v}\cdot\mathbf{w}}{\|\mathbf{v}\|\|\mathbf{w}\|} = \frac{-1}{\sqrt{2}\sqrt{2}} = -\frac{1}{2}$$

and so,

$$\theta = \cos^{-1} -\frac{1}{2} = \frac{2\pi}{3}$$

28. $\langle 1, 1, -1\rangle, \quad \langle 1, -2, -1\rangle$

SOLUTION Since $\langle 1, 1, -1\rangle \cdot \langle 1, -2, -1\rangle = 1 - 2 + 1 = 0$, then the two vectors are orthogonal. Thus, the angle between them is $\pi/2$.

29. Find all values of b for which the vectors are orthogonal.

(a) $\langle b, 3, 2\rangle, \quad \langle 1, b, 1\rangle$

(b) $\langle 4, -2, 7\rangle, \quad \left\langle b^2, b, 0\right\rangle$

SOLUTION

(a) The vectors are orthogonal if and only if the scalar product is zero. That is,

$$\begin{aligned} \langle b, 3, 2\rangle \cdot \langle 1, b, 1\rangle &= 0 \\ b\cdot 1 + 3\cdot b + 2\cdot 1 &= 0 \\ 4b + 2 &= 0 \quad \Rightarrow \quad b = -\frac{1}{2} \end{aligned}$$

(b) We set the scalar product of the two vectors equal to zero and solve for b. This gives

$$\begin{aligned} \langle 4, -2, 7\rangle \cdot \langle b^2, b, 0\rangle &= 0 \\ 4b^2 - 2b + 7\cdot 0 &= 0 \\ 2b(2b-1) &= 0 \quad \Rightarrow \quad b = 0 \text{ or } b = \frac{1}{2} \end{aligned}$$

30. Find a vector that is orthogonal to $\langle -1, 2, 2\rangle$.

SOLUTION We must find a vector $\mathbf{v} = \langle a, b, c\rangle$ such that

$$\begin{aligned} \langle a, b, c\rangle \cdot \langle -1, 2, 2\rangle &= 0 \\ -a + 2b + 2c &= 0 \end{aligned}$$

We choose $c = 1$, $b = 1$, hence $a = 4$. The vector $\mathbf{v} = \langle 4, 1, 1\rangle$ is orthogonal to $\langle -1, 2, 2\rangle$.

31. Find two vectors that are not multiples of each other and are both orthogonal to $\langle 2, 0, -3\rangle$.

SOLUTION We denote by $\langle a, b, c\rangle$, a vector orthogonal to $\langle 2, 0, -3\rangle$. Hence,

$$\begin{aligned} \langle a, b, c\rangle \cdot \langle 2, 0, -3\rangle &= 0 \\ 2a + 0 - 3c &= 0 \\ 2a - 3c &= 0 \quad \Rightarrow \quad a = \frac{3}{2}c \end{aligned}$$

Thus, the vectors orthogonal to $\langle 2, 0, -3\rangle$ are of the form

$$\left\langle \frac{3}{2}c, b, c\right\rangle.$$

We may find two such vectors by setting $c = 0$, $b = 1$ and $c = 2$, $b = 2$. We obtain

$$\mathbf{v}_1 = \langle 0, 1, 0\rangle, \quad \mathbf{v}_2 = \langle 3, 2, 2\rangle.$$

32. Find a vector that is orthogonal to $\mathbf{v} = \langle 1, 2, 1\rangle$ but not to $\mathbf{w} = \langle 1, 0, -1\rangle$.

SOLUTION We want a vector $\langle a, b, c\rangle$ such that $\langle a, b, c\rangle \cdot \langle 1, 2, 1\rangle = 0$ but $\langle a, b, c\rangle \cdot \langle 1, 0, -1\rangle \neq 0$. While we could set up some equations, it's easy to note that if we let $\langle a, b, c\rangle = \mathbf{w} = \langle 1, 0, -1\rangle$, then both conditions are satisfied.

33. Find $\mathbf{v}\cdot\mathbf{e}$ where $\|\mathbf{v}\| = 3$, $\mathbf{e}$ is a unit vector, and the angle between $\mathbf{e}$ and $\mathbf{v}$ is $\frac{2\pi}{3}$.

SOLUTION Since $\mathbf{v}\cdot\mathbf{e} = \|\mathbf{v}\|\|\mathbf{e}\|\cos 2\pi/3$, and $\|\mathbf{v}\| = 3$ and $\|\mathbf{e}\| = 1$, we have $\mathbf{v}\cdot\mathbf{e} = 3\cdot 1\cdot(-1/2) = -3/2$.

34. Assume that $\mathbf{v}$ lies in the yz-plane. Which of the following dot products is equal to zero for all choices of $\mathbf{v}$?

(a) $\mathbf{v} \cdot \langle 0, 2, 1\rangle$

(b) $\mathbf{v} \cdot \mathbf{k}$

(c) $\mathbf{v} \cdot \langle -3, 0, 0\rangle$

(d) $\mathbf{v} \cdot \mathbf{j}$

SOLUTION Since $\mathbf{v}$ lies in the yz-plane, then it must be of the form $\mathbf{v} = \langle 0, v_2, v_3\rangle$. The only dot product which is always equal to zero is (c), since $\mathbf{v} \cdot \langle -3, 0, 0\rangle = 0$.

In Exercises 35–38, simplify the expression.

35. $(\mathbf{v} - \mathbf{w}) \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{w}$

SOLUTION By properties of the dot product we obtain

$$(\mathbf{v} - \mathbf{w}) \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{w} = \mathbf{v} \cdot \mathbf{v} - \mathbf{w} \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{w} = \|\mathbf{v}\|^2 - \mathbf{v} \cdot \mathbf{w} + \mathbf{v} \cdot \mathbf{w} = \|\mathbf{v}\|^2$$

36. $(\mathbf{v} + \mathbf{w}) \cdot (\mathbf{v} + \mathbf{w}) - 2\mathbf{v} \cdot \mathbf{w}$

SOLUTION Using properties of the dot product we obtain

$$\begin{aligned}(\mathbf{v} + \mathbf{w}) \cdot (\mathbf{v} + \mathbf{w}) - 2\mathbf{v} \cdot \mathbf{w} &= \mathbf{v} \cdot (\mathbf{v} + \mathbf{w}) + \mathbf{w} \cdot (\mathbf{v} + \mathbf{w}) - 2\mathbf{v} \cdot \mathbf{w} = \mathbf{v} \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{w} + \mathbf{w} \cdot \mathbf{v} + \mathbf{w} \cdot \mathbf{w} - 2\mathbf{v} \cdot \mathbf{w} \\ &= \|\mathbf{v}\|^2 + \mathbf{v} \cdot \mathbf{w} + \mathbf{v} \cdot \mathbf{w} + \|\mathbf{w}\|^2 - 2\mathbf{v} \cdot \mathbf{w} = \|\mathbf{v}\|^2 + \|\mathbf{w}\|^2\end{aligned}$$

37. $(\mathbf{v} + \mathbf{w}) \cdot \mathbf{v} - (\mathbf{v} + \mathbf{w}) \cdot \mathbf{w}$

SOLUTION We use properties of the dot product to write

$$\begin{aligned}(\mathbf{v} + \mathbf{w}) \cdot \mathbf{v} - (\mathbf{v} + \mathbf{w}) \cdot \mathbf{w} &= \mathbf{v} \cdot \mathbf{v} + \mathbf{w} \cdot \mathbf{v} - \mathbf{v} \cdot \mathbf{w} - \mathbf{w} \cdot \mathbf{w} \\ &= \|\mathbf{v}\|^2 + \mathbf{w} \cdot \mathbf{v} - \mathbf{w} \cdot \mathbf{v} - \|\mathbf{w}\|^2 = \|\mathbf{v}\|^2 - \|\mathbf{w}\|^2\end{aligned}$$

38. $(\mathbf{v} + \mathbf{w}) \cdot \mathbf{v} - (\mathbf{v} - \mathbf{w}) \cdot \mathbf{w}$

SOLUTION By properties of the dot product we get

$$\begin{aligned}(\mathbf{v} + \mathbf{w}) \cdot \mathbf{v} - (\mathbf{v} - \mathbf{w}) \cdot \mathbf{w} &= (\mathbf{v} + \mathbf{w}) \cdot \mathbf{v} - \mathbf{w} \cdot (\mathbf{v} - \mathbf{w}) \\ &= \mathbf{v} \cdot \mathbf{v} + \mathbf{w} \cdot \mathbf{v} - \mathbf{w} \cdot \mathbf{v} + \mathbf{w} \cdot \mathbf{w} \\ &= \mathbf{v} \cdot \mathbf{v} + \mathbf{w} \cdot \mathbf{w} = \|\mathbf{v}\|^2 + \|\mathbf{w}\|^2\end{aligned}$$

In Exercises 39–42, use the properties of the dot product to evaluate the expression, assuming that $\mathbf{u} \cdot \mathbf{v} = 2$, $\|\mathbf{u}\| = 1$, and $\|\mathbf{v}\| = 3$.

39. $\mathbf{u} \cdot (4\mathbf{v})$

SOLUTION Using properties of the dot product we get

$$\mathbf{u} \cdot (4\mathbf{v}) = 4(\mathbf{u} \cdot \mathbf{v}) = 4 \cdot 2 = 8.$$

40. $(\mathbf{u} + \mathbf{v}) \cdot \mathbf{v}$

SOLUTION Using the distributive law and the dot product relation with length we obtain

$$(\mathbf{u} + \mathbf{v}) \cdot \mathbf{v} = \mathbf{u} \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{v} = \mathbf{u} \cdot \mathbf{v} + \|\mathbf{v}\|^2 = 2 + 3^2 = 11.$$

41. $2\mathbf{u} \cdot (3\mathbf{u} - \mathbf{v})$

SOLUTION By properties of the dot product we obtain

$$\begin{aligned}2\mathbf{u} \cdot (3\mathbf{u} - \mathbf{v}) &= (2\mathbf{u}) \cdot (3\mathbf{u}) - (2\mathbf{u}) \cdot \mathbf{v} = 6(\mathbf{u} \cdot \mathbf{u}) - 2(\mathbf{u} \cdot \mathbf{v}) \\ &= 6\|\mathbf{u}\|^2 - 2(\mathbf{u} \cdot \mathbf{v}) = 6 \cdot 1^2 - 2 \cdot 2 = 2\end{aligned}$$

42. $(\mathbf{u} + \mathbf{v}) \cdot (\mathbf{u} - \mathbf{v})$

SOLUTION We use the distributive law, commutativity and the relation with length to write

$$\begin{aligned}(\mathbf{u} + \mathbf{v}) \cdot (\mathbf{u} - \mathbf{v}) &= \mathbf{u} \cdot (\mathbf{u} - \mathbf{v}) + \mathbf{v} \cdot (\mathbf{u} - \mathbf{v}) = \|\mathbf{u}\|^2 - \mathbf{u} \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{v} - \|\mathbf{v}\|^2 \\ &= \|\mathbf{u}\|^2 - \|\mathbf{v}\|^2 = 1^2 - 3^2 = -8\end{aligned}$$

43. Find the angle between $\mathbf{v}$ and $\mathbf{w}$ if $\mathbf{v} \cdot \mathbf{w} = -\|\mathbf{v}\| \, \|\mathbf{w}\|$.

SOLUTION Using the formula for dot product, and the given equation $\mathbf{v} \cdot \mathbf{w} = -\|\mathbf{v}\| \, \|\mathbf{w}\|$, we get:

$$\|\mathbf{v}\| \, \|\mathbf{w}\| \cos\theta = -\|\mathbf{v}\| \, \|\mathbf{w}\|,$$

which implies $\cos\theta = -1$, and so the angle between the two vectors is $\theta = \pi$.

44. Find the angle between $\mathbf{v}$ and $\mathbf{w}$ if $\mathbf{v} \cdot \mathbf{w} = \frac{1}{2}\|\mathbf{v}\|\ \|\mathbf{w}\|$.

SOLUTION Using the formula for dot product, and the given equation $\mathbf{v} \cdot \mathbf{w} = \frac{1}{2}\|\mathbf{v}\|\ \|\mathbf{w}\|$, we get:

$$\|\mathbf{v}\|\ \|\mathbf{w}\| \cos\theta = \frac{1}{2}\|\mathbf{v}\|\ \|\mathbf{w}\|,$$

which implies $\cos\theta = \frac{1}{2}$, and so the angle between the two vectors is $\theta = \pi/3$.

45. Assume that $\|\mathbf{v}\| = 3$, $\|\mathbf{w}\| = 5$ and that the angle between $\mathbf{v}$ and $\mathbf{w}$ is $\theta = \frac{\pi}{3}$.

(a) Use the relation $\|\mathbf{v}+\mathbf{w}\|^2 = (\mathbf{v}+\mathbf{w}) \cdot (\mathbf{v}+\mathbf{w})$ to show that $\|\mathbf{v}+\mathbf{w}\|^2 = 3^2 + 5^2 + 2\mathbf{v}\cdot\mathbf{w}$.

(b) Find $\|\mathbf{v}+\mathbf{w}\|$.

SOLUTION For part (a), we use the distributive property to get:

$$\begin{aligned}\|\mathbf{v}+\mathbf{w}\|^2 &= (\mathbf{v}+\mathbf{w}) \cdot (\mathbf{v}+\mathbf{w})\\ &= \mathbf{v}\cdot\mathbf{v} + \mathbf{v}\cdot\mathbf{w} + \mathbf{w}\cdot\mathbf{v} + \mathbf{w}\cdot\mathbf{w}\\ &= \|\mathbf{v}\|^2 + 2\mathbf{v}\cdot\mathbf{w} + \|\mathbf{w}\|^2\\ &= 3^2 + 5^2 + 2\mathbf{v}\cdot\mathbf{w}\end{aligned}$$

For part (b), we use the definition of dot product on the previous equation to get:

$$\begin{aligned}\|\mathbf{v}+\mathbf{w}\|^2 &= 3^2 + 5^2 + 2\mathbf{v}\cdot\mathbf{w}\\ &= 34 + 2\cdot 3\cdot 5\cdot \cos\pi/3\\ &= 34 + 15 = 49\end{aligned}$$

Thus, $\|\mathbf{v}+\mathbf{w}\| = \sqrt{49} = 7$.

46. Assume that $\|\mathbf{v}\| = 2$, $\|\mathbf{w}\| = 3$, and the angle between $\mathbf{v}$ and $\mathbf{w}$ is $120°$. Determine:

(a) $\mathbf{v}\cdot\mathbf{w}$ **(b)** $\|2\mathbf{v}+\mathbf{w}\|$ **(c)** $\|2\mathbf{v}-3\mathbf{w}\|$

SOLUTION

(a) We use the relation between the dot product and the angle between two vectors to write

$$\mathbf{v}\cdot\mathbf{w} = \|\mathbf{v}\|\|\mathbf{w}\|\cos\theta = 2\cdot 3\cos 120° = 6\cdot\left(-\frac{1}{2}\right) = -3$$

(b) By the relation of the dot product with length and by properties of the dot product we have

$$\begin{aligned}\|2\mathbf{v}+\mathbf{w}\|^2 &= (2\mathbf{v}+\mathbf{w})\cdot(2\mathbf{v}+\mathbf{w}) = 4\mathbf{v}\cdot\mathbf{v} + 2\mathbf{v}\cdot\mathbf{w} + 2\mathbf{w}\cdot\mathbf{v} + \mathbf{w}\cdot\mathbf{w}\\ &= 4\|\mathbf{v}\|^2 + 4\mathbf{v}\cdot\mathbf{w} + \|\mathbf{w}\|^2\end{aligned}$$

We now substitute $\mathbf{v}\cdot\mathbf{w} = -3$ from part (a) and the given information, obtaining

$$\|2\mathbf{v}+\mathbf{w}\|^2 = 4\cdot 2^2 + 4(-3) + 3^2 = 13 \quad\Rightarrow\quad \|2\mathbf{v}+\mathbf{w}\| = \sqrt{13} \approx 3.61$$

(c) We express the length in terms of a dot product and use properties of the dot product. This gives

$$\begin{aligned}\|2\mathbf{v}-3\mathbf{w}\|^2 &= (2\mathbf{v}-3\mathbf{w})\cdot(2\mathbf{v}-3\mathbf{w}) = 4\mathbf{v}\cdot\mathbf{v} - 6\mathbf{v}\cdot\mathbf{w} - 6\mathbf{w}\cdot\mathbf{v} + 9\mathbf{w}\cdot\mathbf{w}\\ &= 4\|\mathbf{v}\|^2 - 12\mathbf{v}\cdot\mathbf{w} + 9\|\mathbf{w}\|^2\end{aligned}$$

Substituting $\mathbf{v}\cdot\mathbf{w} = -3$ from part (a) and the given values yields

$$\|2\mathbf{v}-3\mathbf{w}\|^2 = 4\cdot 2^2 - 12(-3) + 9\cdot 3^2 = 133 \quad\Rightarrow\quad \|2\mathbf{v}-3\mathbf{w}\| = \sqrt{133} \approx 11.53$$

47. Show that if $\mathbf{e}$ and $\mathbf{f}$ are unit vectors such that $\|\mathbf{e}+\mathbf{f}\| = \frac{3}{2}$, then $\|\mathbf{e}-\mathbf{f}\| = \frac{\sqrt{7}}{2}$. *Hint:* Show that $\mathbf{e}\cdot\mathbf{f} = \frac{1}{8}$.

SOLUTION We use the relation of the dot product with length and properties of the dot product to write

$$\begin{aligned}9/4 = \|\mathbf{e}+\mathbf{f}\|^2 &= (\mathbf{e}+\mathbf{f})\cdot(\mathbf{e}+\mathbf{f}) = \mathbf{e}\cdot\mathbf{e} + \mathbf{e}\cdot\mathbf{f} + \mathbf{f}\cdot\mathbf{e} + \mathbf{f}\cdot\mathbf{f}\\ &= \|\mathbf{e}\|^2 + 2\mathbf{e}\cdot\mathbf{f} + \|\mathbf{f}\|^2 = 1^2 + 2\mathbf{e}\cdot\mathbf{f} + 1^2 = 2 + 2\mathbf{e}\cdot\mathbf{f}\end{aligned}$$

We now find $\mathbf{e}\cdot\mathbf{f}$:

$$9/4 = 2 + 2\mathbf{e}\cdot\mathbf{f} \quad\Rightarrow\quad \mathbf{e}\cdot\mathbf{f} = 1/8$$

Hence, using the same method as above, we have:

$$\begin{aligned}\|\mathbf{e}-\mathbf{f}\|^2 &= (\mathbf{e}-\mathbf{f})\cdot(\mathbf{e}-\mathbf{f}) = \mathbf{e}\cdot\mathbf{e}-\mathbf{e}\cdot\mathbf{f}-\mathbf{f}\cdot\mathbf{e}+\mathbf{f}\cdot\mathbf{f}\\ &= \|\mathbf{e}\|^2-2\mathbf{e}\cdot\mathbf{f}+\|\mathbf{f}\|^2 = 1^2-2\mathbf{e}\cdot\mathbf{f}+1^2 = 2-2\mathbf{e}\cdot\mathbf{f} = 2-2/8 = 7/4.\end{aligned}$$

Taking square roots, we get:

$$\|\mathbf{e}-\mathbf{f}\| = \frac{\sqrt{7}}{2}$$

48. Find $\|2\mathbf{e}-3\mathbf{f}\|$ assuming that $\mathbf{e}$ and $\mathbf{f}$ are unit vectors such that $\|\mathbf{e}+\mathbf{f}\| = \sqrt{3/2}$.

SOLUTION We use the relation of the dot product with length and properties of the dot product to write

$$\begin{aligned}3/2 = \|\mathbf{e}+\mathbf{f}\|^2 &= (\mathbf{e}+\mathbf{f})\cdot(\mathbf{e}+\mathbf{f}) = \mathbf{e}\cdot\mathbf{e}+\mathbf{e}\cdot\mathbf{f}+\mathbf{f}\cdot\mathbf{e}+\mathbf{f}\cdot\mathbf{f}\\ &= \|\mathbf{e}\|^2+2\mathbf{e}\cdot\mathbf{f}+\|\mathbf{f}\|^2 = 1^2+2\mathbf{e}\cdot\mathbf{f}+1^2 = 2+2\mathbf{e}\cdot\mathbf{f}\end{aligned}$$

We now find $\mathbf{e}\cdot\mathbf{f}$:

$$3/2 = 2+2\mathbf{e}\cdot\mathbf{f} \quad\Rightarrow\quad \mathbf{e}\cdot\mathbf{f} = -1/4$$

Hence, using the same method as above, we have:

$$\begin{aligned}\|2\mathbf{e}-3\mathbf{f}\|^2 &= (2\mathbf{e}-3\mathbf{f})\cdot(2\mathbf{e}-3\mathbf{f})\\ &= \|2\mathbf{e}\|^2-2\cdot 2\mathbf{e}\cdot 3\mathbf{f}+\|3\mathbf{f}\|^2 = 2^2-12\mathbf{e}\cdot\mathbf{f}+3^2 = 13+3 = 16.\end{aligned}$$

Taking square roots, we get:

$$\|2\mathbf{e}-3\mathbf{f}\| = 4$$

49. Find the angle θ in the triangle in Figure 12.

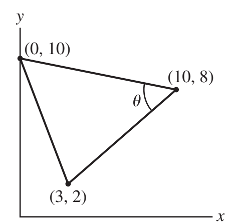


FIGURE 12

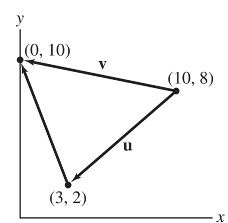
SOLUTION We denote by $\mathbf{u}$ and $\mathbf{v}$ the vectors in the figure.



Hence,

$$\cos\theta = \frac{\mathbf{v}\cdot\mathbf{u}}{\|\mathbf{v}\|\|\mathbf{u}\|} \tag{1}$$

We find the vectors $\mathbf{v}$ and $\mathbf{u}$, and then compute their length and the dot product $\mathbf{v}\cdot\mathbf{u}$. This gives

$$\begin{aligned}\mathbf{v} &= \langle 0-10, 10-8\rangle = \langle -10, 2\rangle\\ \mathbf{u} &= \langle 3-10, 2-8\rangle = \langle -7, -6\rangle\\ \|\mathbf{v}\| &= \sqrt{(-10)^2+2^2} = \sqrt{104}\\ \|\mathbf{u}\| &= \sqrt{(-7)^2+(-6)^2} = \sqrt{85}\\ \mathbf{v}\cdot\mathbf{u} &= \langle -10, 2\rangle\cdot\langle -7, -6\rangle = (-10)\cdot(-7)+2\cdot(-6) = 58\end{aligned}$$

Substituting these values in (1) yields

$$\cos\theta = \frac{58}{\sqrt{104}\sqrt{85}} \approx 0.617$$

Hence the angle of the triangle is 51.91°.

50. Find all three angles in the triangle in Figure 13.

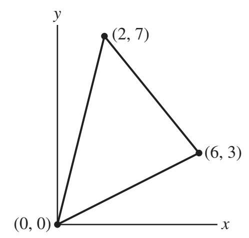


FIGURE 13

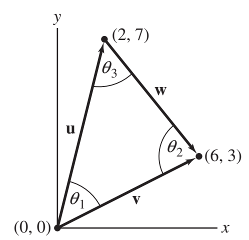
SOLUTION We denote by **u**, **v** and **w** the vectors and by θ_1, θ_2, and θ_3 the angles shown in the figure. We compute the vectors:

$$\mathbf{u} = \langle 2, 7\rangle$$
$$\mathbf{v} = \langle 6, 3\rangle$$
$$\mathbf{w} = \langle 6-2, 3-7\rangle = \langle 4, -4\rangle$$



Since the angles are acute the cosines are positive, so we have

$$\cos\theta_1 = \frac{|\mathbf{u}\cdot\mathbf{v}|}{\|\mathbf{u}\|\|\mathbf{v}\|},$$
$$\cos\theta_2 = \frac{|\mathbf{v}\cdot\mathbf{w}|}{\|\mathbf{v}\|\|\mathbf{w}\|},$$
$$\cos\theta_3 = 180 - (\theta_1 + \theta_2) \qquad (1)$$

We compute the lengths and the dot products in (1):

$$\mathbf{u}\cdot\mathbf{v} = \langle 2, 7\rangle\cdot\langle 6, 3\rangle = 2\cdot 6 + 7\cdot 3 = 33$$
$$\mathbf{v}\cdot\mathbf{w} = \langle 6, 3\rangle\cdot\langle 4, -4\rangle = 6\cdot 4 + 3\cdot(-4) = 12$$
$$\|\mathbf{u}\| = \sqrt{2^2+7^2} = \sqrt{53}$$
$$\|\mathbf{v}\| = \sqrt{6^2+3^2} = \sqrt{45}$$
$$\|\mathbf{w}\| = \sqrt{4^2+(-4)^2} = \sqrt{32}$$

Substituting in (1) and solving for acute angles yields

$$\cos\theta_1 = \frac{33}{\sqrt{53}\sqrt{45}} \approx 0.676 \quad\Rightarrow\quad \theta_1 \approx 47.47^\circ$$
$$\cos\theta_2 = \frac{12}{\sqrt{45}\sqrt{32}} \approx 0.316 \quad\Rightarrow\quad \theta_2 \approx 71.58^\circ$$

The sum of the angles in a triangle is 180°, hence

$$\theta_3 = 180^\circ - (47.47 + 71.58) \approx 60.95^\circ.$$

In Exercises 51–58, find the projection of **u** *along* **v**.

51. $\mathbf{u} = \langle 2, 5 \rangle, \quad \mathbf{v} = \langle 1, 1 \rangle$

SOLUTION We first compute the following dot products:

$$\mathbf{u} \cdot \mathbf{v} = \langle 2, 5 \rangle \cdot \langle 1, 1 \rangle = 7$$
$$\mathbf{v} \cdot \mathbf{v} = \|\mathbf{v}\|^2 = 1^2 + 1^2 = 2$$

The projection of **u** along **v** is the following vector:

$$\mathbf{u}_{||} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right) \mathbf{v} = \frac{7}{2}\mathbf{v} = \left\langle \frac{7}{2}, \frac{7}{2} \right\rangle$$

52. $\mathbf{u} = \langle 2, -3 \rangle, \quad \mathbf{v} = \langle 1, 2 \rangle$

SOLUTION We first compute the following dot products:

$$\mathbf{u} \cdot \mathbf{v} = \langle 2, -3 \rangle \cdot \langle 1, 2 \rangle = -4$$
$$\mathbf{v} \cdot \mathbf{v} = \|\mathbf{v}\|^2 = 1^2 + 2^2 = 5$$

The projection of **u** along **v** is the following vector:

$$\mathbf{u}_{||} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right) \mathbf{v} = \frac{-4}{5}\mathbf{v} = \left\langle \frac{-4}{5}, \frac{-8}{5} \right\rangle$$

53. $\mathbf{u} = \langle -1, 2, 0 \rangle, \quad \mathbf{v} = \langle 2, 0, 1 \rangle$

SOLUTION The projection of **u** along **v** is the following vector:

$$\mathbf{u}_{||} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right) \mathbf{v}$$

We compute the values in this expression:

$$\mathbf{u} \cdot \mathbf{v} = \langle -1, 2, 0 \rangle \cdot \langle 2, 0, 1 \rangle = -1 \cdot 2 + 2 \cdot 0 + 0 \cdot 1 = -2$$
$$\mathbf{v} \cdot \mathbf{v} = \|\mathbf{v}\|^2 = 2^2 + 0^2 + 1^2 = 5$$

Hence,

$$\mathbf{u}_{||} = -\frac{2}{5}\langle 2, 0, 1 \rangle = \left\langle -\frac{4}{5}, 0, -\frac{2}{5} \right\rangle.$$

54. $\mathbf{u} = \langle 1, 1, 1 \rangle, \quad \mathbf{v} = \langle 1, 1, 0 \rangle$

SOLUTION We first compute the following dot products:

$$\mathbf{u} \cdot \mathbf{v} = \langle 1, 1, 1 \rangle \cdot \langle 1, 1, 0 \rangle = 1 \cdot 1 + 1 \cdot 1 + 1 \cdot 0 = 2$$
$$\mathbf{v} \cdot \mathbf{v} = \|\mathbf{v}\|^2 = 1^2 + 1^2 + 0^2 = 2$$

The projection of **u** along **v** is the following vector:

$$\mathbf{u}_{||} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right) \mathbf{v} = \frac{2}{2}\mathbf{v} = \mathbf{v} = \langle 1, 1, 0 \rangle$$

55. $\mathbf{u} = 5\mathbf{i} + 7\mathbf{j} - 4\mathbf{k}, \quad \mathbf{v} = \mathbf{k}$

SOLUTION The projection of **u** along **v** is the following vector:

$$\mathbf{u}_{||} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right) \mathbf{v}$$

We compute the dot products:

$$\mathbf{u} \cdot \mathbf{v} = (5\mathbf{i} + 7\mathbf{j} - 4\mathbf{k}) \cdot \mathbf{k} = -4\mathbf{k} \cdot \mathbf{k} = -4$$
$$\mathbf{v} \cdot \mathbf{v} = \|\mathbf{v}\|^2 = \|\mathbf{k}\|^2 = 1$$

Hence,

$$\mathbf{u}_{||} = \frac{-4}{1}\mathbf{k} = -4\mathbf{k}$$

56. $\mathbf{u} = \mathbf{i} + 29\mathbf{k}, \quad \mathbf{v} = \mathbf{j}$

SOLUTION Since $\mathbf{u} \cdot \mathbf{v} = (\mathbf{i} + 29\mathbf{k}) \cdot \mathbf{j} = \mathbf{i} \cdot \mathbf{j} + 29\mathbf{k} \cdot \mathbf{j} = 0$, $\mathbf{u}$ is orthogonal to $\mathbf{v}$, the projection of $\mathbf{u}$ along $\mathbf{v}$ is the zero vector

$$\mathbf{u}_{||} = \mathbf{0}$$

57. $\mathbf{u} = \langle a, b, c \rangle, \quad \mathbf{v} = \mathbf{i}$

SOLUTION The component of $\mathbf{u}$ along $\mathbf{v}$ is a, since

$$\mathbf{u} \cdot \mathbf{e_v} = (a\mathbf{i} + b\mathbf{j} + c\mathbf{k}) \cdot \mathbf{i} = a$$

Therefore, the projection of $\mathbf{u}$ along $\mathbf{v}$ is the vector

$$\mathbf{u}_{||} = (\mathbf{u} \cdot \mathbf{e_v})\mathbf{e_v} = a\mathbf{i}$$

58. $\mathbf{u} = \langle a, a, b \rangle, \quad \mathbf{v} = \mathbf{i} - \mathbf{j}$

SOLUTION We compute the following dot product:

$$\mathbf{u} \cdot \mathbf{v} = (a\mathbf{i} + a\mathbf{j} + b\mathbf{k}) \cdot (\mathbf{i} - \mathbf{j}) = (a\mathbf{i} + a\mathbf{j} + b\mathbf{k}) \cdot (\mathbf{i} - \mathbf{j} + 0\mathbf{k}) = a \cdot 1 + a \cdot (-1) + b \cdot 0 = 0$$

The dot product is zero, hence the vectors $\mathbf{u}$ and $\mathbf{v}$ are orthogonal, and the projection of $\mathbf{u}$ along $\mathbf{v}$ is the zero vector:

$$\mathbf{u}_{||} = \mathbf{0}$$

In Exercises 59 and 60, compute the component of $\mathbf{u}$ *along* $\mathbf{v}$.

59. $\mathbf{u} = \langle 3, 2, 1 \rangle, \quad \mathbf{v} = \langle 1, 0, 1 \rangle$

SOLUTION We first compute the following dot products:

$$\mathbf{u} \cdot \mathbf{v} = \langle 3, 2, 1 \rangle \cdot \langle 1, 0, 1 \rangle = 4$$
$$\mathbf{v} \cdot \mathbf{v} = \|\mathbf{v}\|^2 = 1^2 + 1^2 = 2$$

The component of $\mathbf{u}$ along $\mathbf{v}$ is the length of the projection of $\mathbf{u}$ along $\mathbf{v}$

$$\left\| \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}} \right) \mathbf{v} \right\| = \frac{4}{2} \|\mathbf{v}\| = 2\|\mathbf{v}\| = 2\sqrt{2}$$

60. $\mathbf{u} = \langle 3, 0, 9 \rangle, \quad \mathbf{v} = \langle 1, 2, 2 \rangle$

SOLUTION We first compute the following dot products:

$$\mathbf{u} \cdot \mathbf{v} = \langle 3, 0, 9 \rangle \cdot \langle 1, 2, 2 \rangle = 21$$
$$\mathbf{v} \cdot \mathbf{v} = \|\mathbf{v}\|^2 = 1^2 + 2^2 + 2^2 = 9$$

The component of $\mathbf{u}$ along $\mathbf{v}$ is the length of the projection of $\mathbf{u}$ along $\mathbf{v}$

$$\left\| \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}} \right) \mathbf{v} \right\| = \frac{21}{9} \|\mathbf{v}\| = \frac{7}{3} \cdot 3 = 7$$

61. Find the length of $\overline{OP}$ in Figure 14.

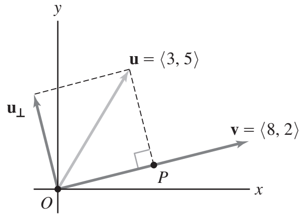


FIGURE 14

SOLUTION This is just the component of $\mathbf{u} = \langle 3, 5\rangle$ along $\mathbf{v} = \langle 8, 2\rangle$. We first compute the following dot products:

$$\mathbf{u} \cdot \mathbf{v} = \langle 3, 5\rangle \cdot \langle 8, 2\rangle = 34$$
$$\mathbf{v} \cdot \mathbf{v} = \|\mathbf{v}\|^2 = 8^2 + 2^2 = 68$$

The component of $\mathbf{u}$ along $\mathbf{v}$ is the length of the projection of $\mathbf{u}$ along $\mathbf{v}$

$$\left\| \left(\frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right) \mathbf{v} \right\| = \frac{34}{68}\|\mathbf{v}\| = \frac{34}{68}\sqrt{68}$$

62. Find $\|\mathbf{u}_\perp\|$ in Figure 14.

SOLUTION From the previous problem (see solution above) we know that the component of $\mathbf{u}$ along $\mathbf{v}$ is $1/2$, and thus the projection is $\mathbf{u}_\| = \langle 4, 1\rangle$. Using the standard formula for $\mathbf{u}_\perp$, we obtain

$$\mathbf{u}_\perp = \mathbf{u} - \mathbf{u}_\| = \langle 3, 5\rangle - \langle 4, 1\rangle = \langle -1, 4\rangle$$

In Exercises 63–68, find the decomposition $\mathbf{a} = \mathbf{a}_{||} + \mathbf{a}_\perp$ *with respect to* $\mathbf{b}$.

63. $\mathbf{a} = \langle 1, 0\rangle, \quad \mathbf{b} = \langle 1, 1\rangle$

SOLUTION

Step 1. We compute $\mathbf{a} \cdot \mathbf{b}$ and $\mathbf{b} \cdot \mathbf{b}$

$$\mathbf{a} \cdot \mathbf{b} = \langle 1, 0\rangle \cdot \langle 1, 1\rangle = 1 \cdot 1 + 0 \cdot 1 = 1$$
$$\mathbf{b} \cdot \mathbf{b} = \|\mathbf{b}\|^2 = 1^2 + 1^2 = 2$$

Step 2. We find the projection of $\mathbf{a}$ along $\mathbf{b}$:

$$\mathbf{a}_{||} = \left(\frac{\mathbf{a} \cdot \mathbf{b}}{\mathbf{b} \cdot \mathbf{b}}\right)\mathbf{b} = \frac{1}{2}\langle 1, 1\rangle = \left\langle \frac{1}{2}, \frac{1}{2}\right\rangle$$

Step 3. We find the orthogonal part as the difference:

$$\mathbf{a}_\perp = \mathbf{a} - \mathbf{a}_{||} = \langle 1, 0\rangle - \left\langle \frac{1}{2}, \frac{1}{2}\right\rangle = \left\langle \frac{1}{2}, -\frac{1}{2}\right\rangle$$

Hence,

$$\mathbf{a} = \mathbf{a}_{||} + \mathbf{a}_\perp = \left\langle \frac{1}{2}, \frac{1}{2}\right\rangle + \left\langle \frac{1}{2}, -\frac{1}{2}\right\rangle.$$

64. $\mathbf{a} = \langle 2, -3\rangle, \quad \mathbf{b} = \langle 5, 0\rangle$

SOLUTION We first compute $\mathbf{a} \cdot \mathbf{b}$ and $\mathbf{b} \cdot \mathbf{b}$ to find the projection of $\mathbf{a}$ along $\mathbf{b}$:

$$\mathbf{a} \cdot \mathbf{b} = \langle 2, -3\rangle \cdot \langle 5, 0\rangle = 10$$
$$\mathbf{b} \cdot \mathbf{b} = \|\mathbf{b}\|^2 = 5^2 + 0^2 = 25$$

Hence,

$$\mathbf{a}_{||} = \left(\frac{\mathbf{a} \cdot \mathbf{b}}{\mathbf{b} \cdot \mathbf{b}}\right)\mathbf{b} = \frac{10}{25}\langle 5, 0\rangle = \langle 2, 0\rangle$$

We now find the vector $\mathbf{a}_\perp$ orthogonal to $\mathbf{b}$ by computing the difference:

$$\mathbf{a} - \mathbf{a}_{||} = \langle 2, -3\rangle - \langle 2, 0\rangle = \langle 0, -3\rangle$$

Thus, we have

$$\mathbf{a} = \mathbf{a}_{||} + \mathbf{a}_\perp = \langle 2, 0\rangle + \langle 0, -3\rangle$$

65. $\mathbf{a} = \langle 4, -1, 0\rangle, \quad \mathbf{b} = \langle 0, 1, 1\rangle$

SOLUTION We first compute $\mathbf{a} \cdot \mathbf{b}$ and $\mathbf{b} \cdot \mathbf{b}$ to find the projection of $\mathbf{a}$ along $\mathbf{b}$:

$$\mathbf{a} \cdot \mathbf{b} = \langle 4, -1, 0\rangle \cdot \langle 0, 1, 1\rangle = 4 \cdot 0 + (-1) \cdot 1 + 0 \cdot 1 = -1$$
$$\mathbf{b} \cdot \mathbf{b} = \|\mathbf{b}\|^2 = 0^2 + 1^2 + 1^2 = 2$$

Hence,

$$\mathbf{a}_{||} = \left(\frac{\mathbf{a}\cdot\mathbf{b}}{\mathbf{b}\cdot\mathbf{b}}\right)\mathbf{b} = \frac{-1}{2}\langle 0, 1, 1\rangle = \left\langle 0, -\frac{1}{2}, -\frac{1}{2}\right\rangle$$

We now find the vector $\mathbf{a}_{\perp}$ orthogonal to $\mathbf{b}$ by computing the difference:

$$\mathbf{a} - \mathbf{a}_{||} = \langle 4, -1, 0\rangle - \left\langle 0, -\frac{1}{2}, -\frac{1}{2}\right\rangle = \left\langle 4, -\frac{1}{2}, \frac{1}{2}\right\rangle$$

Thus, we have

$$\mathbf{a} = \mathbf{a}_{||} + \mathbf{a}_{\perp} = \left\langle 0, -\frac{1}{2}, -\frac{1}{2}\right\rangle + \left\langle 4, -\frac{1}{2}, \frac{1}{2}\right\rangle$$

66. $\mathbf{a} = \langle 4, -1, 5\rangle, \quad \mathbf{b} = \langle 2, 1, 1\rangle$

SOLUTION We first compute $\mathbf{a}\cdot\mathbf{b}$ and $\mathbf{b}\cdot\mathbf{b}$ to find the projection of $\mathbf{a}$ along $\mathbf{b}$:

$$\mathbf{a}\cdot\mathbf{b} = \langle 4, -1, 5\rangle \cdot \langle 2, 1, 1\rangle = 12$$
$$\mathbf{b}\cdot\mathbf{b} = \|\mathbf{b}\|^2 = 2^2 + 1^2 + 1^2 = 6$$

Hence,

$$\mathbf{a}_{||} = \left(\frac{\mathbf{a}\cdot\mathbf{b}}{\mathbf{b}\cdot\mathbf{b}}\right)\mathbf{b} = 2\langle 2, 1, 1\rangle = \langle 4, 2, 2\rangle$$

We now find the vector $\mathbf{a}_{\perp}$ orthogonal to $\mathbf{b}$ by computing the difference:

$$\mathbf{a} - \mathbf{a}_{||} = \langle 4, -1, 5\rangle - \langle 4, 2, 2\rangle = \langle 0, -3, 3\rangle$$

Thus, we have

$$\mathbf{a} = \mathbf{a}_{||} + \mathbf{a}_{\perp} = \langle 4, 2, 2\rangle + \langle 0, -3, 3\rangle$$

67. $\mathbf{a} = \langle x, y\rangle, \quad \mathbf{b} = \langle 1, -1\rangle$

SOLUTION We first compute $\mathbf{a}\cdot\mathbf{b}$ and $\mathbf{b}\cdot\mathbf{b}$ to find the projection of $\mathbf{a}$ along $\mathbf{b}$:

$$\mathbf{a}\cdot\mathbf{b} = \langle x, y\rangle \cdot \langle 1, -1\rangle = x - y$$
$$\mathbf{b}\cdot\mathbf{b} = \|\mathbf{b}\|^2 = 1^2 + (-1)^2 = 2$$

Hence,

$$\mathbf{a}_{||} = \left(\frac{\mathbf{a}\cdot\mathbf{b}}{\mathbf{b}\cdot\mathbf{b}}\right)\mathbf{b} = \frac{x-y}{2}\langle 1, -1\rangle = \left\langle \frac{x-y}{2}, \frac{y-x}{2}\right\rangle$$

We now find the vector $\mathbf{a}_{\perp}$ orthogonal to $\mathbf{b}$ by computing the difference:

$$\mathbf{a} - \mathbf{a}_{||} = \langle x, y\rangle - \left\langle \frac{x-y}{2}, \frac{y-x}{2}\right\rangle = \left\langle \frac{x+y}{2}, \frac{x+y}{2}\right\rangle$$

Thus, we have

$$\mathbf{a} = \mathbf{a}_{||} + \mathbf{a}_{\perp} = \left\langle \frac{x-y}{2}, \frac{y-x}{2}\right\rangle + \left\langle \frac{x+y}{2}, \frac{x+y}{2}\right\rangle$$

68. $\mathbf{a} = \langle x, y, z\rangle, \quad \mathbf{b} = \langle 1, 1, 1\rangle$

SOLUTION We first compute $\mathbf{a}\cdot\mathbf{b}$ and $\mathbf{b}\cdot\mathbf{b}$ to find the projection of $\mathbf{a}$ along $\mathbf{b}$:

$$\mathbf{a}\cdot\mathbf{b} = \langle x, y, z\rangle \cdot \langle 1, 1, 1\rangle = x + y + z$$
$$\mathbf{b}\cdot\mathbf{b} = \|\mathbf{b}\|^2 = 1^2 + 1^2 + 1^2 = 3$$

Hence,

$$\mathbf{a}_{||} = \left(\frac{\mathbf{a}\cdot\mathbf{b}}{\mathbf{b}\cdot\mathbf{b}}\right)\mathbf{b} = \frac{x+y+z}{3}\langle 1, 1, 1\rangle = \left\langle \frac{x+y+z}{3}, \frac{x+y+z}{3}, \frac{x+y+z}{3}\right\rangle$$

We now find the vector $\mathbf{a}_\perp$ orthogonal to $\mathbf{b}$ by computing the difference:

$$\mathbf{a} - \mathbf{a}_{||} = \langle x, y, z\rangle - \left\langle \frac{x+y+z}{3}, \frac{x+y+z}{3}, \frac{x+y+z}{3} \right\rangle = \left\langle \frac{2x-y-z}{3}, \frac{-x+2y-z}{3}, \frac{-x-y+2z}{3} \right\rangle$$

Thus, we have

$$\mathbf{a} = \mathbf{a}_{||} + \mathbf{a}_\perp = \left\langle \frac{x+y+z}{3}, \frac{x+y+z}{3}, \frac{x+y+z}{3} \right\rangle + \left\langle \frac{2x-y-z}{3}, \frac{-x+2y-z}{3}, \frac{-x-y+2z}{3} \right\rangle$$

69. Let $\mathbf{e}_\theta = \langle \cos\theta, \sin\theta\rangle$. Show that $\mathbf{e}_\theta \cdot \mathbf{e}_\psi = \cos(\theta - \psi)$ for any two angles θ and ψ.

SOLUTION First, $\mathbf{e}_\theta$ is a unit vector since by a trigonometric identity we have

$$\|\mathbf{e}_\theta\| = \sqrt{\cos^2\theta + \sin^2\theta} = \sqrt{1} = 1$$

The cosine of the angle α between $\mathbf{e}_\theta$ and the vector $\mathbf{i}$ in the direction of the positive x-axis is

$$\cos\alpha = \frac{\mathbf{e}_\theta \cdot \mathbf{i}}{\|\mathbf{e}_\theta\| \cdot \|\mathbf{i}\|} = \mathbf{e}_\theta \cdot \mathbf{i} = ((\cos\theta)\mathbf{i} + (\sin\theta)\mathbf{j}) \cdot \mathbf{i} = \cos\theta$$

The solution of $\cos\alpha = \cos\theta$ for angles between 0 and π is $\alpha = \theta$. That is, the vector $\mathbf{e}_\theta$ makes an angle θ with the x-axis. We now use the trigonometric identity

$$\cos\theta\cos\psi + \sin\theta\sin\psi = \cos(\theta - \psi)$$

to obtain the following equality:

$$\mathbf{e}_\theta \cdot \mathbf{e}_\psi = \langle \cos\theta, \sin\theta\rangle \cdot \langle \cos\psi, \sin\psi\rangle = \cos\theta\cos\psi + \sin\theta\sin\psi = \cos(\theta - \psi)$$

70. Let $\mathbf{v}$ and $\mathbf{w}$ be vectors in the plane.

(a) Use Theorem 2 to explain why the dot product $\mathbf{v} \cdot \mathbf{w}$ does not change if both $\mathbf{v}$ and $\mathbf{w}$ are rotated by the same angle θ.

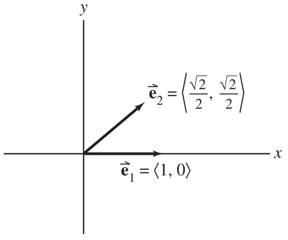
(b) Sketch the vectors $\mathbf{e}_1 = \langle 1, 0\rangle$ and $\mathbf{e}_2 = \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle$, and determine the vectors $\mathbf{e}_1', \mathbf{e}_2'$ obtained by rotating $\mathbf{e}_1, \mathbf{e}_2$ through an angle $\frac{\pi}{4}$. Verify that $\mathbf{e}_1 \cdot \mathbf{e}_2 = \mathbf{e}_1' \cdot \mathbf{e}_2'$.

SOLUTION

(a) By Theorem 2,

$$\mathbf{v} \cdot \mathbf{w} = \|\mathbf{v}\|\|\mathbf{w}\| \cos\alpha$$

where α is the angle between $\mathbf{v}$ and $\mathbf{w}$. Since rotation by an angle θ does not change the angle between the vectors, nor the norms of the vectors, the dot product $\mathbf{v} \cdot \mathbf{w}$ remains unchanged.



(b) Notice from the picture that if we rotate $\mathbf{e}_1$ by $\pi/4$, we get $\mathbf{e}_2$, and when we rotate $\mathbf{e}_2$ by the same amount we get a unit vector along the y axis. Thus, $\mathbf{e}_1' = \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle$ and $\mathbf{e}_2' = \langle 0, 1\rangle$. Note that $\mathbf{e}_1 \cdot \mathbf{e}_2 = 1 \cdot \frac{\sqrt{2}}{2} + 0 \cdot \frac{\sqrt{2}}{2} = \frac{\sqrt{2}}{2}$ and $\mathbf{e}_1' \cdot \mathbf{e}_2' = 0 \cdot \frac{\sqrt{2}}{2} + 1 \cdot \frac{\sqrt{2}}{2} = \frac{\sqrt{2}}{2}$. Thus, $\mathbf{e}_1 \cdot \mathbf{e}_2 = \mathbf{e}_1' \cdot \mathbf{e}_2'$.

In Exercises 71–74, refer to Figure 15.

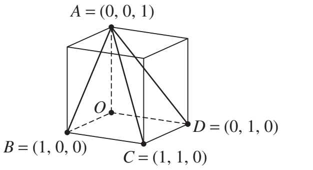


FIGURE 15 Unit cube in $\mathbf{R}^3$.

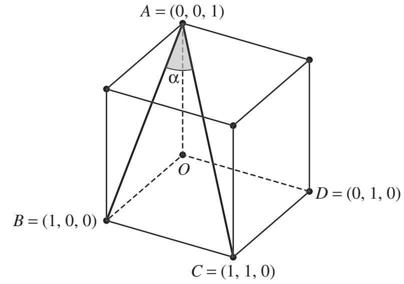
71. Find the angle between $\overline{AB}$ and $\overline{AC}$.

SOLUTION The cosine of the angle α between the vectors $\overrightarrow{AB}$ and $\overrightarrow{AC}$ is

$$\cos\alpha = \frac{\overrightarrow{AB}\cdot\overrightarrow{AC}}{\|\overrightarrow{AB}\|\|\overrightarrow{AC}\|} \tag{1}$$



We compute the vectors $\overrightarrow{AB}$ and $\overrightarrow{AC}$ and then calculate their dot product and lengths. We get

$$\begin{aligned}
\overrightarrow{AB} &= \langle 1-0, 0-0, 0-1\rangle = \langle 1, 0, -1\rangle\\
\overrightarrow{AC} &= \langle 1-0, 1-0, 0-1\rangle = \langle 1, 1, -1\rangle\\
\overrightarrow{AB}\cdot\overrightarrow{AC} &= \langle 1, 0, -1\rangle\cdot\langle 1, 1, -1\rangle = 1\cdot 1 + 0\cdot 1 + (-1)\cdot(-1) = 2\\
\|\overrightarrow{AB}\| &= \sqrt{1^2+0^2+(-1)^2} = \sqrt{2}\\
\|\overrightarrow{AC}\| &= \sqrt{1^2+1^2+(-1)^2} = \sqrt{3}
\end{aligned}$$

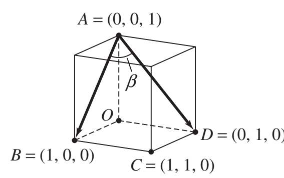
Substituting in (1) and solving for $0 \le \alpha \le 90^\circ$ gives

$$\cos\alpha = \frac{2}{\sqrt{2}\cdot\sqrt{3}} \approx 0.816 \quad\Rightarrow\quad \alpha \approx 35.31^\circ.$$

72. Find the angle between $\overline{AB}$ and $\overline{AD}$.

SOLUTION The cosine of the angle β between the vectors $\overrightarrow{AB}$ and $\overrightarrow{AD}$ is

$$\cos\beta = \frac{\overrightarrow{AB}\cdot\overrightarrow{AD}}{\|\overrightarrow{AB}\|\|\overrightarrow{AD}\|} \tag{1}$$



We compute the vectors $\overrightarrow{AB}$ and $\overrightarrow{AD}$ and then calculate their dot product and lengths. This gives

$$\begin{aligned}
\overrightarrow{AB} &= \langle 1-0, 0-0, 0-1\rangle = \langle 1, 0, -1\rangle\\
\overrightarrow{AD} &= \langle 0-0, 1-0, 0-1\rangle = \langle 0, 1, -1\rangle\\
\overrightarrow{AB}\cdot\overrightarrow{AD} &= \langle 1, 0, -1\rangle\cdot\langle 0, 1, -1\rangle = 1\cdot 0 + 0\cdot 1 + (-1)\cdot(-1) = 1\\
\|\overrightarrow{AB}\| &= \sqrt{1^2+0^2+(-1)^2} = \sqrt{2}\\
\|\overrightarrow{AD}\| &= \sqrt{0^2+1^2+(-1)^2} = \sqrt{2}
\end{aligned}$$

Substituting in (1) and solving for $0 \le \beta \le 90^\circ$ gives

$$\cos\beta = \frac{1}{\sqrt{2}\cdot\sqrt{2}} = \frac{1}{2} \quad\Rightarrow\quad \beta = 60^\circ.$$

It's interesting to note that we could have done this problem in a much simpler way. The triangle *ABD* is equilateral since each side is the diagonal of a unit square. Hence, all interior angles of the triangle are 60 degrees!

73. Calculate the projection of $\overrightarrow{AC}$ along $\overrightarrow{AD}$.

SOLUTION $\overline{DC}$ is perpendicular to the face OAD of the cube. Hence, it is orthogonal to the segment $\overline{AD}$ on this face. Therefore, the projection of the vector $\overrightarrow{AC}$ along $\overrightarrow{AD}$ is the vector $\overrightarrow{AD}$ itself.

74. Calculate the projection of $\overrightarrow{AD}$ along $\overrightarrow{AB}$.

SOLUTION The projection of $\overrightarrow{AD}$ along $\overrightarrow{AB}$ is the following vector:

$$\overrightarrow{AD}_{\|} = \left(\frac{\overrightarrow{AD}\cdot\overrightarrow{AB}}{\overrightarrow{AB}\cdot\overrightarrow{AB}}\right)\overrightarrow{AB} \tag{1}$$

We compute the vectors $\overrightarrow{AB}$ and $\overrightarrow{AD}$ and then calculate the dot product appearing in (1). We obtain

$$\begin{aligned}
\overrightarrow{AB} &= \langle 1-0, 0-0, 0-1\rangle = \langle 1, 0, -1\rangle \\
\overrightarrow{AD} &= \langle 0-0, 1-0, 0-1\rangle = \langle 0, 1, -1\rangle \\
\overrightarrow{AB}\cdot\overrightarrow{AD} &= \langle 1, 0, -1\rangle\cdot\langle 0, 1, -1\rangle = 1\cdot 0 + 0\cdot 1 + (-1)\cdot(-1) = 1 \\
\overrightarrow{AB}\cdot\overrightarrow{AB} &= \|\overrightarrow{AB}\|^2 = 1^2 + 0^2 + (-1)^2 = 2
\end{aligned}$$

Substituting in (1) gives

$$\overrightarrow{AD}_{\|} = \frac{1}{2}\langle 1, 0, -1\rangle = \left\langle \frac{1}{2}, 0, -\frac{1}{2}\right\rangle.$$

75. Let $\mathbf{v}$ and $\mathbf{w}$ be nonzero vectors and set $\mathbf{u} = \mathbf{e_v} + \mathbf{e_w}$. Use the dot product to show that the angle between $\mathbf{u}$ and $\mathbf{v}$ is equal to the angle between $\mathbf{u}$ and $\mathbf{w}$. Explain this result geometrically with a diagram.

SOLUTION We denote by α the angle between $\mathbf{u}$ and $\mathbf{v}$ and by β the angle between $\mathbf{u}$ and $\mathbf{w}$. Since $\mathbf{e_v}$ and $\mathbf{e_w}$ are vectors in the directions of $\mathbf{v}$ and $\mathbf{w}$ respectively, α is the angle between $\mathbf{u}$ and $\mathbf{e_v}$ and β is the angle between $\mathbf{u}$ and $\mathbf{e_w}$. The cosines of these angles are thus

$$\cos\alpha = \frac{\mathbf{u}\cdot\mathbf{e_v}}{\|\mathbf{u}\|\|\mathbf{e_v}\|} = \frac{\mathbf{u}\cdot\mathbf{e_v}}{\|\mathbf{u}\|}; \quad \cos\beta = \frac{\mathbf{u}\cdot\mathbf{e_w}}{\|\mathbf{u}\|\|\mathbf{e_w}\|} = \frac{\mathbf{u}\cdot\mathbf{e_w}}{\|\mathbf{u}\|}$$

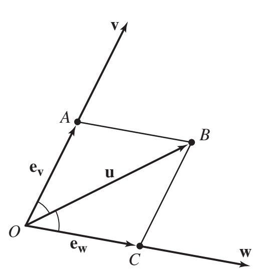
To show that $\cos\alpha = \cos\beta$ (which implies that $\alpha = \beta$) we must show that

$$\mathbf{u}\cdot\mathbf{e_v} = \mathbf{u}\cdot\mathbf{e_w}.$$

We compute the two dot products:

$$\begin{aligned}
\mathbf{u}\cdot\mathbf{e_v} &= (\mathbf{e_v}+\mathbf{e_w})\cdot\mathbf{e_v} = \mathbf{e_v}\cdot\mathbf{e_v} + \mathbf{e_w}\cdot\mathbf{e_v} = 1 + \mathbf{e_w}\cdot\mathbf{e_v} \\
\mathbf{u}\cdot\mathbf{e_w} &= (\mathbf{e_v}+\mathbf{e_w})\cdot\mathbf{e_w} = \mathbf{e_v}\cdot\mathbf{e_w} + \mathbf{e_w}\cdot\mathbf{e_w} = \mathbf{e_v}\cdot\mathbf{e_w} + 1
\end{aligned}$$

We see that $\mathbf{u}\cdot\mathbf{e_v} = \mathbf{u}\cdot\mathbf{e_w}$. We conclude that $\cos\alpha = \cos\beta$, hence $\alpha = \beta$. Geometrically, $\mathbf{u}$ is a diagonal in the rhombus $OABC$ (see figure), hence it bisects the angle $\sphericalangle AOC$ of the rhombus.



76. Let $\mathbf{v}$, $\mathbf{w}$, and $\mathbf{a}$ be nonzero vectors such that $\mathbf{v}\cdot\mathbf{a}=\mathbf{w}\cdot\mathbf{a}$. Is it true that $\mathbf{v}=\mathbf{w}$? Either prove this or give a counterexample.

SOLUTION The equality $\mathbf{v}\cdot\mathbf{a}=\mathbf{w}\cdot\mathbf{a}$ is equivalent to the following equality:

$$\begin{aligned}\mathbf{v}\cdot\mathbf{a}&=\mathbf{w}\cdot\mathbf{a}\\ \mathbf{v}\cdot\mathbf{a}-\mathbf{w}\cdot\mathbf{a}&=0\\ (\mathbf{v}-\mathbf{w})\cdot\mathbf{a}&=0\end{aligned}$$

That is, $\mathbf{v}-\mathbf{w}$ is orthogonal to $\mathbf{a}$ rather than $\mathbf{v}=\mathbf{w}$. Consider the following counterexample:

$$\mathbf{a}=\langle 1,0,1\rangle;\quad \mathbf{v}=\langle 3,1,1\rangle;\quad \mathbf{w}=\langle 4,1,0\rangle$$

Obviously, $\mathbf{v}\neq\mathbf{w}$, but $\mathbf{v}\cdot\mathbf{a}=\mathbf{w}\cdot\mathbf{a}$ since

$$\begin{aligned}\mathbf{v}\cdot\mathbf{a}&=\langle 3,1,1\rangle\cdot\langle 1,0,1\rangle=3\cdot 1+1\cdot 0+1\cdot 1=4\\ \mathbf{w}\cdot\mathbf{a}&=\langle 4,1,0\rangle\cdot\langle 1,0,1\rangle=4\cdot 1+1\cdot 0+0\cdot 1=4\end{aligned}$$

77. Calculate the force (in newtons) required to push a 40-kg wagon up a 10° incline (Figure 16).

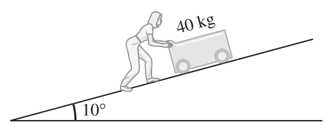


FIGURE 16

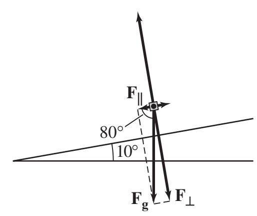
SOLUTION Gravity exerts a force $\mathbf{F}_g$ of magnitude $40g$ newtons where $g=9.8$. The magnitude of the force required to push the wagon equals the component of the force $\mathbf{F}_g$ along the ramp. Resolving $\mathbf{F}_g$ into a sum $\mathbf{F}_g=\mathbf{F}_{||}+\mathbf{F}_{\perp}$, where $\mathbf{F}_{||}$ is the force along the ramp and $\mathbf{F}_{\perp}$ is the force orthogonal to the ramp, we need to find the magnitude of $\mathbf{F}_{||}$. The angle between $\mathbf{F}_g$ and the ramp is $90^\circ-10^\circ=80^\circ$. Hence,

$$\mathbf{F}_{||}=\|\mathbf{F}_g\|\cos 80^\circ=40\cdot 9.8\cdot\cos 80^\circ\approx 68.07\text{ N}.$$



Therefore the minimum force required to push the wagon is 68.07 N. (Actually, this is the force required to keep the wagon from sliding down the hill; any slight amount greater than this force will serve to push it up the hill.)

78. A force $\mathbf{F}$ is applied to each of two ropes (of negligible weight) attached to opposite ends of a 40-kg wagon and making an angle of 35° with the horizontal (Figure 17). What is the maximum magnitude of $\mathbf{F}$ (in newtons) that can be applied without lifting the wagon off the ground?

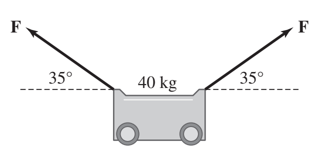


FIGURE 17

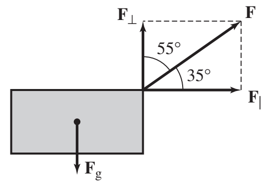
SOLUTION With two ropes at either end, both at the same angle with the horizontal and both with the same force, pulling on the 40-kg wagon, each rope will need to lift 20 kg. Let's look at the situation on the right-hand side of the wagon. We resolve the force $\mathbf{F}$ on the right-hand rope into a sum $\mathbf{F}=\mathbf{F}_{||}+\mathbf{F}_{\perp}$ where $\mathbf{F}_{||}$ is the horizontal force and $\mathbf{F}_{\perp}$ is the force orthogonal to the ground. The wagon will not be lifted off the ground if the magnitude of $\mathbf{F}_{\perp}$, that is the component of $\mathbf{F}$ along the direction orthogonal to the ground, is equal to (but not more than) the magnitude of the force due to gravity from 20 kg (remember, each rope needs to only lift half of the wagon, and remember also that the acceleration due to gravity is 9.8 meters per second squared). That is,

$$20(9.8)=\|\mathbf{F}_{\perp}\| \qquad (1)$$

The angle between $\mathbf{F}$ and a vector orthogonal to the ground is $90^\circ-35^\circ=55^\circ$, hence, $20(9.8)=196=\|\mathbf{F}\|\cos 55^\circ$



This gives us

$$196 = \|\mathbf{F}\| \cos 55^\circ \quad \Rightarrow \quad \|\mathbf{F}\| = \frac{196}{\cos 55^\circ} \approx 341 \text{ Newtons}$$

The maximum force that can be applied is of magnitude 341 newtons on each rope.

79. A light beam travels along the ray determined by a unit vector $\mathbf{L}$, strikes a flat surface at point P, and is reflected along the ray determined by a unit vector $\mathbf{R}$, where $\theta_1 = \theta_2$ (Figure 18). Show that if $\mathbf{N}$ is the unit vector orthogonal to the surface, then

$$\mathbf{R} = 2(\mathbf{L} \cdot \mathbf{N})\mathbf{N} - \mathbf{L}$$

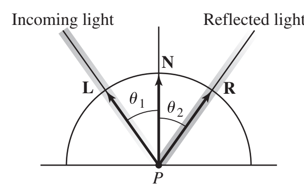


FIGURE 18

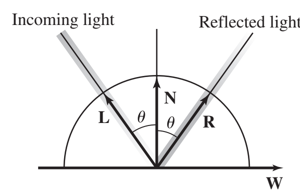
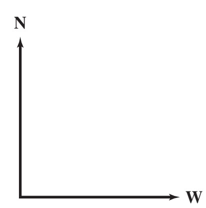
SOLUTION We denote by $\mathbf{W}$ a unit vector orthogonal to $\mathbf{N}$ in the direction shown in the figure, and let $\theta_1 = \theta_2 = \theta$.



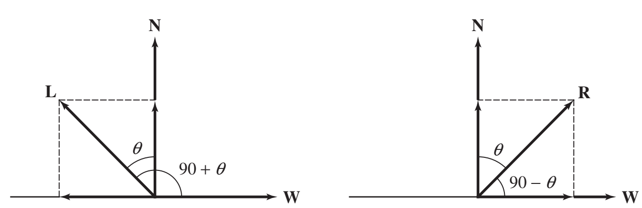
We resolve the unit vectors $\mathbf{R}$ and $\mathbf{L}$ into a sum of forces along $\mathbf{N}$ and $\mathbf{W}$. This gives

$$\begin{aligned} \mathbf{R} &= \cos(90 - \theta)\mathbf{W} + \cos\theta\mathbf{N} = \sin\theta\mathbf{W} + \cos\theta\mathbf{N} \\ \mathbf{L} &= -\cos(90 - \theta)\mathbf{W} + \cos\theta\mathbf{N} = -\sin\theta\mathbf{W} + \cos\theta\mathbf{N} \end{aligned} \tag{1}$$



Now, since

$$\mathbf{L} \cdot \mathbf{N} = \|\mathbf{L}\|\|\mathbf{N}\| \cos\theta = 1 \cdot 1 \cos\theta = \cos\theta$$



we have by (1):

$$\begin{aligned} 2(\mathbf{L} \cdot \mathbf{N})\mathbf{N} - \mathbf{L} &= (2\cos\theta)\mathbf{N} - \mathbf{L} = (2\cos\theta)\mathbf{N} - ((-\sin\theta)\mathbf{W} + (\cos\theta)\mathbf{N}) \\ &= (2\cos\theta)\mathbf{N} + (\sin\theta)\mathbf{W} - (\cos\theta)\mathbf{N} = (\sin\theta)\mathbf{W} + (\cos\theta)\mathbf{N} = \mathbf{R} \end{aligned}$$

80. Let P and Q be antipodal (opposite) points on a sphere of radius r centered at the origin and let R be a third point on the sphere (Figure 19). Prove that $\overline{PR}$ and $\overline{QR}$ are orthogonal.

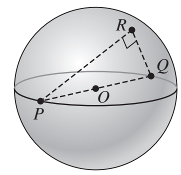


FIGURE 19

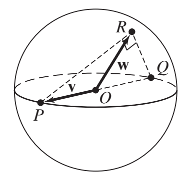
SOLUTION We denote the vectors $\overrightarrow{OP}$ and $\overrightarrow{OR}$ by

$$\mathbf{v} = \overrightarrow{OP}, \quad \mathbf{w} = \overrightarrow{OR}$$



Thus,

$$\overrightarrow{PR} = \overrightarrow{PO} + \overrightarrow{OR} = -\mathbf{v} + \mathbf{w}$$
$$\overrightarrow{RQ} = \overrightarrow{RO} + \overrightarrow{OQ} = -\mathbf{w} - \mathbf{v}$$

We now show that $\overrightarrow{PR} \cdot \overrightarrow{RQ} = 0$:

$$\begin{aligned}\overrightarrow{PR} \cdot \overrightarrow{RQ} &= (-\mathbf{v} + \mathbf{w}) \cdot (-\mathbf{w} - \mathbf{v}) = (\mathbf{v} - \mathbf{w}) \cdot (\mathbf{v} + \mathbf{w}) \\ &= \mathbf{v} \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{w} - \mathbf{w} \cdot \mathbf{v} - \mathbf{w} \cdot \mathbf{w} = \|\mathbf{v}\|^2 - \|\mathbf{w}\|^2\end{aligned}$$

The lengths $\|\mathbf{v}\|$ and $\|\mathbf{w}\|$ equal the radius r of the sphere, hence,

$$\overrightarrow{PR} \cdot \overrightarrow{RQ} = \|\mathbf{v}\|^2 - \|\mathbf{w}\|^2 = r^2 - r^2 = 0$$

The dot product of $\overrightarrow{PR}$ and $\overrightarrow{RQ}$ is zero, therefore the two vectors are orthogonal.

81. Prove that $\|\mathbf{v} + \mathbf{w}\|^2 - \|\mathbf{v} - \mathbf{w}\|^2 = 4\mathbf{v} \cdot \mathbf{w}$.

SOLUTION We compute the following values:

$$\|\mathbf{v} + \mathbf{w}\|^2 = (\mathbf{v} + \mathbf{w}) \cdot (\mathbf{v} + \mathbf{w}) = \mathbf{v} \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{w} + \mathbf{w} \cdot \mathbf{v} + \mathbf{w} \cdot \mathbf{w} = \|\mathbf{v}\|^2 + 2\mathbf{v} \cdot \mathbf{w} + \|\mathbf{w}\|^2$$
$$\|\mathbf{v} - \mathbf{w}\|^2 = (\mathbf{v} - \mathbf{w}) \cdot (\mathbf{v} - \mathbf{w}) = \mathbf{v} \cdot \mathbf{v} - \mathbf{v} \cdot \mathbf{w} - \mathbf{w} \cdot \mathbf{v} - \mathbf{w} \cdot \mathbf{w} = \|\mathbf{v}\|^2 - 2\mathbf{v} \cdot \mathbf{w} + \|\mathbf{w}\|^2$$

Hence,

$$\|\mathbf{v} + \mathbf{w}\|^2 - \|\mathbf{v} - \mathbf{w}\|^2 = (\|\mathbf{v}\|^2 + 2\mathbf{v} \cdot \mathbf{w} + \|\mathbf{w}\|^2) - (\|\mathbf{v}\|^2 - 2\mathbf{v} \cdot \mathbf{w} + \|\mathbf{w}\|^2) = 4\mathbf{v} \cdot \mathbf{w}$$

82. Use Exercise 81 to show that $\mathbf{v}$ and $\mathbf{w}$ are orthogonal if and only if $\|\mathbf{v} - \mathbf{w}\| = \|\mathbf{v} + \mathbf{w}\|$.

SOLUTION In Exercise 81 we showed that

$$\|\mathbf{v} + \mathbf{w}\|^2 - \|\mathbf{v} - \mathbf{w}\|^2 = 4\mathbf{v} \cdot \mathbf{w}$$

The vectors $\mathbf{v} \cdot \mathbf{w}$ are orthogonal if and only if $\mathbf{v} \cdot \mathbf{w} = 0$. That is, if and only if

$$\|\mathbf{v} + \mathbf{w}\|^2 - \|\mathbf{v} - \mathbf{w}\|^2 = 0$$

or

$$\|\mathbf{v} + \mathbf{w}\| = \|\mathbf{v} - \mathbf{w}\|.$$

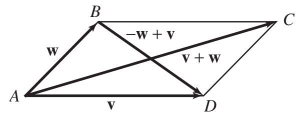
83. Show that the two diagonals of a parallelogram are perpendicular if and only if its sides have equal length. *Hint:* Use Exercise 82 to show that $\mathbf{v} - \mathbf{w}$ and $\mathbf{v} + \mathbf{w}$ are orthogonal if and only if $\|\mathbf{v}\| = \|\mathbf{w}\|$.

SOLUTION We denote the vectors $\overrightarrow{AB}$ and $\overrightarrow{AD}$ by

$$\mathbf{w} = \overrightarrow{AB}, \quad \mathbf{v} = \overrightarrow{AD}.$$

Then,

$$\overrightarrow{AC} = \mathbf{w} + \mathbf{v}, \quad \overrightarrow{BD} = -\mathbf{w} + \mathbf{v}.$$



The diagonals are perpendicular if and only if the vectors $\mathbf{v} + \mathbf{w}$ and $\mathbf{v} - \mathbf{w}$ are orthogonal. By Exercise 82 these vectors are orthogonal if and only if the norms of the sum $(\mathbf{v} + \mathbf{w}) + (\mathbf{v} - \mathbf{w}) = 2\mathbf{v}$ and the difference $(\mathbf{v} + \mathbf{w}) - (\mathbf{v} - \mathbf{w}) = 2\mathbf{w}$ are equal, that is,

$$\|2\mathbf{v}\| = \|2\mathbf{w}\|$$
$$2\|\mathbf{v}\| = 2\|\mathbf{w}\| \quad \Rightarrow \quad \|\mathbf{v}\| = \|\mathbf{w}\|$$

84. Verify the Distributive Law:

$$\mathbf{u} \cdot (\mathbf{v} + \mathbf{w}) = \mathbf{u} \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{w}$$

SOLUTION We denote the components of the vectors $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$ by

$$\mathbf{u} = \langle a_1, a_2, a_3 \rangle; \quad \mathbf{v} = \langle b_1, b_2, b_3 \rangle; \quad \mathbf{w} = \langle c_1, c_2, c_3 \rangle$$

We compute the left-hand side:

$$\begin{aligned}\mathbf{u} \cdot (\mathbf{v} + \mathbf{w}) &= \langle a_1, a_2, a_3 \rangle \left(\langle b_1, b_2, b_3 \rangle + \langle c_1, c_2, c_3 \rangle \right) \\ &= \langle a_1, a_2, a_3 \rangle \cdot \langle b_1 + c_1, b_2 + c_2, b_3 + c_3 \rangle \\ &= \langle a_1(b_1 + c_1), a_2(b_2 + c_2), a_3(b_3 + c_3) \rangle\end{aligned}$$

Using the distributive law for scalars and the definitions of vector sum and the dot product we get

$$\begin{aligned}\mathbf{u} \cdot (\mathbf{v} + \mathbf{w}) &= \langle a_1b_1 + a_1c_1, a_2b_2 + a_2c_2, a_3b_3 + a_3c_3 \rangle \\ &= \langle a_1b_1, a_2b_2, a_3b_3 \rangle + \langle a_1c_1, a_2c_2, a_3c_3 \rangle \\ &= \langle a_1, a_2, a_3 \rangle \cdot \langle b_1, b_2, b_3 \rangle + \langle a_1, a_2, a_3 \rangle \cdot \langle c_1, c_2, c_3 \rangle \\ &= \mathbf{u} \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{w}\end{aligned}$$

85. Verify that $(\lambda\mathbf{v}) \cdot \mathbf{w} = \lambda(\mathbf{v} \cdot \mathbf{w})$ for any scalar λ.

SOLUTION We denote the components of the vectors $\mathbf{v}$ and $\mathbf{w}$ by

$$\mathbf{v} = \langle a_1, a_2, a_3 \rangle \quad \mathbf{w} = \langle b_1, b_2, b_3 \rangle$$

Thus,

$$\begin{aligned}(\lambda\mathbf{v}) \cdot \mathbf{w} &= (\lambda\langle a_1, a_2, a_3 \rangle) \cdot \langle b_1, b_2, b_3 \rangle = \langle \lambda a_1, \lambda a_2, \lambda a_3 \rangle \cdot \langle b_1, b_2, b_3 \rangle \\ &= \lambda a_1b_1 + \lambda a_2b_2 + \lambda a_3b_3\end{aligned}$$

Recalling that λ, a_i, and b_i are scalars and using the definitions of scalar multiples of vectors and the dot product, we get

$$(\lambda\mathbf{v}) \cdot \mathbf{w} = \lambda(a_1b_1 + a_2b_2 + a_3b_3) = \lambda\left(\langle a_1, a_2, a_3 \rangle \cdot \langle b_1, b_2, b_3 \rangle\right) = \lambda(\mathbf{v} \cdot \mathbf{w})$$

Further Insights and Challenges

86. Prove the Law of Cosines, $c^2 = a^2 + b^2 - 2ab\cos\theta$, by referring to Figure 20. *Hint:* Consider the right triangle $\triangle PQR$.

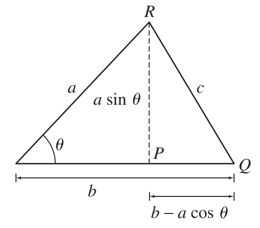


FIGURE 20

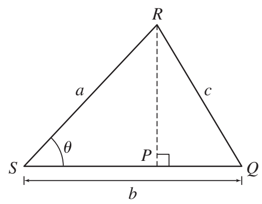
SOLUTION We denote the vertices of the triangle by S, Q, and R. Since $\overrightarrow{RQ} = \overrightarrow{RS} + \overrightarrow{SQ}$, we have

$$\begin{aligned} c^2 &= \|\overrightarrow{RQ}\|^2 = \overrightarrow{RQ}\cdot\overrightarrow{RQ} = \left(\overrightarrow{RS}+\overrightarrow{SQ}\right)\cdot\left(\overrightarrow{RS}+\overrightarrow{SQ}\right) \\ &= \overrightarrow{RS}\cdot\overrightarrow{RS} + \overrightarrow{RS}\cdot\overrightarrow{SQ} + \overrightarrow{SQ}\cdot\overrightarrow{RS} + \overrightarrow{SQ}\cdot\overrightarrow{SQ} \\ &= \|\overrightarrow{RS}\|^2 + 2\overrightarrow{RS}\cdot\overrightarrow{SQ} + \|\overrightarrow{SQ}\|^2 \\ c^2 &= a^2 + 2\overrightarrow{RS}\cdot\overrightarrow{SQ} + b^2 \end{aligned} \tag{1}$$



We find the dot product $\overrightarrow{RS}\cdot\overrightarrow{SQ}$. The angle between the vectors $\overrightarrow{RS}$ and $\overrightarrow{SQ}$ is θ, hence,

$$\overrightarrow{SR}\cdot\overrightarrow{SQ} = \|\overrightarrow{SR}\|\cdot\|\overrightarrow{SQ}\|\cos\theta = ab\cos\theta.$$

Therefore,

$$\overrightarrow{RS}\cdot\overrightarrow{SQ} = -\overrightarrow{SR}\cdot\overrightarrow{SQ} = -ab\cos\theta \tag{2}$$

Substituting (2) in (1) yields

$$c^2 = a^2 - 2ab\cos\theta + b^2 = a^2 + b^2 - 2ab\cos\theta.$$

(Note that we did not need to use the point P.)

87. In this exercise, we prove the Cauchy–Schwarz inequality: If $\mathbf{v}$ and $\mathbf{w}$ are any two vectors, then

$$|\mathbf{v}\cdot\mathbf{w}| \le \|\mathbf{v}\|\,\|\mathbf{w}\| \tag{6}$$

(a) Let $f(x) = \|x\mathbf{v} + \mathbf{w}\|^2$ for x a scalar. Show that $f(x) = ax^2 + bx + c$, where $a = \|\mathbf{v}\|^2$, $b = 2\mathbf{v}\cdot\mathbf{w}$, and $c = \|\mathbf{w}\|^2$.

(b) Conclude that $b^2 - 4ac \le 0$. *Hint:* Observe that $f(x) \ge 0$ for all x.

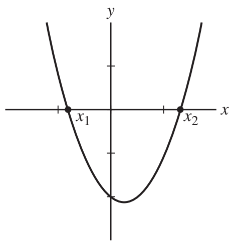
SOLUTION

(a) We express the norm as a dot product and compute it:

$$\begin{aligned} f(x) &= \|x\mathbf{v}+\mathbf{w}\|^2 = (x\mathbf{v}+\mathbf{w})\cdot(x\mathbf{v}+\mathbf{w}) \\ &= x^2\mathbf{v}\cdot\mathbf{v} + x\mathbf{v}\cdot\mathbf{w} + x\mathbf{w}\cdot\mathbf{v} + \mathbf{w}\cdot\mathbf{w} = \|\mathbf{v}\|^2x^2 + 2(\mathbf{v}\cdot\mathbf{w})x + \|\mathbf{w}\|^2 \end{aligned}$$

Hence, $f(x) = ax^2 + bx + c$, where $a = \|\mathbf{v}\|^2$, $b = 2\mathbf{v}\cdot\mathbf{w}$, and $c = \|\mathbf{w}\|^2$.

(b) If f has distinct real roots x_1 and x_2, then $f(x)$ is negative for x between x_1 and x_2, but this is impossible since f is the square of a length.



$f(x) = ax^2 + bx + c,\ a > 0$

Using properties of quadratic functions, it follows that f has a nonpositive discriminant. That is, $b^2 - 4ac \le 0$. Substituting the values for a, b, and c, we get

$$4(\mathbf{v}\cdot\mathbf{w})^2 - 4\|\mathbf{v}\|^2\|\mathbf{w}\|^2 \le 0$$
$$(\mathbf{v}\cdot\mathbf{w})^2 \le \|\mathbf{v}\|^2\|\mathbf{w}\|^2$$

Taking the square root of both sides we obtain

$$|\mathbf{v}\cdot\mathbf{w}| \le \|\mathbf{v}\|\|\mathbf{w}\|$$

88. Use (6) to prove the Triangle Inequality

$$\|\mathbf{v}+\mathbf{w}\| \le \|\mathbf{v}\| + \|\mathbf{w}\|$$

Hint: First use the Triangle Inequality for numbers to prove

$$|(\mathbf{v}+\mathbf{w})\cdot(\mathbf{v}+\mathbf{w})| \le |(\mathbf{v}+\mathbf{w})\cdot\mathbf{v}| + |(\mathbf{v}+\mathbf{w})\cdot\mathbf{w}|$$

SOLUTION Using the relation between the length and dot product we have

$$\begin{aligned}\|\mathbf{v}+\mathbf{w}\|^2 &= (\mathbf{v}+\mathbf{w})\cdot(\mathbf{v}+\mathbf{w}) = \mathbf{v}\cdot\mathbf{v} + \mathbf{v}\cdot\mathbf{w} + \mathbf{w}\cdot\mathbf{v} + \mathbf{w}\cdot\mathbf{w}\\ &= \|\mathbf{v}\|^2 + 2\mathbf{v}\cdot\mathbf{w} + \|\mathbf{w}\|^2 \qquad (1)\end{aligned}$$

Obviously, $\mathbf{v}\cdot\mathbf{w} \le |\mathbf{v}\cdot\mathbf{w}|$. Also, by the Cauchy–Schwarz inequality $|\mathbf{v}\cdot\mathbf{w}| \le \|\mathbf{v}\|\|\mathbf{w}\|$. Therefore, $\mathbf{v}\cdot\mathbf{w} \le \|\mathbf{v}\|\|\mathbf{w}\|$, and combining this with (1) we get

$$\|\mathbf{v}+\mathbf{w}\|^2 = \|\mathbf{v}\|^2 + 2\mathbf{v}\cdot\mathbf{w} + \|\mathbf{w}\|^2 \le \|\mathbf{v}\|^2 + 2\|\mathbf{v}\|\|\mathbf{w}\| + \|\mathbf{w}\|^2 = (\|\mathbf{v}\| + \|\mathbf{w}\|)^2$$

That is,

$$\|\mathbf{v}+\mathbf{w}\|^2 \le (\|\mathbf{v}\| + \|\mathbf{w}\|)^2$$

Taking the square roots of both sides and recalling that the length is nonnegative, we get

$$\|\mathbf{v}+\mathbf{w}\| \le \|\mathbf{v}\| + \|\mathbf{w}\|$$

89. This exercise gives another proof of the relation between the dot product and the angle θ between two vectors $\mathbf{v} = \langle a_1, b_1\rangle$ and $\mathbf{w} = \langle a_2, b_2\rangle$ in the plane. Observe that $\mathbf{v} = \|\mathbf{v}\|\langle\cos\theta_1, \sin\theta_1\rangle$ and $\mathbf{w} = \|\mathbf{w}\|\langle\cos\theta_2, \sin\theta_2\rangle$, with θ_1 and θ_2 as in Figure 21. Then use the addition formula for the cosine to show that

$$\mathbf{v}\cdot\mathbf{w} = \|\mathbf{v}\|\,\|\mathbf{w}\|\cos\theta$$

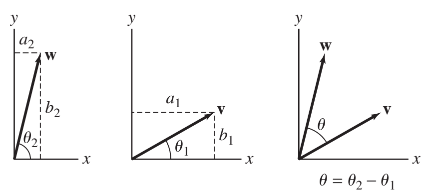


FIGURE 21

SOLUTION Using the trigonometric function for angles in right triangles, we have

$$a_2 = \|\mathbf{v}\|\sin\theta_1, \qquad a_1 = \|\mathbf{v}\|\cos\theta_1$$
$$b_2 = \|\mathbf{w}\|\sin\theta_2, \qquad b_1 = \|\mathbf{w}\|\cos\theta_2$$

Hence, using the given identity we obtain

$$\mathbf{v}\cdot\mathbf{w} = \langle a_1, a_2\rangle \cdot \langle b_1, b_2\rangle = a_1b_1 + a_2b_2 = \|\mathbf{v}\|\cos\theta_1\|\mathbf{w}\|\cos\theta_2 + \|\mathbf{v}\|\sin\theta_1\|\mathbf{w}\|\sin\theta_2$$
$$= \|\mathbf{v}\|\|\mathbf{w}\|(\cos\theta_1\cos\theta_2 + \sin\theta_1\sin\theta_2) = \|\mathbf{v}\|\|\mathbf{w}\|\cos(\theta_1 - \theta_2)$$

That is,

$$\mathbf{v}\cdot\mathbf{w} = \|\mathbf{v}\|\|\mathbf{w}\|\cos(\theta)$$

90. Let $\mathbf{v} = \langle x, y\rangle$ and

$$\mathbf{v}_\theta = \langle x\cos\theta + y\sin\theta, -x\sin\theta + y\cos\theta\rangle$$

Prove that the angle between $\mathbf{v}$ and $\mathbf{v}_\theta$ is θ.

SOLUTION The dot product of the vectors $\mathbf{v}$ and $\mathbf{v}_\theta$ is

$$\begin{aligned}\mathbf{v}\cdot\mathbf{v}_\theta &= \langle x, y\rangle \cdot \langle x\cos\theta + y\sin\theta, -x\sin\theta + y\cos\theta\rangle\\ &= x(x\cos\theta + y\sin\theta) + y(-x\sin\theta + y\cos\theta)\\ &= x^2\cos\theta + xy\sin\theta - xy\sin\theta + y^2\cos\theta\\ &= (x^2 + y^2)\cos\theta\end{aligned}$$

That is,

$$\mathbf{v}\cdot\mathbf{v}_\theta = (x^2 + y^2)\cos\theta \tag{1}$$

On the other hand, if α denotes the angle between $\mathbf{v}$ and $\mathbf{v}_\theta$, we have

$$\mathbf{v}\cdot\mathbf{v}_\theta = \|\mathbf{v}\|\|\mathbf{v}_\theta\|\cos\alpha \tag{2}$$

We compute the lengths. Using the identities $\cos^2\theta + \sin^2\theta = 1$ and $2\sin\theta\cos\theta = \sin 2\theta$, we obtain

$$\begin{aligned}\|\mathbf{v}\| &= \sqrt{\langle x, y\rangle} = \sqrt{x^2 + y^2}\\ \|\mathbf{v}_\theta\| &= \sqrt{(x\cos\theta + y\sin\theta)^2 + (-x\sin\theta + y\cos\theta)^2}\\ &= \sqrt{x^2\cos^2\theta + xy\sin 2\theta + y^2\sin^2\theta + x^2\sin^2\theta - xy\sin 2\theta + y^2\cos^2\theta}\\ &= \sqrt{x^2(\cos^2\theta + \sin^2\theta) + y^2(\sin^2\theta + \cos^2\theta)} = \sqrt{x^2\cdot 1 + y^2\cdot 1} = \sqrt{x^2 + y^2}\end{aligned}$$

Substituting the lengths in (2) yields

$$\mathbf{v}\cdot\mathbf{v}_\theta = \sqrt{x^2 + y^2}\cdot\sqrt{x^2 + y^2}\cos\alpha = (x^2 + y^2)\cos\alpha \tag{3}$$

We now equate (1) and (3) to obtain

$$\begin{aligned}(x^2 + y^2)\cos\theta &= (x^2 + y^2)\cos\alpha\\ \cos\theta &= \cos\alpha\end{aligned}$$

The solution for angles between 0° and 180° is $\alpha = 0$. That is, the angle between $\mathbf{v}$ and $\mathbf{v}_\theta$ is θ.

91. Let $\mathbf{v}$ be a nonzero vector. The angles α, β, γ between $\mathbf{v}$ and the unit vectors $\mathbf{i}, \mathbf{j}, \mathbf{k}$ are called the direction angles of $\mathbf{v}$ (Figure 22). The cosines of these angles are called the **direction cosines** of $\mathbf{v}$. Prove that

$$\cos^2\alpha + \cos^2\beta + \cos^2\gamma = 1$$

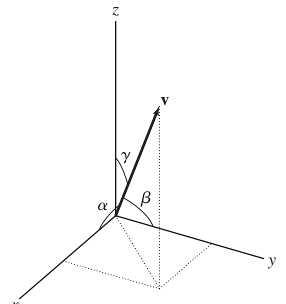

FIGURE 22 Direction angles of $\mathbf{v}$.

SOLUTION We use the relation between the dot product and the angle between two vectors to write

$$\cos\alpha = \frac{\mathbf{v}\cdot\mathbf{i}}{\|\mathbf{v}\|\|\mathbf{i}\|} = \frac{\mathbf{v}\cdot\mathbf{i}}{\|\mathbf{v}\|}$$
$$\cos\beta = \frac{\mathbf{v}\cdot\mathbf{j}}{\|\mathbf{v}\|\|\mathbf{j}\|} = \frac{\mathbf{v}\cdot\mathbf{j}}{\|\mathbf{v}\|} \tag{1}$$
$$\cos\gamma = \frac{\mathbf{v}\cdot\mathbf{k}}{\|\mathbf{v}\|\|\mathbf{k}\|} = \frac{\mathbf{v}\cdot\mathbf{k}}{\|\mathbf{v}\|}$$

We compute the values involved in (1). Letting $\mathbf{v} = \langle v_1, v_2, v_3\rangle$ we get

$$\mathbf{v}\cdot\mathbf{i} = \langle v_1, v_2, v_3\rangle \cdot \langle 1, 0, 0\rangle = v_1$$
$$\mathbf{v}\cdot\mathbf{j} = \langle v_1, v_2, v_3\rangle \cdot \langle 0, 1, 0\rangle = v_2$$
$$\mathbf{v}\cdot\mathbf{k} = \langle v_1, v_2, v_3\rangle \cdot \langle 0, 0, 1\rangle = v_3$$
$$\|\mathbf{v}\| = \sqrt{v_1^2 + v_2^2 + v_3^2} \tag{2}$$

We now substitute (2) into (1) to obtain

$$\cos\alpha = \frac{v_1}{\|\mathbf{v}\|}, \quad \cos\beta = \frac{v_2}{\|\mathbf{v}\|}, \quad \cos\gamma = \frac{v_3}{\|\mathbf{v}\|}$$

Finally, we compute the sum of squares of the direction cosines:

$$\cos^2\alpha + \cos^2\beta + \cos^2\gamma = \left(\frac{v_1}{\|\mathbf{v}\|}\right)^2 + \left(\frac{v_2}{\|\mathbf{v}\|}\right)^2 + \left(\frac{v_3}{\|\mathbf{v}\|}\right)^2 = \frac{1}{\|\mathbf{v}\|^2}(v_1^2 + v_2^2 + v_3^2) = \frac{1}{\|\mathbf{v}\|^2}\cdot\|\mathbf{v}\|^2 = 1$$

92. Find the direction cosines of $\mathbf{v} = \langle 3, 6, -2\rangle$.

SOLUTION Let α, β, γ denote the angles between $\mathbf{v}$ and the unit vectors $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ respectively. We need to compute $\cos\alpha$, $\cos\beta$, and $\cos\gamma$. Using the formula for the angle between two vectors and the lengths $\|\mathbf{i}\| = \|\mathbf{j}\| = \|\mathbf{k}\| = 1$, $\|\mathbf{v}\| = \sqrt{3^2 + 6^2 + (-2)^2} = 7$ we get

$$\cos\alpha = \frac{\mathbf{v}\cdot\mathbf{i}}{\|\mathbf{v}\|\|\mathbf{i}\|} = \frac{(3\mathbf{i} + 6\mathbf{j} - 2\mathbf{k})\cdot\mathbf{i}}{7} = \frac{3}{7}$$
$$\cos\beta = \frac{\mathbf{v}\cdot\mathbf{j}}{\|\mathbf{v}\|\|\mathbf{j}\|} = \frac{(3\mathbf{i} + 6\mathbf{j} - 2\mathbf{k})\cdot\mathbf{j}}{7} = \frac{6}{7}$$
$$\cos\gamma = \frac{\mathbf{v}\cdot\mathbf{k}}{\|\mathbf{v}\|\|\mathbf{k}\|} = \frac{(3\mathbf{i} + 6\mathbf{j} - 2\mathbf{k})\cdot\mathbf{k}}{7} = -\frac{2}{7}$$

93. The set of all points $X = (x, y, z)$ equidistant from two points P, Q in $\mathbf{R}^3$ is a plane (Figure 23). Show that X lies on this plane if

$$\overrightarrow{PQ}\cdot\overrightarrow{OX} = \frac{1}{2}\left(\|\overrightarrow{OQ}\|^2 - \|\overrightarrow{OP}\|^2\right) \tag{7}$$

Hint: If R is the midpoint of $\overline{PQ}$, then X is equidistant from P and Q if and only if $\overrightarrow{XR}$ is orthogonal to $\overrightarrow{PQ}$.

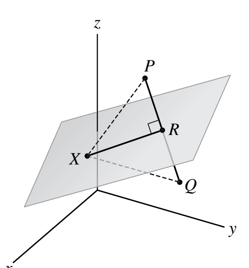

FIGURE 23

SOLUTION Let R be the midpoint of the segment $\overline{PQ}$. The points $X = (x, y, z)$ that are equidistant from P and Q are the points for which the vector $\overrightarrow{XR}$ is orthogonal to $\overrightarrow{PQ}$. That is,

$$\overrightarrow{XR}\cdot\overrightarrow{PQ} = 0 \tag{1}$$

Since $\overrightarrow{XR} = \overrightarrow{XO} + \overrightarrow{OR}$ we have by (1):

$$O = \left(\overrightarrow{XO} + \overrightarrow{OR}\right) \cdot \overrightarrow{PQ} = \overrightarrow{XO} \cdot \overrightarrow{PQ} + \overrightarrow{OR} \cdot \overrightarrow{PQ} = -\overrightarrow{OX} \cdot \overrightarrow{PQ} + \overrightarrow{OR} \cdot \overrightarrow{PQ}$$

Transferring sides we get

$$\overrightarrow{OX} \cdot \overrightarrow{PQ} = \overrightarrow{OR} \cdot \overrightarrow{PQ} \tag{2}$$

We now write $\overrightarrow{PQ} = \overrightarrow{PO} + \overrightarrow{OQ}$ on the right-hand-side of (2), and $\overrightarrow{OR} = \dfrac{\overrightarrow{OP} + \overrightarrow{OQ}}{2}$. We get

$$\begin{aligned}\overrightarrow{OX} \cdot \overrightarrow{PQ} &= \frac{1}{2}\left(\overrightarrow{OP} + \overrightarrow{OQ}\right) \cdot \left(\overrightarrow{PO} + \overrightarrow{OQ}\right) = \frac{1}{2}\left(\overrightarrow{OP} + \overrightarrow{OQ}\right) \cdot \left(\overrightarrow{OQ} - \overrightarrow{OP}\right) \\ &= \frac{1}{2}\left(\overrightarrow{OP} \cdot \overrightarrow{OQ} - \overrightarrow{OP} \cdot \overrightarrow{OP} + \overrightarrow{OQ} \cdot \overrightarrow{OQ} - \overrightarrow{OQ} \cdot \overrightarrow{OP}\right) = \frac{1}{2}\left(\|\overrightarrow{OQ}\|^2 - \|\overrightarrow{OP}\|^2\right)\end{aligned}$$

Thus, we showed that the vector equation of the plane is

$$\overrightarrow{OX} \cdot \overrightarrow{PQ} = \frac{1}{2}\left(\|\overrightarrow{OQ}\|^2 - \|\overrightarrow{OP}\|^2\right).$$

94. Sketch the plane consisting of all points $X = (x, y, z)$ equidistant from the points $P = (0, 1, 0)$ and $Q = (0, 0, 1)$. Use Eq. (7) to show that X lies on this plane if and only if $y = z$.

SOLUTION As seen in the solution to Problem 93, the point $X = (x, y, z)$ lies on the plane iff Eq. (7) holds. Using this equation with $X = (x, y, z)$, $P = (0, 1, 0)$, and $Q = (0, 0, 1)$ gives

$$\langle x, y, z\rangle \cdot \langle 0, -1, 1\rangle = \frac{1}{2}(1^2 - 1^2) = 0$$

This gives us $0x - 1y + 1z = 0$, which gives us $y = z$, as desired.

95. Use Eq. (7) to find the equation of the plane consisting of all points $X = (x, y, z)$ equidistant from $P = (2, 1, 1)$ and $Q = (1, 0, 2)$.

SOLUTION Using Eq. (7) with $X = (x, y, z)$, $P = (2, 1, 1)$, and $Q = (1, 0, 2)$ gives

$$\langle x, y, z\rangle \cdot \langle -1, -1, 1\rangle = \frac{1}{2}\left((\sqrt{5})^2 - (\sqrt{6})^2\right) = -\frac{1}{2}$$

This gives us $-1x - 1y + 1z = -\frac{1}{2}$, which leads to $2x + 2y - 2z = 1$.

12.4 The Cross Product (LT Section 13.4)

Preliminary Questions

1. What is the (1, 3) minor of the matrix $\begin{vmatrix} 3 & 4 & 2 \\ -5 & -1 & 1 \\ 4 & 0 & 3 \end{vmatrix}$?

SOLUTION The (1, 3) minor is obtained by crossing out the first row and third column of the matrix. That is,

$$\begin{vmatrix} 3 & 4 & 2 \\ -5 & -1 & 1 \\ 4 & 0 & 3 \end{vmatrix} \quad \Rightarrow \quad \begin{vmatrix} -5 & -1 \\ 4 & 0 \end{vmatrix}$$

2. The angle between two unit vectors $\mathbf{e}$ and $\mathbf{f}$ is $\frac{\pi}{6}$. What is the length of $\mathbf{e} \times \mathbf{f}$?

SOLUTION We use the Formula for the Length of the Cross Product:

$$\|\mathbf{e} \times \mathbf{f}\| = \|\mathbf{e}\|\|\mathbf{f}\| \sin\theta$$

Since $\mathbf{e}$ and $\mathbf{f}$ are unit vectors, $\|\mathbf{e}\| = \|\mathbf{f}\| = 1$. Also $\theta = \frac{\pi}{6}$, therefore,

$$\|\mathbf{e} \times \mathbf{f}\| = 1 \cdot 1 \cdot \sin\frac{\pi}{6} = \frac{1}{2}$$

The length of $\mathbf{e} \times \mathbf{f}$ is $\frac{1}{2}$.

3. What is $\mathbf{u} \times \mathbf{w}$, assuming that $\mathbf{w} \times \mathbf{u} = \langle 2, 2, 1 \rangle$?

SOLUTION By anti-commutativity of the cross product, we have

$$\mathbf{u} \times \mathbf{w} = -\mathbf{w} \times \mathbf{u} = -\langle 2, 2, 1 \rangle = \langle -2, -2, -1 \rangle$$

4. Find the cross product without using the formula:

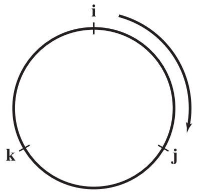
(a) $\langle 4, 8, 2 \rangle \times \langle 4, 8, 2 \rangle$ **(b)** $\langle 4, 8, 2 \rangle \times \langle 2, 4, 1 \rangle$

SOLUTION By properties of the cross product, the cross product of parallel vectors is the zero vector. In particular, the cross product of a vector with itself is the zero vector. Since $\langle 4, 8, 2 \rangle = 2\langle 2, 4, 1 \rangle$, the vectors $\langle 4, 8, 2 \rangle$ and $\langle 2, 4, 1 \rangle$ are parallel. We conclude that

$$\langle 4, 8, 2 \rangle \times \langle 4, 8, 2 \rangle = \mathbf{0} \quad \text{and} \quad \langle 4, 8, 2 \rangle \times \langle 2, 4, 1 \rangle = \mathbf{0}.$$

5. What are $\mathbf{i} \times \mathbf{j}$ and $\mathbf{i} \times \mathbf{k}$?

SOLUTION The cross product $\mathbf{i} \times \mathbf{j}$ and $\mathbf{i} \times \mathbf{k}$ are determined by the right-hand rule. We can also use the following figure to determine these cross-products:



We get

$$\mathbf{i} \times \mathbf{j} = \mathbf{k} \text{ and } \mathbf{i} \times \mathbf{k} = -\mathbf{j}$$

6. When is the cross product $\mathbf{v} \times \mathbf{w}$ equal to zero?

SOLUTION The cross product $\mathbf{v} \times \mathbf{w}$ is equal to zero if one of the vectors $\mathbf{v}$ or $\mathbf{w}$ (or both) is the zero vector, or if $\mathbf{v}$ and $\mathbf{w}$ are parallel vectors.

Exercises

In Exercises 1–4, calculate the 2×2 determinant.

1. $\begin{vmatrix} 1 & 2 \\ 4 & 3 \end{vmatrix}$

SOLUTION Using the definition of 2×2 determinant we get

$$\begin{vmatrix} 1 & 2 \\ 4 & 3 \end{vmatrix} = 1 \cdot 3 - 2 \cdot 4 = -5$$

2. $\begin{vmatrix} \frac{2}{3} & \frac{1}{6} \\ -5 & 2 \end{vmatrix}$

SOLUTION Using the definition we get

$$\begin{vmatrix} \frac{2}{3} & \frac{1}{6} \\ -5 & 2 \end{vmatrix} = \frac{2}{3} \cdot 2 - \frac{1}{6} \cdot (-5) = \frac{4}{3} + \frac{5}{6} = \frac{13}{6}$$

3. $\begin{vmatrix} -6 & 9 \\ 1 & 1 \end{vmatrix}$

SOLUTION We evaluate the determinant to obtain

$$\begin{vmatrix} -6 & 9 \\ 1 & 1 \end{vmatrix} = -6 \cdot 1 - 9 \cdot 1 = -15$$

4. $\begin{vmatrix} 9 & 25 \\ 5 & 14 \end{vmatrix}$

SOLUTION The value of the 2×2 determinant is

$$\begin{vmatrix} 9 & 25 \\ 5 & 14 \end{vmatrix} = 9 \cdot 14 - 5 \cdot 25 = 1$$

In Exercises 5–8, calculate the 3×3 *determinant.*

5. $\begin{vmatrix} 1 & 2 & 1 \\ 4 & -3 & 0 \\ 1 & 0 & 1 \end{vmatrix}$

SOLUTION Using the definition of 3×3 determinant we obtain

$$\begin{aligned} \begin{vmatrix} 1 & 2 & 1 \\ 4 & -3 & 0 \\ 1 & 0 & 1 \end{vmatrix} &= 1\begin{vmatrix} -3 & 0 \\ 0 & 1 \end{vmatrix} - 2\begin{vmatrix} 4 & 0 \\ 1 & 1 \end{vmatrix} + 1\begin{vmatrix} 4 & -3 \\ 1 & 0 \end{vmatrix} \\ &= 1 \cdot (-3 \cdot 1 - 0 \cdot 0) - 2 \cdot (4 \cdot 1 - 0 \cdot 1) + 1 \cdot (4 \cdot 0 - (-3) \cdot 1) \\ &= -3 - 8 + 3 = -8 \end{aligned}$$

6. $\begin{vmatrix} 1 & 0 & 1 \\ -2 & 0 & 3 \\ 1 & 3 & -1 \end{vmatrix}$

SOLUTION We evaluate the 3×3 determinant to obtain

$$\begin{aligned} \begin{vmatrix} 1 & 0 & 1 \\ -2 & 0 & 3 \\ 1 & 3 & -1 \end{vmatrix} &= 1\begin{vmatrix} 0 & 3 \\ 3 & -1 \end{vmatrix} - 0\begin{vmatrix} -2 & 3 \\ 1 & -1 \end{vmatrix} + 1\begin{vmatrix} -2 & 0 \\ 1 & 3 \end{vmatrix} \\ &= 1 \cdot (0 \cdot (-1) - 3 \cdot 3) - 0 + 1 \cdot (-2 \cdot 3 - 0 \cdot 1) \\ &= -9 - 6 = -15 \end{aligned}$$

7. $\begin{vmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \\ -3 & -4 & 2 \end{vmatrix}$

SOLUTION We have

$$\begin{aligned} \begin{vmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \\ -3 & -4 & 2 \end{vmatrix} &= 1\begin{vmatrix} 4 & 6 \\ -4 & 2 \end{vmatrix} - 2\begin{vmatrix} 2 & 6 \\ -3 & 2 \end{vmatrix} + 3\begin{vmatrix} 2 & 4 \\ -3 & -4 \end{vmatrix} \\ &= 1(4 \cdot 2 - 6 \cdot (-4)) - 2(2 \cdot 2 - 6 \cdot (-3)) + 3(2 \cdot (-4) - 4 \cdot (-3)) \\ &= 32 - 44 + 12 = 0 \end{aligned}$$

8. $\begin{vmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{vmatrix}$

SOLUTION We have

$$\begin{aligned} \begin{vmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{vmatrix} &= 1\begin{vmatrix} 0 & -1 \\ 1 & 0 \end{vmatrix} - 0\begin{vmatrix} 0 & -1 \\ 0 & 0 \end{vmatrix} + 0\begin{vmatrix} 0 & 0 \\ 0 & 1 \end{vmatrix} \\ &= 1(0 \cdot 0 - 1 \cdot (-1)) \\ &= 1 \end{aligned}$$

In Exercises 9–12, calculate $\mathbf{v} \times \mathbf{w}$.

9. $\mathbf{v} = \langle 1, 2, 1 \rangle, \quad \mathbf{w} = \langle 3, 1, 1 \rangle$

SOLUTION Using the definition of the cross product we get

$$\mathbf{v} \times \mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 1 \\ 3 & 1 & 1 \end{vmatrix} = \begin{vmatrix} 2 & 1 \\ 1 & 1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 1 \\ 3 & 1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 2 \\ 3 & 1 \end{vmatrix} \mathbf{k}$$
$$= (2-1)\mathbf{i} - (1-3)\mathbf{j} + (1-6)\mathbf{k} = \mathbf{i} + 2\mathbf{j} - 5\mathbf{k}$$

10. $\mathbf{v} = \langle 2, 0, 0 \rangle, \quad \mathbf{w} = \langle -1, 0, 1 \rangle$

SOLUTION By the definition of the cross product we have

$$\mathbf{v} \times \mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 0 & 0 \\ -1 & 0 & 1 \end{vmatrix} = \begin{vmatrix} 0 & 0 \\ 0 & 1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 2 & 0 \\ -1 & 1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 2 & 0 \\ -1 & 0 \end{vmatrix} \mathbf{k}$$
$$= (0-0)\,\mathbf{i} - (2-0)\,\mathbf{j} + (0-0)\,\mathbf{k} = -2\mathbf{j}$$

11. $\mathbf{v} = \left\langle \frac{2}{3}, 1, \frac{1}{2} \right\rangle, \quad \mathbf{w} = \langle 4, -6, 3 \rangle$

SOLUTION We have

$$\mathbf{v} \times \mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{2}{3} & 1 & \frac{1}{2} \\ 4 & -6 & 3 \end{vmatrix} = \begin{vmatrix} 1 & \frac{1}{2} \\ -6 & 3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} \frac{2}{3} & \frac{1}{2} \\ 4 & 3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} \frac{2}{3} & 1 \\ 4 & -6 \end{vmatrix} \mathbf{k}$$
$$= (3+3)\,\mathbf{i} - (2-2)\,\mathbf{j} + (-4-4)\,\mathbf{k} = 6\mathbf{i} - 8\mathbf{k}$$

12. $\mathbf{v} = \langle 1, 1, 0 \rangle, \quad \mathbf{w} = \langle 0, 1, 1 \rangle$

SOLUTION The cross product $\mathbf{v} \times \mathbf{w}$ is the following vector:

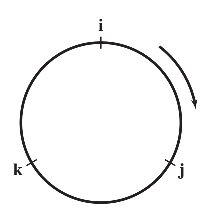
$$\mathbf{v} \times \mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ 1 & 1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 1 \\ 0 & 1 \end{vmatrix} \mathbf{k}$$
$$= (1-0)\,\mathbf{i} - (1-0)\,\mathbf{j} + (1-0)\,\mathbf{k} = \mathbf{i} - \mathbf{j} + \mathbf{k}$$

In Exercises 13–16, use the relations in Eq. (5) to calculate the cross product.

13. $(\mathbf{i} + \mathbf{j}) \times \mathbf{k}$

SOLUTION We use basic properties of the cross product to obtain

$$(\mathbf{i} + \mathbf{j}) \times \mathbf{k} = \mathbf{i} \times \mathbf{k} + \mathbf{j} \times \mathbf{k} = -\mathbf{j} + \mathbf{i}$$



$$\mathbf{i} \times \mathbf{k} = -\mathbf{j}$$
$$\mathbf{j} \times \mathbf{k} = \mathbf{i}$$

14. $(\mathbf{j} - \mathbf{k}) \times (\mathbf{j} + \mathbf{k})$

SOLUTION Using properties of the cross product we get

$$(\mathbf{j} - \mathbf{k}) \times (\mathbf{j} + \mathbf{k}) = (\mathbf{j} - \mathbf{k}) \times \mathbf{j} + (\mathbf{j} - \mathbf{k}) \times \mathbf{k} = \mathbf{j} \times \mathbf{j} - \mathbf{k} \times \mathbf{j} + \mathbf{j} \times \mathbf{k} - \mathbf{k} \times \mathbf{k}$$
$$= \mathbf{0} + \mathbf{i} + \mathbf{i} - \mathbf{0} = 2\mathbf{i}$$

15. $(\mathbf{i} - 3\mathbf{j} + 2\mathbf{k}) \times (\mathbf{j} - \mathbf{k})$

SOLUTION Using the distributive law we obtain

$$\begin{aligned}(\mathbf{i} - 3\mathbf{j} + 2\mathbf{k}) \times (\mathbf{j} - \mathbf{k}) &= (\mathbf{i} - 3\mathbf{j} + 2\mathbf{k}) \times \mathbf{j} - (\mathbf{i} - 3\mathbf{j} + 2\mathbf{k}) \times (\mathbf{k}) \\ &= \mathbf{i} \times \mathbf{j} + 2\mathbf{k} \times \mathbf{j} - \mathbf{i} \times \mathbf{k} - (-3\mathbf{j}) \times \mathbf{k} \\ &= \mathbf{i} + \mathbf{j} + \mathbf{k}\end{aligned}$$

16. $(2\mathbf{i} - 3\mathbf{j} + 4\mathbf{k}) \times (\mathbf{i} + \mathbf{j} - 7\mathbf{k})$

SOLUTION We use the distributive law to obtain

$$\begin{aligned}(2\mathbf{i} - 3\mathbf{j} + 4\mathbf{k}) \times (\mathbf{i} + \mathbf{j} - 7\mathbf{k}) &= (2\mathbf{i} - 3\mathbf{j} + 4\mathbf{k}) \times \mathbf{i} + (2\mathbf{i} - 3\mathbf{j} + 4\mathbf{k}) \times \mathbf{j} + (2\mathbf{i} - 3\mathbf{j} + 4\mathbf{k}) \times (-7\mathbf{k}) \\ &= 2\mathbf{i} \times \mathbf{i} - 3\mathbf{j} \times \mathbf{i} + 4\mathbf{k} \times \mathbf{i} + 2\mathbf{i} \times \mathbf{j} - 3\mathbf{j} \times \mathbf{j} + 4\mathbf{k} \times \mathbf{j} - 14\mathbf{i} \times \mathbf{k} \\ &\quad + 21\mathbf{j} \times \mathbf{k} - 28\mathbf{k} \times \mathbf{k} \\ &= \mathbf{0} + 3\mathbf{i} \times \mathbf{j} - 4\mathbf{i} \times \mathbf{k} + 2\mathbf{i} \times \mathbf{j} - \mathbf{0} - 4\mathbf{j} \times \mathbf{k} - 14\mathbf{i} \times \mathbf{k} + 21\mathbf{j} \times \mathbf{k} - \mathbf{0} \\ &= 5\mathbf{i} \times \mathbf{j} - 18\mathbf{i} \times \mathbf{k} + 17\mathbf{j} \times \mathbf{k} = 5\mathbf{k} + 18\mathbf{j} + 17\mathbf{i} \\ &= 17\mathbf{i} + 18\mathbf{j} + 5\mathbf{k}\end{aligned}$$

In Exercises 17–22, calculate the cross product assuming that

$$\mathbf{u} \times \mathbf{v} = \langle 1, 1, 0 \rangle, \quad \mathbf{u} \times \mathbf{w} = \langle 0, 3, 1 \rangle, \quad \mathbf{v} \times \mathbf{w} = \langle 2, -1, 1 \rangle$$

17. $\mathbf{v} \times \mathbf{u}$

SOLUTION Using the properties of the cross product we obtain

$$\mathbf{v} \times \mathbf{u} = -\mathbf{u} \times \mathbf{v} = \langle -1, -1, 0 \rangle$$

18. $\mathbf{v} \times (\mathbf{u} + \mathbf{v})$

SOLUTION Using the properties of the cross product we obtain

$$\mathbf{v} \times \mathbf{u} + \mathbf{v} \times \mathbf{v} = -\mathbf{u} \times \mathbf{v} + \mathbf{0} = \langle -1, -1, 0 \rangle$$

19. $\mathbf{w} \times (\mathbf{u} + \mathbf{v})$

SOLUTION Using the properties of the cross product we obtain

$$\mathbf{w} \times (\mathbf{u} + \mathbf{v}) = \mathbf{w} \times \mathbf{u} + \mathbf{w} \times \mathbf{v} = -\mathbf{u} \times \mathbf{w} - \mathbf{v} \times \mathbf{w} = \langle -2, -2, -2 \rangle .$$

20. $(3\mathbf{u} + 4\mathbf{w}) \times \mathbf{w}$

SOLUTION Using the properties of the cross product we obtain

$$(3\mathbf{u} + 4\mathbf{w}) \times \mathbf{w} = 3\mathbf{u} \times \mathbf{w} + 4\mathbf{w} \times \mathbf{w} = \langle 0, 9, 3 \rangle$$

21. $(\mathbf{u} - 2\mathbf{v}) \times (\mathbf{u} + 2\mathbf{v})$

SOLUTION Using the properties of the cross product we obtain

$$\begin{aligned}(\mathbf{u} - 2\mathbf{v}) \times (\mathbf{u} + 2\mathbf{v}) &= (\mathbf{u} - 2\mathbf{v}) \times \mathbf{u} + (\mathbf{u} - 2\mathbf{v}) \times 2\mathbf{v} = \mathbf{u} \times \mathbf{u} - 2\mathbf{v} \times \mathbf{u} + \mathbf{u} \times 2\mathbf{v} - 4\mathbf{v} \times \mathbf{v} \\ &= 0 + 2\mathbf{u} \times \mathbf{v} + 2\mathbf{u} \times \mathbf{v} - 0 = 0 + 4\mathbf{u} \times \mathbf{v} = \langle 4, 4, 0 \rangle\end{aligned}$$

22. $(\mathbf{v}+\mathbf{w})\times(3\mathbf{u}+2\mathbf{v})$

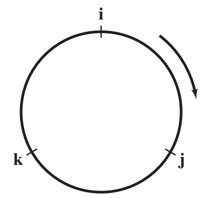
SOLUTION Using the properties of the cross product we obtain

$$\begin{aligned}(\mathbf{v}+\mathbf{w})\times(3\mathbf{u}+2\mathbf{v}) &= \mathbf{v}\times 3\mathbf{u}+\mathbf{w}\times 3\mathbf{u}+\mathbf{v}\times 2\mathbf{v}+\mathbf{w}\times 2\mathbf{v}\\ &= -3\mathbf{u}\times\mathbf{v}-3\mathbf{u}\times\mathbf{w}+0-2\mathbf{v}\times\mathbf{w}=\langle -7,-10,-5\rangle\end{aligned}$$

23. Let $\mathbf{v}=\langle a,b,c\rangle$. Calculate $\mathbf{v}\times\mathbf{i}$, $\mathbf{v}\times\mathbf{j}$, and $\mathbf{v}\times\mathbf{k}$.

SOLUTION We write $\mathbf{v}=a\mathbf{i}+b\mathbf{j}+c\mathbf{k}$ and use the distributive law:

$$\mathbf{v}\times\mathbf{i}=(a\mathbf{i}+b\mathbf{j}+c\mathbf{k})\times\mathbf{i}=a\mathbf{i}\times\mathbf{i}+b\mathbf{j}\times\mathbf{i}+c\mathbf{k}\times\mathbf{i}=a\cdot\mathbf{0}-b\mathbf{k}+c\mathbf{j}=-b\mathbf{k}+c\mathbf{j}=\langle 0,c,-b\rangle$$
$$\mathbf{v}\times\mathbf{j}=(a\mathbf{i}+b\mathbf{j}+c\mathbf{k})\times\mathbf{j}=a\mathbf{i}\times\mathbf{j}+b\mathbf{j}\times\mathbf{j}+c\mathbf{k}\times\mathbf{j}=a\mathbf{k}+b\mathbf{0}-c\mathbf{i}=a\mathbf{k}-c\mathbf{i}=\langle -c,0,a\rangle$$
$$\mathbf{v}\times\mathbf{k}=(a\mathbf{i}+b\mathbf{j}+c\mathbf{k})\times\mathbf{k}=a\mathbf{i}\times\mathbf{k}+b\mathbf{j}\times\mathbf{k}+c\mathbf{k}\times\mathbf{k}=-a\mathbf{j}+b\mathbf{i}+c\mathbf{0}=-a\mathbf{j}+b\mathbf{i}=\langle b,-a,0\rangle$$



24. Find $\mathbf{v}\times\mathbf{w}$, where $\mathbf{v}$ and $\mathbf{w}$ are vectors of length 3 in the xz-plane, oriented as in Figure 15, and $\theta=\frac{\pi}{6}$.

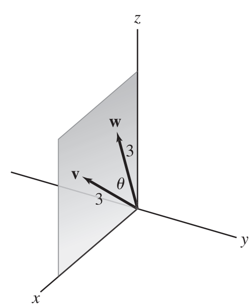


FIGURE 15

SOLUTION Recall that $\|\mathbf{v}\times\mathbf{w}\|=\|\mathbf{v}\|\|\mathbf{w}\|\sin\theta$, and since the vectors $\mathbf{v}$, $\mathbf{w}$ have length 3 and since the angle θ is $\pi/6$, we get that the cross product $\mathbf{v}\times\mathbf{w}$ has length $3\cdot 3\cdot\frac{1}{2}$ which is $\frac{9}{2}$. By the Right-Hand Rule, $\mathbf{v}\times\mathbf{w}$ must point along the negative y-axis. Thus, $\mathbf{v}\times\mathbf{w}=\langle 0,-\frac{9}{2},0\rangle$.

In Exercises 25 and 26, refer to Figure 16.

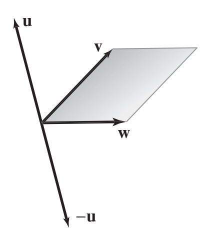

FIGURE 16

25. Which of $\mathbf{u}$ and $-\mathbf{u}$ is equal to $\mathbf{v}\times\mathbf{w}$?

SOLUTION The direction of $\mathbf{v}\times\mathbf{w}$ is determined by the right-hand rule, that is, our thumb points in the direction of $\mathbf{v}\times\mathbf{w}$ when the fingers of our right hand curl from $\mathbf{v}$ to $\mathbf{w}$. Therefore $\mathbf{v}\times\mathbf{w}$ equals $-\mathbf{u}$ rather than $\mathbf{u}$.

26. Which of the following form a right-handed system?

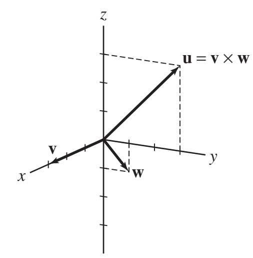
(a) $\{\mathbf{v},\mathbf{w},\mathbf{u}\}$ **(b)** $\{\mathbf{w},\mathbf{v},\mathbf{u}\}$ **(c)** $\{\mathbf{v},\mathbf{u},\mathbf{w}\}$

(d) $\{\mathbf{u},\mathbf{v},\mathbf{w}\}$ **(e)** $\{\mathbf{w},\mathbf{v},-\mathbf{u}\}$ **(f)** $\{\mathbf{v},-\mathbf{u},\mathbf{w}\}$

SOLUTION Applying the right-hand rule (and assuming that $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$ are all mutually perpendicular), we see that only (b) and (c) form a right-handed system.

27. Let $\mathbf{v} = \langle 3, 0, 0\rangle$ and $\mathbf{w} = \langle 0, 1, -1\rangle$. Determine $\mathbf{u} = \mathbf{v} \times \mathbf{w}$ using the geometric properties of the cross product rather than the formula.

SOLUTION The cross product $\mathbf{u} = \mathbf{v} \times \mathbf{w}$ is orthogonal to $\mathbf{v}$.



Since $\mathbf{v}$ lies along the x-axis, $\mathbf{u}$ lies in the yz-plane, therefore $\mathbf{u} = \langle 0, b, c\rangle$. $\mathbf{u}$ is also orthogonal to $\mathbf{w}$, so $\mathbf{u} \cdot \mathbf{w} = 0$. This gives $\mathbf{u} \cdot \mathbf{w} = \langle 0, b, c\rangle \cdot \langle 0, 1, -1\rangle = b - c = 0 \Rightarrow b = c$. Thus, $\mathbf{u} = \langle 0, b, b\rangle$. By the right-hand rule, $\mathbf{u}$ points to the positive z-direction so $b > 0$. We compute the length of $\mathbf{u}$. Since $\mathbf{v} \cdot \mathbf{w} = \langle 3, 0, 0\rangle \cdot \langle 0, 1, -1\rangle = 0$, $\mathbf{v}$ and $\mathbf{w}$ are orthogonal. Hence,

$$\|\mathbf{v} \times \mathbf{w}\| = \|\mathbf{v}\|\|\mathbf{w}\| \sin\frac{\pi}{2} = \|\mathbf{v}\|\|\mathbf{w}\| = 3 \cdot \sqrt{2}.$$

Also since $b > 0$, we have

$$\|\mathbf{u}\| = \|\langle 0, b, b\rangle\| = \sqrt{2b^2} = b\sqrt{2}$$

Equating the lengths gives

$$b\sqrt{2} = 3\sqrt{2} \quad \Rightarrow \quad b = 3.$$

We conclude that $\mathbf{u} = \mathbf{v} \times \mathbf{w} = \langle 0, 3, 3\rangle$.

28. What are the possible angles θ between two unit vectors $\mathbf{e}$ and $\mathbf{f}$ if $\|\mathbf{e} \times \mathbf{f}\| = \frac{1}{2}$?

SOLUTION Using the length of the cross product we have

$$\frac{1}{2} = \|\mathbf{e} \times \mathbf{f}\| = \|\mathbf{e}\|\|\mathbf{f}\| \sin\theta = 1 \cdot 1 \sin\theta.$$

That is, $\sin\theta = \frac{1}{2}$. The solution for $0 \le \theta \le \pi$ are $\theta_1 = \frac{\pi}{6}$ and $\theta_2 = \pi - \frac{\pi}{6} = \frac{5\pi}{6}$. We conclude that the possible angles between $\mathbf{e}$ and $\mathbf{f}$ are $\frac{\pi}{6}$ or $\frac{5\pi}{6}$.

29. Show that if $\mathbf{v}$ and $\mathbf{w}$ lie in the yz-plane, then $\mathbf{v} \times \mathbf{w}$ is a multiple of $\mathbf{i}$.

SOLUTION $\mathbf{v} \times \mathbf{w}$ is orthogonal to $\mathbf{v}$ and $\mathbf{w}$. Since $\mathbf{v}$ and $\mathbf{w}$ lie in the yz-plane, $\mathbf{v} \times \mathbf{w}$ must lie along the x axis which is perpendicular to yz-plane. That is, $\mathbf{v} \times \mathbf{w}$ is a scalar multiple of the unit vector $\mathbf{i}$.

30. Find the two unit vectors orthogonal to both $\mathbf{a} = \langle 3, 1, 1\rangle$ and $\mathbf{b} = \langle -1, 2, 1\rangle$.

SOLUTION The cross product $\mathbf{a} \times \mathbf{b}$ is orthogonal to $\mathbf{a}$ and $\mathbf{b}$, therefore the desired vectors $\mathbf{u}_1$ and $\mathbf{u}_2$ are the unit vectors in the direction of $\mathbf{a} \times \mathbf{b}$ and $-\mathbf{a} \times \mathbf{b}$ respectively. That is,

$$\mathbf{u}_1 = \frac{\mathbf{a} \times \mathbf{b}}{\|\mathbf{a} \times \mathbf{b}\|}, \quad \mathbf{u}_2 = -\frac{\mathbf{a} \times \mathbf{b}}{\|\mathbf{a} \times \mathbf{b}\|} \tag{1}$$

We compute the cross product vector $\mathbf{a} \times \mathbf{b}$ and its length:

$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & 1 & 1 \\ -1 & 2 & 1 \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ 2 & 1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 3 & 1 \\ -1 & 1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 3 & 1 \\ -1 & 2 \end{vmatrix}\mathbf{k}$$

$$= (1-2)\mathbf{i} - (3+1)\mathbf{j} + (6+1)\mathbf{k} = -\mathbf{i} - 4\mathbf{j} + 7\mathbf{k} = \langle -1, -4, 7\rangle$$

$$\|\mathbf{a} \times \mathbf{b}\| = \sqrt{(-1)^2 + (-4)^2 + 7^2} = \sqrt{66}$$

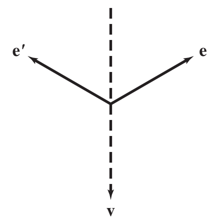
Substituting into (1) we get

$$\mathbf{u}_1 = \left\langle -\frac{1}{\sqrt{66}}, -\frac{4}{\sqrt{66}}, \frac{7}{\sqrt{66}} \right\rangle, \quad \mathbf{u}_2 = \left\langle \frac{1}{\sqrt{66}}, \frac{4}{\sqrt{66}}, -\frac{7}{\sqrt{66}} \right\rangle$$

31. Let $\mathbf{e}$ and $\mathbf{e}'$ be unit vectors in $\mathbf{R}^3$ such that $\mathbf{e} \perp \mathbf{e}'$. Use the geometric properties of the cross product to compute $\mathbf{e} \times (\mathbf{e}' \times \mathbf{e})$.

SOLUTION Let $\mathbf{u} = \mathbf{e} \times \left(\mathbf{e}' \times \mathbf{e}\right)$ and $\mathbf{v} = \mathbf{e}' \times \mathbf{e}$. The vector $\mathbf{v}$ is orthogonal to $\mathbf{e}'$ and $\mathbf{e}$, hence $\mathbf{v}$ is orthogonal to the plane π defined by $\mathbf{e}'$ and $\mathbf{e}$. Now $\mathbf{u}$ is orthogonal to $\mathbf{v}$, hence $\mathbf{u}$ lies in the plane π orthogonal to $\mathbf{v}$. $\mathbf{u}$ is orthogonal to $\mathbf{e}$, which is in this plane, hence $\mathbf{u}$ is a multiple of $\mathbf{e}'$:

$$\mathbf{u} = \lambda \mathbf{e}' \tag{1}$$



The right-hand rule implies that $\mathbf{u}$ is in the direction of $\mathbf{e}'$, hence $\lambda > 0$. To find λ, we compute the length of $\mathbf{u}$:

$$\|\mathbf{v}\| = \|\mathbf{e}' \times \mathbf{e}\| = \|\mathbf{e}'\|\|\mathbf{e}\| \sin\frac{\pi}{2} = 1 \cdot 1 \cdot 1 = 1$$

$$\|\mathbf{u}\| = \|\mathbf{e} \times \mathbf{v}\| = \|\mathbf{e}\|\|\mathbf{v}\| \sin\frac{\pi}{2} = 1 \cdot 1 \cdot 1 = 1 \tag{2}$$

Combining (1), (2), and $\lambda > 0$ we conclude that

$$\mathbf{u} = \mathbf{e} \times \left(\mathbf{e}' \times \mathbf{e}\right) = \mathbf{e}'.$$

32. Calculate the force $\mathbf{F}$ on an electron (charge $q = -1.6 \times 10^{-19}$ C) moving with velocity 10^5 m/s in the direction $\mathbf{i}$ in a uniform magnetic field $\mathbf{B}$, where $\mathbf{B} = 0.0004\mathbf{i} + 0.0001\mathbf{j}$ teslas (see Example 5).

SOLUTION The force $\mathbf{F}$ on an electron moving at velocity $\mathbf{v}$ in a uniform magnetic field $\mathbf{B}$ is

$$\mathbf{F} = q(\mathbf{v} \times \mathbf{B}) \quad \text{where} \quad q = -1.6 \cdot 10^{-19} \text{ coulombs}.$$

In our example, $\mathbf{v} = 10^5\mathbf{i}$ and $\mathbf{B} = 0.0004\mathbf{i} + 0.0001\mathbf{j}$, hence,

$$\begin{aligned} \mathbf{F} &= q10^5\mathbf{i} \times (0.0004\mathbf{i} + 0.0001\mathbf{j}) = 10q\mathbf{i} \times (4\mathbf{i} + \mathbf{j}) = 10q\,(4\mathbf{i} \times \mathbf{i} + \mathbf{i} \times \mathbf{j}) \\ &= 10q\,(\mathbf{0} + \mathbf{k}) = 10q\mathbf{k} = (-1.6 \cdot 10^{-18})\mathbf{k} \end{aligned}$$

33. An electron moving with velocity $\mathbf{v}$ in the plane experiences a force $\mathbf{F} = q(\mathbf{v} \times \mathbf{B})$, where q is the charge on the electron and $\mathbf{B}$ is a uniform magnetic field pointing directly out of the page. Which of the two vectors $\mathbf{F}_1$ or $\mathbf{F}_2$ in Figure 17 represents the force on the electron? Remember that q is negative.

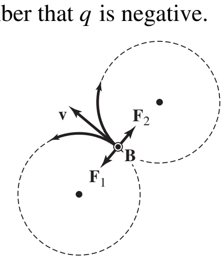


FIGURE 17 The magnetic field vector $\mathbf{B}$ points directly out of the page.

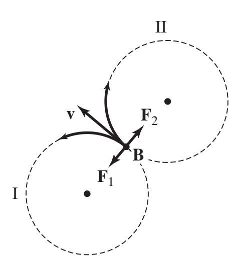
SOLUTION Since the magnetic field $\mathbf{B}$ points directly out of the page (toward us), the right-hand rule implies that the cross product $\mathbf{v} \times \mathbf{B}$ is in the direction of $\mathbf{F}_2$ (see figure).



Since $\mathbf{F} = q\,(\mathbf{v} \times \mathbf{B})$ and $q < 0$, the force $\mathbf{F}$ on the electron is represented by the opposite vector $\mathbf{F}_1$.

34. Calculate the scalar triple product $\mathbf{u}\cdot(\mathbf{v}\times\mathbf{w})$, where $\mathbf{u}=\langle 1,1,0\rangle$, $\mathbf{v}=\langle 3,-2,2\rangle$, and $\mathbf{w}=\langle 4,-1,2\rangle$.

SOLUTION The scalar triple product is the following 3×3 determinant:

$$\mathbf{u}\cdot(\mathbf{v}\times\mathbf{w})=\begin{vmatrix}1&1&0\\3&-2&2\\4&-1&2\end{vmatrix}=1\begin{vmatrix}-2&2\\-1&2\end{vmatrix}-1\begin{vmatrix}3&2\\4&2\end{vmatrix}+0\begin{vmatrix}3&-2\\4&-1\end{vmatrix}$$
$$=1\cdot(-4+2)-1\cdot(6-8)+0=-2+2=0$$

35. Verify identity (10) for vectors $\mathbf{v}=\langle 3,-2,2\rangle$ and $\mathbf{w}=\langle 4,-1,2\rangle$.

SOLUTION We compute the cross product $\mathbf{v}\times\mathbf{w}$:

$$\mathbf{v}\times\mathbf{w}=\begin{vmatrix}\mathbf{i}&\mathbf{j}&\mathbf{k}\\3&-2&2\\4&-1&2\end{vmatrix}=\begin{vmatrix}-2&2\\-1&2\end{vmatrix}\mathbf{i}-\begin{vmatrix}3&2\\4&2\end{vmatrix}\mathbf{j}+\begin{vmatrix}3&-2\\4&-1\end{vmatrix}\mathbf{k}$$
$$=(-4+2)\mathbf{i}-(6-8)\mathbf{j}+(-3+8)\mathbf{k}=-2\mathbf{i}+2\mathbf{j}+5\mathbf{k}=\langle -2,2,5\rangle$$

We now find the dot product $\mathbf{v}\cdot\mathbf{w}$:

$$\mathbf{v}\cdot\mathbf{w}=\langle 3,-2,2\rangle\cdot\langle 4,-1,2\rangle=3\cdot 4+(-2)\cdot(-1)+2\cdot 2=18$$

Finally we compute the squares of the lengths of $\mathbf{v}$, $\mathbf{w}$ and $\mathbf{v}\times\mathbf{w}$:

$$\|\mathbf{v}\|^2=3^2+(-2)^2+2^2=17$$
$$\|\mathbf{w}\|^2=4^2+(-1)^2+2^2=21$$
$$\|\mathbf{v}\times\mathbf{w}\|^2=(-2)^2+2^2+5^2=33$$

We now verify the equality:

$$\|\mathbf{v}\|^2\|\mathbf{w}\|^2-(\mathbf{v}\cdot\mathbf{w})^2=17\cdot 21-18^2=33=\|\mathbf{v}\times\mathbf{w}\|^2$$

36. Find the volume of the parallelepiped spanned by $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$ in Figure 18.

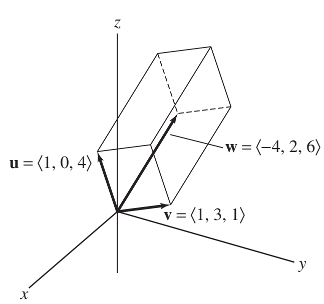


FIGURE 18

SOLUTION Using $\mathbf{u}=\langle 1,0,4\rangle$, $\mathbf{v}=\langle 1,3,1\rangle$ and $\mathbf{w}=\langle -4,2,6\rangle$, the scalar triple product is the following 3×3 determinant:

$$\mathbf{u}\cdot(\mathbf{v}\times\mathbf{w})=\begin{vmatrix}1&0&4\\1&3&1\\-4&2&6\end{vmatrix}=1\cdot(18-2)-0+4(2+12)=16+56=72$$

37. Find the area of the parallelogram spanned by $\mathbf{v}$ and $\mathbf{w}$ in Figure 18.

SOLUTION The area of the parallelogram equals the length of the cross product of the two vectors $\mathbf{v}=\langle 1,3,1\rangle$ and $\mathbf{w}=\langle -4,2,6\rangle$. We calculate the cross product as follows:

$$\mathbf{v}\times\mathbf{w}=\begin{vmatrix}\mathbf{i}&\mathbf{j}&\mathbf{k}\\1&3&1\\-4&2&6\end{vmatrix}=(18-2)\mathbf{i}-(6+4)\mathbf{j}+(2+12)\mathbf{k}=16\mathbf{i}-10\mathbf{j}+14\mathbf{k}$$

The length of this vector $16\mathbf{i}-10\mathbf{j}+14\mathbf{k}$ is $\sqrt{16^2+10^2+14^2}=2\sqrt{138}$. Thus, the area of the parallelogram is $2\sqrt{138}$.

38. Calculate the volume of the parallelepiped spanned by

$$\mathbf{u} = \langle 2, 2, 1 \rangle, \qquad \mathbf{v} = \langle 1, 0, 3 \rangle, \qquad \mathbf{w} = \langle 0, -4, 0 \rangle$$

SOLUTION Using $\mathbf{u} = \langle 2, 2, 1 \rangle$, $\mathbf{v} = \langle 1, 0, 3 \rangle$, and $\mathbf{w} = \langle 0, -4, 0 \rangle$, the volume is given by the following scalar triple product:

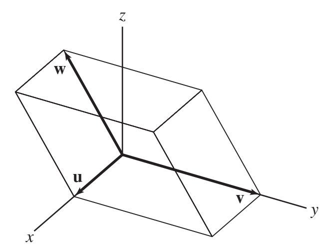
$$\mathbf{u} \cdot (\mathbf{v} \times \mathbf{w}) = \begin{vmatrix} 2 & 2 & 1 \\ 1 & 0 & 3 \\ 0 & -4 & 0 \end{vmatrix} = 2(0+12) - 2(0-0) + 1(-4-0) = 24 - 4 = 20.$$

39. Sketch and compute the volume of the parallelepiped spanned by

$$\mathbf{u} = \langle 1, 0, 0 \rangle, \qquad \mathbf{v} = \langle 0, 2, 0 \rangle, \qquad \mathbf{w} = \langle 1, 1, 2 \rangle$$

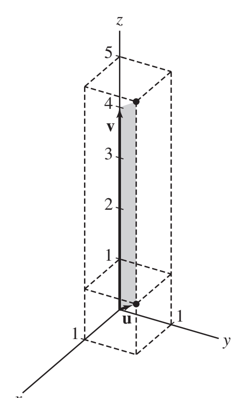
SOLUTION Using $\mathbf{u} = \langle 1, 0, 0 \rangle$, $\mathbf{v} = \langle 0, 2, 0 \rangle$, and $\mathbf{w} = \langle 1, 1, 2 \rangle$, the volume is given by the following scalar triple product:

$$\mathbf{u} \cdot (\mathbf{v} \times \mathbf{w}) = \begin{vmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 1 & 1 & 2 \end{vmatrix} = 1(4-0) - 0 + 0 = 4.$$



40. Sketch the parallelogram spanned by $\mathbf{u} = \langle 1, 1, 1 \rangle$ and $\mathbf{v} = \langle 0, 0, 4 \rangle$, and compute its area.

SOLUTION The parallelogram spanned by $\mathbf{u} = \langle 1, 1, 1 \rangle$ and $\mathbf{v} = \langle 0, 0, 4 \rangle$ is shown in the figure.



We find its area A using the formula for the area of a parallelogram:

$$A = \|\mathbf{u} \times \mathbf{v}\|$$

We first find the cross product vector $\mathbf{u} \times \mathbf{v}$:

$$\mathbf{u} \times \mathbf{v} = (\mathbf{i} + \mathbf{j} + \mathbf{k}) \times 4\mathbf{k} = 4\mathbf{i} \times \mathbf{k} + 4\mathbf{j} \times \mathbf{k} + 4\mathbf{k} \times \mathbf{k} = -4\mathbf{j} + 4\mathbf{i} + \mathbf{0} = 4\mathbf{i} - 4\mathbf{j} = 4\langle 1, -1, 0 \rangle$$

Hence,

$$A = \|4\langle 1, -1, 0 \rangle\| = 4\|\langle 1, -1, 0 \rangle\| = 4\sqrt{1^2 + (-1)^2 + 0^2} = 4\sqrt{2}$$

41. Calculate the area of the parallelogram spanned by $\mathbf{u} = \langle 1, 0, 3 \rangle$ and $\mathbf{v} = \langle 2, 1, 1 \rangle$.

SOLUTION The area of the parallelogram is the length of the vector $\mathbf{u} \times \mathbf{v}$. We first compute this vector:

$$\mathbf{u} \times \mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 3 \\ 2 & 1 & 1 \end{vmatrix} = \begin{vmatrix} 0 & 3 \\ 1 & 1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 3 \\ 2 & 1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 0 \\ 2 & 1 \end{vmatrix} \mathbf{k} = -3\mathbf{i} - (1-6)\mathbf{j} + \mathbf{k} = -3\mathbf{i} + 5\mathbf{j} + \mathbf{k}$$

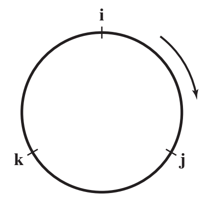
The area A is the length

$$A = \|\mathbf{u} \times \mathbf{v}\| = \sqrt{(-3)^2 + 5^2 + 1^2} = \sqrt{35} \approx 5.92.$$

42. Find the area of the parallelogram determined by the vectors $\langle a, 0, 0\rangle$ and $\langle 0, b, c\rangle$.

SOLUTION The area A is the length of the cross product of the two vectors. We first compute the cross product:

$$\langle a, 0, 0\rangle \times \langle 0, b, c\rangle = a\mathbf{i} \times (b\mathbf{j} + c\mathbf{k}) = ab\mathbf{i} \times \mathbf{j} + ac\mathbf{i} \times \mathbf{k} = ab\mathbf{k} - ac\mathbf{j} = \langle 0, -ac, ab\rangle$$

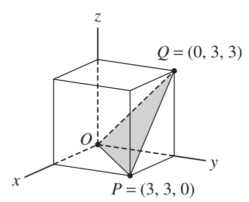


The area of the parallelogram is therefore

$$A = \|\langle 0, -ac, ab\rangle\| = \sqrt{0^2 + (-ac)^2 + (ab)^2} = \sqrt{a^2c^2 + a^2b^2} = |a|\sqrt{b^2 + c^2}$$

43. Sketch the triangle with vertices at the origin O, $P = (3, 3, 0)$, and $Q = (0, 3, 3)$, and compute its area using cross products.

SOLUTION The triangle OPQ is shown in the following figure.



The area S of the triangle is half of the area of the parallelogram determined by the vectors $\overrightarrow{OP} = \langle 3, 3, 0\rangle$ and $\overrightarrow{OQ} = \langle 0, 3, 3\rangle$. Thus,

$$S = \frac{1}{2}\|\overrightarrow{OP} \times \overrightarrow{OQ}\| \tag{1}$$

We compute the cross product:

$$\overrightarrow{OP} \times \overrightarrow{OQ} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & 3 & 0 \\ 0 & 3 & 3 \end{vmatrix} = \begin{vmatrix} 3 & 0 \\ 3 & 3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 3 & 0 \\ 0 & 3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 3 & 3 \\ 0 & 3 \end{vmatrix}\mathbf{k}$$

$$= 9\mathbf{i} - 9\mathbf{j} + 9\mathbf{k} = 9\langle 1, -1, 1\rangle$$

Substituting into (1) gives

$$S = \frac{1}{2}\|9\langle 1, -1, 1\rangle\| = \frac{9}{2}\|\langle 1, -1, 1\rangle\| = \frac{9}{2}\sqrt{1^2 + (-1)^2 + 1^2} = \frac{9\sqrt{3}}{2} \approx 7.8$$

The area of the triangle is $S = \frac{9\sqrt{3}}{2} \approx 7.8$.

44. Use the cross product to find the area of the triangle with vertices $P = (1, 1, 5)$, $Q = (3, 4, 3)$, and $R = (1, 5, 7)$ (Figure 19).

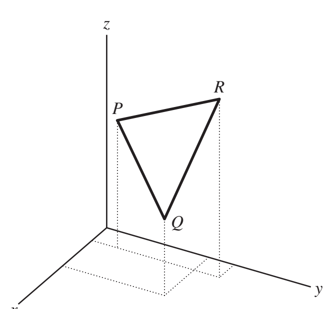


FIGURE 19

SOLUTION The area S of the triangle is half of the area of the parallelogram spanned by $\overrightarrow{PQ}$ and $\overrightarrow{PR}$. We use the formula for the area of a parallelogram via cross product to write

$$S = \frac{1}{2}\|\overrightarrow{PQ} \times \overrightarrow{PR}\|$$

We compute the vectors $\overrightarrow{PQ}$ and $\overrightarrow{PR}$:

$$\overrightarrow{PQ} = \langle 3-1, 4-1, 3-5\rangle = \langle 2, 3, -2\rangle$$
$$\overrightarrow{PR} = \langle 1-1, 5-1, 7-5\rangle = \langle 0, 4, 2\rangle$$

We now find the cross product $\overrightarrow{PQ} \times \overrightarrow{PR}$ by computing the following determinant:

$$\overrightarrow{PQ} \times \overrightarrow{PR} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 3 & -2 \\ 0 & 4 & 2 \end{vmatrix} = \begin{vmatrix} 3 & -2 \\ 4 & 2 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2 & -2 \\ 0 & 2 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2 & 3 \\ 0 & 4 \end{vmatrix}\mathbf{k} = 14\mathbf{i} - 4\mathbf{j} + 8\mathbf{k}$$

Thus, we get

$$S = \frac{1}{2}\|14\mathbf{i} - 4\mathbf{j} + 8\mathbf{k}\| = \frac{1}{2}\sqrt{14^2 + (-4)^2 + 8^2} = \frac{1}{2}\cdot 2\sqrt{69} = \sqrt{69} \approx 8.3$$

In Exercises 45–47, verify the identity using the formula for the cross product.

45. $\mathbf{v} \times \mathbf{w} = -\mathbf{w} \times \mathbf{v}$

SOLUTION Let $\mathbf{v} = \langle a, b, c\rangle$ and $\mathbf{w} = \langle d, e, f\rangle$. By the definition of the cross product we have

$$\mathbf{v} \times \mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a & b & c \\ d & e & f \end{vmatrix} = \begin{vmatrix} b & c \\ e & f \end{vmatrix}\mathbf{i} - \begin{vmatrix} a & c \\ d & f \end{vmatrix}\mathbf{j} + \begin{vmatrix} a & b \\ d & e \end{vmatrix}\mathbf{k} = (bf - ec)\mathbf{i} - (af - dc)\mathbf{j} + (ae - db)\mathbf{k}$$

We also have

$$-\mathbf{w} \times \mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -d & -e & -f \\ a & b & c \end{vmatrix} = (-ec + bf)\mathbf{i} - (-dc + af)\mathbf{j} + (-db + ea)\mathbf{k}$$

Thus, $\mathbf{v} \times \mathbf{w} = -\mathbf{w} \times \mathbf{v}$, as desired.

46. $(\lambda\mathbf{v}) \times \mathbf{w} = \lambda(\mathbf{v} \times \mathbf{w})$ (λ a scalar)

SOLUTION Let $\mathbf{v} = \langle a_1, a_2, a_3\rangle$ and $\mathbf{w} = \langle b_1, b_2, b_3\rangle$. We compute $(\lambda\mathbf{v}) \times \mathbf{w}$:

$$\begin{aligned}(\lambda\mathbf{v}) \times \mathbf{w} = \langle \lambda a_1, \lambda a_2, \lambda a_3\rangle \times \langle b_1, b_2, b_3\rangle &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \lambda a_1 & \lambda a_2 & \lambda a_3 \\ b_1 & b_2 & b_3 \end{vmatrix} \\ &= \begin{vmatrix} \lambda a_2 & \lambda a_3 \\ b_2 & b_3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} \lambda a_1 & \lambda a_3 \\ b_1 & b_3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} \lambda a_1 & \lambda a_2 \\ b_1 & b_2 \end{vmatrix}\mathbf{k} \\ &= (\lambda a_2 b_3 - \lambda a_3 b_2)\,\mathbf{i} - (\lambda a_1 b_3 - \lambda a_3 b_1)\,\mathbf{j} + (\lambda a_1 b_2 - \lambda a_2 b_1)\,\mathbf{k} \\ &= \lambda\,(a_2 b_3 - a_3 b_2)\,\mathbf{i} - \lambda\,(a_1 b_3 - a_3 b_1)\,\mathbf{j} + \lambda\,(a_1 b_2 - a_2 b_1)\,\mathbf{k} \\ &= \lambda\,((a_2 b_3 - a_3 b_2)\,\mathbf{i} - (a_1 b_3 - a_3 b_1)\,\mathbf{j} + (a_1 b_2 - a_2 b_1)\,\mathbf{k})\end{aligned}$$

We compute $\lambda\,(\mathbf{v} \times \mathbf{w})$:

$$\lambda\,(\mathbf{v} \times \mathbf{w}) = \lambda\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix} = \lambda\,((a_2 b_3 - a_3 b_2)\,\mathbf{i} - (a_1 b_3 - a_3 b_1)\,\mathbf{j} + (a_1 b_2 - a_2 b_1)\,\mathbf{k})$$

The two vectors are equal.

47. $(\mathbf{u} + \mathbf{v}) \times \mathbf{w} = \mathbf{u} \times \mathbf{w} + \mathbf{v} \times \mathbf{w}$

SOLUTION We let $\mathbf{u} = \langle a_1, a_2, a_3\rangle$, $\mathbf{v} = \langle b_1, b_2, b_3\rangle$ and $\mathbf{w} = \langle c_1, c_2, c_3\rangle$. Computing the left-hand side gives

$$(\mathbf{u} + \mathbf{v}) \times \mathbf{w} = \langle a_1 + b_1, a_2 + b_2, a_3 + b_3\rangle \times \langle c_1, c_2, c_3\rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 + b_1 & a_2 + b_2 & a_3 + b_3 \\ c_1 & c_2 & c_3 \end{vmatrix}$$

$$= \begin{vmatrix} a_2+b_2 & a_3+b_3 \\ c_2 & c_3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} a_1+b_1 & a_3+b_3 \\ c_1 & c_3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} a_1+b_1 & a_2+b_2 \\ c_1 & c_2 \end{vmatrix} \mathbf{k}$$

$$= (c_3(a_2+b_2) - c_2(a_3+b_3))\,\mathbf{i} - (c_3\,(a_1+b_1) - c_1\,(a_3+b_3))\,\mathbf{j} + (c_2(a_1+b_1) - c_1(a_2+b_2))\,\mathbf{k}$$

We now compute the right-hand-side of the equality:

$$\mathbf{u}\times\mathbf{w}+\mathbf{v}\times\mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ c_1 & c_2 & c_3 \end{vmatrix} + \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix}$$

$$= \begin{vmatrix} a_2 & a_3 \\ c_2 & c_3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} a_1 & a_3 \\ c_1 & c_3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} a_1 & a_2 \\ c_1 & c_2 \end{vmatrix} \mathbf{k} + \begin{vmatrix} b_2 & b_3 \\ c_2 & c_3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} b_1 & b_3 \\ c_1 & c_3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} b_1 & b_2 \\ c_1 & c_2 \end{vmatrix} \mathbf{k}$$

$$= (a_2c_3 - a_3c_2)\mathbf{i} - (a_1c_3 - a_3c_1)\mathbf{j} + (a_1c_2 - a_2c_1)\mathbf{k}$$

$$+ (b_2c_3 - b_3c_2)\mathbf{i} - (b_1c_3 - b_3c_1)\mathbf{j} + (b_1c_2 - b_2c_1)\mathbf{k}$$

$$= (a_2c_3 - a_3c_2 + b_2c_3 - b_3c_2)\mathbf{i} - (a_1c_3 - a_3c_1 + b_1c_3 - b_3c_1)\mathbf{j} + (a_1c_2 - a_2c_1 + b_1c_2 - b_2c_1)\mathbf{k}$$

$$= (c_3(a_2+b_2) - c_2(a_3+b_3))\,\mathbf{i} - (c_3(a_1+b_1) - c_1(a_3+b_3))\,\mathbf{j} + (c_2(a_1+b_1) - c_1(a_2+b_2))\,\mathbf{k}$$

The results are the same. Hence,

$$(\mathbf{u}+\mathbf{v})\times\mathbf{w} = \mathbf{u}\times\mathbf{w}+\mathbf{v}\times\mathbf{w}.$$

48. Use the geometric description in Theorem 1 to prove Theorem 2 (iii): $\mathbf{v}\times\mathbf{w} = \mathbf{0}$ if and only if $\mathbf{w} = \lambda\mathbf{v}$ for some scalar λ or $\mathbf{v} = \mathbf{0}$.

SOLUTION $\mathbf{v}\times\mathbf{w} = \mathbf{0}$ if and only if $\|\mathbf{v}\times\mathbf{w}\| = 0$, that is, using Theorem 2 (b), if and only if

$$\|\mathbf{v}\|\|\mathbf{w}\|\sin\theta = 0$$

where θ is the angle between $\mathbf{v}$ and $\mathbf{w}$. This equality holds only if at least one of the vectors $\mathbf{v}$ or $\mathbf{w}$ is the zero vector or $\sin\theta = 0$. The solutions of $\sin\theta = 0$ for angles between 0 and 180° are $\theta = 0$ and $\theta = 180°$, that is, $\mathbf{v}$ and $\mathbf{w}$ are parallel vectors. To summarize, we conclude that $\mathbf{v}\times\mathbf{w} = \mathbf{0}$ if and only if $\mathbf{v} = \mathbf{0}$ or $\mathbf{w} = \mathbf{0}$ or $\mathbf{w} = \lambda\mathbf{v}$. This can be written as

$$\mathbf{v} = \mathbf{0} \quad \text{or} \quad \mathbf{w} = \lambda\mathbf{v}.$$

49. Verify the relations (5).

SOLUTION We must verify the following relations:

$$\mathbf{i}\times\mathbf{j} = \mathbf{k}, \quad \mathbf{j}\times\mathbf{k} = \mathbf{i}, \quad \mathbf{k}\times\mathbf{i} = \mathbf{j}, \quad \mathbf{i}\times\mathbf{i} = \mathbf{j}\times\mathbf{j} = \mathbf{k}\times\mathbf{k} = \mathbf{0}$$

We compute the cross products using the definition of the cross product. This gives

$$\mathbf{i}\times\mathbf{j} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{vmatrix} = \begin{vmatrix} 0 & 0 \\ 1 & 0 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 0 \\ 0 & 0 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix} \mathbf{k} = \mathbf{k}$$

$$\mathbf{j}\times\mathbf{k} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 0 & 0 \\ 0 & 1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 0 & 1 \\ 0 & 0 \end{vmatrix} \mathbf{k} = \mathbf{i}$$

$$\mathbf{k}\times\mathbf{i} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{vmatrix} = \begin{vmatrix} 0 & 1 \\ 0 & 0 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 0 & 1 \\ 1 & 0 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 0 & 0 \\ 1 & 0 \end{vmatrix} \mathbf{k} = \mathbf{j}$$

$$\mathbf{i}\times\mathbf{i} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{vmatrix} = \begin{vmatrix} 0 & 0 \\ 0 & 0 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 0 \\ 1 & 0 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 0 \\ 1 & 0 \end{vmatrix} \mathbf{k} = \mathbf{0}$$

$$\mathbf{j}\times\mathbf{j} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ 1 & 0 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 0 & 0 \\ 0 & 0 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 0 & 1 \\ 0 & 1 \end{vmatrix} \mathbf{k} = \mathbf{0}$$

$$\mathbf{k}\times\mathbf{k} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 0 & 1 \\ 0 & 0 & 1 \end{vmatrix} = \begin{vmatrix} 0 & 1 \\ 0 & 1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 0 & 1 \\ 0 & 1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 0 & 0 \\ 0 & 0 \end{vmatrix} \mathbf{k} = \mathbf{0}$$

50. Show that

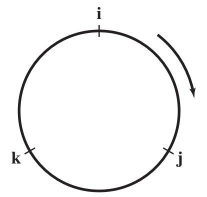
$$(\mathbf{i} \times \mathbf{j}) \times \mathbf{j} \neq \mathbf{i} \times (\mathbf{j} \times \mathbf{j})$$

Conclude that the Associative Law does not hold for cross products.

SOLUTION Using the cross products of the unit vectors **i**, **j**, and **k**, we obtain

$$(\mathbf{i} \times \mathbf{j}) \times \mathbf{j} = \mathbf{k} \times \mathbf{j} = -\mathbf{i}$$

$$\mathbf{i} \times (\mathbf{j} \times \mathbf{j}) = \mathbf{i} \times \mathbf{0} = \mathbf{0}$$



Since $(\mathbf{i} \times \mathbf{j}) \times \mathbf{j} \neq \mathbf{i} \times (\mathbf{j} \times \mathbf{j})$ the associative law does not hold for cross products.

51. The components of the cross product have a geometric interpretation. Show that the absolute value of the **k**-component of $\mathbf{v} \times \mathbf{w}$ is equal to the area of the parallelogram spanned by the projections $\mathbf{v}_0$ and $\mathbf{w}_0$ onto the xy-plane (Figure 20).

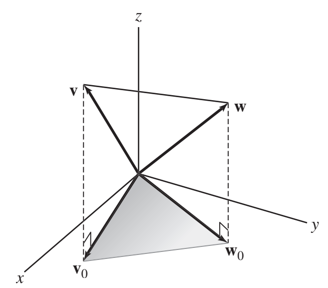


FIGURE 20

SOLUTION Let $\mathbf{v} = \langle a_1, a_2, a_3 \rangle$ and $\mathbf{w} = \langle b_1, b_2, b_3 \rangle$, hence, $\mathbf{v}_0 = \langle a_1, a_2, 0 \rangle$ and $\mathbf{w}_0 = \langle b_1, b_2, 0 \rangle$. The area S of the parallelogram spanned by $\mathbf{v}_0$ and $\mathbf{w}_0$ is the following value:

$$S = \|\mathbf{v}_0 \times \mathbf{w}_0\| \tag{1}$$

We compute the cross product:

$$\mathbf{v}_0 \times \mathbf{w}_0 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & 0 \\ b_1 & b_2 & 0 \end{vmatrix} = \begin{vmatrix} a_2 & 0 \\ b_2 & 0 \end{vmatrix} \mathbf{i} - \begin{vmatrix} a_1 & 0 \\ b_1 & 0 \end{vmatrix} \mathbf{j} + \begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix} \mathbf{k}$$

$$= 0\mathbf{i} - 0\mathbf{j} + (a_1 b_2 - a_2 b_1)\mathbf{k} = \langle 0, 0, a_1 b_2 - a_2 b_1 \rangle$$

Using (1) we have

$$S = \sqrt{0^2 + 0^2 + (a_1 b_2 - a_2 b_1)^2} = |a_1 b_2 - a_2 b_1| \tag{2}$$

We now compute $\mathbf{v} \times \mathbf{w}$:

$$\mathbf{v} \times \mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix} = \begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} a_1 & a_3 \\ b_1 & b_3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix} \mathbf{k}$$

The **k**-component of $\mathbf{v} \times \mathbf{w}$ is, thus,

$$\begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix} = a_1 b_2 - a_2 b_1 \tag{3}$$

By (2) and (3) we obtain the desired result.

52. Formulate and prove analogs of the result in Exercise 51 for the **i**- and **j**-components of $\mathbf{v} \times \mathbf{w}$.

SOLUTION The analogs for the **i** and **j** components of $\mathbf{v} \times \mathbf{w}$ are the following statements:

(a) The area of the parallelogram spanned by the projections $\mathbf{v}'$ and $\mathbf{w}'$ of vectors $\mathbf{v}$, $\mathbf{w}$ onto the xz-plane is equal to the absolute value of the **j**-component of $\mathbf{v} \times \mathbf{w}$.

(b) The area of the parallelogram spanned by the projections $\mathbf{v}'$ and $\mathbf{w}'$ of vectors $\mathbf{v}$, $\mathbf{w}$ onto the yz-plane is equal to the absolute value of the **i**-component of $\mathbf{v} \times \mathbf{w}$.

(c) If $\mathbf{v} = \langle a_1, a_2, a_3 \rangle$ and $\mathbf{w} = \langle b_1, b_2, b_3 \rangle$ then $\mathbf{v}' = \langle a_1, 0, a_3 \rangle$ and $\mathbf{w}' = \langle b_1, 0, b_3 \rangle$. The area S of the parallelogram spanned by $\mathbf{v}'$ and $\mathbf{w}'$ is

$$S = \|\mathbf{v}' \times \mathbf{w}'\| \tag{1}$$

We compute the cross product:

$$\mathbf{v}' \times \mathbf{w}' = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & 0 & a_3 \\ b_1 & 0 & b_3 \end{vmatrix} = \begin{vmatrix} 0 & a_3 \\ 0 & b_3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} a_1 & a_3 \\ b_1 & b_3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} a_1 & 0 \\ b_1 & 0 \end{vmatrix} \mathbf{k}$$

$$= 0\mathbf{i} - (a_1 b_3 - a_3 b_1)\mathbf{j} + 0\mathbf{k} = -(a_1 b_3 - a_3 b_1)\mathbf{j}$$

Combining with (1) we get

$$S = \| -(a_1 b_3 - a_3 b_1)\mathbf{j}\| = |a_1 b_3 - a_3 b_1| \tag{2}$$

We now find the cross product $\mathbf{v} \times \mathbf{w}$:

$$\mathbf{v} \times \mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix} = \begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} a_1 & a_3 \\ b_1 & b_3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix} \mathbf{k}$$

The $\mathbf{j}$-component of the cross product is

$$-\begin{vmatrix} a_1 & a_3 \\ b_1 & b_3 \end{vmatrix} = -(a_1 b_3 - a_3 b_1) \tag{3}$$

By (2) and (3) we obtain the desired result.

Proof of (b). In this case, $\mathbf{v}' = \langle 0, a_2, a_3 \rangle$ and $\mathbf{w}' = \langle 0, b_2, b_3 \rangle$. The area S of the parallelogram spanned by $\mathbf{v}'$ and $\mathbf{w}'$ is

$$S = \|\mathbf{v}' \times \mathbf{w}'\| \tag{4}$$

We compute the cross product:

$$\mathbf{v}' \times \mathbf{w}' = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & a_2 & a_3 \\ 0 & b_2 & b_3 \end{vmatrix} = \begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 0 & a_3 \\ 0 & b_3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 0 & a_2 \\ 0 & b_2 \end{vmatrix} \mathbf{k} = (a_2 b_3 - a_3 b_2)\mathbf{i}$$

Hence, by (4) we get

$$S = \|(a_2 b_3 - a_3 b_2)\,\mathbf{i}\| = |a_2 b_3 - a_3 b_2|\|\mathbf{i}\| = |a_2 b_3 - a_3 b_2| \tag{5}$$

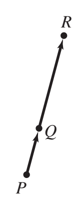
We now identify the $\mathbf{i}$ component of $\mathbf{v} \times \mathbf{w}$ as seen in the proof of part (a):

$$\begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix} = a_2 b_3 - a_3 b_2 \tag{6}$$

By (5) and (6) we obtain the desired result.

53. Show that three points P, Q, R are collinear (lie on a line) if and only if $\overrightarrow{PQ} \times \overrightarrow{PR} = \mathbf{0}$.

SOLUTION The points P, Q, and R lie on one line if and only if the vectors $\overrightarrow{PQ}$ and $\overrightarrow{PR}$ are parallel. By basic properties of the cross product this is equivalent to $\overrightarrow{PQ} \times \overrightarrow{PR} = \mathbf{0}$.



54. Use the result of Exercise 53 to determine whether the points P, Q, and R are collinear, and if not, find a vector normal to the plane containing them.

(a) $P = (2, 1, 0)$, $Q = (1, 5, 2)$, $R = (-1, 13, 6)$

(b) $P = (2, 1, 0)$, $Q = (-3, 21, 10)$, $R = (5, -2, 9)$

(c) $P = (1, 1, 0)$, $Q = (1, -2, -1)$, $R = (3, 2, -4)$

SOLUTION

(a) Let $P = (2, 1, 0)$, $Q = (1, 5, 2)$, $R = (-1, 13, 6)$. By the result of Exercise 53, the points are collinear if and only if $\overrightarrow{PQ} \times \overrightarrow{PR} = \mathbf{0}$. We compute these vectors:

$$\overrightarrow{PQ} = \langle 1-2, 5-1, 2-0\rangle = \langle -1, 4, 2\rangle = -\mathbf{i} + 4\mathbf{j} + 2\mathbf{k}$$
$$\overrightarrow{PR} = \langle -1-2, 13-1, 6-0\rangle = \langle -3, 12, 6\rangle = -3\mathbf{i} + 12\mathbf{j} + 6\mathbf{k}$$

The cross product of these vectors is

$$\overrightarrow{PQ} \times \overrightarrow{PR} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -1 & 4 & 2 \\ -3 & 12 & 6 \end{vmatrix} = \begin{vmatrix} 4 & 2 \\ 12 & 6 \end{vmatrix}\mathbf{i} - \begin{vmatrix} -1 & 2 \\ -3 & 6 \end{vmatrix}\mathbf{j} + \begin{vmatrix} -1 & 4 \\ -3 & 12 \end{vmatrix}\mathbf{k}$$
$$= (24-24)\mathbf{i} - (-6+6)\mathbf{j} + (-12+12)\mathbf{k} = \mathbf{0}$$

The cross product is the zero vector, hence the points P, Q, R are collinear.

(b) Let $P = (2, 1, 0)$, $Q = (-3, 21, 10)$, $R = (5, -2, 9)$. To check if $\overrightarrow{PQ} \times \overrightarrow{PR} = \mathbf{0}$ we first compute these vectors:

$$\overrightarrow{PQ} = \langle -3-2, 21-1, 10-0\rangle = \langle -5, 20, 10\rangle = -5\mathbf{i} + 20\mathbf{j} + 10\mathbf{k}$$
$$\overrightarrow{PR} = \langle 5-2, -2-1, 9-0\rangle = \langle 3, -3, 9\rangle = 3\mathbf{i} - 3\mathbf{j} + 9\mathbf{k}$$

We find the cross product:

$$\overrightarrow{PQ} \times \overrightarrow{PR} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -5 & 20 & 10 \\ 3 & -3 & 9 \end{vmatrix} = \begin{vmatrix} 20 & 10 \\ -3 & 9 \end{vmatrix}\mathbf{i} - \begin{vmatrix} -5 & 10 \\ 3 & 9 \end{vmatrix}\mathbf{j} + \begin{vmatrix} -5 & 20 \\ 3 & -3 \end{vmatrix}\mathbf{k}$$
$$= (180+30)\mathbf{i} - (-45-30)\mathbf{j} + (15-60)\mathbf{k} = 210\mathbf{i} + 75\mathbf{j} - 45\mathbf{k} \neq \mathbf{0}$$

The cross product is not the zero vector, hence the points P, Q and R are not collinear.

(c) Let $P = (1, 1, 0)$, $Q = (1, -2, -1)$, $R = (3, 2, -4)$. These points are not collinear if $\overrightarrow{PQ} \times \overrightarrow{PR} \neq \mathbf{0}$. We find $\overrightarrow{PQ}$ and $\overrightarrow{PR}$:

$$\overrightarrow{PQ} = \langle 1-1, -2-1, -1-0\rangle = \langle 0, -3, -1\rangle = -3\mathbf{j} - \mathbf{k}$$
$$\overrightarrow{PR} = \langle 3-1, 2-1, -4-0\rangle = \langle 2, 1, -4\rangle = 2\mathbf{i} + \mathbf{j} - 4\mathbf{k}$$

Thus,

$$\overrightarrow{PQ} \times \overrightarrow{PR} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & -3 & -1 \\ 2 & 1 & -4 \end{vmatrix} = \begin{vmatrix} -3 & -1 \\ 1 & -4 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 0 & -1 \\ 2 & -4 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 0 & -3 \\ 2 & 1 \end{vmatrix}\mathbf{k}$$
$$= (12+1)\mathbf{i} - (0+2)\mathbf{j} + (0+6)\mathbf{k} = 13\mathbf{i} - 2\mathbf{j} + 6\mathbf{k}$$

Since $\overrightarrow{PQ} \times \overrightarrow{PR} \neq \mathbf{0}$, the points P, Q, R are not collinear, rather, there is exactly one plane containing them. A vector normal to this plane is orthogonal to $\overrightarrow{PQ}$ and $\overrightarrow{PR}$. The cross product $\overrightarrow{PQ} \times \overrightarrow{PR} = 13\mathbf{i} - 2\mathbf{j} + 6\mathbf{k}$ is such a vector.

55. Solve the equation $\langle 1, 1, 1\rangle \times \mathbf{X} = \langle 1, -1, 0\rangle$, where $\mathbf{X} = \langle x, y, z\rangle$. *Note:* There are infinitely many solutions.

SOLUTION Let $\mathbf{X} = \langle a, b, c\rangle$. We compute the cross product:

$$\langle 1, 1, 1\rangle \times \langle a, b, c\rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & 1 \\ a & b & c \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ b & c \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 1 \\ a & c \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 1 \\ a & b \end{vmatrix}\mathbf{k}$$
$$= (c-b)\mathbf{i} - (c-a)\mathbf{j} + (b-a)\mathbf{k} = \langle c-b, a-c, b-a\rangle$$

The equation for $\mathbf{X}$ is, thus,

$$\langle c-b, a-c, b-a\rangle = \langle 1, -1, 0\rangle$$

Equating corresponding components we get

$$\begin{aligned} c-b &= 1 \\ a-c &= -1 \\ b-a &= 0 \end{aligned}$$

The third equation implies $a = b$. Substituting in the first and second equations gives

$$\begin{aligned} c-a &= 1 \\ a-c &= -1 \end{aligned} \quad \Rightarrow \quad c = a+1$$

The solution is thus, $b = a$, $c = a + 1$. The corresponding solutions $\mathbf{X}$ are

$$\mathbf{X} = \langle a, b, c \rangle = \langle a, a, a + 1 \rangle$$

One possible solution is obtained for $a = 0$, that is, $\mathbf{X} = \langle 0, 0, 1 \rangle$.

56. Explain geometrically why $\langle 1, 1, 1 \rangle \times \mathbf{X} = \langle 1, 0, 0 \rangle$ has no solution, where $\mathbf{X} = \langle x, y, z \rangle$.

SOLUTION The cross product vector $\langle 1, 0, 0 \rangle$ must be orthogonal to the vector $\langle 1, 1, 1 \rangle$. This condition is not satisfied since

$$\langle 1, 1, 1 \rangle \cdot \langle 1, 0, 0 \rangle = 1 \cdot 1 + 1 \cdot 0 + 1 \cdot 0 = 1 \neq 0$$

Therefore, there is no vector $\mathbf{X}$ that satisfies the equation.

57. Let $\mathbf{X} = \langle x, y, z \rangle$. Show that $\mathbf{i} \times \mathbf{X} = \mathbf{v}$ has a solution if and only if $\mathbf{v}$ is contained in the yz-plane (the $\mathbf{i}$-component is zero).

SOLUTION The cross product vector $\mathbf{i} \times \mathbf{X} = \mathbf{v}$ must be orthogonal to the vector $\mathbf{i} = \langle 1, 0, 0 \rangle$. This condition is true if and only if $\langle 1, 0, 0 \rangle \cdot \mathbf{v} = 0$, which is true if and only if the $\mathbf{i}$-component of $\mathbf{v}$ is zero (that is, $\mathbf{v}$ is in the yz-plane).

58. Suppose that vectors $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$ are mutually orthogonal—that is, $\mathbf{u} \perp \mathbf{v}$, $\mathbf{u} \perp \mathbf{w}$, and $\mathbf{v} \perp \mathbf{w}$. Prove that $(\mathbf{u} \times \mathbf{v}) \times \mathbf{w} = \mathbf{0}$ and $\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = \mathbf{0}$.

SOLUTION The cross product $\mathbf{u} \times \mathbf{v}$ is orthogonal to $\mathbf{u}$ and $\mathbf{v}$, hence it is parallel to $\mathbf{w}$. The cross product of parallel vectors is the zero vector, hence $(\mathbf{u} \times \mathbf{v}) \times \mathbf{w} = \mathbf{0}$. Similarly, the cross product $\mathbf{v} \times \mathbf{w}$ is orthogonal to $\mathbf{v}$ and $\mathbf{w}$, hence it is parallel to $\mathbf{u}$. Since the cross product of parallel vectors is the zero vector, we conclude that $\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = \mathbf{0}$.

*In Exercises 59–62: The **torque** about the origin O due to a force $\mathbf{F}$ acting on an object with position vector $\mathbf{r}$ is the vector quantity $\tau = \mathbf{r} \times \mathbf{F}$. If several forces $\mathbf{F}_j$ act at positions $\mathbf{r}_j$, then the net torque (units: N-m or lb-ft) is the sum*

$$\tau = \sum \mathbf{r}_j \times \mathbf{F}_j$$

Torque measures how much the force causes the object to rotate. By Newton's Laws, τ is equal to the rate of change of angular momentum.

59. Calculate the torque τ about O acting at the point P on the mechanical arm in Figure 21(A), assuming that a 25-N force acts as indicated. Ignore the weight of the arm itself.

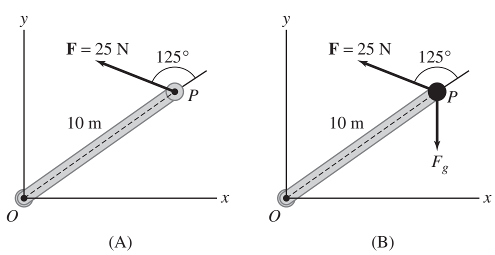


FIGURE 21

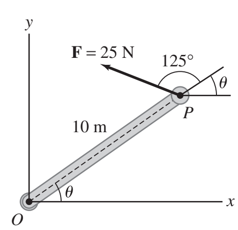
SOLUTION We denote by O and P the points shown in the figure and compute the position vector $\mathbf{r} = \overrightarrow{OP}$ and the force vector $\mathbf{F}$.



Denoting by θ the angle between the arm and the x-axis we have

$$\mathbf{r} = \overrightarrow{OP} = 10\,(\cos\theta\mathbf{i} + \sin\theta\mathbf{j})$$

The angle between the force vector $\mathbf{F}$ and the x-axis is $(\theta + 125^\circ)$, hence,

$$\mathbf{F} = 25\left(\cos\left(\theta + 125^\circ\right)\mathbf{i} + \sin\left(\theta + 125^\circ\right)\mathbf{j}\right)$$

The torque τ about O acting at the point P is the cross product $\tau = \mathbf{r} \times \mathbf{F}$. We compute it using the cross products of the unit vectors $\mathbf{i}$ and $\mathbf{j}$:

$$\begin{aligned}
\tau = \mathbf{r} \times \mathbf{F} &= 10\,(\cos\theta\mathbf{i} + \sin\theta\mathbf{j}) \times 25\left(\cos\left(\theta + 125^\circ\right)\mathbf{i} + \sin\left(\theta + 125^\circ\right)\mathbf{j}\right) \\
&= 250\,(\cos\theta\mathbf{i} + \sin\theta\mathbf{j}) \times \left(\cos\left(\theta + 125^\circ\right)\mathbf{i} + \sin\left(\theta + 125^\circ\right)\mathbf{j}\right) \\
&= 250\left(\cos\theta\sin\left(\theta + 125^\circ\right)\mathbf{k} + \sin\theta\cos\left(\theta + 125^\circ\right)(-\mathbf{k})\right) \\
&= 250\left(\sin\left(\theta + 125^\circ\right)\cos\theta - \sin\theta\cos\left(\theta + 125^\circ\right)\right)\mathbf{k}
\end{aligned}$$

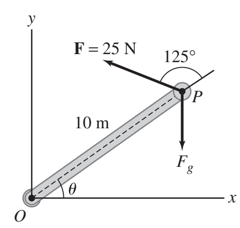
We now use the identity $\sin\alpha\cos\beta - \sin\beta\cos\alpha = \sin(\alpha - \beta)$ to obtain

$$\tau = 250\sin\left(\theta + 125^\circ - \theta\right)\mathbf{k} = 250\sin 125^\circ\mathbf{k} \approx 204.79\mathbf{k}$$

60. Calculate the net torque about O at P, assuming that a 30-kg mass is attached at P [Figure 21(B)]. The force $\mathbf{F}_g$ due to gravity on a mass m has magnitude $9.8m$ m/s^2 in the downward direction.

SOLUTION We denote by τ_1 and τ_2 the torques due to the forces $\mathbf{F}$ and $\mathbf{F}_g$ respectively. Let θ denote the angle between the arm and the x-axis, and $\mathbf{r} = \overrightarrow{OP}$ the position vector. The net torque about O at P is

$$\tau = \mathbf{r} \times \mathbf{F} + \mathbf{r} \times \mathbf{F}_g = \tau_1 + \tau_2 \tag{1}$$



In Exercise 59 we found that

$$\tau_1 = 204.79\mathbf{k} \tag{2}$$

We compute the torque τ_2:

$$\begin{aligned}
\tau_2 = \mathbf{r} \times \mathbf{F}_g &= 10\,(\cos\theta\mathbf{i} + \sin\theta\mathbf{j}) \times 9.8 \cdot 30\,(-\mathbf{j}) \\
&= 2940\,(\cos\theta\mathbf{i} + \sin\theta\mathbf{j}) \times (-\mathbf{j}) \\
&= 2940\cos\theta\,(-\mathbf{k}) = -2940\cos\theta\mathbf{k}
\end{aligned} \tag{3}$$

Combining (1), (2), and (3) we obtain

$$\tau = 204.79\mathbf{k} - 2940\cos\theta\mathbf{k} = (204.79 - 2940\cos\theta)\mathbf{k}$$

61. Let τ be the net torque about O acting on the robotic arm of Figure 22. Assume that the two segments of the arms have mass m_1 and m_2 (in kg) and that a weight of m_3 kg is located at the endpoint P. In calculating the torque, we may assume that the entire mass of each arm segment lies at the midpoint of the arm (its center of mass). Show that the position vectors of the masses m_1, m_2, and m_3 are

$$\begin{aligned}
\mathbf{r}_1 &= \frac{1}{2}L_1(\sin\theta_1\mathbf{i} + \cos\theta_1\mathbf{j}) \\
\mathbf{r}_2 &= L_1(\sin\theta_1\mathbf{i} + \cos\theta_1\mathbf{j}) + \frac{1}{2}L_2(\sin\theta_2\mathbf{i} - \cos\theta_2\mathbf{j}) \\
\mathbf{r}_3 &= L_1(\sin\theta_1\mathbf{i} + \cos\theta_1\mathbf{j}) + L_2(\sin\theta_2\mathbf{i} - \cos\theta_2\mathbf{j})
\end{aligned}$$

Then show that

$$\tau = -g\left(L_1\left(\frac{1}{2}m_1 + m_2 + m_3\right)\sin\theta_1 + L_2\left(\frac{1}{2}m_2 + m_3\right)\sin\theta_2\right)\mathbf{k}$$

where $g = 9.8m/s^2$. To simplify the computation, note that all three gravitational forces act in the $-\mathbf{j}$ direction, so the $\mathbf{j}$-components of the position vectors $\mathbf{r}_i$ do not contribute to the torque.

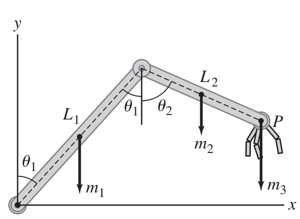


FIGURE 22

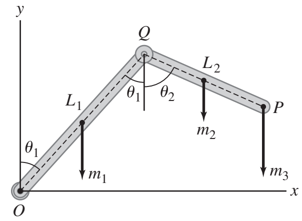
SOLUTION We denote by O, P, and Q the points shown in the figure.



The coordinates of O and Q are

$$O = (0, 0), \quad Q = (L_1 \sin\theta_1, L_1 \cos\theta_1)$$

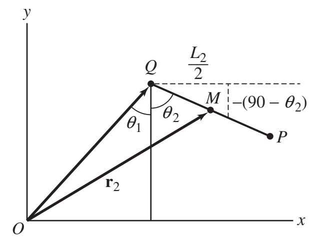
The midpoint of the segment OQ is, thus,

$$\left(\frac{0 + L_1 \sin\theta_1}{2}, \frac{0 + L_1 \cos\theta_1}{2}\right) = \left(\frac{L_1 \sin\theta_1}{2}, \frac{L_1 \cos\theta_1}{2}\right)$$

Since the mass m_1 is assumed to lie at the midpoint of the arm, the position vector of m_1 is

$$\mathbf{r}_1 = \frac{L_1}{2}(\sin\theta_1\mathbf{i} + \cos\theta_1\mathbf{j}) \tag{1}$$

We now find the position vector $\mathbf{r}_2$ of m_2. We have (see figure)



$$\mathbf{r}_2 = \overrightarrow{OQ} + \overrightarrow{QM} \tag{2}$$

$$\overrightarrow{OQ} = L_1 \sin\theta_1\mathbf{i} + L_1 \cos\theta_1\mathbf{j} = L_1(\sin\theta_1\mathbf{i} + \cos\theta_1\mathbf{j}) \tag{3}$$

The vector $\overrightarrow{QM}$ makes an angle of $-\left(90^\circ - \theta_2\right)$ with the x axis and has length $\frac{L_2}{2}$, hence,

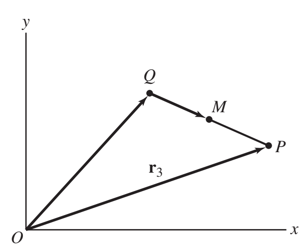
$$\overrightarrow{QM} = \frac{L_2}{2}\left(\cos\left(-\left(90^\circ - \theta_2\right)\right)\mathbf{i} + \sin\left(-\left(90^\circ - \theta_2\right)\right)\mathbf{j}\right) = \frac{L_2}{2}(\sin\theta_2\mathbf{i} - \cos\theta_2\mathbf{j}) \tag{4}$$

Combining (2), (3) and (4) we get

$$\mathbf{r}_2 = L_1(\sin\theta_1\mathbf{i} + \cos\theta_1\mathbf{j}) + \frac{L_2}{2}(\sin\theta_2\mathbf{i} - \cos\theta_2\mathbf{j}) \tag{5}$$

Finally, we find the position vector $\mathbf{r}_3$:

$$\mathbf{r}_3 = \overrightarrow{OQ} + \overrightarrow{QP} = \overrightarrow{OQ} + 2\overrightarrow{QM}$$



Substituting (3) and (4) we get

$$\mathbf{r}_3 = L_1(\sin\theta_1\mathbf{i} + \cos\theta_1\mathbf{j}) + L_2(\sin\theta_2\mathbf{i} - \cos\theta_2\mathbf{j}) \tag{6}$$

The net torque is the following vector:

$$\tau = \mathbf{r}_1 \times (-m_1 g\mathbf{j}) + \mathbf{r}_2 \times (-m_2 g\mathbf{j}) + \mathbf{r}_3 \times (-m_3 g\mathbf{j})$$

In computing the cross products, the $\mathbf{j}$ components of $\mathbf{r}_1$, $\mathbf{r}_2$ and $\mathbf{r}_3$ do not contribute to the torque since $\mathbf{j} \times \mathbf{j} = \mathbf{0}$. We thus consider only the $\mathbf{i}$ components of $\mathbf{r}_1$, $\mathbf{r}_2$ and $\mathbf{r}_3$ in (1), (5) and (6). This gives

$$\begin{aligned}
\tau &= \frac{L_1}{2}\sin\theta_1 \mathbf{i} \times (-m_1 g\mathbf{j}) + \left(L_1 \sin\theta_1 + \frac{L_2}{2}\sin\theta_2\right)\mathbf{i} \times (-m_2 g\mathbf{j}) + (L_1 \sin\theta_1 + L_2 \sin\theta_2)\,\mathbf{i} \times (-m_3 g\mathbf{j}) \\
&= -\frac{L_1 m_1 g \sin\theta_1}{2}\mathbf{k} - \left(L_1 m_2 g \sin\theta_1 + \frac{L_2 m_2 g}{2}\sin\theta_2\right)\mathbf{k} - (L_1 m_3 g \sin\theta_1 + L_2 m_3 g \sin\theta_2)\,\mathbf{k} \\
&= -g\left(L_1\left(\frac{1}{2}m_1 + m_2 + m_3\right)\sin\theta_1 + L_2\left(\frac{1}{2}m_2 + m_3\right)\sin\theta_2\right)\mathbf{k}
\end{aligned}$$

62. Continuing with Exercise 61, suppose that $L_1 = 3$ m, $L_2 = 2$ m, $m_1 = 15$ kg, $m_2 = 20$ kg, and $m_3 = 18$ kg. If the angles θ_1, θ_2 are equal (say, to θ), what is the maximum allowable value of θ if we assume that the robotic arm can sustain a maximum torque of 1200 N-m?

SOLUTION Setting the given values $L_1 = 3$, $L_2 = 2$, $m_1 = 15$, $m_2 = 20$, $m_3 = 18$, and $\theta_1 = \theta_2 = \theta$ in the formula for τ obtained in Exercise 61 we get

$$\tau = -g\left(3\left(\frac{15}{2} + 20 + 18\right)\sin\theta + 2\left(\frac{20}{2} + 18\right)\sin\theta\right)\mathbf{k} = -1886.5\sin\theta\mathbf{k}$$

Thus,

$$\|\tau\| = 1886.5\sin\theta$$

Since the maximum torque sustained by the robotic arm is 1200 ft-lbs, we have

$$\begin{aligned}
1886.5\sin\theta &\le 1200 \\
\sin\theta &\le \frac{1200}{1886.5} \approx 0.636
\end{aligned}$$

The solution for acute angles is

$$\theta \le 39.5^\circ$$

The maximum allowable value of θ is $\theta = 39.5^\circ$.

Further Insights and Challenges

63. Show that 3×3 determinants can be computed using the **diagonal rule**: Repeat the first two columns of the matrix and form the products of the numbers along the six diagonals indicated. Then add the products for the diagonals that slant from left to right and subtract the products for the diagonals that slant from right to left.

$$\det(A) = \left|\begin{array}{ccc|ccc} a_{11} & a_{12} & a_{13} & a_{11} & a_{12} & \\ a_{21} & a_{22} & a_{23} & a_{21} & a_{22} & \\ a_{31} & a_{32} & a_{33} & a_{31} & a_{32} & \\ - & - & - & + & + & + \end{array}\right.$$

$$= a_{11}a_{22}a_{33} + a_{12}a_{23}a_{31} + a_{13}a_{21}a_{32} - a_{13}a_{22}a_{31} - a_{11}a_{23}a_{32} - a_{12}a_{21}a_{33}$$

SOLUTION Using the definition of 3×3 determinants given in Eq. (2) we get

$$\det(A) = a_{11}\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} - a_{12}\begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} + a_{13}\begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix}$$

Using the definition of 2×2 determinants given in Eq. (1) we get

$$\begin{aligned}
\det(A) &= a_{11}(a_{22}a_{33} - a_{23}a_{32}) - a_{12}(a_{21}a_{33} - a_{23}a_{31}) + a_{13}(a_{21}a_{32} - a_{22}a_{31}) \\
&= a_{11}a_{22}a_{33} - a_{11}a_{23}a_{32} - a_{12}a_{21}a_{33} + a_{12}a_{23}a_{31} + a_{13}a_{21}a_{32} - a_{13}a_{22}a_{31} \\
&= a_{11}a_{22}a_{33} + a_{12}a_{23}a_{31} + a_{13}a_{21}a_{32} - a_{13}a_{22}a_{31} - a_{11}a_{23}a_{32} - a_{12}a_{21}a_{33}
\end{aligned}$$

64. Use the diagonal rule to calculate $\begin{vmatrix} 2 & 4 & 3 \\ 0 & 1 & -7 \\ -1 & 5 & 3 \end{vmatrix}$.

SOLUTION We form the following matrix:

$$\begin{array}{ccc|cc} 2 & 4 & 3 & 2 & 4 \\ 0 & 1 & -7 & 0 & 1 \\ -1 & 5 & 3 & -1 & 5 \end{array}$$

We now form the diagonals which slant from left to right and the diagonals which slant from right to left and assign corresponding sign to each diagonal:

$$\begin{array}{ccccc} 2 & 4 & 3 & 2 & 4 \\ 0 & 1 & -7 & 0 & 1 \\ -1 & 5 & 3 & -1 & 5 \end{array}$$
$$- \quad - \quad - \qquad + \quad + \quad +$$

We add the products for the diagonals with a positive sign and subtract the products for the diagonals with a negative sign. This gives

$$\begin{vmatrix} 2 & 4 & 3 \\ 0 & 1 & -7 \\ -1 & 5 & 3 \end{vmatrix} = 2 \cdot 1 \cdot 3 + 4 \cdot (-7) \cdot (-1) + 3 \cdot 0 \cdot 5 - 3 \cdot 1 \cdot (-1) - 2 \cdot (-7) \cdot 5 - 4 \cdot 0 \cdot 3 = 107$$

65. Prove that $\mathbf{v} \times \mathbf{w} = \mathbf{v} \times \mathbf{u}$ if and only if $\mathbf{u} = \mathbf{w} + \lambda\mathbf{v}$ for some scalar λ. Assume that $\mathbf{v} \neq \mathbf{0}$.

SOLUTION Transferring sides and using the distributive law and the property of parallel vectors, we obtain the following equivalent equalities:

$$\begin{aligned} \mathbf{v} \times \mathbf{w} &= \mathbf{v} \times \mathbf{u} \\ \mathbf{0} &= \mathbf{v} \times \mathbf{u} - \mathbf{v} \times \mathbf{w} \\ \mathbf{0} &= \mathbf{v} \times (\mathbf{u} - \mathbf{w}) \end{aligned}$$

This holds if and only if there exists a scalar λ such that

$$\begin{aligned} \mathbf{u} - \mathbf{w} &= \lambda\mathbf{v} \\ \mathbf{u} &= \mathbf{w} + \lambda\mathbf{v} \end{aligned}$$

66. Use Eq. (10) to prove the Cauchy–Schwarz inequality:

$$|\mathbf{v} \cdot \mathbf{w}| \le \|\mathbf{v}\| \; \|\mathbf{w}\|$$

Show that equality holds if and only if $\mathbf{w}$ is a multiple of $\mathbf{v}$ or at least one of $\mathbf{v}$ and $\mathbf{w}$ is zero.

SOLUTION Transferring sides in Eq. (10) we get

$$(\mathbf{v} \cdot \mathbf{w})^2 = \|\mathbf{v}\|^2\|\mathbf{w}\|^2 - \|\mathbf{v} \times \mathbf{w}\|^2 \tag{1}$$

Since $\|\mathbf{v} \times \mathbf{w}\|^2 \ge 0$, we have

$$(\mathbf{v} \cdot \mathbf{w})^2 \le \|\mathbf{v}\|^2\|\mathbf{w}\|^2$$

Taking the square root of both sides gives

$$|\mathbf{v} \cdot \mathbf{w}| \le \|\mathbf{v}\|\|\mathbf{w}\|$$

Equality $|\mathbf{v} \cdot \mathbf{w}| = \|\mathbf{v}\|\|\mathbf{w}\|$ holds if and only if $(\mathbf{v} \cdot \mathbf{w})^2 = \|\mathbf{v}\|^2\|\mathbf{w}\|^2$, that is by (1), if and only if $\|\mathbf{v} \times \mathbf{w}\| = 0$, or $\mathbf{v} \times \mathbf{w} = \mathbf{0}$. This is equivalent to $\mathbf{w} = \lambda\mathbf{v}$ for some scalar λ, or $\mathbf{v} = \mathbf{0}$ (Theorem 3 (c)).

67. Show that if $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$ are nonzero vectors and $(\mathbf{u} \times \mathbf{v}) \times \mathbf{w} = \mathbf{0}$, then either (i) $\mathbf{u}$ and $\mathbf{v}$ are parallel, or (ii) $\mathbf{w}$ is orthogonal to $\mathbf{u}$ and $\mathbf{v}$.

SOLUTION By the theorem on basic properties of the cross product, part (c), it follows that $(\mathbf{u} \times \mathbf{v}) \times \mathbf{w} = \mathbf{0}$ if and only if

- $\mathbf{u} \times \mathbf{v} = \mathbf{0}$ or
- $\mathbf{w} = \lambda\,(\mathbf{u} \times \mathbf{v})$

We consider the two possibilities.

1. $\mathbf{u} \times \mathbf{v} = \mathbf{0}$ is equivalent to $\mathbf{u}$ and $\mathbf{v}$ being parallel vectors or one of them being the zero vector.
2. The cross product $\mathbf{u} \times \mathbf{v}$ is orthogonal to $\mathbf{u}$ and $\mathbf{v}$, hence $\mathbf{w} = \lambda\,(\mathbf{u} \times \mathbf{v})$ implies that $\mathbf{w}$ is also orthogonal to $\mathbf{u}$ and $\mathbf{v}$ (for $\lambda \neq 0$) or $\mathbf{w} = \mathbf{0}$ (for $\lambda = 0$).

Conclusions: $(\mathbf{u} \times \mathbf{v}) \times \mathbf{w} = \mathbf{0}$ implies that either $\mathbf{u}$ and $\mathbf{v}$ are parallel, or $\mathbf{w}$ is orthogonal to $\mathbf{u}$ and $\mathbf{v}$, or one of the vectors $\mathbf{u}$, $\mathbf{v}$, $\mathbf{w}$ is the zero vector.

68. Suppose that $\mathbf{u}$, $\mathbf{v}$, $\mathbf{w}$ are nonzero and

$$(\mathbf{u} \times \mathbf{v}) \times \mathbf{w} = \mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = \mathbf{0}$$

Show that $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$ are either mutually parallel or mutually perpendicular. *Hint:* Use Exercise 67.

SOLUTION First notice that since $\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = \mathbf{0}$, also,

$$(\mathbf{v} \times \mathbf{w}) \times \mathbf{u} = -\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = \mathbf{0}$$

Using Exercise 67 for nonzero vectors, we obtain

$$(\mathbf{u} \times \mathbf{v}) \times \mathbf{w} = \mathbf{0} \Rightarrow \mathbf{u} \parallel \mathbf{v} \text{ or } (\mathbf{w} \perp \mathbf{u} \text{ and } \mathbf{w} \perp \mathbf{v}) \tag{1}$$

$$(\mathbf{v} \times \mathbf{w}) \times \mathbf{u} = \mathbf{0} \Rightarrow \mathbf{w} \parallel \mathbf{v} \text{ or } (\mathbf{u} \perp \mathbf{v} \text{ and } \mathbf{u} \perp \mathbf{w}) \tag{2}$$

We consider each of the two possibilities in (1):

Case 1: $\mathbf{u} \parallel \mathbf{v}$ In this case, $\mathbf{u}$ is not orthogonal to $\mathbf{v}$. Hence, by (2), $\mathbf{w} \parallel \mathbf{v}$ must hold. Thus, the vectors $\mathbf{u}$, $\mathbf{v}$ and $\mathbf{w}$ are parallel.

Case 2: $\mathbf{w} \perp \mathbf{u}$ and $\mathbf{w} \perp \mathbf{v}$ In this case, $\mathbf{w}$ and $\mathbf{v}$ are not parallel. Hence, by (2), $\mathbf{u} \perp \mathbf{v}$ and $\mathbf{u} \perp \mathbf{w}$ must hold. Thus, the vectors $\mathbf{u}$, $\mathbf{v}$ and $\mathbf{w}$ are mutually perpendicular.

Conclusion: If $(\mathbf{u} \times \mathbf{v}) \times \mathbf{w} = \mathbf{0}$ and $\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = \mathbf{0}$ for nonzero vectors $\mathbf{u}$, $\mathbf{v}$, $\mathbf{w}$ then these vectors are parallel or mutually perpendicular.

69. Let $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$ be nonzero vectors, and set

$$\mathbf{v} = \mathbf{a} \times (\mathbf{b} \times \mathbf{c}), \qquad \mathbf{w} = (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}$$

(a) Prove that

(i) $\mathbf{v}$ lies in the plane spanned by $\mathbf{b}$ and $\mathbf{c}$.

(ii) $\mathbf{v}$ is orthogonal to $\mathbf{a}$.

(b) Prove that $\mathbf{w}$ also satisfies (i) and (ii). Conclude that $\mathbf{v}$ and $\mathbf{w}$ are parallel.

(c) Show algebraically that $\mathbf{v} = \mathbf{w}$ (Figure 23).

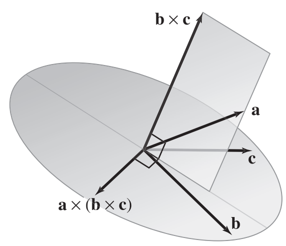


FIGURE 23

SOLUTION

(a) Since $\mathbf{v}$ is the cross product of $\mathbf{a}$ and another vector $(\mathbf{b} \times \mathbf{c})$, then $\mathbf{v}$ is orthogonal to $\mathbf{a}$. Furthermore, $\mathbf{v}$ is orthogonal to $(\mathbf{b} \times \mathbf{c})$, so it is orthogonal to the normal vector to the plane containing $\mathbf{b}$ and $\mathbf{c}$, so $\mathbf{v}$ must be in that plane.

(b) $\mathbf{w} \cdot \mathbf{a} = ((\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}) \cdot \mathbf{a} = (\mathbf{a} \cdot \mathbf{c})(\mathbf{b} \cdot \mathbf{a}) - (\mathbf{a} \cdot \mathbf{b})(\mathbf{c} \cdot \mathbf{a}) = 0$ (since $\mathbf{a} \cdot \mathbf{c} = \mathbf{c} \cdot \mathbf{a}$ and $\mathbf{b} \cdot \mathbf{a} = \mathbf{a} \cdot \mathbf{b}$). Thus, $\mathbf{w}$ is orthogonal to $\mathbf{a}$. Also, $\mathbf{w}$ is a multiple of $\mathbf{b}$ and $\mathbf{c}$, so $\mathbf{w}$ must be in the plane containing $\mathbf{b}$ and $\mathbf{c}$.

Now, if $\mathbf{a}$ is perpendicular to the plane spanned by $\mathbf{b}$ and $\mathbf{c}$, then $\mathbf{a}$ is parallel to $\mathbf{b} \times \mathbf{c}$ and so $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = 0$, which means $\mathbf{v} = 0$, but also $\mathbf{a} \cdot \mathbf{b} = \mathbf{a} \cdot \mathbf{c} = 0$ which means $\mathbf{w} = 0$. Thus, $\mathbf{v}$ and $\mathbf{w}$ are parallel (in fact, equal).

Now, if $\mathbf{a}$ is not perpendicular to the plane spanned by $\mathbf{b}$ and $\mathbf{c}$, then the set of vectors on that plane that are also perpendicular to $\mathbf{a}$ form a line, and thus all such vectors are parallel. We conclude that $\mathbf{v}$ and $\mathbf{w}$, being on that plane and perpendicular to $\mathbf{a}$, are parallel.

(c) On the one hand,

$$\begin{aligned}
\mathbf{v} = \mathbf{a} \times (\mathbf{b} \times \mathbf{c}) &= \langle a_1, a_2, a_3 \rangle \times \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} \\
&= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ (b_2c_3 - b_3c_2) & (b_3c_1 - b_1c_3) & (b_1c_2 - b_2c_1) \end{vmatrix} \\
&= \big\langle a_2(b_1c_2 - b_2c_1) - a_3(b_3c_1 - b_1c_3), a_3(b_2c_3 - b_3c_2) - a_1(b_1c_2 - b_2c_1), \\
&\quad a_1(b_3c_1 - b_1c_3) - a_2(b_2c_3 - b_3c_2)\big\rangle
\end{aligned}$$

but on the other hand,

$$\begin{aligned}
\mathbf{w} &= (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c} \\
&= (a_1c_1 + a_2c_2 + a_3c_3)\langle b_1, b_2, b_3 \rangle - (a_1b_1 + a_2b_2 + a_3b_3)\langle c_1, c_2, c_3 \rangle
\end{aligned}$$

$$= \langle a_2c_2b_1 + a_3c_3b_1 - a_2b_2c_1 - a_3b_3c_1, a_1c_1b_2 + a_3c_3b_2 - a_1b_1c_2 - a_3b_3c_2,$$
$$a_1c_1b_3 + a_2c_2b_3 - a_1b_1c_3 - a_2b_2c_3\rangle$$
$$= \langle a_2(b_1c_2 - b_2c_1) - a_3(b_3c_1 - b_1c_3), a_3(b_2c_3 - b_3c_2) - a_1(b_1c_2 - b_2c_1),$$
$$a_1(b_3c_1 - b_1c_3) - a_2(b_2c_3 - b_3c_2)\rangle$$

which is the same as $\mathbf{v}$.

70. Use Exercise 69 to prove the identity

$$(\mathbf{a} \times \mathbf{b}) \times \mathbf{c} - \mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \cdot \mathbf{b})\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{a}$$

SOLUTION We have

$$\begin{aligned}(\mathbf{a} \times \mathbf{b}) \times \mathbf{c} - \mathbf{a} \times (\mathbf{b} \times \mathbf{c}) &= -\mathbf{c} \times (\mathbf{a} \times \mathbf{b}) - \mathbf{a} \times (\mathbf{b} \times \mathbf{c}) \\ &= -[(\mathbf{c} \cdot \mathbf{b})\mathbf{a} - (\mathbf{c} \cdot \mathbf{a})\mathbf{b}] - [(\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}] \\ &= -(\mathbf{c} \cdot \mathbf{b})\mathbf{a} + (\mathbf{a} \cdot \mathbf{b})\mathbf{c} = (\mathbf{a} \cdot \mathbf{b})\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{a}\end{aligned}$$

as desired.

71. Show that if $\mathbf{a}, \mathbf{b}$ are nonzero vectors such that $\mathbf{a} \perp \mathbf{b}$, then there exists a vector $\mathbf{X}$ such that

$$\mathbf{a} \times \mathbf{X} = \mathbf{b} \qquad \boxed{13}$$

Hint: Show that if $\mathbf{X}$ is orthogonal to $\mathbf{b}$ and is not a multiple of $\mathbf{a}$, then $\mathbf{a} \times \mathbf{X}$ is a multiple of $\mathbf{b}$.

SOLUTION We define the following vectors:

$$\mathbf{X} = \frac{\mathbf{b} \times \mathbf{a}}{\|\mathbf{a}\|^2}, \quad \mathbf{c} = \mathbf{X} \times \mathbf{a} \qquad (1)$$

We show that $\mathbf{c} = \mathbf{b}$. Since $\mathbf{X}$ is orthogonal to $\mathbf{a}$ and $\mathbf{b}$, $\mathbf{X}$ is orthogonal to the plane of $\mathbf{a}$ and $\mathbf{b}$. But $\mathbf{c}$ is orthogonal to $\mathbf{X}$, hence $\mathbf{c}$ is contained in the plane of $\mathbf{a}$ and $\mathbf{b}$, that is, $\mathbf{a}$, $\mathbf{b}$ and $\mathbf{c}$ are in the same plane. Now the vectors $\mathbf{a}$, $\mathbf{b}$ and $\mathbf{c}$ are in one plane, and the vectors $\mathbf{c}$ and $\mathbf{b}$ are orthogonal to $\mathbf{a}$.

It follows that $\mathbf{c}$ and $\mathbf{b}$ are parallel. (2)

We now show that $\|\mathbf{c}\| = \|\mathbf{b}\|$. We use the cross-product identity to obtain

$$\|\mathbf{c}\|^2 = \|\mathbf{X} \times \mathbf{a}\|^2 = \|\mathbf{X}\|^2\|\mathbf{a}\|^2 - (\mathbf{X} \cdot \mathbf{a})^2$$

$\mathbf{X}$ is orthogonal to $\mathbf{a}$, hence $\mathbf{X} \cdot \mathbf{a} = 0$, and we obtain

$$\|\mathbf{c}\|^2 = \|\mathbf{X}\|^2\|\mathbf{a}\|^2 = \left\|\frac{\mathbf{b} \times \mathbf{a}}{\|\mathbf{a}\|^2}\right\|^2 \|\mathbf{a}\|^2 = \frac{1}{\|\mathbf{a}\|^4}\|\mathbf{b} \times \mathbf{a}\|^2\|\mathbf{a}\|^2 = \frac{1}{\|\mathbf{a}\|^2}\|\mathbf{b} \times \mathbf{a}\|^2$$

By the given data, $\mathbf{a}$ and $\mathbf{b}$ are orthogonal vectors, so,

$$\|\mathbf{c}\|^2 = \frac{1}{\|\mathbf{a}\|^2}\left(\|\mathbf{b}\|^2\|\mathbf{a}\|^2\right) = \|\mathbf{b}\|^2 \Rightarrow \|\mathbf{c}\| = \|\mathbf{b}\| \qquad (3)$$

By (2) and (3) it follows that $\mathbf{c} = \mathbf{b}$ or $\mathbf{c} = -\mathbf{b}$. We thus proved that the vector $\mathbf{X} = \frac{\mathbf{b} \times \mathbf{a}}{\|\mathbf{a}\|^2}$ satisfies $\mathbf{X} \times \mathbf{a} = \mathbf{b}$ or $\mathbf{X} \times \mathbf{a} = -\mathbf{b}$. If $\mathbf{X} \times \mathbf{a} = -\mathbf{b}$, then $(-\mathbf{X}) \times \mathbf{a} = \mathbf{b}$. Hence, there exists a vector $\mathbf{X}$ such that $\mathbf{X} \times \mathbf{a} = \mathbf{b}$.

72. Show that if $\mathbf{a}, \mathbf{b}$ are nonzero vectors such that $\mathbf{a} \perp \mathbf{b}$, then the set of all solutions of Eq. (13) is a line with $\mathbf{a}$ as direction vector. *Hint:* Let $\mathbf{X}_0$ be any solution (which exists by Exercise 71), and show that every other solution is of the form $\mathbf{X}_0 + \lambda\mathbf{a}$ for some scalar λ.

SOLUTION By Exercise 71 there exists a solution $\mathbf{X}_0$ of the equation $\mathbf{X} \times \mathbf{a} = \mathbf{b}$. Let $\mathbf{X}$ be any solution of this equation. Thus,

$$\mathbf{X}_0 \times \mathbf{a} = \mathbf{b}$$
$$\mathbf{X} \times \mathbf{a} = \mathbf{b}$$

We subtract the first equation from the second and use the distributive law to obtain

$$\mathbf{X} \times \mathbf{a} - \mathbf{X}_0 \times \mathbf{a} = \mathbf{b} - \mathbf{b} = \mathbf{0}$$
$$(\mathbf{X} - \mathbf{X}_0) \times \mathbf{a} = \mathbf{0} \quad \Rightarrow \quad \mathbf{a} \times (\mathbf{X} - \mathbf{X}_0) = \mathbf{0}$$

We now use the basic properties of the cross product to conclude that there exists a scalar λ such that

$$\mathbf{X} - \mathbf{x_0} = \lambda\mathbf{a} \quad \text{or} \quad \mathbf{X} = \mathbf{x_0} + \lambda\mathbf{a}$$

This is a parametric equation of the line through $\mathbf{x_0}$ with $\mathbf{a}$ as a direction vector.

73. Assume that $\mathbf{v}$ and $\mathbf{w}$ lie in the first quadrant in $\mathbf{R}^2$ as in Figure 24. Use geometry to prove that the area of the parallelogram is equal to $\det\begin{pmatrix}\mathbf{v}\\ \mathbf{w}\end{pmatrix}$.

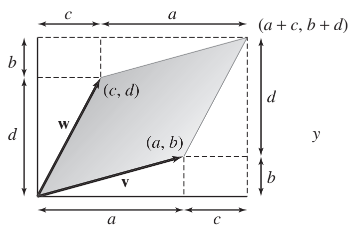

FIGURE 24

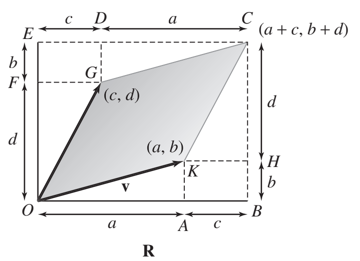
SOLUTION We denote the components of $\mathbf{u}$ and $\mathbf{v}$ by

$$\mathbf{u} = \langle c, d\rangle$$
$$\mathbf{v} = \langle a, b\rangle$$

We also denote by $O, A, B, C, D, E, F, G, H, K$ the points shown in the figure.



Since $OGCK$ is a parallelogram, it follows by geometrical properties that the triangles OFG and KHC and also the triangles DGC and AKO are congruent. It also follows that the rectangles $EFDG$ and $ABHK$ have equal areas. We use the following notation:

A: The area of the parallelogram
S: The area of the rectangle $OBCE$
S_1: The area of the rectangle $EFDG$
S_2: The area of the triangle OFG
S_3: The area of the triangle DGC

Hence,

$$A = S - 2(S_1 + S_2 + S_3) \tag{1}$$

Using the formulas for the areas of rectangles and triangles we have (see figure)

$$S = OB \cdot OE = (a + c)(d + b)$$
$$S_1 = bc, \quad S_2 = \frac{cd}{2}, \quad S_3 = \frac{ab}{2}$$

Substituting into (1) we get

$$\begin{aligned} A &= (a + c)(d + b) - 2\left(bc + \frac{cd}{2} + \frac{ab}{2}\right) \\ &= ad + ab + cd + cb - 2bc - cd - ab \qquad (2) \\ &= ad - bc \end{aligned}$$

On the other hand,

$$\det\begin{pmatrix} \mathbf{v} \\ \mathbf{w} \end{pmatrix} = \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc \tag{3}$$

By (2) and (3) we obtain the desired result.

74. Consider the tetrahedron spanned by vectors **a**, **b**, and **c** as in Figure 25(A). Let A, B, C be the faces containing the origin O, and let D be the fourth face opposite O. For each face F, let $\mathbf{v}_F$ be the vector normal to the face, pointing outside the tetrahedron, of magnitude equal to twice the area of F. Prove the relations

$$\mathbf{v}_A + \mathbf{v}_B + \mathbf{v}_C = \mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a}$$

$$\mathbf{v}_A + \mathbf{v}_B + \mathbf{v}_C + \mathbf{v}_D = 0$$

Hint: Show that $\mathbf{v}_D = (\mathbf{c} - \mathbf{b}) \times (\mathbf{b} - \mathbf{a})$.

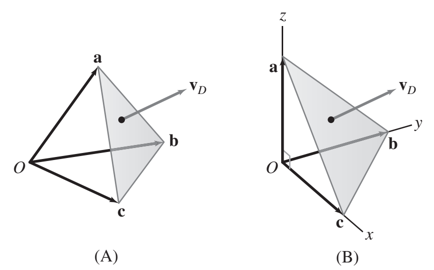


FIGURE 25 The vector $\mathbf{v}_D$ is perpendicular to the face.

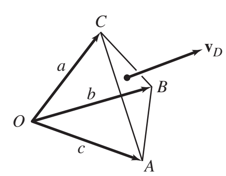
SOLUTION We first show that $\mathbf{v}_D = (\mathbf{c} - \mathbf{a}) \times (\mathbf{b} - \mathbf{a})$.



Since $\mathbf{v}_D$ is normal to the face D, it is orthogonal to the vectors $\mathbf{c} - \mathbf{a}$ and $\mathbf{b} - \mathbf{a}$, hence it is parallel to the cross product of these two vectors. In other words, there exists a scalar $\lambda > 0$ such that (using the right-hand rule)

$$\mathbf{v}_D = \lambda\,(\mathbf{c} - \mathbf{a}) \times (\mathbf{b} - \mathbf{a})$$

The area of the face D is half of the area of the parallelogram spanned by $\mathbf{c} - \mathbf{a}$ and $\mathbf{b} - \mathbf{a}$. The area of the parallelogram is $\|(\mathbf{c} - \mathbf{a}) \times (\mathbf{b} - \mathbf{a})\|$. Hence,

$$\|\mathbf{v}_D\| = \|\,(\mathbf{c} - \mathbf{a}) \times (\mathbf{b} - \mathbf{a})\,\|$$

Combining the above equations we have

$$\mathbf{v}_D = (\mathbf{c} - \mathbf{a}) \times (\mathbf{b} - \mathbf{a})$$

Now, since $\mathbf{v}_A$ is normal to the face A, it is orthogonal to the vectors **a** and **c**, therefore it is parallel to $\mathbf{c} \times \mathbf{a}$. The area of the face A is $\frac{1}{2}\|\mathbf{c} \times \mathbf{a}\|$, which is also half the length of $\mathbf{v}_A$. Hence, using the right-hand rule we get

$$\mathbf{v}_A = \mathbf{c} \times \mathbf{a}$$

Similarly, we have

$$\mathbf{v}_B = \mathbf{a} \times \mathbf{b}, \quad \mathbf{v}_C = \mathbf{b} \times \mathbf{c}$$

Combining gives us

$$\mathbf{v}_A + \mathbf{v}_B + \mathbf{v}_C = (\mathbf{c} \times \mathbf{a} + \mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c}) = (\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a})$$

We evaluate $\mathbf{v}_D$ using the distributive law:

$$\mathbf{v}_D = (\mathbf{c} - \mathbf{a}) \times (\mathbf{b} - \mathbf{a}) = (\mathbf{c} \times \mathbf{b} - \mathbf{a} \times \mathbf{b} - \mathbf{c} \times \mathbf{a} + \mathbf{a} \times \mathbf{a}) = -\mathbf{b} \times \mathbf{c} - \mathbf{a} \times \mathbf{b} - \mathbf{c} \times \mathbf{a}$$

Hence,

$$\mathbf{v}_A + \mathbf{v}_B + \mathbf{v}_C + \mathbf{v}_D = (\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} - \mathbf{b} \times \mathbf{c} - \mathbf{a} \times \mathbf{b} - \mathbf{c} \times \mathbf{a}) = \mathbf{0}$$

75. In the notation of Exercise 74, suppose that **a**, **b**, **c** are mutually perpendicular as in Figure 25(B). Let S_F be the area of face F. Prove the following three-dimensional version of the Pythagorean Theorem:

$$S_A^2 + S_B^2 + S_C^2 = S_D^2$$

SOLUTION Since $\|\mathbf{v}_D\| = S_D$ then using Exercise 74 we obtain

$$\begin{aligned} S_D^2 &= \|\mathbf{v}_D\|^2 = \mathbf{v}_D \cdot \mathbf{v}_D = (\mathbf{v}_A + \mathbf{v}_B + \mathbf{v}_C) \cdot (\mathbf{v}_A + \mathbf{v}_B + \mathbf{v}_C) \\ &= \mathbf{v}_A \cdot \mathbf{v}_A + \mathbf{v}_A \cdot \mathbf{v}_B + \mathbf{v}_A \cdot \mathbf{v}_C + \mathbf{v}_B \cdot \mathbf{v}_A + \mathbf{v}_B \cdot \mathbf{v}_B + \mathbf{v}_B \cdot \mathbf{v}_C + \mathbf{v}_C \cdot \mathbf{v}_A + \mathbf{v}_C \cdot \mathbf{v}_B + \mathbf{v}_C \cdot \mathbf{v}_C \\ &= \|\mathbf{v}_A\|^2 + \|\mathbf{v}_B\|^2 + \|\mathbf{v}_C\|^2 + 2\,(\mathbf{v}_A \cdot \mathbf{v}_B + \mathbf{v}_A \cdot \mathbf{v}_C + \mathbf{v}_B \cdot \mathbf{v}_C) \qquad (1) \end{aligned}$$

Now, the normals $\mathbf{v}_A$, $\mathbf{v}_B$, and $\mathbf{v}_C$ to the coordinate planes are mutually orthogonal, hence,

$$\mathbf{v}_A \cdot \mathbf{v}_B = \mathbf{v}_A \cdot \mathbf{v}_C = \mathbf{v}_B \cdot \mathbf{v}_C = 0 \qquad (2)$$

Combining (1) and (2) and using the relations $\|\mathbf{v}_F\| = S_F$ we obtain

$$S_D^2 = S_A^2 + S_B^2 + S_C^2$$

12.5 Planes in Three-Space (LT Section 13.5)

Preliminary Questions

1. What is the equation of the plane parallel to $3x + 4y - z = 5$ passing through the origin?

SOLUTION The two planes are parallel, therefore the vector $\mathbf{n} = \langle 3, 4, -1 \rangle$ that is normal to the given plane is also normal to the plane we need to find. This plane is passing through the origin, hence we may substitute $\langle x_0, y_0, z_0 \rangle = \langle 0, 0, 0 \rangle$ in the vector form of the equation of the plane. This gives

$$\mathbf{n} \cdot \langle x, y, z \rangle = \mathbf{n} \cdot \langle x_0, y_0, z_0 \rangle$$

$$\langle 3, 4, -1 \rangle \cdot \langle x, y, z \rangle = \langle 3, 4, -1 \rangle \cdot \langle 0, 0, 0 \rangle = 0$$

or in scalar form

$$3x + 4y - z = 0$$

2. The vector **k** is normal to which of the following planes?

(a) $x = 1$ **(b)** $y = 1$ **(c)** $z = 1$

SOLUTION The planes $x = 1$, $y = 1$, and $z = 1$ are orthogonal to the x, y, and z-axes respectively. Since the plane $z = 1$ is orthogonal to the z-axis, the vector **k** is normal to this plane.

3. Which of the following planes is not parallel to the plane $x + y + z = 1$?

(a) $2x + 2y + 2z = 1$ **(b)** $x + y + z = 3$
(c) $x - y + z = 0$

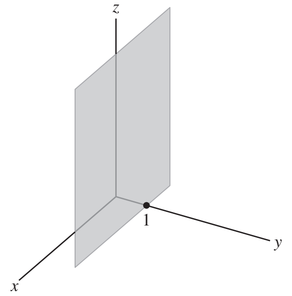
SOLUTION The two planes are parallel if vectors that are normal to the planes are parallel. The vector $\mathbf{n} = \langle 1, 1, 1 \rangle$ is normal to the plane $x + y + z = 1$. We identify the following normals:

- $\mathbf{v} = \langle 2, 2, 2 \rangle$ is normal to plane (a)
- $\mathbf{u} = \langle 1, 1, 1 \rangle$ is normal to plane (b)
- $\mathbf{w} = \langle 1, -1, 1 \rangle$ is normal to plane (c)

The vectors **v** and **u** are parallel to **n**, whereas **w** is not. (These vectors are not constant multiples of each other). Therefore, only plane (c) is not parallel to the plane $x + y + z = 1$.

4. To which coordinate plane is the plane $y = 1$ parallel?

SOLUTION The plane $y = 1$ is parallel to the xz-plane.



5. Which of the following planes contains the z-axis?

(a) $z = 1$ **(b)** $x + y = 1$ **(c)** $x + y = 0$

SOLUTION The points on the z-axis are the points with zero x and y coordinates. A plane contains the z-axis if and only if the points $(0, 0, c)$ satisfy the equation of the plane for all values of c.

(a) Plane (a) does not contain the z-axis, rather it is orthogonal to this axis. Only the point $(0, 0, 1)$ is on the plane.

(b) $x = 0$ and $y = 0$ do not satisfy the equation of the plane, since $0 + 0 \neq 1$. Therefore the plane does not contain the z-axis.

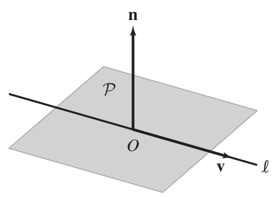
(c) The plane $x + y = 0$ contains the z-axis since $x = 0$ and $y = 0$ satisfy the equation of the plane.

6. Suppose that a plane $\mathcal{P}$ with normal vector $\mathbf{n}$ and a line $\mathcal{L}$ with direction vector $\mathbf{v}$ both pass through the origin and that $\mathbf{n} \cdot \mathbf{v} = 0$. Which of the following statements is correct?

(a) $\mathcal{L}$ is contained in $\mathcal{P}$.

(b) $\mathcal{L}$ is orthogonal to $\mathcal{P}$.

SOLUTION The direction vector of the line $\mathcal{L}$ is orthogonal to the vector $\mathbf{n}$ that is normal to the plane. Therefore, $\mathcal{L}$ is either parallel or contained in the plane. Since the origin is common to $\mathcal{L}$ and $\mathcal{P}$, the line is contained in the plane. That is, statement (a) is correct.



Exercises

In Exercises 1–8, write the equation of the plane with normal vector **n** *passing through the given point in each of the three forms (one vector form and two scalar forms).*

1. $\mathbf{n} = \langle 1, 3, 2\rangle$, $(4, -1, 1)$

SOLUTION The vector equation is

$$\langle 1, 3, 2\rangle \cdot \langle x, y, z\rangle = \langle 1, 3, 2\rangle \cdot \langle 4, -1, 1\rangle = 4 - 3 + 2 = 3$$

To obtain the scalar forms we compute the dot product on the left-hand side of the previous equation:

$$x + 3y + 2z = 3$$

or in the other scalar form:

$$(x - 4) + 3(y + 1) + 2(z - 1) + 4 - 3 + 2 = 3$$
$$(x - 4) + 3(y + 1) + 2(z - 1) = 0$$

2. $\mathbf{n} = \langle -1, 2, 1\rangle$, $(3, 1, 9)$

SOLUTION The vector equation is

$$\langle -1, 2, 1\rangle \cdot \langle x, y, z\rangle = \langle -1, 2, 1\rangle \cdot \langle 3, 1, 9\rangle = -3 + 2 + 9 = 8$$

To obtain the scalar form we compute the dot product on the left-hand side above:

$$-x + 2y + z = 8$$

or in the other scalar form:

$$-(x - 3) + 2(y - 1) + (z - 9) = 8 + 3 - 2 - 9 = 0$$
$$-(x - 3) + 2(y - 1) + (z - 9) = 0$$

3. $\mathbf{n} = \langle -1, 2, 1\rangle$, $(4, 1, 5)$

SOLUTION The vector form is

$$\langle -1, 2, 1\rangle \cdot \langle x, y, z\rangle = \langle -1, 2, 1\rangle \cdot \langle 4, 1, 5\rangle = -4 + 2 + 5 = 3$$

To obtain the scalar form we compute the dot product above:

$$-x + 2y + z = 3$$

or in the other scalar form:

$$-(x-4)+2(y-1)+(z-5)=3+4-2-5=0$$
$$-(x-4)+2(y-1)+(z-5)=0$$

4. $\mathbf{n}=\langle 2,-4,1\rangle$, $\left(\frac{1}{3},\frac{2}{3},1\right)$

SOLUTION The vector form is

$$\langle 2,-4,1\rangle\cdot\langle x,y,z\rangle=\langle 2,-4,1\rangle\cdot\left\langle\frac{1}{3},\frac{2}{3},1\right\rangle=\frac{2}{3}-\frac{8}{3}+1=-1$$

We find the scalar form by computing the dot product above:

$$2x-4y+z=-1$$

or in the form:

$$2\left(x-\frac{1}{3}\right)-4\left(y-\frac{2}{3}\right)+(z-1)=-1-\frac{2}{3}+\frac{8}{3}-1=0$$
$$2\left(x-\frac{1}{3}\right)-4\left(y-\frac{2}{3}\right)+(z-1)=0$$

5. $\mathbf{n}=\mathbf{i}$, $(3,1,-9)$

SOLUTION We find the vector form of the equation of the plane. We write the vector $\mathbf{n}=\mathbf{i}$ as $\mathbf{n}=\langle 1,0,0\rangle$ and obtain

$$\langle 1,0,0\rangle\cdot\langle x,y,z\rangle=\langle 1,0,0\rangle\cdot\langle 3,1,-9\rangle=3+0+0=3$$

Computing the dot product above gives the scalar form:

$$x+0+0=3$$
$$x=3$$

Or in the other scalar form:

$$(x-3)+0\cdot(y-1)+0\cdot(z+9)=3-3=0$$

6. $\mathbf{n}=\mathbf{j}$, $\left(-5,\frac{1}{2},\frac{1}{2}\right)$

SOLUTION Writing $\mathbf{n}=\mathbf{j}$ in the form $\mathbf{n}=\langle 0,1,0\rangle$ we obtain the following vector form of the equation of the plane:

$$\langle 0,1,0\rangle\cdot\langle x,y,z\rangle=\langle 0,1,0\rangle\cdot\left\langle -5,\frac{1}{2},\frac{1}{2}\right\rangle=0+\frac{1}{2}+0=\frac{1}{2}$$

We compute the dot product to obtain the scalar form:

$$0x+1y+0z=\frac{1}{2}$$
$$y=\frac{1}{2}$$

or in the other scalar form:

$$0(x+5)+\left(y-\frac{1}{2}\right)+0\left(z-\frac{1}{2}\right)=0$$

7. $\mathbf{n}=\mathbf{k}$, $(6,7,2)$

SOLUTION We write the normal $\mathbf{n}=\mathbf{k}$ in the form $\mathbf{n}=\langle 0,0,1\rangle$ and obtain the following vector form of the equation of the plane:

$$\langle 0,0,1\rangle\cdot\langle x,y,z\rangle=\langle 0,0,1\rangle\cdot\langle 6,7,2\rangle=0+0+2=2$$

We compute the dot product to obtain the scalar form:

$$0x+0y+1z=2$$
$$z=2$$

or in the other scalar form:

$$0(x-6)+0(y-7)+1(z-2)=0$$

8. $\mathbf{n} = \mathbf{i} - \mathbf{k}$, $(4, 2, -8)$

SOLUTION We write the normal $\mathbf{n} = \mathbf{i} - \mathbf{k}$ in the form $\mathbf{n} = \langle 1, 0, -1\rangle$ and obtain the following vector form of the equation of the plane:

$$\langle 1, 0, -1\rangle \cdot \langle x, y, z\rangle = \langle 1, 0, -1\rangle \cdot \langle 4, 2, -8\rangle = 4 + 0 + 8 = 12$$

To find the scalar form we compute the dot product:

$$x - z = 12$$

or the other scalar form:

$$(x - 4) + 0(y - 2) - (z + 8) = 12 - 4 - 8 = 0$$

9. Write down the equation of any plane through the origin.

SOLUTION We can use any equation $ax + by + cz = d$ which contains the point $(x, y, z) = (0, 0, 0)$. One solution (and there are many) is $x + y + z = 0$.

10. Write down the equations of any two distinct planes with normal vector $\mathbf{n} = \langle 3, 2, 1\rangle$ that do not pass through the origin.

SOLUTION The equation of a plane with normal vector $\mathbf{n} = \langle 3, 2, 1\rangle$ is $\langle 3, 2, 1\rangle \cdot \langle x, y, z\rangle = d$, or in other words, $3x + 2y + z = d$. Since we do not want the planes to pass through the origin, we want values of d such that $(x, y, z) = (0, 0, 0)$ is not on the plane. This will hold for any $d \neq 0$, so two possible solutions (and there are many) are $3x + 2y + z = 1$ and $3x + 2y + z = 2$.

11. Which of the following statements are true of a plane that is parallel to the yz-plane?

(a) $\mathbf{n} = \langle 0, 0, 1\rangle$ is a normal vector.

(b) $\mathbf{n} = \langle 1, 0, 0\rangle$ is a normal vector.

(c) The equation has the form $ay + bz = d$

(d) The equation has the form $x = d$

SOLUTION

(a) For $\mathbf{n} = \langle 0, 0, 1\rangle$ a normal vector, the plane would be parallel to the xy-plane, not the yz-plane. This statement is false.

(b) For $\mathbf{n} = \langle 1, 0, 0\rangle$ a normal vector, the plane would be parallel to the yz-plane. This statement is true.

(c) For the equation $ay + bz = d$, this plane intersects the yz-plane at $y = 0$, $z = d/b$ or $y = d/a$, $z = 0$ depending on whether a or b is non-zero, but it is not equal to the yz-plane (which has equation $x = d$) Thus, it is not parallel to the yz-plane This statement is false.
