(d) For the equation of the form $x = d$, this has $\langle 1, 0, 0\rangle$ as a normal vector and is parallel to the yz-plane. This statement is true.

12. Find a normal vector $\mathbf{n}$ and an equation for the planes in Figures 7(A)–(C).

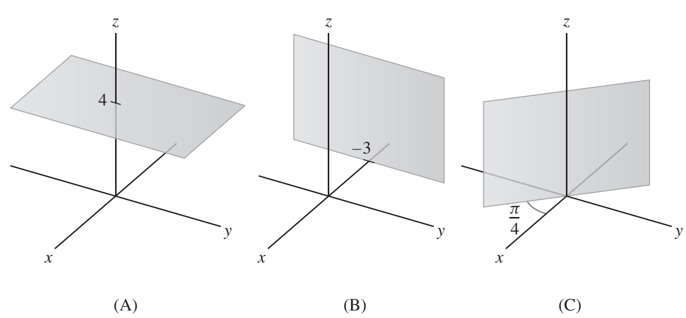

FIGURE 7

SOLUTION

(a) This plane has normal vector pointing straight up, so $\mathbf{n} = \langle 0, 0, 1\rangle$, and it contains the point $(0, 0, 4)$, so it has equation $0(x - 0) + 0(y - 0) + 1(z - 4) = 0$, which becomes $z = 4$.

(b) This plane has normal vector pointing along the x-axis, so $\mathbf{n} = \langle 1, 0, 0\rangle$, and it contains the point $(-3, 0, 0)$, so it has equation $1(x - -3) + 0(y - 0) + 0(z - 0) = 0$, which becomes $x = -3$.

(c) This plane has normal vector pointing along the line $y = x$, so $\mathbf{n} = \langle 1, 1, 0\rangle$, and it contains the point $(0, 0, 0)$, so it has equation $1(x - 0) + 1(y - 0) + 0(z - 0) = 0$, which becomes $x + y = 0$.

In Exercises 13–16, find a vector normal to the plane with the given equation.

13. $9x - 4y - 11z = 2$

SOLUTION Using the scalar form of the equation of the plane, a vector normal to the plane is the coefficients vector:

$$\mathbf{n} = \langle 9, -4, -11 \rangle$$

14. $x - z = 0$

SOLUTION We write the equation in vector form $\langle 1, 0, -1 \rangle \cdot \langle x, y, z \rangle = 0$ and identify $\mathbf{n} = \langle 1, 0, -1 \rangle$ as a vector normal to the plane.

15. $3(x - 4) - 8(y - 1) + 11z = 0$

SOLUTION Using the scalar form of the equation of the plane, $3x - 8y + 11z = 4$ a vector normal to the plane is the coefficients vector:

$$\mathbf{n} = \langle 3, -8, 11 \rangle$$

16. $x = 1$

SOLUTION The equation in vector form is

$$\langle 1, 0, 0 \rangle \cdot \langle x, y, z \rangle = 1$$

Therefore, the vector $\mathbf{n} = \langle 1, 0, 0 \rangle$ is normal to the plane.

In Exercises 17–20, find an equation of the plane passing through the three points given.

17. $P = (2, -1, 4), \quad Q = (1, 1, 1), \quad R = (3, 1, -2)$

SOLUTION We go through the steps below:

Step 1. Find the normal vector $\mathbf{n}$. The vectors $\mathbf{a} = \overrightarrow{PQ}$ and $\mathbf{b} = \overrightarrow{PR}$ lie on the plane, hence the cross product $\mathbf{n} = \mathbf{a} \times \mathbf{b}$ is normal to the plane. We compute the cross product:

$$\mathbf{a} = \overrightarrow{PQ} = \langle 1 - 2, 1 - (-1), 1 - 4 \rangle = \langle -1, 2, -3 \rangle$$
$$\mathbf{b} = \overrightarrow{PR} = \langle 3 - 2, 1 - (-1), -2 - 4 \rangle = \langle 1, 2, -6 \rangle$$
$$\mathbf{n} = \mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -1 & 2 & -3 \\ 1 & 2 & -6 \end{vmatrix} = \begin{vmatrix} 2 & -3 \\ 2 & -6 \end{vmatrix} \mathbf{i} - \begin{vmatrix} -1 & -3 \\ 1 & -6 \end{vmatrix} \mathbf{j} + \begin{vmatrix} -1 & 2 \\ 1 & 2 \end{vmatrix} \mathbf{k}$$
$$= -6\mathbf{i} - 9\mathbf{j} - 4\mathbf{k} = \langle -6, -9, -4 \rangle$$

Step 2. Choose a point on the plane. We choose any one of the three points on the plane, for instance $Q = (1, 1, 1)$. Using the vector form of the equation of the plane we get

$$\mathbf{n} \cdot \langle x, y, z \rangle = \mathbf{n} \cdot \langle x_0, y_0, z_0 \rangle$$
$$\langle -6, -9, -4 \rangle \cdot \langle x, y, z \rangle = \langle -6, -9, -4 \rangle \cdot \langle 1, 1, 1 \rangle$$

Computing the dot products we obtain the following equation:

$$-6x - 9y - 4z = -6 - 9 - 4 = -19$$
$$6x + 9y + 4z = 19$$

18. $P = (5, 1, 1), \quad Q = (1, 1, 2), \quad R = (2, 1, 1)$

SOLUTION Note that these three points all have a y-value of 1. So, consider the equation $y = 1$; it is the equation of a plane, and all three points P, Q, R satisfy the equation $y = 1$, so all three points P, Q, R are on this plane, so we are done! (We could also solve this problem using the traditional method of finding a normal vector, etc., and we will get the same answer of $y = 1$.)

19. $P = (1, 0, 0), \quad Q = (0, 1, 1), \quad R = (2, 0, 1)$

SOLUTION We use the vector form of the equation of the plane:

$$\mathbf{n} \cdot \langle x, y, z \rangle = d \tag{1}$$

To find the normal vector to the plane, $\mathbf{n}$, we first compute the vectors $\overrightarrow{PQ}$ and $\overrightarrow{PR}$ that lie in the plane, and then find the cross product of these vectors. This gives

$$\overrightarrow{PQ} = \langle 0, 1, 1\rangle - \langle 1, 0, 0\rangle = \langle -1, 1, 1\rangle$$

$$\overrightarrow{PR} = \langle 2, 0, 1\rangle - \langle 1, 0, 0\rangle = \langle 1, 0, 1\rangle$$

$$\mathbf{n} = \overrightarrow{PQ} \times \overrightarrow{PR} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -1 & 1 & 1 \\ 1 & 0 & 1 \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ 0 & 1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} -1 & 1 \\ 1 & 1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} -1 & 1 \\ 1 & 0 \end{vmatrix}\mathbf{k}$$

$$= \mathbf{i} + 2\mathbf{j} - \mathbf{k} = \langle 1, 2, -1\rangle \tag{2}$$

We now choose any one of the three points in the plane, say $P = (1, 0, 0)$, and compute d:

$$d = \mathbf{n} \cdot \overrightarrow{OP} = \langle 1, 2, -1\rangle \cdot \langle 1, 0, 0\rangle = 1 \cdot 1 + 2 \cdot 0 + (-1) \cdot 0 = 1 \tag{3}$$

Finally we substitute (2) and (3) into (1) to obtain the following equation of the plane:

$$\langle 1, 2, -1\rangle \cdot \langle x, y, z\rangle = 1$$

$$x + 2y - z = 1$$

20. $P = (2, 0, 0), \quad Q = (0, 4, 0), \quad R = (0, 0, 2)$

SOLUTION We go through the following steps:

Step 1. Find a normal vector $\mathbf{n}$. The normal vector $\mathbf{n}$ must be orthogonal to the vectors $\mathbf{a} = \overrightarrow{PQ}$ and $\mathbf{b} = \overrightarrow{PR}$ in the plane, hence we may choose $\mathbf{n}$ as the cross product $\mathbf{n} = \mathbf{a} \times \mathbf{b}$. We compute $\mathbf{n}$:

$$\mathbf{a} = \overrightarrow{PQ} = \langle 0 - 2, 4 - 0, 0 - 0\rangle = \langle -2, 4, 0\rangle$$

$$\mathbf{b} = \overrightarrow{PR} = \langle 0 - 2, 0 - 0, 2 - 0\rangle = \langle -2, 0, 2\rangle$$

$$\mathbf{n} = \mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2 & 4 & 0 \\ -2 & 0 & 2 \end{vmatrix} = \begin{vmatrix} 4 & 0 \\ 0 & 2 \end{vmatrix}\mathbf{i} - \begin{vmatrix} -2 & 0 \\ -2 & 2 \end{vmatrix}\mathbf{j} + \begin{vmatrix} -2 & 4 \\ -2 & 0 \end{vmatrix}\mathbf{k}$$

$$= 8\mathbf{i} + 4\mathbf{j} + 8\mathbf{k} = \langle 8, 4, 8\rangle$$

Step 2. Choose a point on the plane. We choose a point on the plane, for instance $(x_0, y_0, z_0) = (2, 0, 0)$. Using the vector form of the equation we get

$$\mathbf{n} \cdot \langle x, y, z\rangle = \mathbf{n} \cdot \langle x_0, y_0, z_0\rangle$$

$$\langle 8, 4, 8\rangle \cdot \langle x, y, z\rangle = \langle 8, 4, 8\rangle \cdot \langle 2, 0, 0\rangle$$

We compute the dot products:

$$8x + 4y + 8z = 16 + 0 + 0 = 16$$

$$2x + y + 2z = 4$$

In Exercises 21–28, find the equation of the plane with the given description.

21. Passes through O and is parallel to $4x - 9y + z = 3$

SOLUTION The vector $\mathbf{n} = \langle 4, -9, 1\rangle$ is normal to the plane $4x - 9y + z = 3$, and so is also normal to the parallel plane. Setting $\mathbf{n} = \langle 4, -9, 1\rangle$ and $(x_0, y_0, z_0) = (0, 0, 0)$ in the vector equation of the plane yields

$$\langle 4, -9, 1\rangle \cdot \langle x, y, z\rangle = \langle 4, -9, 1\rangle \cdot \langle 0, 0, 0\rangle = 0$$

$$4x - 9y + z = 0$$

22. Passes through $(4, 1, 9)$ and is parallel to $x + y + z = 3$

SOLUTION We write the equation of the plane $x + y + z = 3$ in vector form:

$$\langle 1, 1, 1\rangle \cdot \langle x, y, z\rangle = 3$$

We identify $\mathbf{n} = \langle 1, 1, 1\rangle$ as a vector normal to the plane. This vector is also normal to the parallel plane. We substitute $\mathbf{n} = \langle 1, 1, 1\rangle$ and $(x_0, y_0, z_0) = (4, 1, 9)$ in the vector equation of the plane to obtain

$$\langle 1, 1, 1\rangle \cdot \langle x, y, z\rangle = \langle 1, 1, 1\rangle \cdot \langle 4, 1, 9\rangle$$

$$x + y + z = 4 + 1 + 9 = 14$$

$$x + y + z = 14$$

23. Passes through $(4, 1, 9)$ and is parallel to $x = 3$

SOLUTION The vector form of the plane $x = 3$ is

$$\langle 1, 0, 0\rangle \cdot \langle x, y, z\rangle = 3$$

Hence, $\mathbf{n} = \langle 1, 0, 0\rangle$ is normal to this plane. This vector is also normal to the parallel plane. Setting $(x_0, y_0, z_0) = (4, 1, 9)$ and $\mathbf{n} = \langle 1, 0, 0\rangle$ in the vector equation of the plane yields

$$\langle 1, 0, 0\rangle \cdot \langle x, y, z\rangle = \langle 1, 0, 0\rangle \cdot \langle 4, 1, 9\rangle = 4 + 0 + 0 = 4$$

or

$$x + 0 + 0 = 4 \quad \Rightarrow \quad x = 4$$

24. Passes through $P = (3, 5, -9)$ and is parallel to the xz-plane

SOLUTION The xz-plane is the plane $y = 0$, which has normal vector $\mathbf{n} = \langle 0, 1, 0\rangle$. Using this in the scalar equation of the plane gives us:

$$0(x - 3) + 1(y - 5) + 0(z - -9) = 0 \quad \Rightarrow \quad y = 5$$

25. Passes through $(-2, -3, 5)$ and has normal vector $\mathbf{i} + \mathbf{k}$

SOLUTION We substitute $\mathbf{n} = \langle 1, 0, 1\rangle$ and $(x_0, y_0, z_0) = (-2, -3, 5)$ in the vector equation of the plane to obtain

$$\langle 1, 0, 1\rangle \cdot \langle x, y, z\rangle = \langle 1, 0, 1\rangle \cdot \langle -2, -3, 5\rangle$$

or

$$\begin{aligned} x + 0 + z &= -2 + 0 + 5 = 3 \\ x + z &= 3 \end{aligned}$$

26. Contains the lines $\mathbf{r}_1(t) = \langle t, 2t, 3t\rangle$ and $\mathbf{r}_2(t) = \langle 3t, t, 8t\rangle$

SOLUTION Since the plane contains the lines $\ell_1(t) = \langle t, 2t, 3t\rangle$ and $\ell_2(t) = \langle 3t, t, 8t\rangle$, the direction vectors $\mathbf{v}_1 = \langle 1, 2, 3\rangle$ and $\mathbf{v}_2 = \langle 3, 1, 8\rangle$ of the lines lie in the plane. Therefore the cross product $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2$ is normal to the plane. We compute the cross product:

$$\begin{aligned} \mathbf{n} = \langle 1, 2, 3\rangle \times \langle 3, 1, 8\rangle &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 3 \\ 3 & 1 & 8 \end{vmatrix} = \begin{vmatrix} 2 & 3 \\ 1 & 8 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 3 \\ 3 & 8 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 2 \\ 3 & 1 \end{vmatrix} \mathbf{k} \\ &= 13\mathbf{i} + \mathbf{j} - 5\mathbf{k} = \langle 13, 1, -5\rangle \end{aligned}$$

We now must choose a point on the plane. Since the line $\ell_1(t) = \langle t, 2t, 3t\rangle$ is contained in the plane, all of its points are on the plane. We choose the point corresponding to $t = 1$, that is,

$$\langle x_0, y_0, z_0\rangle = \langle 1, 2 \cdot 1, 3 \cdot 1\rangle = \langle 1, 2, 3\rangle$$

We now use the vector equation of the plane to determine the equation of the desired plane:

$$\begin{aligned} \mathbf{n} \cdot \langle x, y, z\rangle &= \mathbf{n} \cdot \langle x_0, y_0, z_0\rangle \\ \langle 13, 1, -5\rangle \cdot \langle x, y, z\rangle &= \langle 13, 1, -5\rangle \cdot \langle 1, 2, 3\rangle \\ 13x + y - 5z &= 13 + 2 - 15 = 0 \\ 13x + y - 5z &= 0 \end{aligned}$$

27. Contains the lines $\mathbf{r}_1(t) = \langle 2, 1, 0\rangle + \langle t, 2t, 3t\rangle$ and $\mathbf{r}_2(t) = \langle 2, 1, 0\rangle + \langle 3t, t, 8t\rangle$

SOLUTION Since the plane contains the lines $\mathbf{r}_1(t)$ and $\mathbf{r}_2(t)$, the direction vectors $\mathbf{v}_1 = \langle 1, 2, 3\rangle$ and $\mathbf{v}_2 = \langle 3, 1, 8\rangle$ of the lines lie in the plane. Therefore the cross product $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2$ is normal to the plane. We compute the cross product:

$$\begin{aligned} \mathbf{n} = \langle 1, 2, 3\rangle \times \langle 3, 1, 8\rangle &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 3 \\ 3 & 1 & 8 \end{vmatrix} = \begin{vmatrix} 2 & 3 \\ 1 & 8 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 3 \\ 3 & 8 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 2 \\ 3 & 1 \end{vmatrix} \mathbf{k} \\ &= 13\mathbf{i} + \mathbf{j} - 5\mathbf{k} = \langle 13, 1, -5\rangle \end{aligned}$$

We now must choose a point on the plane. Since the line $\mathbf{r}_1(t) = \langle 2+t, 1+2t, 3t\rangle$ is contained in the plane, all of its points are on the plane. We choose the point corresponding to $t = 0$, that is,

$$\langle x_0, y_0, z_0\rangle = \langle 2, 1, 0\rangle$$

We now use the vector equation of the plane to determine the equation of the desired plane:

$$\mathbf{n}\cdot\langle x, y, z\rangle = \mathbf{n}\cdot\langle x_0, y_0, z_0\rangle$$
$$\langle 13, 1, -5\rangle\cdot\langle x, y, z\rangle = \langle 13, 1, -5\rangle\cdot\langle 2, 1, 0\rangle$$
$$13x + y - 5z = 26 + 1 + 0 = 27$$
$$13x + y - 5z = 27$$

28. Contains $P = (-1, 0, 1)$ and $\mathbf{r}(t) = \langle t+1, 2t, 3t-1\rangle$

SOLUTION Since the line $\ell(t) = \langle t+1, 2t, 3t-1\rangle$ is contained in the plane, its direction vector $\mathbf{v} = \langle 1, 2, 3\rangle$ lies in the plane. To find a second vector on the plane we first choose a point on the line, say, the point corresponding to $t = 0$. That is,

$$Q = (0+1, 2\cdot 0, 0-1) = (1, 0, -1)$$

Now, since the points $P = (-1, 0, 1)$ and $Q = (1, 0, -1)$ are on the plane, the vector $\mathbf{u} = \overrightarrow{PQ}$ lies on the plane. We find it here:

$$\mathbf{u} = \overrightarrow{PQ} = \langle 1-(-1), 0-0, -1-1\rangle = \langle 2, 0, -2\rangle$$

We now compute a vector normal to the plane, by finding the cross product $\mathbf{n} = \mathbf{v}\times\mathbf{u}$:

$$\mathbf{n} = \mathbf{v}\times\mathbf{u} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 3 \\ 2 & 0 & -2 \end{vmatrix} = \begin{vmatrix} 2 & 3 \\ 0 & -2 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 3 \\ 2 & -2 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 2 \\ 2 & 0 \end{vmatrix}\mathbf{k}$$
$$= -4\mathbf{i} + 8\mathbf{j} - 4\mathbf{k} = \langle -4, 8-4\rangle$$

Finally we substitute $\mathbf{n} = \langle -4, 8, -4\rangle$ and the given point $P = (x_0, y_0, z_0) = (-1, 0, 1)$ in the vector equation of the plane to obtain

$$\mathbf{n}\cdot\langle x, y, z\rangle = \mathbf{n}\cdot\langle x_0, y_0, z_0\rangle$$
$$\langle -4, 8, -4\rangle\cdot\langle x, y, z\rangle = \langle -4, 8, -4\rangle\cdot\langle -1, 0, 1\rangle$$

or

$$-4x + 8y - 4z = 4 + 0 - 4 = 0$$
$$x - 2y + z = 0$$

29. Are the planes $\frac{1}{2}x + 2x - y = 5$ and $3x + 12x - 6y = 1$ parallel?

SOLUTION The planes $2\frac{1}{2}x - y = 5$ and $15x - 6y = 1$, are parallel if and only if the vectors $\mathbf{n}_1 = \left\langle 2\frac{1}{2}, -1, 0\right\rangle$ and $\mathbf{n}_2 = \langle 15, -6, 0\rangle$ normal to the planes are parallel. Since $\mathbf{n}_2 = 6\mathbf{n}_1$ the planes are parallel.

30. Let a, b, c be constants. Which two of the following equations define the plane passing through $(a, 0, 0)$, $(0, b, 0)$, $(0, 0, c)$?

(a) $ax + by + cz = 1$

(b) $bcx + acy + abz = abc$

(c) $bx + cy + az = 1$

(d) $\dfrac{x}{a} + \dfrac{y}{b} + \dfrac{z}{c} = 1$

SOLUTION

(a) Substituting $x = a$, $y = 0$, $z = 0$ in the left-hand side of the equation of the plane $ax + by + cz = 1$ gives

$$a\cdot a + b\cdot 0 + c\cdot 0 = a^2$$

If $a \neq \pm 1$, the point $(a, 0, 0)$ does not lie on the plane.

(b) Substituting $x = a$, $y = z = 0$ in the left-hand side of the equation $bcx + acy + abz = abc$ gives

$$bca + ac\cdot 0 + ab\cdot 0 = bca$$

Thus, the point $(a, 0, 0)$ is on the plane. Similarly we check the other two points $(0, b, 0)$ and $(0, 0, c)$:

$$bc\cdot 0 + acb + ab\cdot 0 = acb$$
$$bc\cdot 0 + ac\cdot 0 + abc = abc$$

We conclude that the three points are on the plane.

(c) We substitute $x = a$, $y = 0$, $z = 0$ in the left-hand side of the equation of the plane $bx + cy + az = 1$:

$$ba + c \cdot 0 + a \cdot 0 = ab$$

If $ab \neq 1$, the point $(a, 0, 0)$ is not on the plane.

(d) We substitute coordinates of the points in the left-hand side of the equation of the plane $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$:

$$(a, 0, 0): \quad \frac{a}{a} + \frac{0}{b} + \frac{0}{c} = 1$$

$$(0, b, 0): \quad \frac{0}{a} + \frac{b}{b} + \frac{0}{c} = 1$$

$$(0, 0, c): \quad \frac{0}{a} + \frac{0}{b} + \frac{c}{c} = 1$$

We conclude that the three points are on the plane.

31. Find an equation of the plane $\mathcal{P}$ in Figure 8.

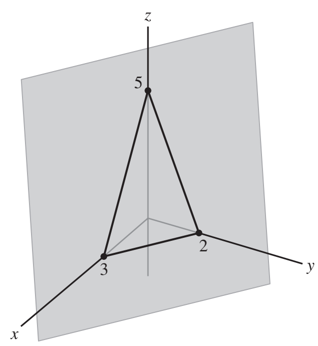

FIGURE 8

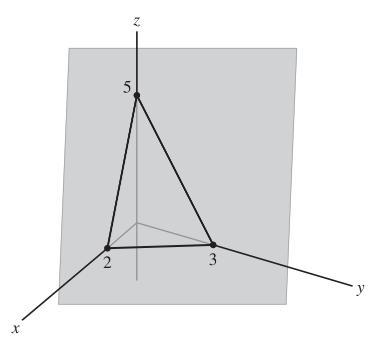
SOLUTION We must find the equation of the plane passing though the points $P = (3, 0, 0)$, $Q = (0, 2, 0)$, and $R = (0, 0, 5)$.



We use the following steps:

Step 1. Find a normal vector $\mathbf{n}$. The vectors $\mathbf{a} = \overrightarrow{PQ}$ and $\mathbf{b} = \overrightarrow{PR}$ lie in the plane, hence the cross product $\mathbf{n} = \mathbf{a} \times \mathbf{b}$ is normal to the plane. We compute the cross product:

$$\mathbf{a} = \overrightarrow{PQ} = \langle 0 - 3, 2 - 0, 0 - 0 \rangle = \langle -3, 2, 0 \rangle$$

$$\mathbf{b} = \overrightarrow{PR} = \langle 0 - 3, 0 - 0, 5 - 0 \rangle = \langle -3, 0, 5 \rangle$$

$$\mathbf{n} = \mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -3 & 2 & 0 \\ -3 & 0 & 5 \end{vmatrix} = \begin{vmatrix} 2 & 0 \\ 0 & 5 \end{vmatrix} \mathbf{i} - \begin{vmatrix} -3 & 0 \\ -3 & 5 \end{vmatrix} \mathbf{j} + \begin{vmatrix} -3 & 2 \\ -3 & 0 \end{vmatrix} \mathbf{k}$$

$$= 10\mathbf{i} + 15\mathbf{j} + 6\mathbf{k} = \langle 10, 15, 6 \rangle$$

Step 2. Choose a point on the plane. We choose one of the points on the plane, say $P = (3, 0, 0)$. Substituting $\mathbf{n} = \langle 10, 15, 6 \rangle$ and $(x_0, y_0, z_0) = (3, 0, 0)$ in the vector form of the equation of the plane gives

$$\mathbf{n} \cdot \langle x, y, z \rangle = \mathbf{n} \cdot \langle x_0, y_0, z_0 \rangle$$

$$\langle 10, 15, 6 \rangle \cdot \langle x, y, z \rangle = \langle 10, 15, 6 \rangle \cdot \langle 3, 0, 0 \rangle$$

Computing the dot products we get the following scalar form of the equation of the plane:

$$10x + 15y + 6z = 10 \cdot 3 + 0 + 0 = 30$$
$$10x + 15y + 6z = 30$$

32. Verify that the plane $x - y + 5z = 10$ and the line $\mathbf{r}(t) = \langle 1, 0, 1\rangle + t\,\langle -2, 1, 1\rangle$ intersect at $P = (-3, 2, 3)$.

SOLUTION We verify that the point $P = (-3, 2, 3)$ is contained in both the plane and the line. Substituting the coordinates of P in the equation of the plane gives

$$-3 - 2 + 5 \cdot 3 = 10 \quad \Rightarrow \quad P \text{ is on the plane.}$$

The parametric equations of the line are

$$x = 1 - 2t, \quad y = t, \quad z = 1 + t$$

We verify that there exists a value of t such that

$$x = 1 - 2t = -3$$
$$y = t = 2$$
$$z = 1 + t = 3$$

$t = 2$ satisfies the three equations, hence the point $P = (-3, 2, 3)$ is on the line. Since P is on the plane and also on the line, the plane and the line intersect at this point. (Notice that we haven't proved that P is the only intersection point.)

In Exercises 33–36, find the intersection of the line and the plane.

33. $x + y + z = 14, \quad \mathbf{r}(t) = \langle 1, 1, 0\rangle + t\,\langle 0, 2, 4\rangle$

SOLUTION The line has parametric equations

$$x = 1, \quad y = 1 + 2t, \quad z = 4t$$

To find a value of t for which (x, y, z) lies on the plane, we substitute the parametric equations in the equation of the plane and solve for t:

$$x + y + z = 14$$
$$1 + (1 + 2t) + 4t = 14$$
$$6t = 12 \quad \Rightarrow \quad t = 2$$

The point P of intersection has coordinates

$$x = 1, \quad y = 1 + 2 \cdot 2 = 5, \quad z = 4 \cdot 2 = 8$$

That is, $P = (1, 5, 8)$.

34. $2x + y = 3, \quad \mathbf{r}(t) = \langle 2, -1, -1\rangle + t\,\langle 1, 2, -4\rangle$

SOLUTION The parametric equations of the line are

$$x = 2 + t, \quad y = -1 + 2t, \quad z = -1 - 4t \tag{1}$$

We substitute the parametric equations in the equation of the plane and solve for t, to find the value of t for which (x, y, z) lies on the plane. We obtain

$$2x + y = 3$$
$$2(2 + t) + (-1 + 2t) = 3$$
$$4 + 2t - 1 + 2t = 3$$
$$4t = 0 \quad \Rightarrow \quad t = 0$$

We find the coordinates of the point P of intersection by substituting $t = 0$ in the parametric equations (1). We obtain

$$x = 2 + 0 = 2, \quad y = -1 + 2 \cdot 0 = -1, \quad z = -1 - 4 \cdot 0 = -1$$

That is,

$$P = (2, -1, -1).$$

35. $z = 12, \quad \mathbf{r}(t) = t\,\langle -6, 9, 36\rangle$

SOLUTION The parametric equations of the line are

$$x = -6t, \quad y = 9t, \quad z = 36t \tag{1}$$

We substitute the parametric equations in the equation of the plane and solve for t:

$$z = 12$$
$$36t = 12 \quad \Rightarrow \quad t = \frac{1}{3}$$

The value of the parameter at the point of intersection is $t = \frac{1}{3}$. Substituting into (1) gives the coordinates of the point P of intersection:

$$x = -6 \cdot \frac{1}{3} = -2, \quad y = 9 \cdot \frac{1}{3} = 3, \quad z = 36 \cdot \frac{1}{3} = 12$$

That is,

$$P = (-2, 3, 12)\,.$$

36. $x - z = 6, \quad \mathbf{r}(t) = \langle 1, 0, -1\rangle + t\,\langle 4, 9, 2\rangle$

SOLUTION The parametric equations of the line are

$$x = 1 + 4t, \quad y = 9t, \quad z = -1 + 2t \tag{1}$$

We substitute the parametric equations in the equation of the plane and solve for t:

$$\begin{aligned} x - z &= 6 \\ 1 + 4t - (-1 + 2t) &= 6 \\ 1 + 4t + 1 - 2t &= 6 \\ 2t &= 4 \quad \Rightarrow \quad t = 2 \end{aligned}$$

The value of the parameter at the point P of intersection is $t = 2$. We find the coordinates of P by substituting $t = 2$ in (1). This gives

$$x = 1 + 4 \cdot 2 = 9, \quad y = 9 \cdot 2 = 18, \quad z = -1 + 2 \cdot 2 = 3$$

That is,

$$P = (9, 18, 3)\,.$$

In Exercises 37–42, find the trace of the plane in the given coordinate plane.

37. $3x - 9y + 4z = 5, \quad yz$

SOLUTION The yz-plane has the equation $x = 0$, hence the intersection of the plane with the yz-plane must satisfy both $x = 0$ and the equation of the plane $3x - 9y + 4z = 5$. That is, this is the set of all points $(0, y, z)$ in the yz-plane such that $-9y + 4z = 5$.

38. $3x - 9y + 4z = 5, \quad xz$

SOLUTION The trace of the plane in the xz coordinate plane is obtained by substituting $y = 0$ in the equation of the plane $3x - 9y + 4z = 5$. This gives the line $3x + 4z = 5$ in the xz-plane.

39. $3x + 4z = -2, \quad xy$

SOLUTION The trace of the plane $3x + 4z = -2$ in the xy coordinate plane is the set of all points that satisfy the equation of the plane and the equation $z = 0$ of the xy coordinate plane. Thus, we substitute $z = 0$ in $3x + 4z = -2$ to obtain the line $3x = -2$ or $x = -\frac{2}{3}$ in the xy-plane.

40. $3x + 4z = -2, \quad xz$

SOLUTION The xz-plane has equation $y = 0$, hence the intersection of the plane $3x + 4z = -2$ with the xz-plane is the set of all points $(x, 0, z)$ such that $3x + 4z = -2$. This is a line in the xz-plane.

41. $-x + y = 4, \quad xz$

SOLUTION The trace of the plane $-x + y = 4$ on the xz-plane is the set of all points that satisfy both the equation of the given plane and the equation $y = 0$ of the xz-plane. That is, the set of all points $(x, 0, z)$ such that $-x + 0 = 4$, or $x = -4$. This is a vertical line in the xz-plane.

42. $-x + y = 4, \quad yz$

SOLUTION The trace of the plane $-x + y = 4$ on the yz-plane is the set of all points that satisfy both the equation of the plane and the equation $x = 0$ of the yz-plane. That is, the set of all points $(0, y, z)$ such that $-0 + y = 4$, or $y = 4$. This is a vertical line in the yz-plane.

43. Does the plane $x = 5$ have a trace in the yz-plane? Explain.

SOLUTION The yz-plane has the equation $x = 0$, hence the x-coordinates of the points in this plane are zero, whereas the x-coordinates of the points in the plane $x = 5$ are 5. Thus, the two planes have no common points.

44. Give equations for two distinct planes whose trace in the xy-plane has equation $4x + 3y = 8$.

SOLUTION The xy-plane has the equation $z = 0$, hence the trace of a plane $ax + by + cz = 0$ in the xy-plane is obtained by substituting $z = 0$ in the equation of the plane. Therefore, the following two planes have trace $4x + 3y = 8$ in the xy-plane:

$$4x + 3y + z = 8; \quad 4x + 3y - 5z = 8$$

45. Give equations for two distinct planes whose trace in the yz-plane has equation $y = 4z$.

SOLUTION The yz-plane has the equation $x = 0$, hence the trace of a plane $ax + by + cz = 0$ in the yz-plane is obtained by substituting $x = 0$ in the equation of the plane. Therefore, the following two planes have trace $y = 4z$ (that is, $y - 4z = 0$) in the yz-plane:

$$x + y - 4z = 0; \quad 2x + y - 4z = 0$$

46. Find parametric equations for the line through $P_0 = (3, -1, 1)$ perpendicular to the plane $3x + 5y - 7z = 29$.

SOLUTION We need to find a direction vector for the line. Since the line is perpendicular to the plane $3x + 5y - 7z = 29$, it is parallel to the vector $\mathbf{n} = \langle 3, 5, -7\rangle$ normal to the plane. Hence, $\mathbf{n}$ is a direction vector for the line. The vector parametrization of the line is, thus,

$$\mathbf{r}(t) = \langle 3, -1, 1\rangle + t\langle 3, 5, -7\rangle$$

This yields the parametric equations

$$x = 3 + 3t, \quad y = -1 + 5t, \quad z = 1 - 7t$$

47. Find all planes in $\mathbf{R}^3$ whose intersection with the xz-plane is the line with equation $3x + 2z = 5$.

SOLUTION The intersection of the plane $ax + by + cz = d$ with the xz-plane is obtained by substituting $y = 0$ in the equation of the plane. This gives the following line in the xz-plane:

$$ax + cz = d$$

This is the equation of the line $3x + 2z = 5$ if and only if for some $\lambda \neq 0$,

$$a = 3\lambda, \quad c = 2\lambda, \quad d = 5\lambda$$

Notice that b can have any value. The planes are thus

$$(3\lambda)x + by + (2\lambda)z = 5\lambda, \quad \lambda \neq 0.$$

48. Find all planes in $\mathbf{R}^3$ whose intersection with the xy-plane is the line $\mathbf{r}(t) = t\,\langle 2, 1, 0\rangle$.

SOLUTION The intersection of the plane $ax + by + cz = d$ with the xy-plane is obtained by substituting $z = 0$ in the equation of the plane. This gives the line $ax + by = d$, in the xy-plane. We find the equation of the line $\mathbf{l}\,(t) = t\langle 2, 1, 0\rangle$. On this line we have

$$\begin{array}{l} x = 2t \\ y = t \end{array} \quad \Rightarrow \quad y = \frac{1}{2}x \Rightarrow x - 2y = 0$$

We thus must have $d = 0$ and $\frac{b}{a} = -2$, $a \neq 0$. That is, $d = 0$, $b = -2a$, $a \neq 0$. Notice that c can have any value. Hence, the planes are

$$ax - 2ay + cz = 0, a \neq 0$$

In Exercises 49–54, compute the angle between the two planes, defined as the angle θ (between 0 and π) between their normal vectors (Figure 9).

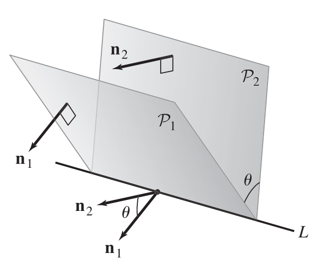


FIGURE 9 By definition, the angle between two planes is the angle between their normal vectors.

49. Planes with normals $\mathbf{n}_1 = \langle 1, 0, 1\rangle$, $\mathbf{n}_2 = \langle -1, 1, 1\rangle$

SOLUTION Using the formula for the angle between two vectors we get

$$\cos\theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{\|\mathbf{n}_1\|\|\mathbf{n}_2\|} = \frac{\langle 1, 0, 1\rangle \cdot \langle -1, 1, 1\rangle}{\|\langle 1, 0, 1\rangle\|\|\langle -1, 1, 1\rangle\|} = \frac{-1+0+1}{\sqrt{1^2+0+1^2}\sqrt{(-1)^2+1^2+1^2}} = 0$$

The solution for $0 \le \theta < \pi$ is $\theta = \frac{\pi}{2}$.

50. Planes with normals $\mathbf{n}_1 = \langle 1, 2, 1\rangle$, $\mathbf{n}_2 = \langle 4, 1, 3\rangle$

SOLUTION By the formula for the angle between two vectors we get

$$\cos\theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{\|\mathbf{n}_1\|\|\mathbf{n}_2\|} = \frac{\langle 1, 2, 1\rangle \cdot \langle 4, 1, 3\rangle}{\|\langle 1, 2, 1\rangle\|\|\langle 4, 1, 3\rangle\|} = \frac{4+2+3}{\sqrt{1^2+2^2+1^2}\sqrt{4^2+1^2+3^2}} = \frac{9}{\sqrt{6}\sqrt{26}} \approx 0.72$$

The solution for $0 \le \theta < \pi$ is $\theta = 0.766$ rad or $\theta = 43.9^\circ$.

51. $2x + 3y + 7z = 2$ and $4x - 2y + 2z = 4$

SOLUTION The planes $2x + 3y + 7z = 2$ and $4x - 2y + 2z = 4$ have the normals $\mathbf{n}_1 = \langle 2, 3, 7\rangle$ and $\mathbf{n}_2 = \langle 4, -2, 2\rangle$ respectively. The cosine of the angle between $\mathbf{n}_1$ and $\mathbf{n}_2$ is

$$\cos\theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{\|\mathbf{n}_1\|\|\mathbf{n}_2\|} = \frac{\langle 2, 3, 7\rangle \cdot \langle 4, -2, 2\rangle}{\|\langle 2, 3, 7\rangle\|\|\langle 4, -2, 2\rangle\|} = \frac{8-6+14}{\sqrt{2^2+3^2+7^2}\sqrt{4^2+(-2)^2+2^2}} = \frac{16}{\sqrt{62}\sqrt{24}} \approx 0.415$$

The solution for $0 \le \theta < \pi$ is $\theta = 1.143$ rad or $\theta = 65.49^\circ$.

52. $x - 3y + z = 3$ and $2x - 3z = 4$

SOLUTION The planes $x - 3y + z = 3$ and $2x - 3z = 4$ have the normals $\mathbf{n}_1 = \langle 1, -3, 1\rangle$ and $\mathbf{n}_2 = \langle 2, 0, -3\rangle$ respectively. We use the formula for the angle between two vectors:

$$\cos\theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{\|\mathbf{n}_1\|\|\mathbf{n}_2\|} = \frac{\langle 1, -3, 1\rangle \cdot \langle 2, 0, -3\rangle}{\|\langle 1, -3, 1\rangle\|\|\langle 2, 0, -3\rangle\|} = \frac{2+0-3}{\sqrt{1^2+(-3)^2+1^2}\sqrt{2^2+0+(-3)^2}} = \frac{-1}{\sqrt{11}\sqrt{13}} \approx -0.084$$

The solution for $0 \le \theta < \pi$ is $\theta = 1.655$ rad or $\theta = 94.80^\circ$.

53. $3(x - 1) - 5y + 2(z - 12) = 0$ and the plane with normal $\mathbf{n} = \langle 1, 0, 1\rangle$

SOLUTION The plane $3(x - 1) - 5y + 2(z - 12) = 0$ has the normal $\mathbf{n}_1 = \langle 3, -5, 2\rangle$, and our second plane has given normal $\mathbf{n}_2 = \langle 1, 0, 1\rangle$. We use the formula for the angle between two vectors:

$$\cos\theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{\|\mathbf{n}_1\|\|\mathbf{n}_2\|} = \frac{\langle 3, -5, 2\rangle \cdot \langle 1, 0, 1\rangle}{\|\langle 3, -5, 2\rangle\|\|\langle 1, 0, 1\rangle\|} = \frac{3+0+2}{\sqrt{3^2+(-5)^2+2^2}\sqrt{1^2+0+1^2}} = \frac{5}{\sqrt{38}\sqrt{2}} \approx 0.5735$$

The solution for $0 \le \theta < \pi$ is $\theta = 0.96$ rad or $\theta = 55^\circ$.

54. The plane through $(1, 0, 0)$, $(0, 1, 0)$, and $(0, 0, 1)$ and the yz-plane

SOLUTION We first must find normal vectors to the planes. The yz-plane has the equation $x = 0$, or in vector form $\langle 1, 0, 0\rangle \cdot \langle x, y, z\rangle = 0$, hence $\mathbf{n}_1 = \langle 1, 0, 0\rangle$ is normal to the plane. We denote the points $P = (1, 0, 0)$, $Q = (0, 1, 0)$ and $R = (0, 0, 1)$ hence the vector $\mathbf{n}_2 = \overrightarrow{PQ} \times \overrightarrow{PR}$ is normal to the plane. We find it here:

$$\overrightarrow{PQ} = \langle 0-1, 1-0, 0-0\rangle = \langle -1, 1, 0\rangle$$

$$\overrightarrow{PR} = \langle 0-1, 0-0, 1-0\rangle = \langle -1, 0, 1\rangle$$

$$\mathbf{n}_2 = \overrightarrow{PQ} \times \overrightarrow{PR} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -1 & 1 & 0 \\ -1 & 0 & 1 \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} -1 & 0 \\ -1 & 1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} -1 & 1 \\ -1 & 0 \end{vmatrix}\mathbf{k} = \mathbf{i} + \mathbf{j} + \mathbf{k} = \langle 1, 1, 1\rangle$$

Using the formula for the angle between two vectors we have

$$\cos\theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{\|\mathbf{n}_1\|\|\mathbf{n}_2\|} = \frac{\langle 1, 0, 0\rangle \cdot \langle 1, 1, 1\rangle}{\|\langle 1, 0, 0\rangle\|\|\langle 1, 1, 1\rangle\|} = \frac{1}{\sqrt{3}}$$

The solution for $0 \le \theta < \pi$ is $\theta = 0.955$ rad or $\theta = 54.74^\circ$.

55. Find an equation of a plane making an angle of $\frac{\pi}{2}$ with the plane $3x + y - 4z = 2$.

SOLUTION The angle θ between two planes (chosen so that $0 \le \theta < \pi$) is defined as the angle between their normal vectors. The following vector is normal to the plane $3x + y - 4z = 2$:

$$\mathbf{n}_1 = \langle 3, 1, -4 \rangle$$

Let $\mathbf{n} \cdot \langle x, y, z \rangle = d$ denote the equation of a plane making an angle of $\frac{\pi}{2}$ with the given plane, where $\mathbf{n} = \langle a, b, c \rangle$. Since the two planes are perpendicular, the dot product of their normal vectors is zero. That is,

$$\mathbf{n} \cdot \mathbf{n}_1 = \langle a, b, c \rangle \cdot \langle 3, 1, -4 \rangle = 3a + b - 4c = 0 \quad \Rightarrow \quad b = -3a + 4c$$

Thus, the required planes (there is more than one plane) have the following normal vector:

$$\mathbf{n} = \langle a, -3a + 4c, c \rangle$$

We obtain the following equation:

$$\begin{aligned} \mathbf{n} \cdot \langle x, y, c \rangle &= d \\ \langle a, -3a + 4c, c \rangle \cdot \langle x, y, z \rangle &= d \\ ax + (4c - 3a)y + cz &= d \end{aligned}$$

Every choice of the values of a, c and d yields a plane with the desired property. For example, we set $a = c = d = 1$ to obtain

$$x + y + z = 1$$

56. Let $\mathcal{P}_1$ and $\mathcal{P}_2$ be planes with normal vectors $\mathbf{n}_1$ and $\mathbf{n}_2$. Assume that the planes are not parallel, and let $\mathcal{L}$ be their intersection (a line). Show that $\mathbf{n}_1 \times \mathbf{n}_2$ is a direction vector for $\mathcal{L}$.

SOLUTION A vector which is normal to a plane, is orthogonal to all the vectors in the plane. Since the line $\mathcal{L}$ is on both the planes $\mathcal{P}_1$ and $\mathcal{P}_2$, the normal $\mathbf{n}_1$ to the plane $\mathcal{P}_1$ is orthogonal to the direction vector of $\mathcal{L}$ and the normal $\mathbf{n}_2$ to the plane $\mathcal{P}_2$ is also orthogonal to this vector. That is, the line $\mathcal{L}$ is orthogonal to both $\mathbf{n}_1$ and $\mathbf{n}_2$. The cross product $\mathbf{n}_1 \times \mathbf{n}_2$ is also orthogonal to $\mathbf{n}_1$ and $\mathbf{n}_2$, hence it is parallel to $\mathcal{L}$. In other words $\mathbf{n}_1 \times \mathbf{n}_2$ is a direction vector of $\mathcal{L}$.

57. Find a plane that is perpendicular to the two planes $x + y = 3$ and $x + 2y - z = 4$.

SOLUTION The vector forms of the equations of the planes are $\langle 1, 1, 0 \rangle \cdot \langle x, y, z \rangle = 3$ and $\langle 1, 2, -1 \rangle \cdot \langle x, y, z \rangle = 4$, hence the vectors $\mathbf{n}_1 = \langle 1, 1, 0 \rangle$ and $\mathbf{n}_2 = \langle 1, 2, -1 \rangle$ are normal to the planes. We denote the equation of the planes which are perpendicular to the two planes by

$$ax + by + cz = d \tag{1}$$

Then, the normal $\mathbf{n} = \langle a, b, c \rangle$ to the planes is orthogonal to the normals $\mathbf{n}_1$ and $\mathbf{n}_2$ of the given planes. Therefore, $\mathbf{n} \cdot \mathbf{n}_1 = 0$ and $\mathbf{n} \cdot \mathbf{n}_2 = 0$ which gives us

$$\langle a, b, c \rangle \cdot \langle 1, 1, 0 \rangle = 0, \quad \langle a, b, c \rangle \cdot \langle 1, 2, -1 \rangle = 0$$

We obtain the following equations:

$$\begin{cases} a + b = 0 \\ a + 2b - c = 0 \end{cases}$$

The first equation implies that $b = -a$. Substituting in the second equation we get $a - 2a - c = 0$, or $c = -a$. Substituting $b = -a$ and $c = -a$ in (1) gives (for $a \ne 0$):

$$ax - ay - az = d \quad \Rightarrow \quad x - y - z = \frac{d}{a}$$

$\frac{d}{a}$ is an arbitrary constant which we denote by f. The planes which are perpendicular to the given planes are, therefore,

$$x - y - z = f$$

58. Let $\mathcal{L}$ be the intersection of the planes $x + y + z = 1$ and $x + 2y + 3z = 1$. Use Exercise 56 to find a direction vector for $\mathcal{L}$. Then find a point P on $\mathcal{L}$ by *inspection*, and write down the parametric equations for $\mathcal{L}$.

SOLUTION We identify $\mathbf{n}_1 = \langle 1, 1, 1 \rangle$ and $\mathbf{n}_2 = \langle 1, 2, 3 \rangle$ as normals to the planes $x + y + z = 1$ and $x + 2y + 3z = 1$ respectively. By Exercise 56, the cross product $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2$ is a direction vector of $\mathcal{L}$. We find it here:

$$\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & 1 \\ 1 & 2 & 3 \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ 2 & 3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 1 \\ 1 & 3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 1 \\ 1 & 2 \end{vmatrix} \mathbf{k} = \mathbf{i} - 2\mathbf{j} + \mathbf{k} = \langle 1, -2, 1 \rangle$$

We observe that $x = 1$, $y = 0$, $z = 0$ satisfy the equations of the two planes, hence the point $P = (1, 0, 0)$ is on the line $\mathcal{L}$. The vector parametrization of $\mathcal{L}$ is, thus,

$$\mathbf{r}(t) = \langle 1, 0, 0 \rangle + t\langle 1, -2, 1 \rangle$$

This yields the parametric equations

$$x = 1 + t, \quad y = -2t, \quad z = t.$$

59. Let $\mathcal{L}$ denote the intersection of the planes $x - y - z = 1$ and $2x + 3y + z = 2$. Find parametric equations for the line $\mathcal{L}$. *Hint:* To find a point on $\mathcal{L}$, substitute an arbitrary value for z (say, $z = 2$) and then solve the resulting pair of equations for x and y.

SOLUTION We use Exercise 56 to find a direction vector for the line of intersection $\mathcal{L}$ of the planes $x - y - z = 1$ and $2x + 3y + z = 2$. We identify the normals $\mathbf{n}_1 = \langle 1, -1, -1 \rangle$ and $\mathbf{n}_2 = \langle 2, 3, 1 \rangle$ to the two planes respectively. Hence, a direction vector for $\mathcal{L}$ is the cross product $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2$. We find it here:

$$\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -1 & -1 \\ 2 & 3 & 1 \end{vmatrix} = 2\mathbf{i} - 3\mathbf{j} + 5\mathbf{k} = \langle 2, -3, 5 \rangle$$

We now need to find a point on $\mathcal{L}$. We choose $z = 2$, substitute in the equations of the planes and solve the resulting equations for x and y. This gives

$$\begin{aligned} x - y - 2 &= 1 \\ 2x + 3y + 2 &= 2 \end{aligned} \quad \text{or} \quad \begin{aligned} x - y &= 3 \\ 2x + 3y &= 0 \end{aligned}$$

The 1st equation implies that $y = x - 3$. Substituting in the 2nd equation and solving for x gives

$$\begin{aligned} 2x + 3(x - 3) &= 0 \\ 5x = 9 \quad &\Rightarrow \quad x = \frac{9}{5}, \quad y = \frac{9}{5} - 3 = -\frac{6}{5} \end{aligned}$$

We conclude that the point $\left(\frac{9}{5}, -\frac{6}{5}, 2\right)$ is on $\mathcal{L}$. We now use the vector parametrization of a line to obtain the following parametrization for $\mathcal{L}$:

$$\mathbf{r}(t) = \left\langle \frac{9}{5}, -\frac{6}{5}, 2 \right\rangle + t\langle 2, -3, 5 \rangle$$

This yields the parametric equations

$$x = \frac{9}{5} + 2t, \quad y = -\frac{6}{5} - 3t, \quad z = 2 + 5t$$

60. Find parametric equations for the intersection of the planes $2x + y - 3z = 0$ and $x + y = 1$.

SOLUTION We use Exercise 56 to determine a direction vector $\mathbf{v}$ for the line of intersection $\mathcal{L}$ of the two planes. The planes $2x + y - 3z = 0$ and $x + y = 1$ have normals $\mathbf{n}_1 = \langle 2, 1, -3 \rangle$ and $\mathbf{n}_2 = \langle 1, 1, 0 \rangle$ respectively, hence the cross product $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2$ is parallel to the line $\mathcal{L}$. We find it here:

$$\begin{aligned} \mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 1 & -3 \\ 1 & 1 & 0 \end{vmatrix} = \begin{vmatrix} 1 & -3 \\ 1 & 0 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 2 & -3 \\ 1 & 0 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 2 & 1 \\ 1 & 1 \end{vmatrix} \mathbf{k} \\ &= 3\mathbf{i} - 3\mathbf{j} + \mathbf{k} = \langle 3, -3, 1 \rangle \end{aligned}$$

We now must find a point P_0 on $\mathcal{L}$. We substitute an arbitrary value for z, say $z = 0$, in the equations of the planes $2x + y - 3z = 0$ and $x + y = 1$ and solve the resulting equations for x and y. This gives

$$\begin{aligned} 2x + y &= 0 \\ x + y &= 1 \end{aligned} \quad \Rightarrow \quad x = -1, \ y = 2$$

Thus, the point $P_0 = (-1, 2, 0)$ is on the line $\mathcal{L}$. We now use the vector parametrization of the line to obtain the following parametrization of $\mathcal{L}$:

$$\mathbf{r}(t) = \langle -1, 2, 0 \rangle + t\langle 3, -3, 1 \rangle$$

The parametric equation are thus,

$$x = -1 + 3t, \quad y = 2 - 3t, \quad z = t$$

61. Two vectors $\mathbf{v}$ and $\mathbf{w}$, each of length 12, lie in the plane $x + 2y - 2z = 0$. The angle between $\mathbf{v}$ and $\mathbf{w}$ is $\pi/6$. This information determines $\mathbf{v} \times \mathbf{w}$ up to a sign ± 1. What are the two possible values of $\mathbf{v} \times \mathbf{w}$?

SOLUTION The length of $\mathbf{v} \times \mathbf{w}$ is $\|\mathbf{v}\|\|\mathbf{w}\| \sin\theta$, but since both vectors have length 12 and since the angle between them is $\pi/6$, then the length of $\mathbf{v} \times \mathbf{w}$ is $12 \cdot 12 \cdot 1/2 = 72$. The direction of $\mathbf{v} \times \mathbf{w}$ is perpendicular to the plane containing them, which is the plane $x + 2y - 2z = 0$, which has normal vector $\mathbf{n} = \langle 1, 2, -2\rangle$. Since $\mathbf{v} \times \mathbf{w}$ must have length 72 and must be parallel to $\langle 1, 2, -2\rangle$, then it must be ± 72 times the unit vector $\langle 1, 2, -2\rangle / \sqrt{1^2 + 2^2 + (-2)^2} = \langle 1/3, 2/3, -2/3\rangle$. Thus,

$$\mathbf{v} \times \mathbf{w} = \pm 72 \cdot \langle 1/3, 2/3, -2/3\rangle = \pm 24 \cdot \langle 1, 2, -2\rangle$$

62. The plane

$$\frac{x}{2} + \frac{y}{4} + \frac{z}{3} = 1$$

intersects the x-, y-, and z-axes in points P, Q, and R. Find the area of the triangle $\triangle PQR$.

SOLUTION The points of intersection are found by setting two of the three variables in $\frac{x}{2} + \frac{y}{4} + \frac{z}{3} = 1$ equal to zero at a time. We get the following:

$$P = (2, 0, 0), \quad Q = (0, 4, 0), \quad R = (0, 0, 3)$$

and so we can find the two vectors that span the triangle:

$$\overrightarrow{PQ} = 4\mathbf{j} - 2\mathbf{i}, \quad \overrightarrow{PR} = 3\mathbf{k} - 2\mathbf{i}$$

We have

$$\begin{aligned}\overrightarrow{PQ} \times \overrightarrow{PR} &= (4\mathbf{j} - 2\mathbf{i}) \times (3\mathbf{k} - 2\mathbf{i}) \\ &= 12\mathbf{j} \times \mathbf{k} - 8\mathbf{j} \times \mathbf{i} - 6\mathbf{i} \times \mathbf{k} + 4\mathbf{i} \times \mathbf{i} \\ &= 12\mathbf{i} + 8\mathbf{k} + 6\mathbf{j}\end{aligned}$$

The area of the triangle is

$$\frac{1}{2}\|\overrightarrow{PQ} \times \overrightarrow{PR}\| = \frac{1}{2}\sqrt{144 + 36 + 64} = \frac{1}{2}\sqrt{244} = \sqrt{61}$$

63. In this exercise, we show that the orthogonal distance D from the plane $\mathcal{P}$ with equation $ax + by + cz = d$ to the origin O is equal to (Figure 10)

$$D = \frac{|d|}{\sqrt{a^2 + b^2 + c^2}}$$

Let $\mathbf{n} = \langle a, b, c\rangle$, and let P be the point where the line through $\mathbf{n}$ intersects $\mathcal{P}$. By definition, the orthogonal distance from $\mathcal{P}$ to O is the distance from P to O.

(a) Show that P is the terminal point of $\mathbf{v} = \left(\frac{d}{\mathbf{n} \cdot \mathbf{n}}\right)\mathbf{n}$.

(b) Show that the distance from P to O is D.

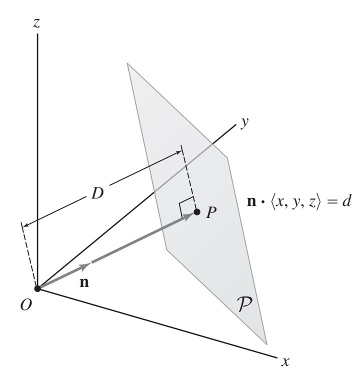

FIGURE 10

SOLUTION Let $\mathbf{v}$ be the vector $\mathbf{v} = \left(\frac{d}{\mathbf{n} \cdot \mathbf{n}}\right)\mathbf{n}$. Then $\mathbf{v}$ is parallel to $\mathbf{n}$ and the two vectors are on the same ray.

(a) First we must show that the terminal point of $\mathbf{v}$ lies on the plane $ax + by + cz = d$. Since the terminal point of $\mathbf{v}$ is the point

$$\left(\frac{d}{\mathbf{n} \cdot \mathbf{n}}\right)(a, b, c) = \left(\frac{da}{a^2 + b^2 + c^2}, \frac{db}{a^2 + b^2 + c^2}, \frac{dc}{a^2 + b^2 + c^2}\right)$$

then we need only show that this point satisfies $ax + by + cz = d$. Plugging in, we find:

$$ax + by + cz = a \cdot \frac{da}{a^2+b^2+c^2} + b \cdot \frac{db}{a^2+b^2+c^2} + c \cdot \frac{dc}{a^2+b^2+c^2} = \frac{a^2d+b^2d+c^2d}{a^2+b^2+c^2} = d$$

(b) We now show that the distance from P to O is D. This distance is just the length of the vector $\mathbf{v}$, which is:

$$\|\mathbf{v}\| = \left(\frac{|d|}{\mathbf{n}\cdot\mathbf{n}}\right)\|\mathbf{n}\| = \frac{|d|}{\|\mathbf{n}\|} = \frac{|d|}{\sqrt{a^2+b^2+c^2}}$$

as desired.

64. Use Exercise 63 to compute the orthogonal distance from the plane $x + 2y + 3z = 5$ to the origin.

SOLUTION Using the formula

$$D = \frac{|d|}{\sqrt{a^2+b^2+c^2}}$$

and since our line is $x + 2y + 3z = 5$, we have $a = 1$, $b = 2$, $c = 3$, $d = 5$, and so we calculate

$$D = \frac{|5|}{\sqrt{1^2+2^2+3^2}} = \frac{5}{\sqrt{14}} \approx 1.3363$$

Further Insights and Challenges

In Exercises 65 and 66, let $\mathcal{P}$ be a plane with equation

$$ax + by + cz = d$$

and normal vector $\mathbf{n} = \langle a, b, c\rangle$. For any point Q, there is a unique point P on $\mathcal{P}$ that is closest to Q, and is such that $\overline{PQ}$ is orthogonal to $\mathcal{P}$ (Figure 11).

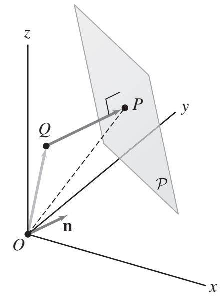

FIGURE 11

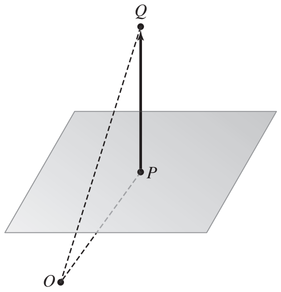
65. Show that the point P on $\mathcal{P}$ closest to Q is determined by the equation

$$\overrightarrow{OP} = \overrightarrow{OQ} + \left(\frac{d - \overrightarrow{OQ}\cdot\mathbf{n}}{\mathbf{n}\cdot\mathbf{n}}\right)\mathbf{n} \qquad \boxed{7}$$

SOLUTION Since $\overrightarrow{PQ}$ is orthogonal to the plane $\mathcal{P}$, it is parallel to the vector $\mathbf{n} = \langle a, b, c\rangle$ which is normal to the plane. Hence,

$$\overrightarrow{PQ} = \lambda\mathbf{n} \qquad (1)$$



Since $\overrightarrow{OP} + \overrightarrow{PQ} = \overrightarrow{OQ}$, we have $\overrightarrow{PQ} = \overrightarrow{OQ} - \overrightarrow{OP}$. Thus, by (1) we get

$$\overrightarrow{OQ} - \overrightarrow{OP} = \lambda \mathbf{n} \quad \Rightarrow \quad \overrightarrow{OP} = \overrightarrow{OQ} - \lambda \mathbf{n} \tag{2}$$

The point P is on the plane, hence $\overrightarrow{OP}$ satisfies the vector form of the equation of the plane, that is,

$$\mathbf{n} \cdot \overrightarrow{OP} = d \tag{3}$$

Substituting (2) into (3) and solving for λ yields

$$\mathbf{n} \cdot \left(\overrightarrow{OQ} - \lambda \mathbf{n}\right) = d$$

$$\mathbf{n} \cdot \overrightarrow{OQ} - \lambda \mathbf{n} \cdot \mathbf{n} = d$$

$$\lambda \mathbf{n} \cdot \mathbf{n} = \mathbf{n} \cdot \overrightarrow{OQ} - d \quad \Rightarrow \quad \lambda = \frac{\mathbf{n} \cdot \overrightarrow{OQ} - d}{\mathbf{n} \cdot \mathbf{n}} \tag{4}$$

Finally, we combine (2) and (4) to obtain

$$\overrightarrow{OP} = \overrightarrow{OQ} + \left(\frac{d - \mathbf{n} \cdot \overrightarrow{OQ}}{\mathbf{n} \cdot \mathbf{n}}\right) \mathbf{n}$$

66. By definition, the distance from a point $Q = (x_1, y_1, z_1)$ to the plane $\mathcal{P}$ is $\|QP\|$ where P is the point on $\mathcal{P}$ that is closest to Q. Prove:

$$\text{Distance from } Q \text{ to } \mathcal{P} = \frac{|ax_1 + by_1 + cz_1 - d|}{\|\mathbf{n}\|} \tag{8}$$

SOLUTION The distance l from Q to P is the length of the vector $\overrightarrow{PQ}$, that is,

$$\ell = \|\overrightarrow{PQ}\| = \|\overrightarrow{OQ} - \overrightarrow{OP}\| \tag{1}$$

By Eq. (7) in Exercise 65,

$$\overrightarrow{OP} - \overrightarrow{OQ} = \left(\frac{d - \overrightarrow{OQ} \cdot \mathbf{n}}{\|\mathbf{n}\|^2}\right) \mathbf{n}$$

Combining with (1) and noticing that $\frac{\mathbf{n}}{\|\mathbf{n}\|}$ is a unit vector, we have

$$\ell = \left\| \left(\frac{d - \overrightarrow{OQ} \cdot \mathbf{n}}{\|\mathbf{n}\|^2}\right) \mathbf{n} \right\| = \frac{|d - \overrightarrow{OQ} \cdot \mathbf{n}|}{\|\mathbf{n}\|} \cdot \left\| \frac{\mathbf{n}}{\|\mathbf{n}\|} \right\| = \frac{|d - \overrightarrow{OQ} \cdot \mathbf{n}|}{\|\mathbf{n}\|} \tag{2}$$

We compute the numerator in (2):

$$|d - \overrightarrow{OQ} \cdot \mathbf{n}| = |d - \langle x_1, y_1, z_1 \rangle \cdot \langle a, b, c \rangle| = |d - (ax_1 + by_1 + cz_1)| = |ax_1 + by_1 + cz_1 - d|$$

Substituting into (2) we obtain the following distance:

$$\ell = \frac{|ax_1 + by_1 + cz_1 - d|}{\|\mathbf{n}\|}$$

67. Use Eq. (7) to find the point P nearest to $Q = (2, 1, 2)$ on the plane $x + y + z = 1$.

SOLUTION We identify $\mathbf{n} = \langle 1, 1, 1 \rangle$ as a vector normal to the plane. By Eq. (7) the nearest point P to Q is determined by

$$\overrightarrow{OP} = \overrightarrow{OQ} + \left(\frac{d - \overrightarrow{OQ} \cdot \mathbf{n}}{\mathbf{n} \cdot \mathbf{n}}\right) \mathbf{n}$$

We substitute $\mathbf{n} = \langle 1, 1, 1 \rangle$, $\overrightarrow{OQ} = \langle 2, 1, 2 \rangle$ and $d = 1$ in this equation to obtain

$$\begin{aligned} \overrightarrow{OP} &= \langle 2, 1, 2 \rangle + \frac{1 - \langle 2, 1, 2 \rangle \cdot \langle 1, 1, 1 \rangle}{\langle 1, 1, 1 \rangle \cdot \langle 1, 1, 1 \rangle} \langle 1, 1, 1 \rangle = \langle 2, 1, 2 \rangle + \frac{1 - (2 + 1 + 2)}{1 + 1 + 1} \langle 1, 1, 1 \rangle \\ &= \langle 2, 1, 2 \rangle - \frac{4}{3} \langle 1, 1, 1 \rangle = \left\langle \frac{2}{3}, -\frac{1}{3}, \frac{2}{3} \right\rangle \end{aligned}$$

The terminal point $P = \left(\frac{2}{3}, -\frac{1}{3}, \frac{2}{3}\right)$ of $\overrightarrow{OP}$ is the nearest point to $Q = (2, 1, 2)$ on the plane.

68. Find the point P nearest to $Q = (-1, 3, -1)$ on the plane

$$x - 4z = 2$$

SOLUTION By Exercise 65, the nearest point P to Q on the plane $ax + by + cz = d$ is determined by the equation

$$\overrightarrow{OP} = \overrightarrow{OQ} + \left(\frac{d - \overrightarrow{OQ} \cdot \mathbf{n}}{\mathbf{n} \cdot \mathbf{n}}\right)\mathbf{n}$$

We identify $\mathbf{n} = \langle 1, 0, -4 \rangle$ as a vector normal to the plane $x - 4z = 2$. We also substitute $d = 2$ and $\overrightarrow{OQ} = \langle -1, 3, -1 \rangle$ to obtain

$$\begin{aligned}\overrightarrow{OP} &= \langle -1, 3, -1 \rangle + \frac{2 - \langle -1, 3, -1 \rangle \cdot \langle 1, 0, -4 \rangle}{\langle 1, 0, -4 \rangle \cdot \langle 1, 0, -4 \rangle}\langle 1, 0, -4 \rangle \\ &= \langle -1, 3, -1 \rangle + \frac{2 - (-1 + 0 + 4)}{1 + 0 + 16}\langle 1, 0, -4 \rangle \\ &= \langle -1, 3, -1 \rangle - \frac{1}{17}\langle 1, 0, -4 \rangle = \left\langle -\frac{18}{17}, 3, -\frac{13}{17} \right\rangle\end{aligned}$$

The desired point P is the terminal point of $\overrightarrow{OP}$, that is, $P = \left(-\frac{18}{17}, 3, -\frac{13}{17}\right)$.

69. Use Eq. (8) to find the distance from $Q = (1, 1, 1)$ to the plane $2x + y + 5z = 2$.

SOLUTION By Eq. (8), the distance from $Q = \langle x_1, y_1, z_1 \rangle$ to the plane $ax + by + cz = d$ is

$$\ell = \frac{|ax_1 + by_1 + cz_1 - d|}{\|\mathbf{n}\|} \tag{1}$$

We identify the vector $\mathbf{n} = \langle 2, 1, 5 \rangle$ as a normal to the plane $2x + y + 5z = 2$. Also $a = 2$, $b = 1$, $c = 5$, $d = 2$, and $(x_1, y_1, z_1) = (1, 1, 1)$. Substituting in (1) above we get

$$\ell = \frac{|2 \cdot 1 + 1 \cdot 1 + 5 \cdot 1 - 2|}{\|\langle 2, 1, 5 \rangle\|} = \frac{6}{\sqrt{2^2 + 1^2 + 5^2}} = \frac{6}{\sqrt{30}} \approx 1.095$$

70. Find the distance from $Q = (1, 2, 2)$ to the plane $\mathbf{n} \cdot \langle x, y, z \rangle = 3$, where $\mathbf{n} = \left\langle \frac{3}{5}, \frac{4}{5}, 0 \right\rangle$.

SOLUTION We write the equation of the plane in scalar form:

$$\begin{aligned}\left\langle \frac{3}{5}, \frac{4}{5}, 0 \right\rangle \cdot \langle x, y, z \rangle &= 3 \\ \frac{3}{5}x + \frac{4}{5}y + 0 &= 3 \\ \frac{3}{5}x + \frac{4}{5}y &= 3\end{aligned}$$

We use Eq. (8) in for the distance ℓ from $Q = (x_1, y_1, z_1)$ to the plane $ax + by + cz = d$:

$$\ell = \frac{|ax_1 + by_1 + cz_1 - d|}{\|\mathbf{n}\|} \tag{1}$$

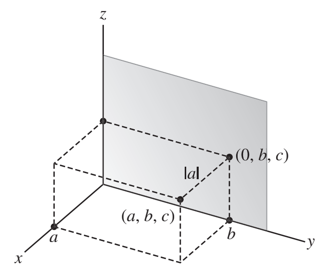
In our example, $a = \frac{3}{5}$, $b = \frac{4}{5}$, $c = 0$, $d = 3$. Also $(x_1, y_1, z_1) = (1, 2, 2)$ and $\mathbf{n} = \left\langle \frac{3}{5}, \frac{4}{5}, 0 \right\rangle$. Substituting these values in the formula (1) for the distance ℓ, we get

$$\ell = \frac{\left|\frac{3}{5} \cdot 1 + \frac{4}{5} \cdot 2 + 0 - 3\right|}{\sqrt{\left(\frac{3}{5}\right)^2 + \left(\frac{4}{5}\right)^2 + 0^2}} = \frac{\frac{4}{5}}{1} = \frac{4}{5}$$

We found that the distance from $Q = (1, 2, 2)$ to the given plane is $\ell = \frac{4}{5}$.

71. What is the distance from $Q = (a, b, c)$ to the plane $x = 0$? Visualize your answer geometrically and explain without computation. Then verify that Eq. (8) yields the same answer.

SOLUTION The plane $x = 0$ is the yz-coordinate plane. The nearest point to Q on the plane is the projection of Q on the plane, which is the point $Q' = (0, b, c)$.



Hence, the distance from Q to the plane is the length of the vector $\overrightarrow{Q'Q} = \langle a, 0, 0\rangle$ which is $|a|$. We now verify that Eq. (8) gives the same answer. The plane $x = 0$ has the vector parametrization $\langle 1, 0, 0\rangle \cdot \langle x, y, z\rangle = 0$, hence $\mathbf{n} = \langle 1, 0, 0\rangle$. The coefficients of the plane $x = 0$ are $A = 1$, $B = C = D = 0$. Also $(x_1, y_1, z_1) = (a, b, c)$. Substituting this value in Eq. (8) we get

$$\frac{|Ax_1 + By_1 + Cz_1 - D|}{\|\mathbf{n}\|} = \frac{|1 \cdot a + 0 + 0 - 0|}{\|\langle 1, 0, 0\rangle\|} = \frac{|a|}{\sqrt{1^2 + 0^2 + 0^2}} = |a|$$

The two answers agree, as expected.

72. The equation of a plane $\mathbf{n} \cdot \langle x, y, z\rangle = d$ is said to be in **normal form** if $\mathbf{n}$ is a unit vector. Show that in this case, $|d|$ is the distance from the plane to the origin. Write the equation of the plane $4x - 2y + 4z = 24$ in normal form.

SOLUTION By Exercise 65 the point Q nearest to the origin on the plane $\mathbf{n} \cdot \langle x, y, z\rangle = d$ is the terminal point of the vector

$$\mathbf{v} = \left(\frac{d}{\|\mathbf{n}\|^2}\right)\mathbf{n}$$

If the equation of the plane is in normal form, $\mathbf{n}$ is a unit vector, hence $\|\mathbf{n}\| = 1$. Therefore Q is the terminal point of the vector

$$\mathbf{v} = d\mathbf{n}$$

The distance from the plane to the origin is the length of $\mathbf{v}$, that is,

$$\|\mathbf{v}\| = \|d\mathbf{n}\| = |d|\|\mathbf{n}\| = |d| \cdot 1 = |d|.$$

The plane $4x - 2x + 4z = 24$ can be written

$$\frac{4x - 2x + 4z}{\sqrt{4^2 + (-2)^2 + 4^2}} = \frac{24}{\sqrt{4^2 + (-2)^2 + 4^2}}$$

or

$$\frac{1}{6}\langle 4, -2, 4\rangle \cdot \langle x, y, z\rangle = 4$$

or

$$\left\langle \frac{2}{3}, -\frac{1}{3}, \frac{2}{3}\right\rangle \cdot \langle x, y, z\rangle = 4, \text{ in normal form.}$$

12.6 A Survey of Quadric Surfaces (LT Section 13.6)

Preliminary Questions

1. True or false? All traces of an ellipsoid are ellipses.

SOLUTION This statement is true, mostly. All traces of an ellipsoid $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 = 1$ are ellipses, except for the traces obtained by intersecting the ellipsoid with the planes $x = \pm a$, $y = \pm b$ and $z = \pm c$. These traces reduce to the single points $(\pm a, 0, 0)$, $(0, \pm b, 0)$ and $(0, 0, \pm c)$ respectively.

2. True or false? All traces of a hyperboloid are hyperbolas.

SOLUTION The statement is false. For a hyperbola in the standard orientation, the horizontal traces are ellipses (or perhaps empty for a hyperbola of two sheets), and the vertical traces are hyperbolas.

3. Which quadric surfaces have both hyperbolas and parabolas as traces?

SOLUTION The hyperbolic paraboloid $z = \left(\frac{x}{a}\right)^2 - \left(\frac{y}{b}\right)^2$ has vertical trace curves which are parabolas. If we set $x = x_0$ or $y = y_0$ we get

$$z = \left(\frac{x_0}{a}\right)^2 - \left(\frac{y}{b}\right)^2 \quad \Rightarrow \quad z = -\left(\frac{y}{b}\right)^2 + C$$

$$z = \left(\frac{x}{a}\right)^2 - \left(\frac{y_0}{b}\right)^2 \quad \Rightarrow \quad z = \left(\frac{x}{a}\right)^2 + C$$

The hyperbolic paraboloid has vertical traces which are hyperbolas, since for $z = z_0$, $(z_0 > 0)$, we get

$$z_0 = \left(\frac{x}{a}\right)^2 - \left(\frac{y}{b}\right)^2$$

4. Is there any quadric surface whose traces are all parabolas?

SOLUTION There is no quadric surface whose traces are all parabolas.

5. A surface is called **bounded** if there exists $M > 0$ such that every point on the surface lies at a distance of at most M from the origin. Which of the quadric surfaces are bounded?

SOLUTION The only quadric surface that is bounded is the ellipsoid

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 = 1.$$

All other quadric surfaces are not bounded, since at least one of the coordinates can increase or decrease without bound.

6. What is the definition of a parabolic cylinder?

SOLUTION A parabolic cylinder consists of all vertical lines passing through a parabola $\mathcal{C}$ in the xy-plane.

Exercises

In Exercises 1–6, state whether the given equation defines an ellipsoid or hyperboloid, and if a hyperboloid, whether it is of one or two sheets.

1. $\left(\frac{x}{2}\right)^2 + \left(\frac{y}{3}\right)^2 + \left(\frac{z}{5}\right)^2 = 1$

SOLUTION This equation is the equation of an ellipsoid.

2. $\left(\frac{x}{5}\right)^2 + \left(\frac{y}{5}\right)^2 - \left(\frac{z}{7}\right)^2 = 1$

SOLUTION The given equation defines a hyperboloid of one sheet.

3. $x^2 + 3y^2 + 9z^2 = 1$

SOLUTION We rewrite the equation as follows:

$$x^2 + \left(\frac{y}{\frac{1}{\sqrt{3}}}\right)^2 + \left(\frac{z}{\frac{1}{3}}\right)^2 = 1$$

This equation defines an ellipsoid.

4. $-\left(\frac{x}{2}\right)^2 - \left(\frac{y}{3}\right)^2 + \left(\frac{z}{5}\right)^2 = 1$

SOLUTION This is the equation of a hyperboloid of two sheets.

5. $x^2 - 3y^2 + 9z^2 = 1$

SOLUTION We rewrite the equation in the form

$$x^2 - \left(\frac{y}{\frac{1}{\sqrt{3}}}\right)^2 + \left(\frac{z}{\frac{1}{3}}\right)^2 = 1$$

This is the equation of a hyperboloid of one sheet.

6. $x^2 - 3y^2 - 9z^2 = 1$

SOLUTION Rewriting the equation in the form

$$x^2 - \left(\frac{y}{\frac{1}{\sqrt{3}}}\right)^2 - \left(\frac{z}{\frac{1}{3}}\right)^2 = 1$$

we identify it as the equation of a hyperboloid of two sheets.

In Exercises 7–12, state whether the given equation defines an elliptic paraboloid, a hyperbolic paraboloid, or an elliptic cone.

7. $z = \left(\frac{x}{4}\right)^2 + \left(\frac{y}{3}\right)^2$

SOLUTION This equation defines an elliptic paraboloid.

8. $z^2 = \left(\frac{x}{4}\right)^2 + \left(\frac{y}{3}\right)^2$

SOLUTION This is the equation of an elliptic cone.

9. $z = \left(\frac{x}{9}\right)^2 - \left(\frac{y}{12}\right)^2$

SOLUTION This equation defines a hyperbolic paraboloid.

10. $4z = 9x^2 + 5y^2$

SOLUTION The equation can be rewritten as

$$z = \left(\frac{x}{\frac{2}{3}}\right)^2 + \left(\frac{y}{\frac{2}{\sqrt{5}}}\right)^2$$

hence it defines an elliptic paraboloid.

11. $3x^2 - 7y^2 = z$

SOLUTION Rewriting the equation as

$$z = \left(\frac{x}{\frac{1}{\sqrt{3}}}\right)^2 - \left(\frac{y}{\frac{1}{\sqrt{7}}}\right)^2$$

we identify it as the equation of a hyperbolic paraboloid.

12. $3x^2 + 7y^2 = 14z^2$

SOLUTION We rewrite the equations as follows:

$$\begin{aligned} 3x^2 + 7y^2 &= 14z^2 \\ 3x^2 &= -7y^2 + 14z^2 \\ \left(\frac{x}{\frac{1}{\sqrt{3}}}\right)^2 &= -\left(\frac{y}{\frac{1}{\sqrt{7}}}\right)^2 + \left(\frac{z}{\frac{1}{\sqrt{14}}}\right)^2 \end{aligned}$$

We identify it as the equation of an elliptic cone.

In Exercises 13–20, state the type of the quadric surface and describe the trace obtained by intersecting with the given plane.

13. $x^2 + \left(\frac{y}{4}\right)^2 + z^2 = 1, \quad y = 0$

SOLUTION The equation $x^2 + \left(\frac{y}{4}\right)^2 + z^2 = 1$ defines an ellipsoid. The xz-trace is obtained by substituting $y = 0$ in the equation of the ellipsoid. This gives the equation $x^2 + z^2 = 1$ which defines a circle in the xz-plane.

14. $x^2 + \left(\frac{y}{4}\right)^2 + z^2 = 1, \quad y = 5$

SOLUTION This equation defines an ellipsoid. Substituting $y = 5$ gives

$$\begin{aligned} x^2 + \left(\frac{5}{4}\right)^2 + z^2 &= 1 \\ x^2 + z^2 &= -\left(\frac{3}{4}\right)^2 \end{aligned}$$

Since $x^2 + y^2 \geq 0$ for all x and z, the trace is an empty set.

15. $x^2 + \left(\frac{y}{4}\right)^2 + z^2 = 1, \quad z = \frac{1}{4}$

SOLUTION The quadric surface is an ellipsoid, since its equation has the form $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 = 1$ for $a = 1$, $b = 4$, $c = 1$. To find the trace obtained by intersecting the ellipsoid with the plane $z = \frac{1}{4}$, we set $z = \frac{1}{4}$ in the equation of the ellipsoid. This gives

$$lx^2 + \left(\frac{y}{4}\right)^2 + \left(\frac{1}{4}\right)^2 = 1$$

$$x^2 + \frac{y^2}{16} = \frac{15}{16}$$

To get the standard form we divide by $\frac{15}{16}$ to obtain

$$\frac{x^2}{\frac{15}{16}} + \frac{y^2}{\frac{16\cdot 15}{16}} = 1 \quad \Rightarrow \quad \left(\frac{x}{\frac{\sqrt{15}}{4}}\right)^2 + \left(\frac{y}{\sqrt{15}}\right)^2 = 1 \tag{1}$$

We conclude that the trace is an ellipse on the xy-plane, whose equation is given in (1).

16. $\left(\frac{x}{2}\right)^2 + \left(\frac{y}{5}\right)^2 - 5z^2 = 1, \quad x = 0$

SOLUTION The equation can be rewritten as

$$\left(\frac{x}{2}\right)^2 + \left(\frac{y}{5}\right)^2 - \left(\frac{z}{\frac{1}{\sqrt{5}}}\right)^2 = 1$$

hence it defines a hyperboloid of one sheet. The yz-trace is obtained by substituting $x = 0$ in the equation of the hyperboloid. This gives

$$\left(\frac{0}{2}\right)^2 + \left(\frac{y}{5}\right)^2 - 5z^2 = 1 \quad \Rightarrow \quad \left(\frac{y}{5}\right)^2 - \left(\frac{z}{\frac{1}{\sqrt{5}}}\right)^2 = 1.$$

This is the equation of a hyperbola in the yz-plane.

17. $\left(\frac{x}{3}\right)^2 + \left(\frac{y}{5}\right)^2 - 5z^2 = 1, \quad y = 1$

SOLUTION Rewriting the equation in the form

$$\left(\frac{x}{3}\right)^2 + \left(\frac{y}{5}\right)^2 - \left(\frac{z}{\frac{1}{\sqrt{5}}}\right)^2 = 1$$

we identify it as the equation of a hyperboloid of one sheet. Substituting $y = 1$ we get

$$\frac{x^2}{9} + \frac{1}{25} - 5z^2 = 1$$

$$\frac{x^2}{9} - 5z^2 = \frac{24}{25}$$

$$\frac{25}{24\cdot 9}x^2 - \frac{25\cdot 5}{24}z^2 = 1$$

$$\left(\frac{x}{\frac{6\sqrt{6}}{5}}\right)^2 - \left(\frac{z}{\frac{2}{5}\sqrt{\frac{6}{5}}}\right)^2 = 1$$

Thus, the trace on the plane $y = 1$ is a hyperbola.

18. $4x^2 + \left(\frac{y}{3}\right)^2 - 2z^2 = -1, \quad z = 1$

SOLUTION We rewrite the equation as follows:

$$\left(\frac{x}{\frac{1}{2}}\right)^2 + \left(\frac{y}{3}\right)^2 - \left(\frac{z}{\frac{1}{\sqrt{2}}}\right)^2 = 1$$

This equation defines a hyperboloid of one sheet. To find the trace of the hyperboloid on the plane $z = 1$, we substitute $z = 1$ in the equation. This gives

$$4x^2 + \left(\frac{y}{3}\right)^2 - 2 \cdot 1^2 = 1$$

$$4x^2 + \frac{y^2}{9} = 3$$

$$\frac{4}{3}x^2 + \frac{y^2}{27} = 1 \quad \Rightarrow \quad \left(\frac{x}{\frac{\sqrt{3}}{2}}\right)^2 + \left(\frac{y}{3 \cdot \sqrt{3}}\right)^2 = 1$$

The trace is an ellipse on the plane $z = 1$.

19. $y = 3x^2, \quad z = 27$

SOLUTION This equation defines a parabolic cylinder, consisting of all vertical lines passing through the parabola $y = 3x^2$ in the xy-plane. Hence, the trace of the cylinder on the plane $z = 27$ is the parabola $y = 3x^2$ on this plane, that is, the following set:

$$\left\{(x, y, z) : y = 3x^2,\ z = 27\right\}.$$

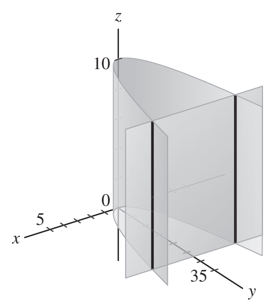
20. $y = 3x^2, \quad y = 27$

SOLUTION The equation $y = 3x^2$ defines a parabolic cylinder consisting of all vertical lines passing through the parabola $y = 3x^2$ in the xy-plane. To find the trace on the plane $y = 27$, we substitute $y = 27$ in the equation of the cylinder:

$$27 = 3x^2$$

$$9 = x^2 \quad \Rightarrow \quad x = 3,\ x = -3$$

Therefore, the trace is the two vertical lines through the points $(-3, 27)$ and $(3, 27)$ in the xy-plane.



21. Match each of the ellipsoids in Figure 12 with the correct equation:

(a) $x^2 + 4y^2 + 4z^2 = 16$

(b) $4x^2 + y^2 + 4z^2 = 16$

(c) $4x^2 + 4y^2 + z^2 = 16$

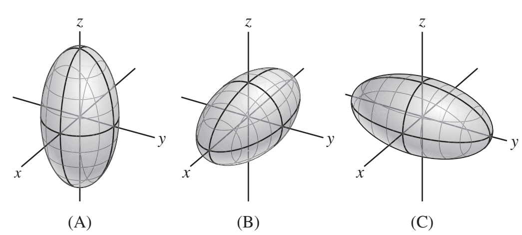


FIGURE 12

SOLUTION

(a) We rewrite the equation in the form

$$\left(\frac{x}{4}\right)^2 + \left(\frac{y}{2}\right)^2 + \left(\frac{z}{2}\right)^2 = 1$$

The ellipsoid intersects the x, y, and z axes at the points $(\pm 4, 0, 0)$, $(0, \pm 2, 0)$, and $(0, 0, \pm 2)$, hence (B) is the corresponding figure.

(b) We rewrite the equation in the form

$$\left(\frac{x}{2}\right)^2 + \left(\frac{y}{4}\right)^2 + \left(\frac{z}{2}\right)^2 = 1$$

The x, y, and z intercepts are $(\pm 2, 0, 0)$, $(0, \pm 4, 0)$, and $(0, 0, \pm 2)$ respectively, hence (C) is the correct figure.

(c) We write the equation in the form

$$\left(\frac{x}{2}\right)^2 + \left(\frac{y}{2}\right)^2 + \left(\frac{z}{4}\right)^2 = 1$$

The x, y, and z intercepts are $(\pm 2, 0, 0)$, $(0, \pm 2, 0)$, and $(0, 0, \pm 4)$ respectively, hence the corresponding figure is (A).

22. Describe the surface that is obtained when, in the equation $\pm 8x^2 \pm 3y^2 \pm z^2 = 1$, we choose (a) all plus signs, (b) one minus sign, and (c) two minus signs.

SOLUTION

(a) Choosing all plus signs in the given equation yields $8x^2 + 3y^2 + z^2 = 1$, or

$$\left(\frac{x}{\sqrt{1/8}}\right)^2 + \left(\frac{y}{\sqrt{1/3}}\right)^2 + z^2 = 1$$

which is the equation of an ellipsoid.

(b) Choosing one minus sign gives the equation of a hyperboloid of one sheet.

(c) Choosing two minus signs gives the equation of a hyperboloid of two sheets.

23. What is the equation of the surface obtained when the elliptic paraboloid $z = \left(\frac{x}{2}\right)^2 + \left(\frac{y}{4}\right)^2$ is rotated about the x-axis by 90°? Refer to Figure 13.

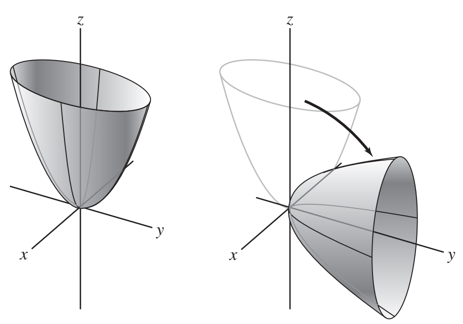

FIGURE 13

SOLUTION The axis of symmetry of the resulting surface is the y-axis rather than the z-axis. Interchanging y and z in the given equation gives the following equation of the rotated paraboloid:

$$y = \left(\frac{x}{2}\right)^2 + \left(\frac{z}{4}\right)^2$$

24. Describe the intersection of the horizontal plane $z = h$ and the hyperboloid $-x^2 - 4y^2 + 4z^2 = 1$. For which values of h is the intersection empty?

SOLUTION To find the intersection of the horizontal plane $z = h$ and the hyperboloid, we substitute $z = h$ in this equation. This gives

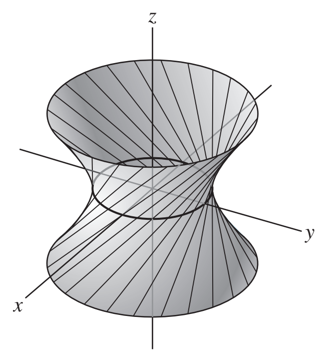
$$-x^2 - 4y^2 + 4h^2 = 1$$
$$4h^2 - 1 = x^2 + 4y^2$$

So, for $4h^2 - 1 > 0$, this is an ellipse, and for $4h^2 - 1 = 0$ this is a point, but for $4h^2 - 1 < 0$ there is no intersection. Solving that last equation for h, we get $4h^2 < 1$, so $h^2 < 1/4$, so $|h| < 1/2$ (also written as $-1/2 < h < 1/2$). Thus, for $|h| < 1/2$ there is no intersection, and for $|h| = 1/2$ the intersection is a point, and for $|h| > 1/2$ the intersection is an ellipse.

In Exercises 25–30, sketch the given surface.

25. $x^2 + y^2 - z^2 = 1$

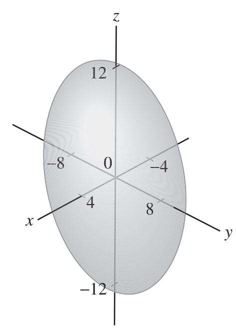
SOLUTION This equation defines a hyperboloid of one sheet. The trace on the plane $z = z_0$ is the circle $x^2 + y^2 = 1 + z_0^2$. The trace on the plane $y = y_0$ is the hyperbola $x^2 - z^2 = 1 - y_0^2$ and the trace on the plane $x = x_0$ is the hyperbola $y^2 - z^2 = 1 - x_0^2$. We obtain the following surface:



Graph of $x^2 + y^2 - z^2 = 1$

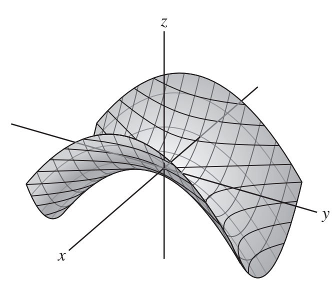
26. $\left(\frac{x}{4}\right)^2 + \left(\frac{y}{8}\right)^2 + \left(\frac{z}{12}\right)^2 = 1$

SOLUTION This equation defines and ellipsoid with x, y and z intercepts at the points $(\pm 4, 0, 0)$, $(0, \pm 8, 0)$ and $(0, 0, \pm 12)$. All the traces of the ellipsoid are ellipses. The surface is shown next:



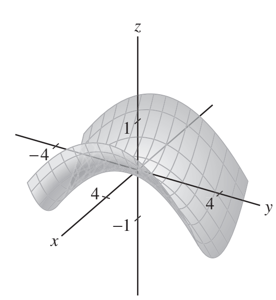
27. $z = \left(\frac{x}{4}\right)^2 + \left(\frac{y}{8}\right)^2$

SOLUTION This equation defines an elliptic paraboloid, as shown in the following figure:



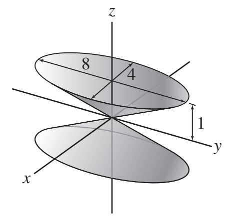
28. $z = \left(\frac{x}{4}\right)^2 - \left(\frac{y}{8}\right)^2$

SOLUTION The hyperbolic paraboloid defined by this equation is shown in the following figure:



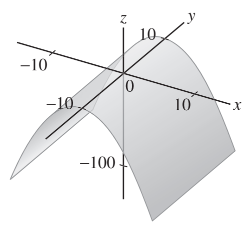
29. $z^2 = \left(\frac{x}{4}\right)^2 + \left(\frac{y}{8}\right)^2$

SOLUTION This equation defines the following elliptic cone:



30. $z = -x^2$

SOLUTION This is the equation of a parabolic cylinder with base $\mathcal{C}$, where $\mathcal{C}$ is the parabola $z = -x^2$ in the xz-plane. The graph of the cylinder is shown next:



Graph of the parabolic cylinder $z = -x^2$

31. Find the equation of the ellipsoid passing through the points marked in Figure 14(A).

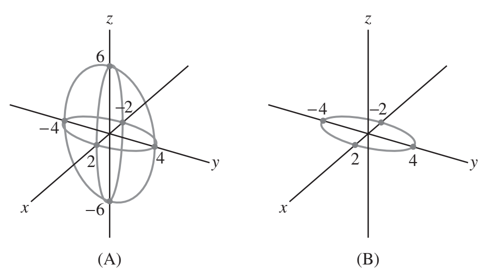


FIGURE 14

SOLUTION The equation of an ellipsoid is

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 = 1 \tag{1}$$

The x, y and z intercepts are $(\pm a, 0, 0)$, $(0, \pm b, 0)$ and $(0, 0, \pm c)$ respectively. The x, y and z intercepts of the desired ellipsoid are $(\pm 2, 0, 0)$, $(0, \pm 4, 0)$ and $(0, 0, \pm 6)$ respectively, hence $a = 2$, $b = 4$ and $c = 6$. Substituting into (1) we get

$$\left(\frac{x}{2}\right)^2 + \left(\frac{y}{4}\right)^2 + \left(\frac{z}{6}\right)^2 = 1.$$

32. Find the equation of the elliptic cylinder passing through the points marked in Figure 14(B).

SOLUTION The equation of the elliptic cylinder in the xyz-coordinate system is

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1 \tag{1}$$

The x and y intercepts are $(\pm a, 0)$ and $(0, \pm b)$ respectively. The x and y intercepts of the desired cylinder are $(\pm 2, 0)$ and $(0, \pm 4)$ respectively, hence $a = 2$ and $b = 4$. Substituting into (1) we obtain the following equation:

$$\left(\frac{x}{2}\right)^2 + \left(\frac{y}{4}\right)^2 = 1.$$

33. Find the equation of the hyperboloid shown in Figure 15(A).

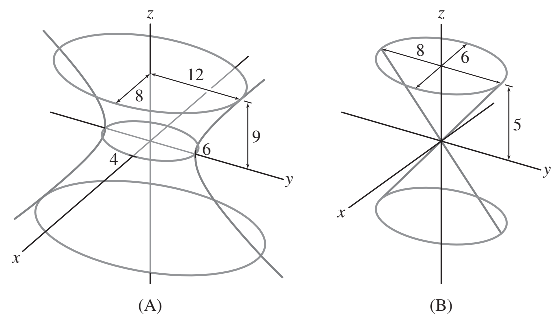

FIGURE 15

SOLUTION The hyperboloid in the figure is of one sheet and the intersections with the planes $z = z_0$ are ellipses. Hence, the equation of the hyperboloid has the form

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 - \left(\frac{z}{c}\right)^2 = 1 \tag{1}$$

Substituting $z = 0$ we get

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$$

By the given information this ellipse has x and y intercepts at the points $(\pm 4, 0)$ and $(0, \pm 6)$ hence $a = 4$, $b = 6$. Substituting in (1) we get

$$\left(\frac{x}{4}\right)^2 + \left(\frac{y}{6}\right)^2 - \left(\frac{z}{c}\right)^2 = 1 \tag{2}$$

Substituting $z = 9$ we get

$$\frac{x^2}{16} + \frac{y^2}{36} - \frac{9^2}{c^2} = 1$$

$$\frac{x^2}{16} + \frac{y^2}{36} = 1 + \frac{81}{c^2} = \frac{c^2 + 81}{c^2}$$

$$\frac{c^2x^2}{16(81 + c^2)} + \frac{c^2y^2}{36(81 + c^2)} = 1$$

$$\left(\frac{x}{\frac{4}{c}\sqrt{81 + c^2}}\right)^2 + \left(\frac{y}{\frac{6}{c}\sqrt{81 + c^2}}\right)^2 = 1$$

By the given information the following must hold:

$$\begin{matrix} \frac{4}{c}\sqrt{81 + c^2} = 8 \\ \frac{6}{c}\sqrt{81 + c^2} = 12 \end{matrix} \quad \Rightarrow \quad \frac{\sqrt{81 + c^2}}{c} = 2 \quad \Rightarrow \quad 81 + c^2 = 4c^2 \quad \Rightarrow \quad 3c^2 = 81$$

Thus, $c = 3\sqrt{3}$, and by substituting in (2) we obtain the following equation:

$$\left(\frac{x}{4}\right)^2 + \left(\frac{y}{6}\right)^2 - \left(\frac{z}{3\sqrt{3}}\right)^2 = 1$$

34. Find the equation of the quadric surface shown in Figure 15(B).

SOLUTION The quadratic surface in the figure is an elliptic cone. The horizontal trace curves are ellipses, hence the equation of the cone has the form

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = \left(\frac{z}{c}\right)^2 \tag{1}$$

The trace on the plane $z = 5$ is the ellipse $\left(\frac{x}{6}\right)^2 + \left(\frac{y}{8}\right)^2 = 1$. Substituting $z = 5$ in (1) gives

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = \left(\frac{5}{c}\right)^2$$

$$\left(\frac{x}{5a/c}\right)^2 + \left(\frac{y}{5b/c}\right)^2 = 1$$

Thus, the following equalities must hold:

$$\frac{5a}{c} = 6 \quad \Rightarrow \quad a = \frac{6c}{5}$$
$$\frac{5b}{c} = 8 \quad \Rightarrow \quad b = \frac{8c}{5}$$

Substituting in (1) gives

$$\left(\frac{x}{6c/5}\right)^2 + \left(\frac{y}{8c/5}\right)^2 = \left(\frac{z}{c}\right)^2$$
$$\frac{1}{c^2}\left(\frac{x}{6/5}\right)^2 + \frac{1}{c^2}\left(\frac{y}{8/5}\right)^2 = \frac{1}{c^2}z^2$$
$$\left(\frac{x}{6/5}\right)^2 + \left(\frac{y}{8/5}\right)^2 = z^2$$
$$\left(\frac{x}{6}\right)^2 + \left(\frac{y}{8}\right)^2 = \left(\frac{z}{5}\right)^2$$

35. Determine the vertical traces of elliptic and parabolic cylinders in standard form.

SOLUTION The vertical traces of elliptic or parabolic cylinders are one or two vertical lines, or an empty set.

36. What is the equation of a hyperboloid of one or two sheets in standard form if every horizontal trace is a circle?

SOLUTION The equation of a hyperboloid (of one sheet) is

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 - \left(\frac{z}{c}\right)^2 = 1$$

or

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1 + \left(\frac{z}{c}\right)^2$$

The horizontal traces are obtained by setting $z = z_0$, that is,

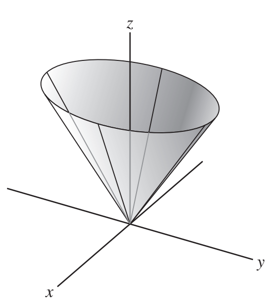
$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1 + \left(\frac{z_0}{c}\right)^2 = \text{constant}$$

This equation defines a circle when $a = b$. Thus, the corresponding hyperboloid is

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{a}\right)^2 - \left(\frac{z}{c}\right)^2 = 1$$

37. Let $\mathcal{C}$ be an ellipse in a horizonal plane lying above the xy-plane. Which type of quadric surface is made up of all lines passing through the origin and a point on $\mathcal{C}$?

SOLUTION The quadric surface is the upper part of an elliptic cone.



38. The eccentricity of a conic section is defined in Section 11.5. Show that the horizontal traces of the ellipsoid

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 = 1$$

are ellipses of the same eccentricity (apart from the traces at height $h = \pm c$, which reduce to a single point). Find the eccentricity.

SOLUTION The intersection of the ellipsoid with the horizonal plane $z = h$ for $|h| < c$ is obtained by substituting $z = h$ in the equation of the ellipsoid . This gives

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{h}{c}\right)^2 = 1$$

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1 - \left(\frac{h}{c}\right)^2 = \frac{c^2 - h^2}{c^2}$$

$$\left(\frac{x}{\frac{a}{c}\sqrt{c^2 - h^2}}\right)^2 + \left(\frac{y}{\frac{b}{c}\sqrt{c^2 - h^2}}\right)^2 = 1$$

This is the equation of an ellipse in the plane $z = h$. Assume $a < b$. The eccentricity of the ellipse is

$$e = \frac{\sqrt{\left[\frac{a}{c}\sqrt{c^2 - h^2}\right]^2 - \left[\frac{b}{c}\sqrt{c^2 - h^2}\right]^2}}{\frac{a}{c}\sqrt{c^2 - h^2}} = \frac{\sqrt{\frac{a^2}{c^2}(c^2 - h^2) - \frac{b^2}{c^2}(c^2 - h^2)}}{\frac{a}{c}\sqrt{c^2 - h^2}}$$

$$= \frac{\sqrt{\frac{(c^2-h^2)}{c^2}(a^2 - b^2)}}{\frac{a}{c}\sqrt{c^2 - h^2}} = \frac{\frac{\sqrt{c^2-h^2}}{c}\sqrt{a^2 - b^2}}{\frac{\sqrt{c^2-h^2}}{c}a} = \frac{\sqrt{a^2 - b^2}}{a} = \sqrt{1 - \left(\frac{b}{a}\right)^2}$$

Since the eccentricity is independent of h, all the horizontal traces are ellipses with the same eccentricity $e = \sqrt{1 - \left(\frac{a}{b}\right)^2}$. If $a > b$, we obtain (in a similar manner) $e = \sqrt{1 - \left(\frac{b}{a}\right)^2}$, again independent of h.

Further Insights and Challenges

39. Let $\mathcal{S}$ be the hyperboloid $x^2 + y^2 = z^2 + 1$ and let $P = (\alpha, \beta, 0)$ be a point on $\mathcal{S}$ in the (x, y)-plane. Show that there are precisely two lines through P entirely contained in $\mathcal{S}$ (Figure 16). *Hint:* Consider the line $\mathbf{r}(t) = \langle \alpha + at, \beta + bt, t\rangle$ through P. Show that $\mathbf{r}(t)$ is contained in $\mathcal{S}$ if (a, b) is one of the two points on the unit circle obtained by rotating (α, β) through $\pm\frac{\pi}{2}$. This proves that a hyperboloid of one sheet is a **doubly ruled surface**, which means that it can be swept out by moving a line in space in two different ways.

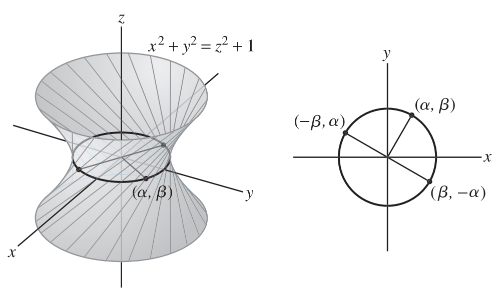


FIGURE 16

SOLUTION The parametric equations of the lines through $P = (\alpha, \beta, 0)$ have the form

$$x = \alpha + ks, \quad y = \beta + \ell s, \quad z = ms$$

Setting the parameter $t = ms$ and replacing $\frac{k}{m}$ and $\frac{\ell}{m}$ by a and b, respectively, we obtain the following (normalized) form

$$x = \alpha + at, \quad y = \beta + bt, \quad z = t$$

The line is entirely contained in S if and only if for all values of the parameter t, the following equality holds:

$$(\alpha + at)^2 + (\beta + bt)^2 = t^2 + 1$$

That is, for all t,

$$\alpha^2 + 2\alpha at + a^2t^2 + \beta^2 + 2\beta bt + b^2t^2 = t^2 + 1$$

$$(a^2 + b^2 - 1)t^2 + 2(\alpha a + \beta b)t + (\alpha^2 + \beta^2 - 1) = 0$$

This equality holds for all t if and only if all the coefficients are zero. That is, if and only if

$$\begin{cases} a^2 + b^2 - 1 = 0 \\ \alpha a + \beta b = 0 \\ \alpha^2 + \beta^2 - 1 = 0 \end{cases}$$

The first and the third equations imply that (a, b) and (α, β) are points on the unit circle $x^2 + y^2 = 1$. The second equation implies that the vector $\mathbf{u} = \langle a, b \rangle$ is orthogonal to the vector $\mathbf{v} = \langle \alpha, \beta \rangle$ (since $\mathbf{u} \cdot \mathbf{v} = a\alpha + b\beta = 0$).

Conclusions: There are precisely two lines through P entirely contained in S. For the direction vectors $(a, b, 1)$ of these lines, (a, b) is obtained by rotating (α, β) through $\pm\frac{\pi}{2}$ about the origin.

In Exercises 40 and 41, let $\mathcal{C}$ be a curve in $\mathbf{R}^3$ not passing through the origin. The cone on $\mathcal{C}$ is the surface consisting of all lines passing through the origin and a point on $\mathcal{C}$ [Figure 17(A)].

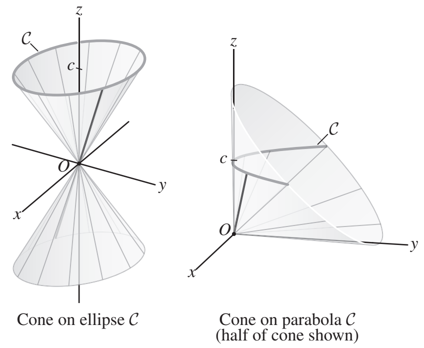

FIGURE 17

40. Show that the elliptic cone $\left(\frac{z}{c}\right)^2 = \left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2$ is, in fact, a cone on the ellipse $\mathcal{C}$ consisting of all points (x, y, c) such that $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$.

SOLUTION

Step 1. We verify that the lines $\overline{OP}$ where P is a point (α, β, c) such that $\left(\frac{\alpha}{a}\right)^2 + \left(\frac{\beta}{b}\right)^2 = 1$ are contained in the elliptic cone $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = \left(\frac{z}{c}\right)^2$. The parametric equations of the line $\overline{OP}$ are

$$x = t\alpha, \quad y = t\beta, \quad z = tc$$

Substituting in the left hand side of the equation of the cone $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = \left(\frac{z}{c}\right)^2$ gives

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = \left(\frac{t\alpha}{a}\right)^2 + \left(\frac{t\beta}{b}\right)^2 = t^2\left(\left(\frac{\alpha}{a}\right)^2 + \left(\frac{\beta}{b}\right)^2\right) = t^2 \cdot 1 = \left(\frac{tc}{c}\right)^2 = \left(\frac{z}{c}\right)^2$$

Therefore, the line $\overline{OP}$ is contained in the elliptic cone.

Step 2. We show that every point (x_0, y_0, z_0) on the elliptic cone is contained in a certain line $\overline{OP}$ where P is a point on $\mathcal{C}$. Since (x_0, y_0, z_0) is on the cone, we have $\left(\frac{x_0}{a}\right)^2 + \left(\frac{y_0}{b}\right)^2 = \left(\frac{z_0}{c}\right)^2$, hence,

$$\left(\frac{x_0}{a\frac{z_0}{c}}\right)^2 + \left(\frac{y_0}{b\frac{z_0}{c}}\right)^2 = 1$$

or

$$\left(\frac{x_0\frac{c}{z_0}}{a}\right)^2 + \left(\frac{y_0\frac{c}{z_0}}{b}\right)^2 = 1 \tag{1}$$

We define P as the point $P = \left(\frac{x_0 c}{z_0}, \frac{y_0 c}{z_0}, c\right)$. By (1) P is on the ellipse $\mathcal{C}$. We show that (x_0, y_0, z_0) lies on the line through the origin and P. The parametric equations of this line are

$$x = t\frac{x_0 c}{z_0}, \quad y = t\frac{y_0 c}{z_0}, \quad z = tc$$

Now, (x_0, y_0, z_0) corresponds to the parameter $t = \frac{z_0}{c}$. This proves that any point $P = (x_0, y_0, z_0)$ on the cone is included in a certain line through the origin and a point on $\mathcal{C}$. By virtue of step 1 and step 2, we conclude that the cone on the ellipse $\mathcal{C}$ is equal to the elliptic cone.

41. Let a and c be nonzero constants and let $\mathcal{C}$ be the parabola at height c consisting of all points (x, ax^2, c) [Figure 17(B)]. Let $\mathcal{S}$ be the cone consisting of all lines passing through the origin and a point on $\mathcal{C}$. This exercise shows that $\mathcal{S}$ is also an elliptic cone.

(a) Show that $\mathcal{S}$ has equation $yz = acx^2$.

(b) Show that under the change of variables $y = u + v$ and $z = u - v$, this equation becomes $acx^2 = u^2 - v^2$ or $u^2 = acx^2 + v^2$ (the equation of an elliptic cone in the variables x, v, u).

SOLUTION A point P on the parabola $\mathcal{C}$ has the form $P = \left(x_0, ax_0^2, c\right)$, hence the parametric equations of the line through the origin and P are

$$x = tx_0, \quad y = tax_0^2, \quad z = tc$$

To find a direct relation between xy and z we notice that

$$yz = tax_0^2ct = ac(tx_0)^2 = acx^2$$

Now, defining new variables $z = u - v$ and $y = u + v$. This equation becomes

$$(u+v)(u-v) = acx^2$$
$$u^2 - v^2 = acx^2 \quad \Rightarrow \quad u^2 = acx^2 + v^2$$

This is the equation of an elliptic cone in the variables x, v, u. We, thus, showed that the cone on the parabola $\mathcal{C}$ is transformed to an elliptic cone by the transformation (change of variables) $y = u + v$, $z = u - v$, $x = x$.

12.7 Cylindrical and Spherical Coordinates (LT Section 13.7)

Preliminary Questions

1. Describe the surfaces $r = R$ in cylindrical coordinates and $\rho = R$ in spherical coordinates.

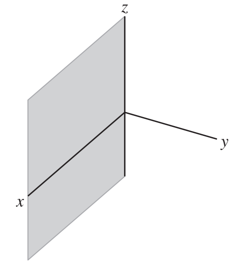
SOLUTION The surface $r = R$ consists of all points located at a distance R from the z-axis. This surface is the cylinder of radius R whose axis is the z-axis. The surface $\rho = R$ consists of all points located at a distance R from the origin. This is the sphere of radius R centered at the origin.

2. Which statement about cylindrical coordinates is correct?

(a) If $\theta = 0$, then P lies on the z-axis.

(b) If $\theta = 0$, then P lies in the xz-plane.

SOLUTION The equation $\theta = 0$ defines the half-plane of all points that project onto the ray $\theta = 0$, that is, onto the nonnegative x-axis. This half plane is part of the (x, z)-plane, therefore if $\theta = 0$, then P lies in the (x, z)-plane.



The half-plane $\theta = 0$

For instance, the point $P = (1, 0, 1)$ satisfies $\theta = 0$, but it does not lie on the z-axis. We conclude that statement (b) is correct and statement (a) is false.

3. Which statement about spherical coordinates is correct?

(a) If $\phi = 0$, then P lies on the z-axis.

(b) If $\phi = 0$, then P lies in the xy-plane.

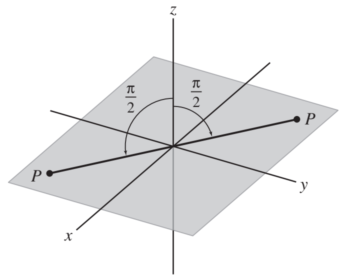
SOLUTION The equation $\phi = 0$ describes the nonnegative z-axis. Therefore, if $\phi = 0$, P lies on the z-axis as stated in (a). Statement (b) is false, since the point $(0, 0, 1)$ satisfies $\phi = 0$, but it does not lie in the (x, y)-plane.

4. The level surface $\phi = \phi_0$ in spherical coordinates, usually a cone, reduces to a half-line for two values of ϕ_0. Which two values?

SOLUTION For $\phi_0 = 0$, the level surface $\phi = 0$ is the upper part of the z-axis. For $\phi_0 = \pi$, the level surface $\phi = \pi$ is the lower part of the z-axis. These are the two values of ϕ_0 where the level surface $\phi = \phi_0$ reduces to a half-line.

5. For which value of ϕ_0 is $\phi = \phi_0$ a plane? Which plane?

SOLUTION For $\phi_0 = \frac{\pi}{2}$, the level surface $\phi = \frac{\pi}{2}$ is the xy-plane.



Exercises

In Exercises 1–4, convert from cylindrical to rectangular coordinates.

1. $(4, \pi, 4)$

SOLUTION By the given data $r = 4$, $\theta = \pi$ and $z = 4$. Hence,

$$\begin{aligned} x &= r\cos\theta = 4\cos\pi = 4\cdot(-1) = -4 \\ y &= r\sin\theta = 4\sin\pi = 4\cdot 0 \\ z &= 4 \end{aligned} \quad\Rightarrow\quad (x, y, z) = (-4, 0, 4)$$

2. $\left(2, \frac{\pi}{3}, -8\right)$

SOLUTION We are given that $(r, \theta, z) = \left(2, \frac{\pi}{3}, -8\right)$. Hence,

$$\begin{aligned} x &= r\cos\theta = 2\cos\frac{\pi}{3} = 2\cdot\frac{1}{2} = 1 \\ y &= r\sin\theta = 2\sin\frac{\pi}{3} = 2\frac{\sqrt{3}}{2} = \sqrt{3} \\ z &= -8 \end{aligned} \quad\Rightarrow\quad (x, y, z) = \left(1, \sqrt{3}, -8\right)$$

3. $\left(0, \frac{\pi}{5}, \frac{1}{2}\right)$

SOLUTION We have $r = 0$, $\theta = \frac{\pi}{5}$, $z = \frac{1}{2}$. Thus,

$$\begin{aligned} x &= r\cos\theta = 0\cdot\cos\frac{\pi}{5} = 0 \\ y &= r\sin\theta = 0\cdot\sin\frac{\pi}{5} = 0 \\ z &= \frac{1}{2} \end{aligned} \quad\Rightarrow\quad (x, y, z) = \left(0, 0, \frac{1}{2}\right)$$

4. $\left(1, \frac{\pi}{2}, -2\right)$

SOLUTION Conversion to rectangular coordinates gives

$$\begin{aligned} x &= r\cos\theta = 1\cdot\cos\frac{\pi}{2} = 1\cdot 0 = 0 \\ y &= r\sin\theta = 1\cdot\sin\frac{\pi}{2} = 1\cdot 1 = 1 \\ z &= -2 \end{aligned} \quad\Rightarrow\quad (x, y, z) = (0, 1, -2)$$

In Exercises 5–10, convert from rectangular to cylindrical coordinates.

5. $(1, -1, 1)$

SOLUTION We are given that $x = 1$, $y = -1$, $z = 1$. We find r:

$$r = \sqrt{x^2 + y^2} = \sqrt{1^2 + (-1)^2} = \sqrt{2}$$

Next we find θ. The point $(x, y) = (1, -1)$ lies in the fourth quadrant, hence,

$$\tan\theta = \frac{y}{x} = \frac{-1}{1} = -1, \quad \frac{3\pi}{2} \le \theta \le 2\pi \quad\Rightarrow\quad \theta = \frac{7\pi}{4}$$

We conclude that the cylindrical coordinates of the point are

$$(r, \theta, z) = \left(\sqrt{2}, \frac{7\pi}{4}, 1\right).$$

6. $(2, 2, 1)$

SOLUTION We are given that $(x, y, z) = (2, 2, 1)$. We first find r:

$$r = \sqrt{x^2 + y^2} = \sqrt{2^2 + 2^2} = \sqrt{8} = 2\sqrt{2}$$

Next we find θ. The point $(x, y) = (2, 2)$ lies in the first quadrant hence $0 \le \theta \le \frac{\pi}{2}$. Therefore,

$$\tan\theta = \frac{y}{x} = \frac{2}{2} = 1, \quad 0 \le \theta \le \frac{\pi}{2} \quad \Rightarrow \quad \theta = \frac{\pi}{4}$$

The cylindrical coordinates of the point are

$$(r, \theta, z) = \left(2\sqrt{2}, \frac{\pi}{4}, 1\right).$$

7. $(1, \sqrt{3}, 7)$

SOLUTION We have $x = 1$, $y = \sqrt{3}$, $z = 7$. We first find r:

$$r = \sqrt{x^2 + y^2} = \sqrt{1^2 + \left(\sqrt{3}\right)^2} = 2$$

Since the point $(x, y) = \left(1, \sqrt{3}\right)$ lies in the first quadrant, $0 \le \theta \le \frac{\pi}{2}$. Hence,

$$\tan\theta = \frac{y}{x} = \frac{\sqrt{3}}{1} = \sqrt{3}, \quad 0 \le \theta \le \frac{\pi}{2} \quad \Rightarrow \quad \theta = \frac{\pi}{3}$$

The cylindrical coordinates are thus

$$(r, \theta, z) = \left(2, \frac{\pi}{3}, 7\right).$$

8. $\left(\frac{3}{2}, \frac{3\sqrt{3}}{2}, 9\right)$

SOLUTION We are given that $(x, y, z) = \left(\frac{3}{2}, \frac{3\sqrt{3}}{2}, 9\right)$. Hence,

$$r = \sqrt{x^2 + y^2} = \sqrt{\left(\frac{3}{2}\right)^2 + \left(\frac{3\sqrt{3}}{2}\right)^2} = \sqrt{\frac{9}{4} + \frac{27}{4}} = \sqrt{\frac{36}{4}} = 3$$

Since the point $(x, y) = \left(\frac{3}{2}, \frac{3\sqrt{3}}{2}\right)$ is in the first quadrant, $0 \le \theta \le \frac{\pi}{2}$. Therefore,

$$\tan\theta = \frac{y}{x} = \frac{3\sqrt{3}/2}{3/2} = \sqrt{3}, \quad 0 \le \theta \le \frac{\pi}{2} \quad \Rightarrow \quad \theta = \frac{\pi}{3}$$

The cylindrical coordinates are thus

$$(r, \theta, z) = \left(3, \frac{\pi}{3}, 9\right).$$

9. $\left(\frac{5}{\sqrt{2}}, \frac{5}{\sqrt{2}}, 2\right)$

SOLUTION We have $x = \frac{5}{\sqrt{2}}$, $y = \frac{5}{\sqrt{2}}$, $z = 2$. We find r:

$$r = \sqrt{x^2 + y^2} = \sqrt{\left(\frac{5}{\sqrt{2}}\right)^2 + \left(\frac{5}{\sqrt{2}}\right)^2} = \sqrt{25} = 5$$

Since the point $(x, y) = \left(\frac{5}{\sqrt{2}}, \frac{5}{\sqrt{2}}\right)$ is in the first quadrant, $0 \le \theta \le \frac{\pi}{2}$, therefore,

$$\tan\theta = \frac{y}{x} = \frac{5/\sqrt{2}}{5/\sqrt{2}} = 1, \quad 0 \le \theta \le \frac{\pi}{2} \quad \Rightarrow \quad \theta = \frac{\pi}{4}$$

The corresponding cylindrical coordinates are

$$(r, \theta, z) = \left(5, \frac{\pi}{4}, 2\right).$$

10. $(3, 3\sqrt{3}, 2)$

SOLUTION We have $x = 3$, $y = 3\sqrt{3}$, and $z = 2$, hence,

$$r = \sqrt{x^2 + y^2} = \sqrt{3^2 + \left(3\sqrt{3}\right)^2} = \sqrt{36} = 6$$

The point $(x, y) = \left(3, 3\sqrt{3}\right)$ is in the first quadrant hence $0 \le \theta \le \frac{\pi}{2}$. Therefore,

$$\tan\theta = \frac{y}{x} = \frac{3\sqrt{3}}{3} = \sqrt{3}, \quad 0 \le \theta \le \frac{\pi}{2} \quad \Rightarrow \quad \theta = \frac{\pi}{3}$$

The cylindrical coordinates of the given point are

$$(r, \theta, z) = \left(6, \frac{\pi}{3}, 2\right).$$

In Exercises 11–16, describe the set in cylindrical coordinates.

11. $x^2 + y^2 \le 1$

SOLUTION The inequality describes a solid cylinder of radius 1 centered on the z-axis. Since $x^2 + y^2 = r^2$, this inequality can be written as $r^2 \le 1$.

12. $x^2 + y^2 + z^2 \le 1$

SOLUTION Since $x^2 + y^2 = r^2$, this inequality can be written as

$$r^2 + z^2 \le 1 \quad \text{or} \quad r^2 \le 1 - z^2$$

13. $y^2 + z^2 \le 4, \quad x = 0$

SOLUTION The projection of the points in this set onto the xy-plane are points on the y axis, thus $\theta = \frac{\pi}{2}$ or $\theta = \frac{3\pi}{2}$. Therefore, $y = r\sin\frac{\pi}{2} = r \cdot 1 = r$ or $y = r\sin\left(\frac{3\pi}{2}\right) = -r$. In both cases, $y^2 = r^2$, thus the inequality $y^2 + z^2 \le 4$ becomes $r^2 + z^2 \le 4$. In cylindrical coordinates, we obtain the following inequality

$$r^2 + z^2 \le 4, \quad \theta = \frac{\pi}{2} \quad \text{or} \quad \theta = \frac{3\pi}{2}$$

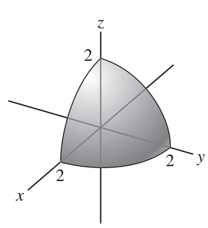
14. $x^2 + y^2 + z^2 = 4, \quad x \ge 0, \quad y \ge 0, \quad z \ge 0$

SOLUTION We express z in terms of x and y. Since $z \ge 0$ we get

$$x^2 + y^2 + z^2 = 4 \quad \Rightarrow \quad z^2 = 4 - (x^2 + y^2) \quad \Rightarrow \quad z = \sqrt{4 - (x^2 + y^2)} \tag{1}$$

The cylindrical coordinates are (r, θ, z) where $x^2 + y^2 = r^2$. Substituting into (1) gives

$$z = \sqrt{4 - r^2} \tag{2}$$



We find the interval for θ. The given set is the part of the sphere $x^2 + y^2 + z^2 = 4$ in the first octant.

$$\text{Hence, the angle } \theta \text{ is changing between 0 and } \frac{\pi}{2}. \tag{3}$$

We combine (2) and (3) to obtain the following representation:

$$z = \sqrt{4 - r^2}, \quad 0 \le \theta \le \frac{\pi}{2}.$$

15. $x^2 + y^2 \le 9, \quad x \ge y$

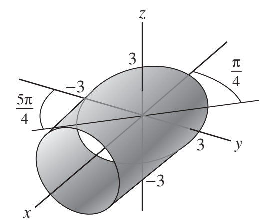
SOLUTION The equation $x^2 + y^2 \le 9$ in cylindrical coordinates becomes $r^2 \le 9$, which becomes $r \le 3$. However, we also have the restriction that $x \ge y$. This means that the projection of our set onto the xy plane is below and to the right of the line $y = x$. In other words, our θ is restricted to $-3\pi/4 \le \theta \le \pi/4$. In conclusion, the answer is:

$$r \le 3, \qquad -3\pi/4 \le \theta \le \pi/4$$

16. $y^2 + z^2 \le 9, \quad x \ge y$

SOLUTION The region $x \ge y$ in the xy-plane is determined by the inequalities $\frac{5\pi}{4} \le \theta \le 2\pi$, $0 \le \theta \le \frac{\pi}{4}$ (and the origin). Since $y = r\sin\theta$, the region $y^2 + z^2 \le 9$ can be written as

$$r^2 \sin^2\theta + z^2 \le 9$$



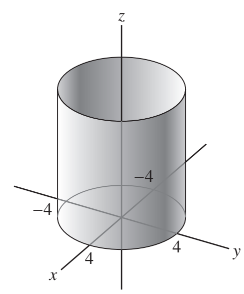
We obtain the following description in cylindrical coordinates:

$$r^2 \sin^2\theta + z^2 \le 9, \quad 0 \le \theta \le \frac{\pi}{4} \quad \text{or} \quad \frac{5\pi}{4} \le \theta \le 2\pi.$$

In Exercises 17–24, sketch the set (described in cylindrical coordinates).

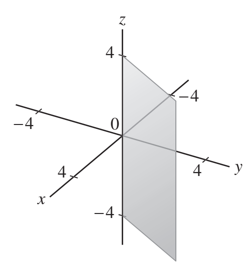
17. $r = 4$

SOLUTION The surface $r = 4$ consists of all points located at a distance 4 from the z-axis. It is a cylinder of radius 4 whose axis is the z-axis. The cylinder is shown in the following figure:



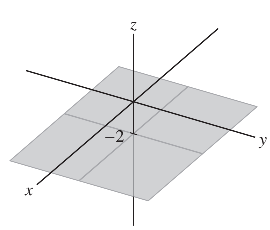
18. $\theta = \dfrac{\pi}{3}$

SOLUTION The equation $\theta = \frac{\pi}{3}$ defines the half plane of all points that project onto the ray $\theta = \frac{\pi}{3}$ in the xy-plane. This half plane is shown in the following figure:



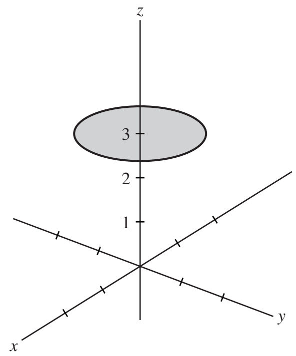
19. $z = -2$

SOLUTION $z = -2$ is the horizontal plane at height -2, shown in the following figure:



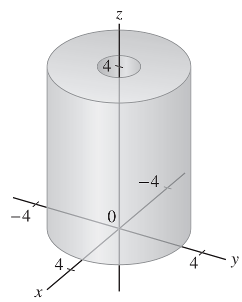
20. $r = 2, \quad z = 3$

SOLUTION This is a circle of radius 2, parallel to the xy-plane but on the plane $z = 3$, as seen in the following figure:



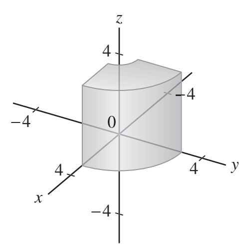
21. $1 \le r \le 3, \quad 0 \le z \le 4$

SOLUTION The region $1 \le r \le 3$, $0 \le z \le 4$ is shown in the following figure:



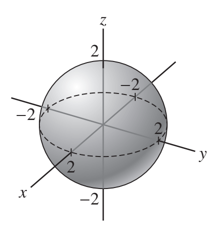
22. $1 \le r \le 3, \quad 0 \le \theta \le \dfrac{\pi}{2}, \quad 0 \le z \le 4$

SOLUTION The inequality $1 \le r \le 3$ implies that the projection of the region on the xy-plane is contained in a ring $1 \le \sqrt{x^2 + y^2} \le 3$. The inequality $0 \le \theta \le \frac{\pi}{2}$ restricts the ring to the first quadrant and $0 \le z \le 4$ determines the height. We obtain the following region:



23. $z^2 + r^2 \le 4$

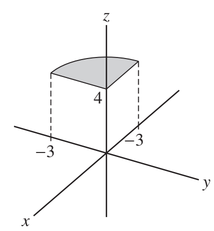
SOLUTION The region $z^2 + r^2 \le 4$ is shown in the following figure:



In rectangular coordinates the inequality is $z^2 + \left(x^2 + y^2\right) \le 4$, or $x^2 + y^2 + z^2 \le 4$, which is a ball of radius 2.

24. $r \le 3, \quad \pi \le \theta \le \dfrac{3\pi}{2}, \quad z = 4$

SOLUTION The region $r \le 3, \pi \le \theta \le \frac{3\pi}{2}, z = 4$ is shown in the following figure:



In Exercises 25–30, find an equation of the form $r = f(\theta, z)$ in cylindrical coordinates for the following surfaces.

25. $z = x + y$

SOLUTION We substitute $x = r\cos\theta$, $y = r\sin\theta$ to obtain the following equation in cylindrical coordinates:

$$\begin{aligned} z &= r\cos\theta + r\sin\theta \\ z &= r(\cos\theta + \sin\theta) \end{aligned} \quad \Rightarrow \quad r = \frac{z}{\cos\theta + \sin\theta}.$$

26. $x^2 + y^2 + z^2 = 4$

SOLUTION Since $x^2 + y^2 = r^2$, we get

$$\begin{aligned} r^2 + z^2 &= 4 \\ r^2 &= 4 - z^2 \quad \Rightarrow \quad r = \sqrt{4 - z^2} \end{aligned}$$

.

27. $\dfrac{x^2}{yz} = 1$

SOLUTION We rewrite the equation in the form

$$\frac{x}{\frac{y}{x}z} = 1$$

Substituting $x = r\cos\theta$ and $\frac{y}{x} = \tan\theta$ we get

$$\begin{aligned} \frac{r\cos\theta}{(\tan\theta)\,z} &= 1 \\ r &= \frac{z\tan\theta}{\cos\theta} \end{aligned}$$

28. $x^2 - y^2 = 4$

SOLUTION We substitute $x = r\cos\theta$, $y = r\sin\theta$ and use the trigonometric identity $\cos^2\theta - \sin^2\theta = \cos 2\theta$. This gives

$$\begin{aligned} r^2\cos^2\theta - r^2\sin^2\theta &= 4 \\ r^2\left(\cos^2\theta - \sin^2\theta\right) &= 4 \\ r^2\cos 2\theta &= 4 \quad \Rightarrow \quad r = \frac{2}{\sqrt{\cos 2\theta}} \end{aligned}$$

29. $x^2 + y^2 = 4$

SOLUTION Since $x^2 + y^2 = r^2$, the equation in cylindrical coordinates is, $r^2 = 4$ or $r = 2$.

30. $z = 3xy$

SOLUTION We substitute $x = r\cos\theta$, $y = r\sin\theta$ and use the trigonometric identity $\sin\theta\cos\theta = \frac{1}{2}\sin 2\theta$. This gives

$$z = 3\,(r\cos\theta)\,(r\sin\theta) = 3r^2\cos\theta\sin\theta = \frac{3}{2}r^2\sin 2\theta$$

Thus,

$$r^2 = \frac{2z}{3\sin 2\theta} \quad \Rightarrow \quad r = \sqrt{\frac{2z}{3\sin 2\theta}}.$$

In Exercises 31–36, convert from spherical to rectangular coordinates.

31. $\left(3, 0, \frac{\pi}{2}\right)$

SOLUTION We are given that $\rho = 3, \theta = 0, \phi = \frac{\pi}{2}$. Using the relations between spherical and rectangular coordinates we have

$$\begin{aligned} x &= \rho \sin\phi \cos\theta = 3 \sin\frac{\pi}{2} \cos 0 = 3 \cdot 1 \cdot 1 = 3 \\ y &= \rho \sin\phi \sin\theta = 3 \sin\frac{\pi}{2} \sin 0 = 3 \cdot 1 \cdot 0 = 0 \qquad \Rightarrow \qquad (x, y, z) = (3, 0, 0) \\ z &= \rho \cos\phi = 3 \cos\frac{\pi}{2} = 3 \cdot 0 = 0 \end{aligned}$$

32. $\left(2, \frac{\pi}{4}, \frac{\pi}{3}\right)$

SOLUTION We are given that $\rho = 2, \theta = \frac{\pi}{4}, \phi = \frac{\pi}{3}$. The relations between the spherical and the rectangular coordinates imply

$$\begin{aligned} x &= \rho \sin\phi \cos\theta = 2 \sin\frac{\pi}{3} \cos\frac{\pi}{4} = 2 \cdot \frac{\sqrt{3}}{2} \cdot \frac{\sqrt{2}}{2} = \frac{\sqrt{6}}{2} \\ y &= \rho \sin\phi \sin\theta = 2 \sin\frac{\pi}{3} \sin\frac{\pi}{4} = 2 \cdot \frac{\sqrt{3}}{2} \cdot \frac{\sqrt{2}}{2} = \frac{\sqrt{6}}{2} \qquad \Rightarrow \qquad (x, y, z) = \left(\frac{\sqrt{6}}{2}, \frac{\sqrt{6}}{2}, 1\right) \\ z &= \rho \cos\phi = 2 \cos\frac{\pi}{3} = 2 \cdot \frac{1}{2} = 1 \end{aligned}$$

33. $(3, \pi, 0)$

SOLUTION We have $\rho = 3, \theta = \pi, \phi = 0$. Hence,

$$\begin{aligned} x &= \rho \sin\phi \cos\theta = 3 \sin 0 \cos\pi = 0 \\ y &= \rho \sin\phi \sin\theta = 3 \sin 0 \sin\pi = 0 \qquad \Rightarrow \qquad (x, y, z) = (0, 0, 3) \\ z &= \rho \cos\phi = 3 \cos 0 = 3 \end{aligned}$$

34. $\left(5, \frac{3\pi}{4}, \frac{\pi}{4}\right)$

SOLUTION We have $\rho = 5, \theta = \frac{3\pi}{4}, \phi = \frac{\pi}{4}$. Using the relations between spherical and rectangular coordinates we have

$$\begin{aligned} x &= \rho \sin\phi \cos\theta = 5 \sin\frac{\pi}{4} \cos\frac{3\pi}{4} = 5 \cdot \frac{\sqrt{2}}{2} \cdot \left(-\frac{\sqrt{2}}{2}\right) = -2.5 \\ y &= \rho \sin\phi \sin\theta = 5 \sin\frac{\pi}{4} \sin\frac{3\pi}{4} = 5 \cdot \frac{\sqrt{2}}{2} \cdot \frac{\sqrt{2}}{2} = 2.5 \qquad \Rightarrow \qquad (x, y, z) = \left(-2.5, 2.5, 2.5\sqrt{2}\right) \\ z &= \rho \cos\phi = 5 \cos\frac{\pi}{4} = 5 \cdot \frac{\sqrt{2}}{2} = 2.5\sqrt{2} \end{aligned}$$

35. $\left(6, \frac{\pi}{6}, \frac{5\pi}{6}\right)$

SOLUTION Since $\rho = 6, \theta = \frac{\pi}{6}$, and $\phi = \frac{5\pi}{6}$ we get

$$\begin{aligned} x &= \rho \sin\phi \cos\theta = 6 \sin\frac{5\pi}{6} \cos\frac{\pi}{6} = 6 \cdot \frac{1}{2} \cdot \frac{\sqrt{3}}{2} = \frac{3\sqrt{3}}{2} \\ y &= \rho \sin\phi \sin\theta = 6 \sin\frac{5\pi}{6} \sin\frac{\pi}{6} = 6 \cdot \frac{1}{2} \cdot \frac{1}{2} = \frac{3}{2} \qquad \Rightarrow \qquad (x, y, z) = \left(\frac{3\sqrt{3}}{2}, \frac{3}{2}, -3\sqrt{3}\right) \\ z &= \rho \cos\phi = 6 \cos\frac{5\pi}{6} = 6 \cdot \left(-\frac{\sqrt{3}}{2}\right) = -3\sqrt{3} \end{aligned}$$

36. (0.5, 3.7, 2)

SOLUTION Using the relations between the spherical and the rectangular coordinates with $\rho = 0.5$, $\theta = 3.7$, and $\phi = 2$, we obtain

$$\begin{aligned} x &= \rho \sin\phi \cos\theta = 0.5 \sin 2 \cos 3.7 = -0.386 \\ y &= \rho \sin\phi \sin\theta = 0.5 \sin 2 \sin 3.7 = -0.241 \quad \Rightarrow \quad (x, y, z) = (-0.386, -0.241, -0.208) \\ z &= \rho \cos\phi = 0.5 \cos 2 = -0.208 \end{aligned}$$

In Exercises 37–42, convert from rectangular to spherical coordinates.

37. $(\sqrt{3}, 0, 1)$

SOLUTION By the given data $x = \sqrt{3}$, $y = 0$, and $z = 1$. We find the radial coordinate:

$$\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{\left(\sqrt{3}\right)^2 + 0^2 + 1^2} = 2$$

The angular coordinate θ satisfies

$$\tan\theta = \frac{y}{x} = \frac{0}{\sqrt{3}} = 0 \quad \Rightarrow \quad \theta = 0 \quad \text{or} \quad \theta = \pi$$

Since the point $(x, y) = \left(\sqrt{3}, 0\right)$ lies in the first quadrant, the correct choice is $\theta = 0$. The angle of declination ϕ satisfies

$$\cos\phi = \frac{z}{\rho} = \frac{1}{2}, \quad 0 \le \phi \le \pi \quad \Rightarrow \quad \phi = \frac{\pi}{3}$$

The spherical coordinates of the given points are thus

$$(\rho, \theta, \phi) = \left(2, 0, \frac{\pi}{3}\right)$$

38. $\left(\frac{\sqrt{3}}{2}, \frac{3}{2}, 1\right)$

SOLUTION We have $x = \frac{\sqrt{3}}{2}$, $y = \frac{3}{2}$, and $z = 1$. The radial coordinate is

$$\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{\left(\frac{\sqrt{3}}{2}\right)^2 + \left(\frac{3}{2}\right)^2 + 1^2} = 2$$

The angular coordinate θ satisfies

$$\tan\theta = \frac{y}{x} = \frac{3/2}{\sqrt{3}/2} = \sqrt{3} \quad \Rightarrow \quad \theta = \frac{\pi}{3} \quad \text{or} \quad \theta = \frac{4\pi}{3}$$

Since the point $(x, y) = \left(\frac{\sqrt{3}}{2}, \frac{3}{2}\right)$ is in the first quadrant, the correct choice is $\theta = \frac{\pi}{3}$. The angle of declination ϕ satisfies

$$\cos\phi = \frac{z}{\rho} = \frac{1}{2}, \quad 0 \le \phi \le \pi \quad \Rightarrow \quad \phi = \frac{\pi}{3}$$

The spherical coordinates are thus

$$(\rho, \theta, \phi) = \left(2, \frac{\pi}{3}, \frac{\pi}{3}\right)$$

39. (1, 1, 1)

SOLUTION We have $x = y = z = 1$. The radial coordinate is

$$\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{1^2 + 1^2 + 1^2} = \sqrt{3}$$

The angular coordinate θ is determined by $\tan\theta = \frac{y}{x} = \frac{1}{1} = 1$ and by the quadrant of the point $(x, y) = (1, 1)$, that is, $\theta = \frac{\pi}{4}$. The angle of declination ϕ satisfies

$$\cos\phi = \frac{z}{\rho} = \frac{1}{\sqrt{3}}, \quad 0 \le \phi \le \pi \quad \Rightarrow \quad \phi = 0.955$$

The spherical coordinates are thus

$$\left(\sqrt{3}, \frac{\pi}{4}, 0.955\right)$$

40. $(1, -1, 1)$

SOLUTION We have $x = 1$, $y = -1$, and $z = 1$. The radial coordinate is

$$\rho = \sqrt{1^2 + (-1)^2 + 1^2} = \sqrt{3}$$

The angular coordinate θ satisfies

$$\tan\theta = \frac{y}{x} = \frac{-1}{1} = -1 \quad \Rightarrow \quad \theta = \frac{3\pi}{4} \text{ or } \theta = \frac{7\pi}{4}$$

Since $(x, y) = (1, -1)$ is in the fourth quadrant, the angle is $\theta = \frac{7\pi}{4}$. The angle of declination satisfies

$$\cos\phi = \frac{z}{\rho} = \frac{1}{\sqrt{3}}, \quad 0 \le \phi \le \pi \quad \Rightarrow \quad \phi = 0.955$$

We conclude that

$$(\rho, \theta, \phi) = \left(\sqrt{3}, \frac{7\pi}{4}, 0.955\right).$$

41. $\left(\frac{1}{2}, \frac{\sqrt{3}}{2}, \sqrt{3}\right)$

SOLUTION We have $x = \frac{1}{2}$, $y = \frac{\sqrt{3}}{2}$, and $z = \sqrt{3}$. Thus

$$\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{\left(\frac{1}{2}\right)^2 + \left(\frac{\sqrt{3}}{2}\right)^2 + \left(\sqrt{3}\right)^2} = 2$$

The angular coordinate θ satisfies $0 \le \theta \le \frac{\pi}{2}$, since the point $(x, y) = \left(\frac{1}{2}, \frac{\sqrt{3}}{2}\right)$ is in the first quadrant. Also $\tan\theta = \frac{y}{x} = \frac{\sqrt{3}/2}{1/2} = \sqrt{3}$, hence the angle is $\theta = \frac{\pi}{3}$. The angle of declination ϕ satisfies

$$\cos\phi = \frac{z}{\rho} = \frac{\sqrt{3}}{2}, \quad 0 \le \phi \le \pi \quad \Rightarrow \quad \phi = \frac{\pi}{6}$$

We conclude that

$$(\rho, \theta, \phi) = \left(2, \frac{\pi}{3}, \frac{\pi}{6}\right)$$

42. $\left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}, \sqrt{3}\right)$

SOLUTION We are given that $x = y = \frac{\sqrt{2}}{2}$ and $z = \sqrt{3}$. Hence,

$$\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{\left(\frac{\sqrt{2}}{2}\right)^2 + \left(\frac{\sqrt{2}}{2}\right)^2 + \left(\sqrt{3}\right)^2} = 2$$

The angle θ satisfies $0 \le \theta \le \frac{\pi}{2}$ since $(x, y) = \left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right)$ is in the first quadrant. Also $\tan\theta = \frac{y}{x} = 1$, hence $\theta = \frac{\pi}{4}$. The angle of declination satisfies

$$\cos\phi = \frac{z}{\rho} = \frac{\sqrt{3}}{2}, \quad 0 \le \phi \le \pi \quad \Rightarrow \quad \phi = \frac{\pi}{6}$$

We conclude that

$$(\rho, \theta, \phi) = \left(2, \frac{\pi}{4}, \frac{\pi}{6}\right).$$

In Exercises 43 and 44, convert from cylindrical to spherical coordinates.

43. $(2, 0, 2)$

SOLUTION We are given that $r = 2$, $\theta = 0$, $z = 2$. Using the conversion formulas, we have

$$\begin{aligned}
\rho &= \sqrt{x^2 + y^2 + z^2} = \sqrt{r^2 + z^2} = \sqrt{2^2 + 2^2} = 2\sqrt{2} \\
\theta &= \theta = 0 \\
\phi &= \cos^{-1}(z/\rho) = \cos^{-1}(2/(2\sqrt{2})) = \pi/4
\end{aligned}$$

44. $(3, \pi, \sqrt{3})$

SOLUTION We are given that $r = 3, \theta = \pi, z = \sqrt{3}$. Using the conversion formulas, we have

$$\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{r^2 + z^2} = \sqrt{3^2 + 3} = 2\sqrt{3}$$
$$\theta = \theta = \pi$$
$$\phi = \cos^{-1}(z/\rho) = \cos^{-1}(\sqrt{3}/(2\sqrt{3})) = \pi/3$$

In Exercises 45 and 46, convert from spherical to cylindrical coordinates.

45. $\left(4, 0, \frac{\pi}{4}\right)$

SOLUTION We are given that $\rho = 4, \theta = 0$, and $\phi = \pi/4$. To find r, we use the formulas $x = r\cos\theta$ and $x = \rho\cos\theta\sin\phi$ to get $r\cos\theta = \rho\cos\theta\sin\phi$, and so

$$r = \rho\sin\phi = 4\sin\pi/4 = 2\sqrt{2}$$

Clearly $\theta = 0$, and as for z,

$$z = \rho\cos\phi = 4\cos\pi/4 = 2\sqrt{2}$$

So, in cylindrical coordinates, our point is $(2\sqrt{2}, 0, 2\sqrt{2})$

46. $\left(2, \frac{\pi}{3}, \frac{\pi}{6}\right)$

SOLUTION We are given that $\rho = 2, \theta = \pi/3$, and $\phi = \pi/6$. To find r, we use the formulas $x = r\cos\theta$ and $x = \rho\cos\theta\sin\phi$ to get $r\cos\theta = \rho\cos\theta\sin\phi$, and so

$$r = \rho\sin\phi = 2\sin\pi/6 = 1$$

Clearly $\theta = \pi/3$, and as for z,

$$z = \rho\cos\phi = 2\cos\pi/6 = \sqrt{3}$$

So, in cylindrical coordinates, our point is $(1, \pi/3, \sqrt{3})$

In Exercises 47–52, describe the given set in spherical coordinates.

47. $x^2 + y^2 + z^2 \le 1$

SOLUTION Substituting $\rho^2 = x^2 + y^2 + z^2$ we obtain $\rho^2 \le 1$ or $0 \le \rho \le 1$.

48. $x^2 + y^2 + z^2 = 1, \quad z \ge 0$

SOLUTION Since $\rho^2 = x^2 + y^2 + z^2$ the equation becomes $\rho^2 = 1$ or $\rho = 1$. The inequality $z \ge 0$ implies that $\cos\phi = \frac{z}{\rho} \ge 0$. Also $0 \le \phi \le \pi$ by definition, hence $0 \le \phi \le \frac{\pi}{2}$. The spherical description of the set is thus

$$\rho = 1, \quad 0 \le \phi \le \frac{\pi}{2}.$$

49. $x^2 + y^2 + z^2 = 1, \quad x \ge 0, \quad y \ge 0, \quad z \ge 0$

SOLUTION By $\rho^2 = x^2 + y^2 + z^2$, we get $\rho^2 = 1$ or $\rho = 1$. The inequalities $x \ge 0$, $y \ge 0$ determine the first quadrant, which is also determined by $0 \le \theta \le \frac{\pi}{2}$. Finally, $z \ge 0$ gives $\cos\phi = \frac{z}{\rho} \ge 0$. Also $0 \le \phi \le \pi$, hence $0 \le \phi \le \frac{\pi}{2}$. We obtain the following description:

$$\rho = 1, \quad 0 \le \theta \le \frac{\pi}{2}, \quad 0 \le \phi \le \frac{\pi}{2}$$

50. $x^2 + y^2 + z^2 \le 1, \quad x = y, \quad x \ge 0, \quad y \ge 0$

SOLUTION Substituting $x^2 + y^2 + z^2 = \rho^2$ yields $\rho^2 \le 1$ or $0 \le \rho \le 1$. The inequalities $x \ge 0$, $y \ge 0$ determine the first quadrant which is also determined by

$$0 \le \theta \le \frac{\pi}{2} \tag{1}$$

The line $y = x$ is determined by $\theta = \frac{\pi}{4}$ or $\theta = \frac{5\pi}{4}$ (and the origin). Combining with (1) we get $\theta = \frac{\pi}{4}$. We conclude that the description of the given set in spherical coordinates is

$$\left\{(\rho, \theta, \phi) : 0 \le \rho \le 1, \theta = \frac{\pi}{4}\right\}$$

51. $y^2 + z^2 \le 4, \quad x = 0$

SOLUTION We substitute $y = \rho\sin\theta\sin\phi$ and $z = \rho\cos\phi$ in the given inequality. This gives

$$4 \ge \rho^2\sin^2\theta\sin^2\phi + \rho^2\cos^2\phi \tag{1}$$

The equality $x = 0$ determines that $\theta = \frac{\pi}{2}$ or $\theta = \frac{3\pi}{2}$ (and the origin). In both cases, $\sin^2\theta = 1$. Hence by (1) we get

$$\begin{aligned} \rho^2\sin^2\phi + \rho^2\cos^2\phi &\le 4 \\ \rho^2(1) &\le 4 \\ \rho &\le 2 \end{aligned}$$

We obtain the following description:

$$\left\{(\rho, \theta, \phi) : 0 \le \rho \le 2, \theta = \frac{\pi}{2} \text{ or } \theta = \frac{3\pi}{2}\right\}$$

52. $x^2 + y^2 = 3z^2$

SOLUTION We substitute the spherical coordinates $x = \rho\sin\phi\cos\theta$, $y = \rho\sin\phi\sin\theta$, $z = \rho\cos\phi$ in the given equation, and simplify. This gives

$$\begin{aligned} \rho^2\sin^2\phi\cos^2\theta + \rho^2\sin^2\phi\sin^2\theta &= 3\rho^2\cos^2\phi \\ \rho^2\sin^2\phi\left(\cos^2\theta + \sin^2\theta\right) &= 3\rho^2\cos^2\phi \\ \rho^2\sin^2\phi \cdot 1 &= 3\rho^2\cos^2\phi \end{aligned}$$

One solution is $\rho = 0$ (the origin). For $\rho \ne 0$ we divide both sides by ρ to obtain

$$\sin^2\phi = 3\cos^2\phi. \tag{1}$$

When $\cos\phi = 0$, $\sin\phi \ne 0$. Hence the points where $\cos\phi = 0$ are not solutions. We, thus, can divide the two sides by $\cos^2\phi$ to obtain

$$\frac{\sin^2\phi}{\cos^2\phi} = 3 \quad \Rightarrow \quad \tan\phi = \sqrt{3} \quad \text{or} \quad \tan\phi = -\sqrt{3}.$$

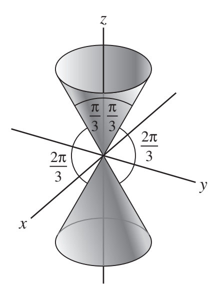
The solutions for $0 \le \phi \le \pi$ are

$$\phi = \frac{\pi}{3} \quad \text{and} \quad \phi = \frac{2\pi}{3}. \tag{2}$$

By (1) and (2) we obtain the following representation in spherical coordinates:

$$\phi = \frac{\pi}{3} \quad \text{or} \quad \phi = \frac{2\pi}{3}. \tag{3}$$

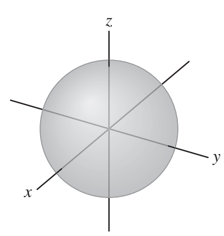
Notice that by (3) we see that the set is the surface obtained while rotating a line that makes an angle of $\frac{\pi}{3}$ with the positive z-axis, about the z-axis. In other words, a double cone.



In Exercises 53–60, sketch the set of points (described in spherical coordinates).

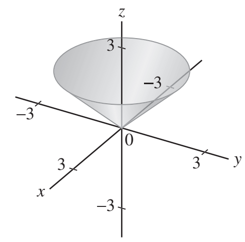
53. $\rho = 4$

SOLUTION $\rho = 4$ describes the sphere of radius 4. This is shown in the following figure:



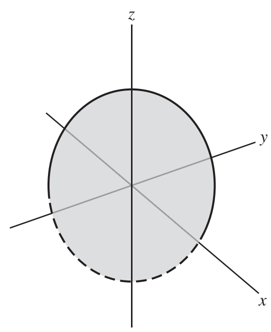
54. $\phi = \dfrac{\pi}{4}$

SOLUTION The level surface $\phi = \frac{\pi}{4}$ is the right-circular cone consisting of points P such that $\overline{OP}$ makes an angle $\frac{\pi}{4}$ with the z-axis, as shown in the following figure:



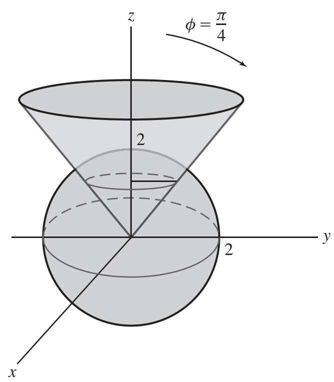
55. $\rho = 2, \quad \theta = \dfrac{\pi}{4}$

SOLUTION The equation $\rho = 2$ is a sphere of radius 2, and the equation $\theta = \frac{\pi}{4}$ is the vertical plane $y = x$. These two surfaces intersect in a (vertical) circle of radius 2, as seen here.



56. $\rho = 2, \quad \phi = \dfrac{\pi}{4}$

SOLUTION The equation $\rho = 2$ is a sphere of radius 2, and the equation $\phi = \frac{\pi}{4}$ is a right circular cone. These two surfaces intersect in a (horizontal) circle of height $\sqrt{2}$ and radius $\sqrt{2}$, as seen here.

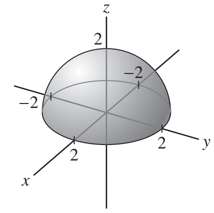


57. $\rho = 2, \quad 0 \le \phi \le \dfrac{\pi}{2}$

SOLUTION The set

$$\rho = 2, \quad 0 \le \phi \le \frac{\pi}{2}$$

is shown in the following figure:



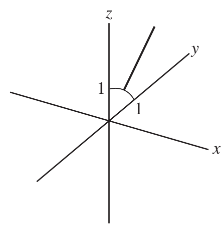
It is the upper half of the sphere with radius 2.

58. $\theta = \frac{\pi}{2}, \quad \phi = \frac{\pi}{4}, \quad \rho \geq 1$

SOLUTION The set

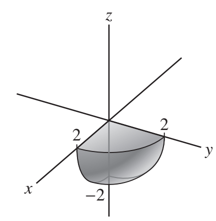
$$\theta = \frac{\pi}{2}, \quad \phi = \frac{\pi}{4}, \quad \rho \geq 1$$

is the line $z = y$ in the first quadrant of the yz-plane that is outside the circle $y^2 + z^2 = 1$. This set is shown in the following figure:



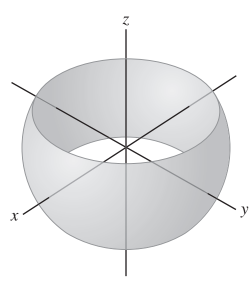
59. $\rho \leq 2, \quad 0 \leq \theta \leq \frac{\pi}{2}, \quad \frac{\pi}{2} \leq \phi \leq \pi$

SOLUTION This set is the part of the ball of radius 2 which is below the first quadrant of the xy-plane, as shown in the following figure:



60. $\rho = 1, \quad \frac{\pi}{3} \leq \phi \leq \frac{2\pi}{3}$

SOLUTION This set is the part of the unit sphere consisting of all the points P such that $\overline{OP}$ makes an angle $\frac{\pi}{3} \leq \phi \leq \frac{2\pi}{3}$ with the z-axis. This set is shown in the following figure:



In Exercises 61–66, find an equation of the form $\rho = f(\theta, \phi)$ in spherical coordinates for the following surfaces.

61. $z = 2$

SOLUTION Since $z = \rho \cos \phi$, we have $\rho \cos \phi = 2$, or $\rho = \frac{2}{\cos \phi}$.

62. $z^2 = 3(x^2 + y^2)$

SOLUTION We use the formulas for x, y and z in terms of ρ, θ and ϕ. This gives

$$\rho^2 \cos^2 \phi = 3\left(\rho^2 \cos^2 \theta \sin^2 \phi + \rho^2 \sin^2 \theta \sin^2 \phi\right) = 3\rho^2 \sin^2 \phi \left(\cos^2 \theta + \sin^2 \theta\right) = 3\rho^2 \sin^2 \phi$$

That is,

$$\rho^2 \cos^2 \phi = 3\rho^2 \sin^2 \phi$$

which gives either $\rho = 0$, or gives the following:

$$\cos^2 \phi = 3 \sin^2 \phi$$

$$\tan^2 \phi = \frac{1}{3}$$

$$\tan\phi = \pm\frac{1}{\sqrt{3}}$$
$$\phi = \frac{\pi}{6} \quad \text{or} \quad \frac{5\pi}{6}$$

Thus, the equation is $\{\rho = 0 \text{ or } \phi = \pi/6 \text{ or } \phi = 5\pi/6\}$.

63. $x = z^2$

SOLUTION Substituting $x = \rho\cos\theta\sin\phi$ and $z = \rho\cos\phi$ we obtain

$$\rho\cos\theta\sin\phi = \rho^2\cos^2\phi$$
$$\cos\theta\sin\phi = \rho\cos^2\phi$$
$$\rho = \frac{\cos\theta\sin\phi}{\cos^2\phi} = \frac{\cos\theta\tan\phi}{\cos\phi}$$

64. $z = x^2 + y^2$

SOLUTION Using the formulas for x, y and z in terms of ρ, θ and ϕ gives

$$\rho\cos\phi = \rho^2\cos^2\theta\sin^2\phi + \rho^2\sin^2\theta\sin^2\phi = \rho^2\sin^2\phi\left(\cos^2\theta + \sin^2\theta\right) = \rho^2\sin^2\phi$$

That is,

$$\rho\cos\phi = \rho^2\sin^2\phi$$
$$\cos\phi = \rho\sin^2\phi$$
$$\rho = \frac{\cos\phi}{\sin^2\phi} = \frac{\cot\phi}{\sin\phi}$$

65. $x^2 - y^2 = 4$

SOLUTION We substitute $x = \rho\cos\theta\sin\phi$ and $y = \rho\sin\theta\sin\phi$ to obtain

$$4 = \rho^2\cos^2\theta\sin^2\phi - \rho^2\sin^2\theta\sin^2\phi = \rho^2\sin^2\phi\left(\cos^2\theta - \sin^2\theta\right)$$

Using the identity $\cos^2\theta - \sin^2\theta = \cos 2\theta$ we get

$$4 = \rho^2\sin^2\phi\cos 2\theta$$
$$\rho^2 = \frac{4}{\sin^2\phi\cos 2\theta}$$

We take the square root of both sides. Since $0 < \phi < \pi$ we have $\sin\phi > 0$, hence,

$$\rho = \frac{2}{\sin\phi\sqrt{\cos 2\theta}}$$

66. $xy = z$

SOLUTION We substitute the formulas for x, y, and z in terms of ρ, θ, and ϕ. This gives

$$\left(\rho\cos\theta\sin\phi\right)\left(\rho\sin\theta\sin\phi\right) = \rho\cos\phi$$

Simplifying and using the identity $\sin\alpha\cos\alpha = \frac{1}{2}\sin 2\alpha$ yields

$$\rho\cos\phi = \rho^2\left(\cos\theta\sin\theta\right)\left(\sin^2\phi\right) = \frac{1}{2}\rho^2\sin 2\theta\sin^2\phi$$

Thus

$$2\cos\phi = \rho\sin 2\theta\sin^2\phi$$
$$\rho = \frac{2\cos\phi}{\sin 2\theta\sin^2\phi}$$

67. Which of (a)–(c) is the equation of the cylinder of radius R in spherical coordinates? Refer to Figure 15.

(a) $R\rho = \sin\phi$ **(b)** $\rho \sin\phi = R$ **(c)** $\rho = R\sin\phi$

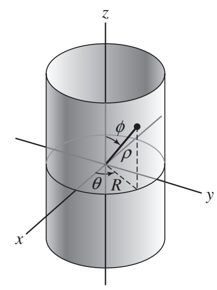


FIGURE 15

SOLUTION The equation of the cylinder of radius R in rectangular coordinates is $x^2 + y^2 = R^2$ (z is unlimited). Substituting the formulas for x and y in terms of ρ, θ and ϕ yields

$$R^2 = \rho^2 \cos^2\theta \sin^2\phi + \rho^2 \sin^2\theta \sin^2\phi = \rho^2 \sin^2\phi\left(\cos^2\theta + \sin^2\theta\right) = \rho^2 \sin^2\phi$$

Hence,

$$R^2 = \rho^2 \sin^2\phi$$

We take the square root of both sides. Since $0 \le \phi \le \pi$, we have $\sin\phi \ge 0$, therefore,

$$R = \rho \sin\phi$$

Equation (b) is the correct answer.

68. Let $P_1 = (1, -\sqrt{3}, 5)$ and $P_2 = (-1, \sqrt{3}, 5)$ in rectangular coordinates. In which quadrants do the projections of P_1 and P_2 onto the xy-plane lie? Find the polar angle θ of each point.

SOLUTION The projections of $P_1 = \left(1, -\sqrt{3}, 5\right)$ and $P_2 = \left(-1, \sqrt{3}, 5\right)$ on the xy-plane are the points $(x, y) = \left(1, -\sqrt{3}\right)$ and $(x, y) = \left(-1, \sqrt{3}\right)$ respectively. These points lie in the fourth and the second quadrant respectively. We find the polar angle θ of P_1. In the fourth quadrant, $\frac{3\pi}{2} \le \theta \le 2\pi$. Also $\tan\theta = \frac{y}{x} = -\sqrt{3}$. Hence $\theta = \frac{5\pi}{3}$. To find the polar angle θ of P_2, we notice that in the second quadrant (where the projection of P_2 on the xy-plane lies) we have $\frac{\pi}{2} \le \theta \le \pi$. Also $\tan\theta = \frac{y}{x} = \frac{\sqrt{3}}{-1} = -\sqrt{3}$, hence $\theta = \frac{2\pi}{3}$.

69. Find the spherical angles (θ, ϕ) for Helsinki, Finland (60.1° N, 25.0° E) and Sao Paulo, Brazil (23.52° S, 46.52° W).

SOLUTION For Helsinki, θ is 25° and ϕ is $90 - 60.1 = 29.9°$.

For Sao Paulo, θ is $360 - 46.52 = 313.48°$ and ϕ is $90 + 23.52 = 113.52°$.

70. Find the longitude and latitude for the points on the globe with angular coordinates $(\theta, \phi) = (\pi/8, 7\pi/12)$ and $(4, 2)$.

SOLUTION For $(\theta, \phi) = (\pi/8, 7\pi/12) = (22.5°, 105°)$, we have latitude $105° - 90° = 15°$ south and longitude 22.5° east.

For $(\theta, \phi) = (4, 2) = (229.18°, 114.59°)$, we have latitude $114.59° - 90° = 24.59°$ south and longitude $360° - 229.18° = 130.82°$ west.

71. Consider a rectangular coordinate system with origin at the center of the earth, z-axis through the North Pole, and x-axis through the prime meridian. Find the rectangular coordinates of Sydney, Australia (34° S, 151° E), and Bogotá, Colombia (4° 32′ N, 74° 15′ W). A minute is $1/60°$. Assume that the earth is a sphere of radius $R = 6370$ km.

SOLUTION We first find the angle (θ, ϕ) for the two towns. For Sydney $\theta = 151°$, since its longitude lies to the east of Greenwich, that is, in the positive θ direction. Sydney's latitude is south of the equator, hence $\phi = 90 + 34 = 124°$.

For Bogota, we have $\theta = 360° - 74°15' = 285°45'$, since $74°15'W$ refers to $74°15'$ in the negative θ direction. The latitude is north of the equator hence $\phi = 90° - 4°32' = 85°28'$.

We now use the formulas of x, y and z in terms of ρ, θ, ϕ to find the rectangular coordinates of the two towns. (Notice that $285°45' = 285.75°$ and $85°28' = 85.47°$).

Sydney:

$$x = \rho\cos\theta\sin\phi = 6370\cos 151° \sin 124° = -4618.8$$

$$y = \rho\sin\theta\sin\phi = 6370\sin 151° \sin 124° = 2560$$

$$z = \rho\cos\phi = 6370\cos 124° = -3562.1$$

Bogota:

$$x = \rho\cos\theta\sin\phi = 6370\cos 285.75^\circ \sin 85.47^\circ = 1723.7$$
$$y = \rho\sin\theta\sin\phi = 6370\sin 285.75^\circ \sin 85.47^\circ = -6111.7$$
$$z = \rho\cos\phi = 6370\cos 85.47^\circ = 503.1$$

72. Find the equation in rectangular coordinates of the quadric surface consisting of the two cones $\phi = \frac{\pi}{4}$ and $\phi = \frac{3\pi}{4}$.

SOLUTION By $\frac{z}{\rho} = \cos\phi$, we have

$$z^2 = \rho^2\cos^2\phi \tag{1}$$

Since $\phi = \frac{\pi}{4}$ or $\phi = \frac{3\pi}{4}$, we have $\cos\phi = \frac{1}{\sqrt{2}}$ or $\cos\phi = -\frac{1}{\sqrt{2}}$, therefore, $\cos^2\phi = \frac{1}{2}$. Substituting in (1) gives

$$z^2 = \frac{\rho^2}{2} \tag{2}$$

Since $\rho^2 = x^2 + y^2 + z^2$, we get $z^2 = \frac{1}{2}(x^2 + y^2 + z^2)$, which becomes $\frac{1}{2}(z^2) = \frac{1}{2}(x^2 + y^2)$, which becomes

$$z^2 = x^2 + y^2$$

Notice that $\phi = \frac{\pi}{4}$ and $\phi = \frac{3\pi}{4}$ imply that z can have both positive and negative values.

73. Find an equation of the form $z = f(r, \theta)$ in cylindrical coordinates for $z^2 = x^2 - y^2$.

SOLUTION In cylindrical coordinates, $x = r\cos\theta$ and $y = r\sin\theta$. Hence,

$$z^2 = x^2 - y^2 = r^2\cos^2\theta - r^2\sin^2\theta$$

We use the identity $\cos^2\theta - \sin^2\theta = \cos 2\theta$ to obtain

$$z^2 = r^2\cos 2\theta \quad\Rightarrow\quad z = \pm r\sqrt{\cos 2\theta}$$

74. Show that $\rho = 2\cos\phi$ is the equation of a sphere with its center on the z-axis. Find its radius and center.

SOLUTION Multiplying the equation by ρ we get

$$\rho^2 = 2\rho\cos\phi$$

We now substitute $\rho^2 = x^2 + y^2 + z^2$ and $\rho\cos\phi = z$ to obtain

$$x^2 + y^2 + z^2 = 2z$$

Transferring sides and completing the square gives

$$x^2 + y^2 + z^2 - 2z = 0$$
$$x^2 + y^2 + (z-1)^2 = 1$$

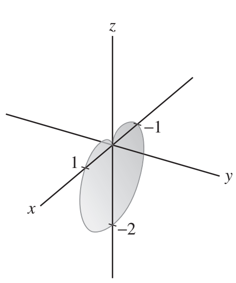
This is the rectangular equation of the sphere of radius 1, centered at the point (0, 0, 1) on the z-axis.

75. Explain the following statement: If the equation of a surface in cylindrical or spherical coordinates does not involve the coordinate θ, then the surface is rotationally symmetric with respect to the z-axis.

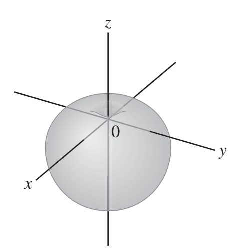
SOLUTION Since the equation of the surface does not involve the coordinate θ, then for every point P on the surface ($P = (\rho_0, \theta_0, \phi_0)$ in spherical coordinates or $P = (r_0, \theta_0, z_0)$ in cylindrical coordinates) so also all the points (ρ_0, θ, ϕ_0) or (r_0, θ, z_0) are on the surface. That is, all the points obtained by rotating P around the z-axis are on the surface. Hence, the surface is rotationally symmetric with respect to the z-axis.

76. CAS Plot the surface $\rho = 1 - \cos\phi$. Then plot the trace of S in the xz-plane and explain why S is obtained by rotating this trace.

SOLUTION The surface $\rho = 1 - \cos\phi$ and its trace in the xz-plane are shown in the following figures:



The trace of S in the xz-plane



The surface $S : \rho = 1 - \cos\phi$

Since the equation of the surface does not involve the coordinate θ, we conclude by Exercise 67 that the surface is rotationally symmetric with respect to the z-axis. Therefore, the points on the surface are obtained by rotating its trace in the xz-plane (or its trace in any other vertical plane) about the z-axis.

77. Find equations $r = g(\theta, z)$ (cylindrical) and $\rho = f(\theta, \phi)$ (spherical) for the hyperboloid $x^2 + y^2 = z^2 + 1$ (Figure 16). Do there exist points on the hyperboloid with $\phi = 0$ or π? Which values of ϕ occur for points on the hyperboloid?

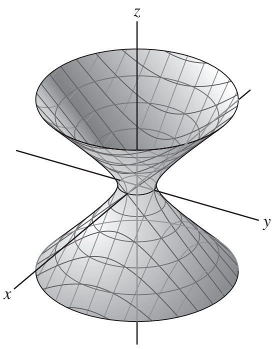


FIGURE 16 The hyperboloid $x^2 + y^2 = z^2 + 1$.

SOLUTION For the cylindrical coordinates (r, θ, z) we have $x^2 + y^2 = r^2$. Substituting into the equation $x^2 + y^2 = z^2 + 1$ gives

$$r^2 = z^2 + 1 \quad \Rightarrow \quad r = \sqrt{z^2 + 1}$$

For the spherical coordinates (ρ, θ, ϕ) we have $x = \rho \sin\phi \cos\theta$, $y = \rho \sin\phi \sin\theta$ and $z = \rho \cos\phi$. We substitute into the equation of the hyperboloid $x^2 + y^2 = z^2 + 1$ and simplify to obtain

$$\begin{aligned} \rho^2 \sin^2\phi \cos^2\theta + \rho^2 \sin^2\phi \sin^2\theta &= \rho^2 \cos^2\phi + 1 \\ \rho^2 \sin^2\phi \left(\cos^2\theta + \sin^2\theta\right) &= \rho^2 \cos^2\phi + 1 \\ \rho^2 \left(\sin^2\phi - \cos^2\phi\right) &= 1 \end{aligned}$$

Using the trigonometric identity $\cos 2\phi = \cos^2\phi - \sin^2\phi$ we get

$$\rho^2 \cdot \left(-\cos 2\phi\right) = 1 \quad \Rightarrow \quad \rho = \sqrt{-\frac{1}{\cos 2\phi}}$$

For $\phi = 0$ and $\phi = \pi$ we have $\cos 2 \cdot 0 = 1$ and $\cos 2\pi = 1$. In both cases $-\frac{1}{\cos 2\phi} = -1 < 0$, hence there is no real value of ρ satisfying $\rho = \sqrt{-\frac{1}{\cos 2\phi}}$. We conclude that there are no points on the hyperboloid with $\phi = 0$ or π.

To obtain a real ρ such that $\rho = \sqrt{-\frac{1}{\cos 2\phi}}$, we must have $-\frac{1}{\cos 2\phi} > 0$. That is, $\cos 2\phi < 0$ (and of course $0 \le \phi \le \pi$). The corresponding values of ϕ are

$$\frac{\pi}{2} < 2\phi \le \frac{3\pi}{2} \quad \Rightarrow \quad \frac{\pi}{4} < \phi \le \frac{3\pi}{4}$$

Further Insights and Challenges

*In Exercises 78–82, a **great circle** on a sphere S with center O is a circle obtained by intersecting S with a plane that passes through O (Figure 17). If P and Q are not antipodal (on opposite sides), there is a unique great circle through P and Q on S (intersect S with the plane through O, P, and Q). The geodesic distance from P to Q is defined as the length of the smaller of the two circular arcs of this great circle.*

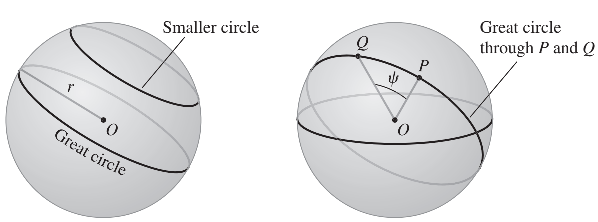

FIGURE 17

78. Show that the geodesic distance from P to Q is equal to $R\psi$, where ψ is the *central angle* between P and Q (the angle between the vectors $\mathbf{v} = \overrightarrow{OP}$ and $\mathbf{u} = \overrightarrow{OQ}$).

SOLUTION We place the xy-coordinate system in the plane of the great circle determined by P and Q, so that O is the origin and the positive x-axis is in the direction of $\overrightarrow{OP}$.

The parametric equation of the circle with the angular coordinate θ as the parameter is $x = R\cos\theta$, $y = R\sin\theta$. Also, P corresponds to $\theta = 0$ and Q corresponds to $\theta = \psi$. By the formula for the arc length we have

$$\overrightarrow{PQ} = \int_0^{\psi} \sqrt{x'(\theta)^2 + y'(\theta)^2}\,d\theta = \int_0^{\psi} \sqrt{(-R\sin\theta)^2 + (R\cos\theta)^2}\,d\theta$$
$$= \int_0^{\psi} \sqrt{R^2\left(\sin^2\theta + \cos^2\theta\right)}\,d\theta = R\int_0^{\psi} 1\cdot d\theta = R\theta\Big|_0^{\psi} = R\psi$$

.

79. Show that the geodesic distance from $Q = (a, b, c)$ to the North Pole $P = (0, 0, R)$ is equal to $R\cos^{-1}\left(\frac{c}{R}\right)$.

SOLUTION Let ψ be the central angle between P and Q, that is, the angle between the vectors $\mathbf{v} = \overrightarrow{OP}$ and $\mathbf{u} = \overrightarrow{OQ}$. By Exercise 78 the geodesic distance from P to Q is $R\psi$. We find ψ. By the formula for the cosine of the angle between two vectors, we have

$$\cos\psi = \frac{\mathbf{u}\cdot\mathbf{v}}{\|\mathbf{u}\|\,\|\mathbf{v}\|} \tag{1}$$

We compute the values in this quotient:

$$\mathbf{u}\cdot\mathbf{v} = \langle 0, 0, R\rangle \cdot \langle a, b, c\rangle = 0 + 0 + Rc = Rc$$
$$\|\mathbf{v}\| = \|\overrightarrow{OP}\| = R$$
$$\|\mathbf{u}\| = \|\overrightarrow{OQ}\| = \sqrt{a^2 + b^2 + c^2} = R$$

Substituting in (1) we get

$$\cos\psi = \frac{Rc}{R^2} = \frac{c}{R} \quad\Rightarrow\quad \psi = \cos^{-1}\left(\frac{c}{R}\right)$$

The geodesic distance from Q to P is thus

$$R\psi = R\cos^{-1}\left(\frac{c}{R}\right)$$

80. The coordinates of Los Angeles are 34° N and 118° W. Find the geodesic distance from the North Pole to Los Angeles, assuming that the earth is a sphere of radius $R = 6370$ km.

SOLUTION We denote by C the z-coordinate of the point Q on the surface of the earth where Los Angeles is located. Then by the previous exercise, the geodesic distance from Q to the north pole is

$$R\cos^{-1}\left(\frac{C}{R}\right) \tag{1}$$

To find C, we first must find the angles (θ, ϕ) for Los Angeles. The angle $118^\circ W$ refers to 118° in the negative θ direction, hence $\theta = 360^\circ - 118^\circ = 242^\circ$. The latitude is north hence $\phi = 90^\circ - 34^\circ = 56^\circ$. The z coordinate of Q is thus

$$C = R\cos\phi = R\cos 56^\circ = 0.56R$$

Substituting in (1) we obtain the following geodesic distance (in this formula the angle is measured in radians):

$$R\cos^{-1}\left(\frac{C}{R}\right) = 6370\cos^{-1}\left(\frac{0.56R}{R}\right) = 6370\cos^{-1}(0.56) = 6225.9km$$

81. Show that the central angle ψ between points P and Q on a sphere (of any radius) with angular coordinates (θ, ϕ) and (θ', ϕ') is equal to

$$\psi = \cos^{-1}\bigl(\sin\phi\sin\phi'\cos(\theta - \theta') + \cos\phi\cos\phi'\bigr)$$

Hint: Compute the dot product of $\overrightarrow{OP}$ and $\overrightarrow{OQ}$. Check this formula by computing the geodesic distance between the North and South Poles.

SOLUTION We denote the vectors $\mathbf{u} = \overrightarrow{OP}$ and $\mathbf{v} = \overrightarrow{OQ}$. By the formula for the angle between two vectors we have

$$\psi = \cos^{-1}\left(\frac{\mathbf{u}\cdot\mathbf{v}}{\|\mathbf{u}\|\|\mathbf{v}\|}\right)$$

Denoting by R the radius of the sphere, we have $\|\mathbf{u}\| = \|\mathbf{v}\| = R$, hence,

$$\psi = \cos^{-1}\left(\frac{\mathbf{u}\cdot\mathbf{v}}{R^2}\right) \tag{1}$$

The rectangular coordinates of $\mathbf{u}$ and $\mathbf{v}$ are

u	v
$x = R\sin\phi\cos\theta$	$x' = R\sin\phi'\cos\theta'$
$y = R\sin\phi\sin\theta$	$y' = R\sin\phi'\sin\theta'$
$z = R\cos\phi$	$z' = R\cos\phi'$

Hence,

$$\begin{aligned}\mathbf{u}\cdot\mathbf{v} &= R^2\sin\phi\cos\theta\sin\phi'\cos\theta' + R^2\sin\phi\sin\theta\sin\phi'\sin\theta' + R^2\cos\phi\cos\phi' \\ &= R^2\left[\sin\phi\sin\phi'\left(\cos\theta\cos\theta' + \sin\theta\sin\theta'\right) + \cos\phi\cos\phi'\right]\end{aligned}$$

We use the identity $\cos(\alpha - \beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta$ to obtain

$$\mathbf{u}\cdot\mathbf{v} = R^2\left(\sin\phi\sin\phi'\cos\left(\theta - \theta'\right) + \cos\phi\cos\phi'\right)$$

Substituting in (1) we obtain

$$\psi = \cos^{-1}\left(\sin\phi\sin\phi'\cos\left(\theta - \theta'\right) + \cos\phi\cos\phi'\right) \tag{2}$$

We now check this formula in the case where P and Q are the north and south poles respectively. In this case $\theta = \theta' = 0$, $\phi = 0$, $\phi' = \pi$. Substituting in (2) gives

$$\psi = \cos^{-1}(\sin 0\sin\pi\cos 0 + \cos 0\cos\pi) = \cos^{-1}(-1) = \pi$$

Using Exercise 78, the geodesic distance between the two poles is $R\psi = R\pi$, in accordance with the formula for the length of a semicircle.

82. Use Exercise 81 to find the geodesic distance between Los Angeles (34° N, 118° W) and Bombay (19° N, 72.8° E).

SOLUTION By Exercise 80 the angles (θ, ϕ) for Los Angeles are $(\theta, \phi) = \left(242^\circ, 56^\circ\right)$. The angles (θ, ϕ) for Bombay are

$$\theta' = 72.8^\circ$$
$$\phi' = 90^\circ - 19^\circ = 71^\circ$$

By Exercise 81, the central angle ψ between the two towns is

$$\psi = \cos^{-1}\left(\sin\phi\sin\phi'\cos\left(\theta - \theta'\right) + \cos\phi\cos\phi'\right)$$

Substituting the angles gives

$$\begin{aligned}\psi &= \cos^{-1}\left(\sin 56^\circ\sin 71^\circ\cos\left(242^\circ - 72.8^\circ\right) + \cos 56^\circ\cos 71^\circ\right) \\ &= \cos^{-1}(-0.77 + 0.18) = \cos^{-1}(-0.59)\end{aligned}$$

The solution for $0 \le \psi \le 180$ is $\psi = 126.2^\circ = 2.2$ rad. Using Exercise 78 with $R = 6370$ km we conclude that the geodesic distance between the two towns is

$$R\psi = 6370 \cdot 2.2 = 14{,}014 \text{ km}.$$

CHAPTER REVIEW EXERCISES

In Exercises 1–6, let $\mathbf{v} = \langle -2, 5\rangle$ *and* $\mathbf{w} = \langle 3, -2\rangle$.

1. Calculate $5\mathbf{w} - 3\mathbf{v}$ and $5\mathbf{v} - 3\mathbf{w}$.

SOLUTION We use the definition of basic vector operations to compute the two linear combinations:

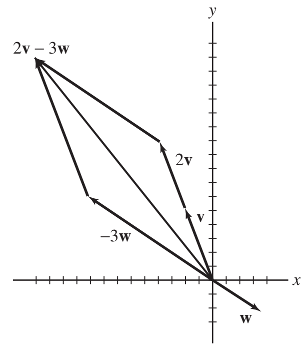
$$5\mathbf{w} - 3\mathbf{v} = 5\langle 3, -2\rangle - 3\langle -2, 5\rangle = \langle 15, -10\rangle + \langle 6, -15\rangle = \langle 21, -25\rangle$$
$$5\mathbf{v} - 3\mathbf{w} = 5\langle -2, 5\rangle - 3\langle 3, -2\rangle = \langle -10, 25\rangle + \langle -9, 6\rangle = \langle -19, 31\rangle$$

2. Sketch **v**, **w**, and 2**v** − 3**w**.

SOLUTION We have,

$$2\mathbf{v} - 3\mathbf{w} = 2\langle -2, 5\rangle - 3\langle 3, -2\rangle = \langle -4, 10\rangle + \langle -9, 6\rangle = \langle -13, 16\rangle$$

The vectors **v**, **w** and 2**v** − 3**w** are shown in the figure below:



3. Find the unit vector in the direction of **v**.

SOLUTION The unit vector in the direction of **v** is

$$\mathbf{e_v} = \frac{1}{\|\mathbf{v}\|}\mathbf{v}$$

We compute the length of **v**:

$$\|\mathbf{v}\| = \sqrt{(-2)^2 + 5^2} = \sqrt{29}$$

Hence,

$$\mathbf{e_v} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle -2, 5\rangle}{\sqrt{29}} = \left\langle \frac{-2}{\sqrt{29}}, \frac{5}{\sqrt{29}} \right\rangle.$$

4. Find the length of **v** + **w**.

SOLUTION We first compute the sum **v** + **w**:

$$\mathbf{v} + \mathbf{w} = \langle -2, 5\rangle + \langle 3, -2\rangle = \langle -2 + 3, 5 - 2\rangle = \langle 1, 3\rangle$$

Using the definition of the length of a vector we obtain

$$\|\mathbf{v} + \mathbf{w}\| = \|\langle 1, 3\rangle\| = \sqrt{1^2 + 3^2} = \sqrt{10}.$$

5. Express **i** as a linear combination $r\mathbf{v} + s\mathbf{w}$.

SOLUTION We use basic properties of vector algebra to write

$$\mathbf{i} = r\mathbf{v} + s\mathbf{w} \tag{1}$$

$$\langle 1, 0\rangle = r\langle -2, 5\rangle + s\langle 3, -2\rangle = \langle -2r + 3s, 5r - 2s\rangle$$

The vector are equivalent, hence,

$$1 = -2r + 3s$$
$$0 = 5r - 2s$$

The second equation implies that $s = \frac{5}{2}r$. We substitute in the first equation and solve for r:

$$1 = -2r + 3 \cdot \frac{5}{2}r$$
$$1 = \frac{11}{2}r$$
$$r = \frac{2}{11} \quad \Rightarrow \quad s = \frac{5}{2} \cdot \frac{2}{11} = \frac{5}{11}$$

Substituting in (1) we obtain

$$\mathbf{i} = \frac{2}{11}\mathbf{v} + \frac{5}{11}\mathbf{w}.$$

6. Find a scalar α such that $\|\mathbf{v} + \alpha\mathbf{w}\| = 6$.

SOLUTION We compute the vector $\mathbf{v} + \alpha\mathbf{w}$:

$$\mathbf{v} + \alpha\mathbf{w} = \langle -2, 5\rangle + \alpha\langle 3, -2\rangle = \langle -2 + 3\alpha, 5 - 2\alpha\rangle$$

The length of $\mathbf{v} + \alpha\mathbf{w}$ is

$$\begin{aligned}\|\mathbf{v} + \alpha\mathbf{w}\| &= \sqrt{(-2+3\alpha)^2 + (5-2\alpha)^2} = \sqrt{4 - 12\alpha + 9\alpha^2 + 25 - 20\alpha + 4\alpha^2}\\ &= \sqrt{13\alpha^2 - 32\alpha + 29}\end{aligned}$$

We obtain the following equation:

$$\sqrt{13\alpha^2 - 32\alpha + 29} = 6$$

Solving for α yields

$$\begin{aligned}13\alpha^2 - 32\alpha + 29 &= 36\\ 13\alpha^2 - 32\alpha - 7 &= 0\\ \alpha_{1,2} = \frac{32 \pm \sqrt{32^2 - 4\cdot 13\cdot(-7)}}{26} &= \frac{16 \pm \sqrt{347}}{13}\end{aligned}$$

The two solutions are thus

$$\alpha = \frac{16 \pm \sqrt{347}}{13}.$$

7. If $P = (1, 4)$ and $Q = (-3, 5)$, what are the components of $\overrightarrow{PQ}$? What is the length of $\overrightarrow{PQ}$?

SOLUTION By the Definition of Components of a Vector we have

$$\overrightarrow{PQ} = \langle -3 - 1, 5 - 4\rangle = \langle -4, 1\rangle$$

The length of $\overrightarrow{PQ}$ is

$$\|\overrightarrow{PQ}\| = \sqrt{(-4)^2 + 1^2} = \sqrt{17}.$$

8. Let $A = (2, -1)$, $B = (1, 4)$, and $P = (2, 3)$. Find the point Q such that $\overrightarrow{PQ}$ is equivalent to $\overrightarrow{AB}$. Sketch $\overrightarrow{PQ}$ and $\overrightarrow{AB}$.

SOLUTION The vectors $\overrightarrow{AB}$ and $\overrightarrow{PQ}$ are equivalent, therefore they have the same components. We denote the point Q by $Q = (a, b)$, and compute the vectors $\overrightarrow{AB}$ and $\overrightarrow{PQ}$. We get

$$\begin{aligned}\overrightarrow{AB} &= \langle 1 - 2, 4 - (-1)\rangle = \langle -1, 5\rangle\\ \overrightarrow{PQ} &= \langle a - 2, b - 3\rangle\end{aligned}$$

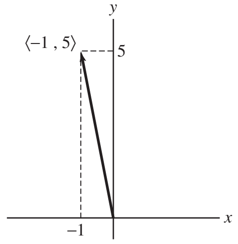
Therefore

$$-1 = a - 2 \quad \text{and} \quad 5 = b - 3$$

or

$$a = 1 \quad \text{and} \quad b = 8$$

Hence the point Q is $Q = (1, 8)$. The equivalent vectors $\overrightarrow{AB} = \overrightarrow{PQ} = \langle -1, 5\rangle$ are shown in the figure:



9. Find the vector with length 3 making an angle of $\frac{7\pi}{4}$ with the positive x-axis.

SOLUTION We denote the vector by $\mathbf{v} = \langle a, b\rangle$. $\mathbf{v}$ makes an angle $\theta = \frac{7\pi}{4}$ with the x-axis, and its length is 3, hence,

$$a = \|\mathbf{v}\| \cos\theta = 3\cos\frac{7\pi}{4} = \frac{3}{\sqrt{2}}$$
$$b = \|\mathbf{v}\| \sin\theta = 3\sin\frac{7\pi}{4} = -\frac{3}{\sqrt{2}}$$

That is,

$$\mathbf{v} = \langle a, b\rangle = \left\langle \frac{3}{\sqrt{2}}, -\frac{3}{\sqrt{2}} \right\rangle.$$

10. Calculate $3(\mathbf{i} - 2\mathbf{j}) - 6(\mathbf{i} + 6\mathbf{j})$.

SOLUTION Using basic properties of vector algebra we have

$$3(\mathbf{i} - 2\mathbf{j}) - 6(\mathbf{i} + 6\mathbf{j}) = 3\mathbf{i} - 6\mathbf{j} - 6\mathbf{i} - 36\mathbf{j} = -3\mathbf{i} - 42\mathbf{j}$$

11. Find the value of β for which $\mathbf{w} = \langle -2, \beta\rangle$ is parallel to $\mathbf{v} = \langle 4, -3\rangle$.

SOLUTION If $\mathbf{v} = \langle 4, -3\rangle$ and $\mathbf{w} = \langle -2, \beta\rangle$ are parallel, there exists a scalar λ such that $\mathbf{w} = \lambda\mathbf{v}$. That is,

$$\langle -2, \beta\rangle = \lambda\langle 4, -3\rangle = \langle 4\lambda, -3\lambda\rangle$$

yielding

$$-2 = 4\lambda \quad \text{and} \quad \beta = -3\lambda$$

These equations imply that $\lambda = -\frac{1}{2}$ and $\lambda = -\frac{\beta}{3}$. Equating the two expressions for λ gives

$$-\frac{1}{2} = -\frac{\beta}{3} \quad \text{or} \quad \beta = \frac{3}{2}.$$

12. Let $P = (1, 4, -3)$.

(a) Find the point Q such that $\overrightarrow{PQ}$ is equivalent to $\langle 3, -1, 5\rangle$.

(b) Find a unit vector $\mathbf{e}$ equivalent to $\overrightarrow{PQ}$.

SOLUTION

(a) Let $Q = (a, b, c)$. Since the vectors $\overrightarrow{PQ}$ and $\langle 3, -1, 5\rangle$ are equivalent they have the same components. That is,

$$\overrightarrow{PQ} = \langle a - 1, b - 4, c - (-3)\rangle = \langle 3, -1, 5\rangle$$

Hence,

$$\begin{array}{lcl} a - 1 = 3 & & a = 4 \\ b - 4 = -1 & \Rightarrow & b = 3 \\ c + 3 = 5 & & c = 2 \end{array}$$

The point Q is thus $Q = (4, 3, 2)$.

(b) The unit vector $\mathbf{e}$ is obtained by dividing $\overrightarrow{PQ}$ by its length:

$$\mathbf{e} = \frac{\overrightarrow{PQ}}{\left\|\overrightarrow{PQ}\right\|} = \frac{\langle 3, -1, 5\rangle}{\sqrt{3^2 + (-1)^2 + 5^2}} = \left\langle \frac{3}{\sqrt{35}}, -\frac{1}{\sqrt{35}}, \frac{5}{\sqrt{35}} \right\rangle$$

Notice that the opposite vector $-\mathbf{e}$ is also a solution.

13. Let $\mathbf{w} = \langle 2, -2, 1\rangle$ and $\mathbf{v} = \langle 4, 5, -4\rangle$. Solve for $\mathbf{u}$ if $\mathbf{v} + 5\mathbf{u} = 3\mathbf{w} - \mathbf{u}$.

SOLUTION Using vector algebra we have

$$\begin{aligned} \mathbf{v} + 5\mathbf{u} &= 3\mathbf{w} - \mathbf{u} \\ 6\mathbf{u} &= 3\mathbf{w} - \mathbf{v} \\ \mathbf{u} &= \frac{1}{2}\mathbf{w} - \frac{1}{6}\mathbf{v} = \left\langle 1, -1, \frac{1}{2} \right\rangle - \left\langle \frac{4}{6}, \frac{5}{6}, -\frac{4}{6} \right\rangle = \left\langle \frac{1}{3}, -\frac{11}{6}, \frac{7}{6} \right\rangle \end{aligned}$$

14. Let $\mathbf{v} = 3\mathbf{i} - \mathbf{j} + 4\mathbf{k}$. Find the length of $\mathbf{v}$ and the vector $2\mathbf{v} + 3(4\mathbf{i} - \mathbf{k})$.

SOLUTION We first compute the length of the vector $\mathbf{v}$:

$$\|\mathbf{v}\| = \|3\mathbf{i} - \mathbf{j} + 4\mathbf{k}\| = \sqrt{3^2 + (-1)^2 + 4^2} = \sqrt{26}$$

We find the vector $2\mathbf{v} + 3(4\mathbf{i} - \mathbf{k})$ using properties of vector algebra:

$$\begin{aligned} 2\mathbf{v} + 3(4\mathbf{i}-\mathbf{k}) &= 2(3\mathbf{i} - \mathbf{j} + 4\mathbf{k}) + 3(4\mathbf{i} - \mathbf{k}) = 6\mathbf{i} - 2\mathbf{j} + 8\mathbf{k} + 12\mathbf{i} - 3\mathbf{k} \\ &= 18\mathbf{i} - 2\mathbf{j} + 5\mathbf{k} \end{aligned}$$

15. Find a parametrization $\mathbf{r}_1(t)$ of the line passing through $(1, 4, 5)$ and $(-2, 3, -1)$. Then find a parametrization $\mathbf{r}_2(t)$ of the line parallel to $\mathbf{r}_1$ passing through $(1, 0, 0)$.

SOLUTION Since the points $P = (-2, 3, -1)$ and $Q = (1, 4, 5)$ are on the line l_1, the vector $\overrightarrow{PQ}$ is a direction vector for the line. We find this vector:

$$\overrightarrow{PQ} = \langle 1 - (-2), 4 - 3, 5 - (-1) \rangle = \langle 3, 1, 6 \rangle$$

Substituting $\mathbf{v} = \langle 3, 1, 6 \rangle$ and $P_0 = \langle 1, 4, 5 \rangle$ in the vector parametrization of the line we obtain the following equation for l_1:

$$\mathbf{r}_1(t) = \overrightarrow{OP_0} + t\mathbf{v}$$

$$\mathbf{r}_1(t) = \langle 1, 4, 5 \rangle + t\langle 3, 1, 6 \rangle = \langle 1 + 3t, 4 + t, 5 + 6t \rangle$$

The line l_2 is parallel to l_1, hence $\overrightarrow{PQ} = \langle 3, 1, 6 \rangle$ is also a direction vector for l_2. Substituting $\mathbf{v} = \langle 3, 1, 6 \rangle$ and $P_0 = (1, 0, 0)$ in the vector parametrization of the line we obtain the following equation for l_2:

$$\mathbf{r}_2(t) = \overrightarrow{OP_0} + t\mathbf{v}$$

$$\mathbf{r}_2(t) = \langle 1, 0, 0 \rangle + t\langle 3, 1, 6 \rangle = \langle 1 + 3t, t, 6t \rangle$$

16. Let $\mathbf{r}_1(t) = \mathbf{v}_1 + t\mathbf{w}_1$ and $\mathbf{r}_2(t) = \mathbf{v}_2 + t\mathbf{w}_2$ be parametrizations of lines $\mathcal{L}_1$ and $\mathcal{L}_2$. For each statement (a)–(e), provide a proof if the statement is true and a counterexample if it is false.

(a) If $\mathcal{L}_1 = \mathcal{L}_2$, then $\mathbf{v}_1 = \mathbf{v}_2$ and $\mathbf{w}_1 = \mathbf{w}_2$.

(b) If $\mathcal{L}_1 = \mathcal{L}_2$ and $\mathbf{v}_1 = \mathbf{v}_2$, then $\mathbf{w}_1 = \mathbf{w}_2$.

(c) If $\mathcal{L}_1 = \mathcal{L}_2$ and $\mathbf{w}_1 = \mathbf{w}_2$, then $\mathbf{v}_1 = \mathbf{v}_2$.

(d) If $\mathcal{L}_1$ is parallel to $\mathcal{L}_2$, then $\mathbf{w}_1 = \mathbf{w}_2$.

(e) If $\mathcal{L}_1$ is parallel to $\mathcal{L}_2$, then $\mathbf{w}_1 = \lambda\mathbf{w}_2$ for some scalar λ.

SOLUTION

(a) This statement is false. Consider the following lines:

$$\mathcal{L}_1: \quad \mathbf{r}_1(t) = \langle 1, 0, 1 \rangle + t\langle 1, 1, 1 \rangle$$

$$\mathcal{L}_2: \quad \mathbf{r}_2(t) = \langle 3, 2, 3 \rangle + t\langle 2, 2, 2 \rangle$$

The line $\mathcal{L}_1$ passes through the points $P = (1, 0, 1)$ (for $t = 0$) and $Q = (2, 1, 2)$ (for $t = 1$). The line $\mathcal{L}_2$ passes through P and Q as well (for $t = -1$ and $t = -\frac{1}{2}$ respectively). Therefore, $\mathcal{L}_1 = \mathcal{L}_2$. However, $\mathbf{v}_1 = \langle 1, 0, 1 \rangle$, $\mathbf{v}_2 = \langle 3, 2, 3 \rangle$, $\mathbf{w}_1 = \langle 1, 1, 1 \rangle$, $\mathbf{w}_2 = \langle 2, 2, 2 \rangle$ hence $\mathbf{v}_1 \neq \mathbf{v}_2$ and $\mathbf{w}_1 \neq \mathbf{w}_2$.

(b) This statement is false. Consider the following lines:

$$\mathcal{L}_1: \quad \mathbf{r}_1(t) = \langle 0, 1, 0 \rangle + t\langle 1, 1, 1 \rangle$$

$$\mathcal{L}_2: \quad \mathbf{r}_2(t) = \langle 0, 1, 0 \rangle + t\langle 2, 2, 2 \rangle$$

The line $\mathcal{L}_1$ passes through the points $P = (0, 1, 0)$ (for $t = 0$) and $Q = (1, 2, 1)$ (for $t = 1$). The line $\mathcal{L}_2$ passes through P and Q as well (for $t = 0$ and $t = \frac{1}{2}$). Therefore, $\mathcal{L}_1 = \mathcal{L}_2$. Also $\mathbf{v}_1 = \mathbf{v}_2$, but $\mathbf{w}_1 \neq \mathbf{w}_2$.

(c) This statement is false. Consider the following lines:

$$\mathcal{L}_1: \quad \mathbf{r}_1(t) = \langle 1, 0, 1 \rangle + t\langle 1, 1, 1 \rangle$$

$$\mathcal{L}_2: \quad \mathbf{r}_2(t) = \langle 2, 1, 2 \rangle + t\langle 1, 1, 1 \rangle$$

The line $\mathcal{L}_1$ passes through $P = (1, 0, 1)$ and $Q = (2, 1, 2)$ (for $t = 1$). The line $\mathcal{L}_2$ passes through $P = (1, 0, 1)$ (for $t = -1$) and $Q = (2, 1, 2)$ (for $t = 0$). Therefore, $\mathcal{L}_1 = \mathcal{L}_2$. Also, $\mathbf{w}_1 = \mathbf{w}_2$ but $\mathbf{v}_1 \neq \mathbf{v}_2$.

(d) This statement is false. Consider the following lines:

$$\mathcal{L}_1: \quad \mathbf{r}_1(t) = \langle 1, 1, 1 \rangle + t\langle 1, 0, 1 \rangle$$
$$\mathcal{L}_2: \quad \mathbf{r}_2(t) = t\langle 2, 0, 2 \rangle$$

We have $\mathbf{w}_1 = \langle 1, 0, 1 \rangle$ and $\mathbf{w}_2 = \langle 2, 0, 2 \rangle$ therefore $\mathbf{w}_2 = 2\mathbf{w}_1$. We conclude that $\mathbf{w}_1$ and $\mathbf{w}_2$ are parallel vectors, hence the lines $\mathcal{L}_1$ and $\mathcal{L}_2$ are parallel although $\mathbf{w}_1 \neq \mathbf{w}_2$.

(e) This statement is correct. If $\mathcal{L}_1$ and $\mathcal{L}_2$ are parallel lines, the direction vectors $\mathbf{w}_1$ and $\mathbf{w}_2$ of these lines are parallel, hence they are scalar multiples of one another.

17. Find a and b such that the lines $\mathbf{r}_1 = \langle 1, 2, 1 \rangle + t\langle 1, -1, 1 \rangle$ and $\mathbf{r}_2 = \langle 3, -1, 1 \rangle + t\langle a, b, -2 \rangle$ are parallel.

SOLUTION The lines are parallel if and only if the direction vectors $\mathbf{v}_1 = \langle 1, -1, 1 \rangle$ and $\mathbf{v}_2 = \langle a, b, -2 \rangle$ are parallel. That is, if and only if there exists a scalar λ such that:

$$\mathbf{v}_2 = \lambda \mathbf{v}_1$$
$$\langle a, b, -2 \rangle = \lambda\langle 1, -1, 1 \rangle = \langle \lambda, -\lambda, \lambda \rangle$$

We obtain the following equations:

$$\begin{aligned} a &= \lambda \\ b &= -\lambda \quad \Rightarrow \quad a = -2, \quad b = 2 \\ -2 &= \lambda \end{aligned}$$

18. Find a such that the lines $\mathbf{r}_1 = \langle 1, 2, 1 \rangle + t\langle 1, -1, 1 \rangle$ and $\mathbf{r}_2 = \langle 3, -1, 1 \rangle + t\langle a, 4, -2 \rangle$ intersect.

SOLUTION If the lines intersect, there exists a point that lies on both lines. That is, there are unique values of t and s such that:

$$\langle 1, 2, 1 \rangle + t\langle 1, -1, 1 \rangle = \langle 3, -1, 1 \rangle + s\langle a, 4, -2 \rangle$$

or

$$\langle 1 + t, 2 - t, 1 + t \rangle = \langle 3 + as, -1 + 4s, 1 - 2s \rangle$$

yielding the following equations:

$$\begin{aligned} 1 + t &= 3 + as & \qquad & t = 2 + as \\ 2 - t &= -1 + 4s & \Rightarrow \quad & t = 3 - 4s \\ 1 + t &= 1 - 2s & & t = -2s \end{aligned}$$

Equating the expressions for t gives the following equations:

$$\begin{aligned} 2 + as &= -2s \\ 3 - 4s &= -2s \end{aligned} \quad \Rightarrow \quad \begin{aligned} (a+2)s &= -2 \\ 2s &= 3 \end{aligned} \quad \Rightarrow \quad s = \frac{3}{2}$$

Substituting $s = \frac{3}{2}$ in the first equation we obtain:

$$(a + 2) \cdot \frac{3}{2} = -2 \quad \Rightarrow \quad a = -\frac{10}{3}.$$

19. Sketch the vector sum $\mathbf{v} = \mathbf{v}_1 - \mathbf{v}_2 + \mathbf{v}_3$ for the vectors in Figure 1(A).

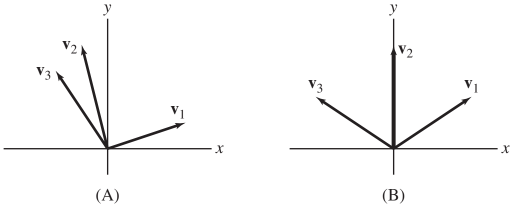


FIGURE 1

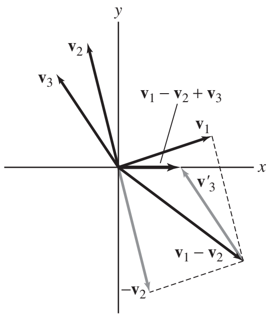
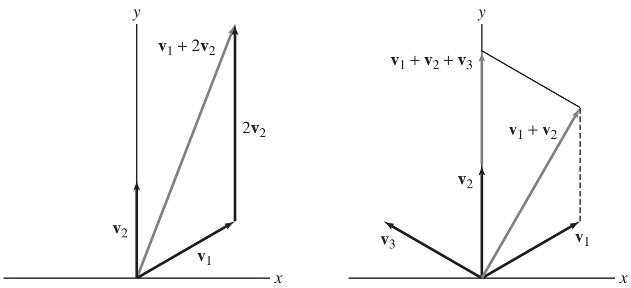
SOLUTION Using the Parallelogram Law we obtain the vector sum shown in the figure.

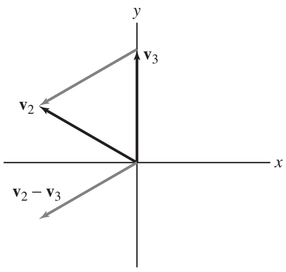


We first add $\mathbf{v}_1$ and $-\mathbf{v}_2$, then we add $\mathbf{v}_3$ to $\mathbf{v}_1 - \mathbf{v}_2$.

20. Sketch the sums $\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3$, $\mathbf{v}_1 + 2\mathbf{v}_2$, and $\mathbf{v}_2 - \mathbf{v}_3$ for the vectors in Figure 1(B).

SOLUTION We use the definition of scalar multiple of a vector and the Parallelogram Law to sketch the vectors.





To form $\mathbf{v}_2 - \mathbf{v}_3$, we draw the vector pointing from $\mathbf{v}_3$ to $\mathbf{v}_2$ and translate it back to the basepoint.

In Exercises 21–26, let $\mathbf{v} = \langle 1, 3, -2 \rangle$ *and* $\mathbf{w} = \langle 2, -1, 4 \rangle$.

21. Compute $\mathbf{v} \cdot \mathbf{w}$.

SOLUTION Using the definition of the dot product we have

$$\mathbf{v} \cdot \mathbf{w} = \langle 1, 3, -2 \rangle \cdot \langle 2, -1, 4 \rangle = 1 \cdot 2 + 3 \cdot (-1) + (-2) \cdot 4 = 2 - 3 - 8 = -9$$

22. Compute the angle between $\mathbf{v}$ and $\mathbf{w}$.

SOLUTION The cosine of the angle θ between $\mathbf{v}$ and $\mathbf{w}$ is

$$\cos\theta = \frac{\mathbf{v} \cdot \mathbf{w}}{\|\mathbf{v}\| \|\mathbf{w}\|} \tag{1}$$

We compute the lengths of the vectors:

$$\|\mathbf{v}\| = \|\langle 1, 3, -2 \rangle\| = \sqrt{1^2 + 3^2 + (-2)^2} = \sqrt{14}$$

$$\|\mathbf{w}\| = \|\langle 2, -1, 4 \rangle\| = \sqrt{2^2 + (-1)^2 + 4^2} = \sqrt{21}$$

In the previous exercise we found that $\mathbf{v} \cdot \mathbf{w} = -9$. Substituting these values in (1) gives

$$\cos\theta = \frac{-9}{\sqrt{14} \cdot \sqrt{21}} = \frac{-9}{7\sqrt{6}} \approx -0.5249$$

The solution for $0 \le \theta \le \pi$ is

$$\theta = 2.123 \text{ rad}.$$

23. Compute $\mathbf{v} \times \mathbf{w}$.

SOLUTION We use the definition of the cross product as a "determinant":

$$\mathbf{v} \times \mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 3 & -2 \\ 2 & -1 & 4 \end{vmatrix} = \begin{vmatrix} 3 & -2 \\ -1 & 4 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & -2 \\ 2 & 4 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 3 \\ 2 & -1 \end{vmatrix} \mathbf{k}$$
$$= (12-2)\mathbf{i} - (4+4)\mathbf{j} + (-1-6)\mathbf{k} = 10\mathbf{i} - 8\mathbf{j} - 7\mathbf{k} = \langle 10, -8, -7 \rangle$$

24. Find the area of the parallelogram spanned by $\mathbf{v}$ and $\mathbf{w}$.

SOLUTION The parallelogram spanned by $\mathbf{v}$ and $\mathbf{w}$ has area $\|\mathbf{v} \times \mathbf{w}\|$. In the previous exercise, we found that $\mathbf{v} \times \mathbf{w} = \langle 10, -8, -7 \rangle$. Therefore the area A of the parallelogram is

$$A = \|\mathbf{v} \times \mathbf{w}\| = \|\langle 10, -8, -7 \rangle\| = \sqrt{10^2 + (-8)^2 + (-7)^2} = \sqrt{213} \approx 14.59$$

25. Find the volume of the parallelepiped spanned by $\mathbf{v}$, $\mathbf{w}$, and $\mathbf{u} = \langle 1, 2, 6 \rangle$.

SOLUTION The volume V of the parallelepiped spanned by $\mathbf{v}$, $\mathbf{w}$ and $\mathbf{u}$ is the following determinant:

$$V = \left| \det \begin{pmatrix} \mathbf{v} \\ \mathbf{w} \\ \mathbf{u} \end{pmatrix} \right| = \begin{vmatrix} 1 & 3 & -2 \\ 2 & -1 & 4 \\ 1 & 2 & 6 \end{vmatrix} = \left| 1 \cdot \begin{vmatrix} -1 & 4 \\ 2 & 6 \end{vmatrix} - 3 \begin{vmatrix} 2 & 4 \\ 1 & 6 \end{vmatrix} - 2 \begin{vmatrix} 2 & -1 \\ 1 & 2 \end{vmatrix} \right|$$
$$= |1 \cdot (-6-8) - 3(12-4) - 2(4+1)| = 48$$

26. Find all the vectors orthogonal to both $\mathbf{v}$ and $\mathbf{w}$.

SOLUTION A vector $\mathbf{u} = \langle a, b, c \rangle$ is orthogonal to $\mathbf{v}$ and to $\mathbf{w}$ if the dot products $\mathbf{u} \cdot \mathbf{v}$ and $\mathbf{u} \cdot \mathbf{w}$ are zero. That is,

$$\mathbf{u} \cdot \mathbf{v} = 0 \quad \text{and} \quad \mathbf{u} \cdot \mathbf{w} = 0.$$

We compute the dot products:

$$\mathbf{u} \cdot \mathbf{v} = \langle a, b, c \rangle \cdot \langle 1, 3, -2 \rangle = a + 3b - 2c$$
$$\mathbf{u} \cdot \mathbf{w} = \langle a, b, c \rangle \cdot \langle 2, -1, 4 \rangle = 2a - b + 4c$$

We obtain the following equations:

$$a + 3b - 2c = 0$$
$$2a - b + 4c = 0$$

The first equation implies $a = 2c - 3b$. Substituting in the second equation and solving for b in terms of c gives

$$2(2c - 3b) - b + 4c = 0$$
$$4c - 6b - b + 4c = 0$$
$$8c - 7b = 0 \quad \Rightarrow \quad b = \frac{8}{7}c$$

We find a in terms of c, using the relation $a = 2c - 3b$:

$$a = 2c - 3 \cdot \frac{8}{7}c = 2c - \frac{24}{7}c = -\frac{10}{7}c.$$

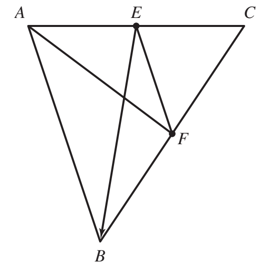
The solutions are, thus,

$$\mathbf{u} = \langle a, b, c \rangle = \left\langle -\frac{10}{7}c, \frac{8}{7}c, c \right\rangle = -\frac{c}{7}\langle 10, -8, -7 \rangle$$

We conclude that the vectors orthogonal to $\mathbf{v}$ and $\mathbf{w}$ are all the vectors parallel to $\langle 10, -8, -7 \rangle$.

27. Use vectors to prove that the line connecting the midpoints of two sides of a triangle is parallel to the third side.

SOLUTION Let E and F be the midpoints of sides AC and BC in a triangle ABC (see figure).



We must show that

$$\overrightarrow{EF} \parallel \overrightarrow{AB}$$

Using the Parallelogram Law we have

$$\overrightarrow{EF} = \overrightarrow{EA} + \overrightarrow{AB} + \overrightarrow{BF} \tag{1}$$

By the definition of the points E and F,

$$\overrightarrow{EA} = \frac{1}{2}\overrightarrow{CA}; \quad \overrightarrow{BF} = \frac{1}{2}\overrightarrow{BC}$$

We substitute (1) to obtain

$$\begin{aligned}\overrightarrow{EF} &= \frac{1}{2}\overrightarrow{CA} + \overrightarrow{AB} + \frac{1}{2}\overrightarrow{BC} = \overrightarrow{AB} + \frac{1}{2}\left(\overrightarrow{CA} + \overrightarrow{BC}\right)\\ &= \overrightarrow{AB} + \frac{1}{2}\left(\overrightarrow{BC} + \overrightarrow{CA}\right) = \overrightarrow{AB} + \frac{1}{2}\overrightarrow{BA} = \overrightarrow{AB} - \frac{1}{2}\overrightarrow{AB} = \frac{1}{2}\overrightarrow{AB}\end{aligned}$$

Therefore, $\overrightarrow{EF}$ is a constant multiple of $\overrightarrow{AB}$, which implies that $\overrightarrow{EF}$ and $\overrightarrow{AB}$ are parallel vectors.

28. Let $\mathbf{v} = \langle 1, -1, 3\rangle$ and $\mathbf{w} = \langle 4, -2, 1\rangle$.

(a) Find the decomposition $\mathbf{v} = \mathbf{v}_{\parallel} + \mathbf{v}_{\perp}$ with respect to $\mathbf{w}$.

(b) Find the decomposition $\mathbf{w} = \mathbf{w}_{\parallel} + \mathbf{w}_{\perp}$ with respect to $\mathbf{v}$.

SOLUTION

(a) Step 1. Compute $\mathbf{v} \cdot \mathbf{w}$ and $\mathbf{w} \cdot \mathbf{w}$. We have the following dot products:

$$\mathbf{v} \cdot \mathbf{w} = \langle 1, -1, 3\rangle \cdot \langle 4, -2, 1\rangle = 4 + 2 + 3 = 9$$
$$\mathbf{w} \cdot \mathbf{w} = \langle 4, -2, 1\rangle \cdot \langle 4, -2, 1\rangle = 16 + 4 + 1 = 21$$

Step 2. Use the formula for $\mathbf{v}_{\parallel}$. We use the following formula:

$$\mathbf{v}_{\parallel} = \text{proj}_{\mathbf{w}}(\mathbf{v}) = \left(\frac{\mathbf{v} \cdot \mathbf{w}}{\mathbf{w} \cdot \mathbf{w}}\right)\mathbf{w}$$

Substituting the dot products from the previous step, we get:

$$\mathbf{v}_{\parallel} = \frac{9}{21}\langle 4, -2, 1\rangle = \left\langle \frac{12}{7}, -\frac{6}{7}, \frac{3}{7}\right\rangle$$

Step 3. Identifying $\mathbf{v}_{\perp}$. The orthogonal part is the following difference:

$$\mathbf{v}_{\perp} = \mathbf{v} - \mathbf{v}_{\parallel} = \langle 1, -1, 3\rangle - \left\langle \frac{12}{7}, -\frac{6}{7}, \frac{3}{7}\right\rangle = \left\langle -\frac{5}{7}, -\frac{1}{7}, \frac{18}{7}\right\rangle$$

The resulting decomposition is:

$$\mathbf{v} = \langle 1, -1, 3\rangle = \underbrace{\left\langle \frac{12}{7}, -\frac{6}{7}, \frac{3}{7}\right\rangle}_{\text{projection along } \mathbf{w}} + \underbrace{\left\langle -\frac{5}{7}, -\frac{1}{7}, \frac{18}{7}\right\rangle}_{\text{orthogonal to } \mathbf{w}}$$

(b) Step 1. Compute $\mathbf{w} \cdot \mathbf{v}$ and $\mathbf{v} \cdot \mathbf{v}$. In part (a) we found that $\mathbf{w} \cdot \mathbf{v} = \mathbf{v} \cdot \mathbf{w} = 9$. We compute the dot product $\mathbf{v} \cdot \mathbf{v}$:

$$\mathbf{v} \cdot \mathbf{v} = \langle 1, -1, 3\rangle \cdot \langle 1, -1, 3\rangle = 1 + 1 + 9 = 11$$

Step 2. Use the formula for $\mathbf{w}_{\parallel}$. We use the following formula:

$$\mathbf{w}_{\parallel} = \text{proj}_{\mathbf{v}}(\mathbf{w}) = \left(\frac{\mathbf{w}\cdot\mathbf{v}}{\mathbf{v}\cdot\mathbf{v}}\right)\mathbf{v}.$$

Substituting the dot products from the previous step, we get:

$$\mathbf{w}_{\parallel} = \frac{9}{11}\langle 1, -1, 3\rangle = \left\langle \frac{9}{11}, -\frac{9}{11}, \frac{27}{11}\right\rangle.$$

Step 3. Identifying $\mathbf{w}_{\perp}$. The orthogonal part is the following difference:

$$\mathbf{w}_{\perp} = \mathbf{w} - \mathbf{w}_{\parallel} = \langle 4, -2, 1\rangle - \left\langle \frac{9}{11}, -\frac{9}{11}, \frac{27}{11}\right\rangle = \left\langle \frac{35}{11}, -\frac{13}{11}, -\frac{16}{11}\right\rangle$$

We obtain the following decomposition:

$$\mathbf{w} = \langle 4, -2, 1\rangle = \underbrace{\left\langle \frac{9}{11}, -\frac{9}{11}, \frac{27}{11}\right\rangle}_{\text{projection along } \mathbf{v}} + \underbrace{\left\langle \frac{35}{11}, -\frac{13}{11}, -\frac{16}{11}\right\rangle}_{\text{orthogonalto } \mathbf{v}}$$

29. Calculate the component of $\mathbf{v} = \left\langle -2, \frac{1}{2}, 3\right\rangle$ along $\mathbf{w} = \langle 1, 2, 2\rangle$.

SOLUTION We first compute the following dot products:

$$\mathbf{v}\cdot\mathbf{w} = \langle -2, \frac{1}{2}, 3\rangle \cdot \langle 1, 2, 2\rangle = 5$$
$$\mathbf{w}\cdot\mathbf{w} = \|\mathbf{w}\|^2 = 1^2 + 2^2 + 2^2 = 9$$

The component of $\mathbf{v}$ along $\mathbf{w}$ is the following number:

$$\left\|\left(\frac{\mathbf{v}\cdot\mathbf{w}}{\mathbf{w}\cdot\mathbf{w}}\right)\mathbf{w}\right\| = \frac{5}{9}\|\mathbf{w}\| = \frac{5}{9}\cdot 3 = \frac{5}{3}$$

30. Calculate the magnitude of the forces on the two ropes in Figure 2.

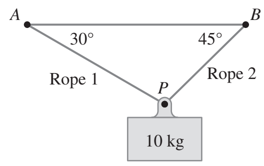


FIGURE 2

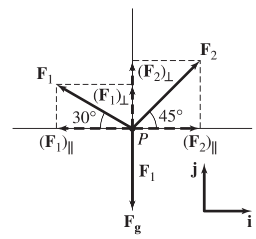
SOLUTION Gravity exerts a force $\mathbf{F}_g$ of magnitude $10g = 98$ newtons. Since the sum of $\mathbf{F}_1$ and $\mathbf{F}_2$ balance the force of gravity, we have

$$\mathbf{F}_1 + \mathbf{F}_2 + \mathbf{F}_g = 0 \tag{1}$$

We resolve $\mathbf{F}_1$, $\mathbf{F}_2$, and $\mathbf{F}_g$ into a sum of a force along the ground and a force orthogonal to the ground.



This gives

$$\begin{aligned}
(\mathbf{F}_1)_{\parallel} &= -(\|\mathbf{F}_1\|\cos 30^\circ)\mathbf{i}, & (\mathbf{F}_1)_{\perp} &= (\|\mathbf{F}_1\|\cos 60^\circ)\mathbf{j}\\
(\mathbf{F}_2)_{\parallel} &= (\|\mathbf{F}_2\|\cos 45^\circ)\mathbf{i}, & (\mathbf{F}_2)_{\perp} &= (\|\mathbf{F}_2\|\cos 45^\circ)\mathbf{j}\\
(\mathbf{F}_g)_{\parallel} &= \mathbf{0}, & (\mathbf{F}_g)_{\perp} &= -10g\mathbf{j} \approx -98\mathbf{j}
\end{aligned}$$

Substituting these forces in (1) gives

$$\left(-\frac{\|\mathbf{F}_1\|\sqrt{3}}{2}\mathbf{i} + \frac{\|\mathbf{F}_1\|}{2}\mathbf{j}\right) + \left(\frac{\|\mathbf{F}_2\|\sqrt{2}}{2}\mathbf{i} + \frac{\|\mathbf{F}_2\|\sqrt{2}}{2}\mathbf{j}\right) - 98\mathbf{j} = 0$$

$$\frac{1}{2}\left(\sqrt{2}\|\mathbf{F}_2\| - \sqrt{3}\|\mathbf{F}_1\|\right)\mathbf{i} + \frac{1}{2}\left(\|\mathbf{F}_1\| + \sqrt{2}\|\mathbf{F}_2\| - 196\right)\mathbf{j} = 0$$

We now equate each component to zero, to obtain

$$\begin{aligned}\frac{\sqrt{2}\|\mathbf{F}_2\| - \sqrt{3}\|\mathbf{F}_1\|}{2} &= 0\\ \frac{\|\mathbf{F}_1\| + \sqrt{2}\|\mathbf{F}_2\|}{2} - 98 &= 0\end{aligned} \quad \Rightarrow \quad \begin{aligned}\|\mathbf{F}_1\| &\approx 71.7\\ \|\mathbf{F}_2\| &\approx 87.8\end{aligned}$$

We conclude that

$$\mathbf{F}_1 = (-71.7\cos 30^\circ)\mathbf{i} + (71.7\cos 60^\circ)\mathbf{j} = -62.1\mathbf{i} + 35.9\mathbf{j}$$

$$\mathbf{F}_2 = (87.8\cos 45^\circ)\mathbf{i} + (87.8\cos 45^\circ)\mathbf{j} = 62.1\mathbf{i} + 62.1\mathbf{j}$$

(As in the statement of the problems, all units are in Newtons.)

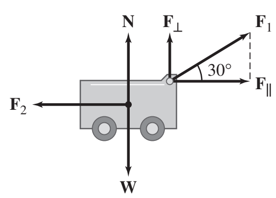
31. A 50-kg wagon is pulled to the right by a force $\mathbf{F}_1$ making an angle of 30° with the ground. At the same time the wagon is pulled to the left by a horizontal force $\mathbf{F}_2$.

(a) Find the magnitude of $\mathbf{F}_1$ in terms of the magnitude of $\mathbf{F}_2$ if the wagon does not move.

(b) What is the maximal magnitude of $\mathbf{F}_1$ that can be applied to the wagon without lifting it?

SOLUTION

(a) By Newton's Law, at equilibrium, the total force acting on the wagon is zero.



We resolve the force $\mathbf{F}_1$ into its components:

$$\mathbf{F}_1 = \mathbf{F}_{\|} + \mathbf{F}_{\perp}$$

where $\mathbf{F}_{\|}$ is the horizontal component and $\mathbf{F}_{\perp}$ is the vertical component. Since the wagon does not move, the magnitude of $\mathbf{F}_{\|}$ must be equal to the magnitude of $\mathbf{F}_2$. That is,

$$\|\mathbf{F}_{\|}\| = \|\mathbf{F}_1\|\cos 30^\circ = \|\mathbf{F}_2\|$$

The above equation gives:

$$\|\mathbf{F}_1\|\frac{\sqrt{3}}{2} = \|\mathbf{F}_2\| \quad \Rightarrow \quad \|\mathbf{F}_1\| = \frac{2\|\mathbf{F}_2\|}{\sqrt{3}}$$

(b) The maximum magnitude of force $\mathbf{F}_1$ that can be applied to the wagon without lifting the wagon is found by comparing the vertical forces:

$$\|\mathbf{F}_1\|\sin 30^\circ = 9.8 \cdot 50$$

$$\|\mathbf{F}_1\| \cdot \frac{1}{2} = 9.8 \cdot 50 \quad \Rightarrow \quad \|\mathbf{F}_1\| = 9.8 \cdot 100 = 980 \text{ N}$$

32. Let $\mathbf{v}$, $\mathbf{w}$, and $\mathbf{u}$ be the vectors in $\mathbf{R}^3$. Which of the following is a scalar?

(a) $\mathbf{v} \times (\mathbf{u} + \mathbf{w})$

(b) $(\mathbf{u} + \mathbf{w}) \cdot (\mathbf{v} \times \mathbf{w})$

(c) $(\mathbf{u} \times \mathbf{w}) + (\mathbf{w} - \mathbf{v})$

SOLUTION

(a) The cross product of the two vectors $\mathbf{v}$ and $\mathbf{u} + \mathbf{w}$ is a vector.

(b) The dot product of the two vectors $\mathbf{u} + \mathbf{w}$ and $\mathbf{v} \times \mathbf{w}$ is a scalar.

(c) The cross product $\mathbf{u} \times \mathbf{w}$ is a vector, therefore the sum of this vector and the vector $\mathbf{w} - \mathbf{v}$ is again a vector.

In Exercises 33–36, let $\mathbf{v} = \langle 1, 2, 4 \rangle$, $\mathbf{u} = \langle 6, -1, 2 \rangle$, *and* $\mathbf{w} = \langle 1, 0, -3 \rangle$. *Calculate the given quantity.*

33. $\mathbf{v} \times \mathbf{w}$

SOLUTION We use the definition of the cross product as a determinant to compute $\mathbf{v} \times \mathbf{w}$:

$$\mathbf{v} \times \mathbf{w} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 4 \\ 1 & 0 & -3 \end{vmatrix} = \begin{vmatrix} 2 & 4 \\ 0 & -3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 4 \\ 1 & -3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 2 \\ 1 & 0 \end{vmatrix} \mathbf{k}$$
$$= (-6 - 0)\mathbf{i} - (-3 - 4)\mathbf{j} + (0 - 2)\mathbf{k} = -6\mathbf{i} + 7\mathbf{j} - 2\mathbf{k} = \langle -6, 7, -2 \rangle$$

34. $\mathbf{w} \times \mathbf{u}$

SOLUTION We compute the cross product as the following determinant:

$$\mathbf{w} \times \mathbf{u} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -3 \\ 6 & -1 & 2 \end{vmatrix} = \begin{vmatrix} 0 & -3 \\ -1 & 2 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & -3 \\ 6 & 2 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 0 \\ 6 & -1 \end{vmatrix} \mathbf{k}$$
$$= (0 - 3)\mathbf{i} - (2 - (-18))\mathbf{j} + (-1 - 0)\mathbf{k} = -3\mathbf{i} - 20\mathbf{j} - \mathbf{k} = \langle -3, -20, -1 \rangle$$

35. $\det \begin{pmatrix} \mathbf{u} \\ \mathbf{v} \\ \mathbf{w} \end{pmatrix}$

SOLUTION We compute the determinant:

$$\det \begin{pmatrix} \mathbf{u} \\ \mathbf{v} \\ \mathbf{w} \end{pmatrix} = \begin{vmatrix} 6 & -1 & 2 \\ 1 & 2 & 4 \\ 1 & 0 & -3 \end{vmatrix} = 6 \cdot \begin{vmatrix} 2 & 4 \\ 0 & -3 \end{vmatrix} + 1 \cdot \begin{vmatrix} 1 & 4 \\ 1 & -3 \end{vmatrix} + 2 \begin{vmatrix} 1 & 2 \\ 1 & 0 \end{vmatrix}$$
$$= 6 \cdot (-6 - 0) + 1 \cdot (-3 - 4) + 2 \cdot (0 - 2) = -47$$

36. $\mathbf{v} \cdot (\mathbf{u} \times \mathbf{w})$

SOLUTION We use the anticommutativity of the cross product and the cross product computed in a previous exercise to write:

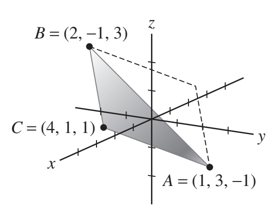
$$\mathbf{u} \times \mathbf{w} = -\mathbf{w} \times \mathbf{u} = -\langle -3, -20, -1 \rangle = \langle 3, 20, 1 \rangle$$

We now compute the dot product:

$$\mathbf{v} \cdot (\mathbf{u} \times \mathbf{w}) = \langle 1, 2, 4 \rangle \cdot \langle 3, 20, 1 \rangle = 1 \cdot 3 + 2 \cdot 20 + 4 \cdot 1 = 47$$

37. Use the cross product to find the area of the triangle whose vertices are $(1, 3, -1)$, $(2, -1, 3)$, and $(4, 1, 1)$.

SOLUTION Let $A = (1, 3, -1)$, $B = (2, -1, 3)$ and $C = (4, 1, 1)$.



The area S of the triangle ABC is half the area of the parallelogram spanned by $\overrightarrow{AB}$ and $\overrightarrow{AC}$. Using the Formula for the Area of the Parallelogram, we conclude that the area of the triangle is:

$$S = \frac{1}{2} \left\| \overrightarrow{AB} \times \overrightarrow{AC} \right\| \tag{1}$$

We first compute the vectors $\overrightarrow{AB}$ and $\overrightarrow{AC}$:

$$\overrightarrow{AB} = \langle 2 - 1, -1 - 3, 3 - (-1) \rangle = \langle 1, -4, 4 \rangle$$
$$\overrightarrow{AC} = \langle 4 - 1, 1 - 3, 1 - (-1) \rangle = \langle 3, -2, 2 \rangle$$

We compute the cross product of the two vectors:

$$\overrightarrow{AB} \times \overrightarrow{AC} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -4 & 4 \\ 3 & -2 & 2 \end{vmatrix} = \begin{vmatrix} -4 & 4 \\ -2 & 2 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 4 \\ 3 & 2 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & -4 \\ 3 & -2 \end{vmatrix} \mathbf{k}$$

$$= (-8 - (-8))\mathbf{i} - (2 - 12)\mathbf{j} + (-2 - (-12))\mathbf{k}$$

$$= 10\mathbf{j} + 10\mathbf{k} = \langle 0, 10, 10 \rangle = 10\langle 0, 1, 1 \rangle$$

The length of $\overrightarrow{AB} \times \overrightarrow{AC}$ is, thus:

$$\left\| \overrightarrow{AB} \times \overrightarrow{AC} \right\| = \| 10\langle 0, 1, 1 \rangle \| = 10 \| \langle 0, 1, 1 \rangle \| = 10\sqrt{0^2 + 1^2 + 1^2} = 10\sqrt{2}$$

Substituting in (1) gives the following area:

$$S = \frac{1}{2} \cdot 10\sqrt{2} = 5\sqrt{2}.$$

38. Calculate $\|\mathbf{v} \times \mathbf{w}\|$ if $\|\mathbf{v}\| = 2$, $\mathbf{v} \cdot \mathbf{w} = 3$, and the angle between $\mathbf{v}$ and $\mathbf{w}$ is $\frac{\pi}{6}$.

SOLUTION Using the definition of the cross product we have:

$$\|\mathbf{v} \times \mathbf{w}\| = \|\mathbf{v}\| \|\mathbf{w}\| \sin \theta.$$

We substitute the given information, obtaining:

$$\|\mathbf{v} \times \mathbf{w}\| = 2\|\mathbf{w}\| \sin \frac{\pi}{6} = 2\|\mathbf{w}\| \cdot \frac{1}{2} = \|\mathbf{w}\| \tag{1}$$

We now must find the length of $\mathbf{w}$. By the Formula for the Cosine of the Angle between Two Vectors we have:

$$\cos \theta = \frac{\mathbf{v} \cdot \mathbf{w}}{\|\mathbf{v}\| \|\mathbf{w}\|}.$$

Substituting the known values and solving for $\|\mathbf{w}\|$ gives:

$$\cos \frac{\pi}{6} = \frac{3}{2\|\mathbf{w}\|} \quad \Rightarrow \quad \|\mathbf{w}\| = \frac{3}{2 \cos \frac{\pi}{6}} = \frac{3}{2 \cdot \frac{\sqrt{3}}{2}} = \sqrt{3} \tag{2}$$

Combining (1) and (2) gives the following length:

$$\|\mathbf{v} \times \mathbf{w}\| = \|\mathbf{w}\| = \sqrt{3}.$$

39. Show that if the vectors $\mathbf{v}$, $\mathbf{w}$ are orthogonal, then $\|\mathbf{v} + \mathbf{w}\|^2 = \|\mathbf{v}\|^2 + \|\mathbf{w}\|^2$.

SOLUTION The vectors $\mathbf{v}$ and $\mathbf{w}$ are orthogonal, hence:

$$\mathbf{v} \cdot \mathbf{w} = 0 \tag{1}$$

Using the relation of the dot product with length and properties of the dot product we obtain:

$$\|\mathbf{v} + \mathbf{w}\|^2 = (\mathbf{v} + \mathbf{w}) \cdot (\mathbf{v} + \mathbf{w}) = \mathbf{v} \cdot (\mathbf{v} + \mathbf{w}) + \mathbf{w} \cdot (\mathbf{v} + \mathbf{w})$$

$$= \mathbf{v} \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{w} + \mathbf{w} \cdot \mathbf{v} + \mathbf{w} \cdot \mathbf{w} = \|\mathbf{v}\|^2 + 2\mathbf{v} \cdot \mathbf{w} + \|\mathbf{w}\|^2 \tag{2}$$

Combining (1) and (2) we get:

$$\|\mathbf{v} + \mathbf{w}\|^2 = \|\mathbf{v}\|^2 + \|\mathbf{w}\|^2.$$

40. Find the angle between $\mathbf{v}$ and $\mathbf{w}$ if $\|\mathbf{v} + \mathbf{w}\| = \|\mathbf{v}\| = \|\mathbf{w}\|$.

SOLUTION The cosine of the angle θ between $\mathbf{v}$ and $\mathbf{w}$ is given by:

$$\cos \theta = \frac{\mathbf{v} \cdot \mathbf{w}}{\|\mathbf{v}\| \|\mathbf{w}\|} \tag{1}$$

We denote by r the value $\|\mathbf{v} + \mathbf{w}\| = \|\mathbf{v}\| = \|\mathbf{w}\| = r$. To find $\mathbf{v} \cdot \mathbf{w}$ in terms of r, we evaluate $\|\mathbf{v} + \mathbf{w}\|$. Using properties of the dot product we obtain:

$$\|\mathbf{v} + \mathbf{w}\|^2 = (\mathbf{v} + \mathbf{w}) \cdot (\mathbf{v} + \mathbf{w}) = \mathbf{v} \cdot (\mathbf{v} + \mathbf{w}) + \mathbf{w} \cdot (\mathbf{v} + \mathbf{w})$$

$$= \mathbf{v} \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{w} + \mathbf{w} \cdot \mathbf{v} + \mathbf{w} \cdot \mathbf{w} = \|\mathbf{v}\|^2 + 2\mathbf{v} \cdot \mathbf{w} + \|\mathbf{w}\|^2$$

That is,

$$r^2 = r^2 + 2\mathbf{v} \cdot \mathbf{w} + r^2$$
$$-r^2 = 2\mathbf{v} \cdot \mathbf{w} \quad \Rightarrow \quad \mathbf{v} \cdot \mathbf{w} = -\frac{r^2}{2}$$

We now substitute $\|\mathbf{v}\| = \|\mathbf{w}\| = r$ and $\mathbf{v} \cdot \mathbf{w} = -\frac{r^2}{2}$ in (1) to obtain:

$$\cos\theta = \frac{-\frac{r^2}{2}}{r \cdot r} = -\frac{1}{2}$$

The solution for $0 \le \theta \le \pi$ is $\theta = \frac{2\pi}{3}$. That is, the angle between $\mathbf{v}$ and $\mathbf{w}$ is $\frac{2\pi}{3}$ rad.

41. Find $\|\mathbf{e} - 4\mathbf{f}\|$, assuming that $\mathbf{e}$ and $\mathbf{f}$ are unit vectors such that $\|\mathbf{e} + \mathbf{f}\| = \sqrt{3}$.

SOLUTION We use the relation of the dot product with length and properties of the dot product to write

$$3 = \|\mathbf{e} + \mathbf{f}\|^2 = (\mathbf{e} + \mathbf{f}) \cdot (\mathbf{e} + \mathbf{f}) = \mathbf{e} \cdot \mathbf{e} + \mathbf{e} \cdot \mathbf{f} + \mathbf{f} \cdot \mathbf{e} + \mathbf{f} \cdot \mathbf{f}$$
$$= \|\mathbf{e}\|^2 + 2\mathbf{e} \cdot \mathbf{f} + \|\mathbf{f}\|^2 = 1^2 + 2\mathbf{e} \cdot \mathbf{f} + 1^2 = 2 + 2\mathbf{e} \cdot \mathbf{f}$$

We now find $\mathbf{e} \cdot \mathbf{f}$:

$$3 = 2 + 2\mathbf{e} \cdot \mathbf{f} \quad \Rightarrow \quad \mathbf{e} \cdot \mathbf{f} = 1/2$$

Hence, using the same method as above, we have:

$$\|\mathbf{e} - 4\mathbf{f}\|^2 = (\mathbf{e} - 4\mathbf{f}) \cdot (\mathbf{e} - 4\mathbf{f})$$
$$= \|\mathbf{e}\|^2 - 2 \cdot \mathbf{e} \cdot 4\mathbf{f} + \|4\mathbf{f}\|^2 = 1^2 - 8\mathbf{e} \cdot \mathbf{f} + 4^2 = 17 - 4 = 13$$

Taking square roots, we get:

$$\|\mathbf{e} - 4\mathbf{f}\| = \sqrt{13}$$

42. Find the area of the parallelogram spanned by vectors $\mathbf{v}$ and $\mathbf{w}$ such that $\|\mathbf{v}\| = \|\mathbf{w}\| = 2$ and $\mathbf{v} \cdot \mathbf{w} = 1$.

SOLUTION The area of the parallelogram is $\|\mathbf{v} \times \mathbf{w}\|$ which equals $\|\mathbf{v}\|\|\mathbf{w}\| \sin\theta$, for θ the angle between the two vectors. Since

$$\mathbf{v} \cdot \mathbf{w} = \|\mathbf{v}\|\|\mathbf{w}\| \cos\theta = 2 \cdot 2 \cdot \cos\theta = 1,$$

then $\cos\theta = 1/4$ and so $\sin\theta = \sqrt{1 - \cos^2\theta} = \sqrt{15/16} = \sqrt{15}/4$. Thus, the area is $\|\mathbf{v}\|\|\mathbf{w}\| \sin\theta = 2 \cdot 2 \cdot \sqrt{15}/4 = \sqrt{15}$

43. Show that the equation $\langle 1, 2, 3\rangle \times \mathbf{v} = \langle -1, 2, a\rangle$ has no solution for $a \ne -1$.

SOLUTION By properties of the cross product, the vector $\langle -1, 2, a\rangle$ is orthogonal to $\langle 1, 2, 3\rangle$, hence the dot product of these vectors is zero. That is:

$$\langle -1, 2, a\rangle \cdot \langle 1, 2, 3\rangle = 0$$

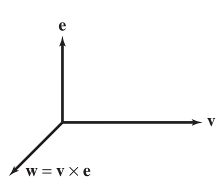
We compute the dot product and solve for a:

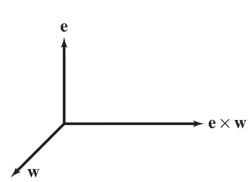
$$-1 + 4 + 3a = 0$$
$$3a = -3 \quad \Rightarrow \quad a = -1$$

We conclude that if the given equation is solvable, then $a = -1$.

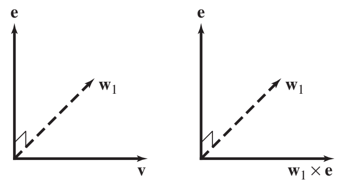
44. Prove with a diagram the following: If $\mathbf{e}$ is a unit vector orthogonal to $\mathbf{v}$, then $\mathbf{e} \times (\mathbf{v} \times \mathbf{e}) = (\mathbf{e} \times \mathbf{v}) \times \mathbf{e} = \mathbf{v}$.

SOLUTION The vectors $\mathbf{w} = \mathbf{v} \times \mathbf{e}$ and $\mathbf{e} \times \mathbf{w}$ are determined by the right-hand rule, as shown in the figure:





Similarly for the vectors $\mathbf{w_1} = \mathbf{e} \times \mathbf{v}$ and $\mathbf{w_1} \times \mathbf{e}$:



In each case, we see that the resulting vector is the vector **v**.

45. Use the identity

$$\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = (\mathbf{u} \cdot \mathbf{w})\,\mathbf{v} - (\mathbf{u} \cdot \mathbf{v})\,\mathbf{w}$$

to prove that

$$\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) + \mathbf{v} \times (\mathbf{w} \times \mathbf{u}) + \mathbf{w} \times (\mathbf{u} \times \mathbf{v}) = \mathbf{0}$$

SOLUTION The given identity implies that:

$$\begin{aligned}
\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) &= (\mathbf{u} \cdot \mathbf{w})\,\mathbf{v} - (\mathbf{u} \cdot \mathbf{v})\,\mathbf{w} \\
\mathbf{v} \times (\mathbf{w} \times \mathbf{u}) &= (\mathbf{v} \cdot \mathbf{u})\,\mathbf{w} - (\mathbf{v} \cdot \mathbf{w})\,\mathbf{u} \\
\mathbf{w} \times (\mathbf{u} \times \mathbf{v}) &= (\mathbf{w} \cdot \mathbf{v})\,\mathbf{u} - (\mathbf{w} \cdot \mathbf{u})\,\mathbf{v}
\end{aligned}$$

Adding the three equations and using the commutativity of the dot product we find that:

$$\begin{aligned}
&\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) + \mathbf{v} \times (\mathbf{w} \times \mathbf{u}) + \mathbf{w} \times (\mathbf{u} \times \mathbf{v}) \\
&\quad = (\mathbf{u} \cdot \mathbf{w} - \mathbf{w} \cdot \mathbf{u})\,\mathbf{v} + (\mathbf{v} \cdot \mathbf{u} - \mathbf{u} \cdot \mathbf{v})\,\mathbf{w} + (\mathbf{w} \cdot \mathbf{v} - \mathbf{v} \cdot \mathbf{w})\,\mathbf{u} = \mathbf{0}
\end{aligned}$$

46. Find an equation of the plane through $(1, -3, 5)$ with normal vector $\mathbf{n} = \langle 2, 1, -4\rangle$.

SOLUTION Using the scalar form of the equation of the plane we have,

$$2x + y - 4z = d = \langle 2, 1, -4\rangle \cdot \langle 1, -3, 5\rangle$$

We compute the dot product:

$$d = \langle 2, 1, -4\rangle \cdot \langle 1, -3, 5\rangle = 2 - 3 - 20 = -21$$

Therefore, the equation of the plane is,

$$2x + y - 4z = -21.$$

47. Write the equation of the plane $\mathcal{P}$ with vector equation

$$\langle 1, 4, -3\rangle \cdot \langle x, y, z\rangle = 7$$

in the form

$$a\,(x - x_0) + b\,(y - y_0) + c\,(z - z_0) = 0$$

Hint: You must find a point $P = (x_0, y_0, z_0)$ on $\mathcal{P}$.

SOLUTION We identify the vector $\mathbf{n} = \langle a, b, c\rangle = \langle 1, 4, -3\rangle$ that is normal to the plane, hence we may choose,

$$a = 1, \quad b = 4, \quad c = -3.$$

We now must find a point in the plane. The point $(x_0, y_0, z_0) = (0, 1, -1)$, for instance, satisfies the equation of the plane, therefore the equation may be written in the form:

$$1(x - 0) + 4(y - 1) - 3(z - (-1)) = 0$$

or

$$(x - 0) + 4(y - 1) - 3(z + 1) = 0$$

48. Find all the planes parallel to the plane passing through the points $(1, 2, 3)$, $(1, 2, 7)$, and $(1, 1, -3)$.

SOLUTION Since the points $A = (1, 2, 3)$, $B = (1, 2, 7)$, $C = (1, 1, -3)$ lie in the plane, the vectors $\overrightarrow{AB}$ and $\overrightarrow{AC}$ are in the plane. We find these vectors:

$$\overrightarrow{AB} = \langle 1-1, 2-2, 7-3\rangle = \langle 0, 0, 4\rangle$$
$$\overrightarrow{AC} = \langle 1-1, 1-2, -3-3\rangle = \langle 0, -1, -6\rangle$$

The cross product $\mathbf{n} = \overrightarrow{AB} \times \overrightarrow{AC}$ is normal to the plane, therefore it is also normal to all the planes that are parallel to this plane. We could compute this cross product, but let's try a slightly more clever approach. Note that the three points A, B, C all satisfy $x = 1$. Thus, the vertical plane $x = 1$ contains these three points; the planes parallel to $x = 1$ are the planes $x = d$ for $d \neq 1$.

49. Find the plane through $P = (4, -1, 9)$ containing the line $\mathbf{r}(t) = \langle 1, 4, -3\rangle + t\langle 2, 1, 1\rangle$.

SOLUTION Since the plane contains the line, the direction vector of the line, $\mathbf{v} = \langle 2, 1, 1\rangle$, is in the plane. To find another vector in the plane, we use the points $A = (1, 4, -3)$ and $B = (4, -1, 9)$ that lie in the plane, and compute the vector $\mathbf{u} = \overrightarrow{AB}$:

$$\mathbf{u} = \overrightarrow{AB} = \langle 4-1, -1-4, 9-(-3)\rangle = \langle 3, -5, 12\rangle$$

We now compute the cross product $\mathbf{n} = \mathbf{v} \times \mathbf{u}$ that is normal to the plane:

$$\mathbf{n} = \mathbf{v} \times \mathbf{u} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 1 & 1 \\ 3 & -5 & 12 \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ -5 & 12 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2 & 1 \\ 3 & 12 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2 & 1 \\ 3 & -5 \end{vmatrix}\mathbf{k}$$
$$= (12+5)\mathbf{i} - (24-3)\mathbf{j} + (-10-3)\mathbf{k} = 17\mathbf{i} - 21\mathbf{j} - 13\mathbf{k} = \langle 17, -21, -13\rangle$$

Finally, we use the vector form of the equation of the plane with $\mathbf{n} = \langle 17, -21, -13\rangle$ and $P_0 = (4, -1, 9)$ to obtain the following equation:

$$\mathbf{n} \cdot \langle x, y, z\rangle = \mathbf{n} \cdot \langle x_0, y_0, z_0\rangle$$
$$\langle 17, -21, -13\rangle \cdot \langle x, y, z\rangle = \langle 17, -21, -13\rangle \cdot \langle 4, -1, 9\rangle$$
$$17x - 21y - 13z = 17 \cdot 4 + 21 - 13 \cdot 9 = -28$$

The equation of the plane is, thus,

$$17x - 21y - 13z = -28.$$

50. Find the intersection of the line $\mathbf{r}(t) = \langle 3t+2, 1, -7t\rangle$ and the plane $2x - 3y + z = 5$.

SOLUTION The line has the parametric equations

$$x = 3t + 2, \quad y = 1, \quad z = -7t$$

We want to find the value of t for which the point (x, y, z) lies on the plane. We substitute the parametric equations in the equation of the plane and solve for t:

$$2(3t+2) - 3 \cdot 1 + (-7t) = 5$$
$$6t + 4 - 3 - 7t = 5$$
$$-t = 4 \quad \Rightarrow \quad t = -4$$

The point P of intersection of the line and the plane has the coordinates:

$$x = 3 \cdot (-4) + 2 = -10, \quad y = 1, \quad z = -7 \cdot (-4) = 28$$

and thus,

$$P = (-10, 1, 28).$$

51. Find the trace of the plane $3x - 2y + 5z = 4$ in the xy-plane.

SOLUTION The xy-plane has equation $z = 0$, therefore the intersection of the plane $3x - 2y + 5z = 4$ with the xy-plane must satisfy both $z = 0$ and the equation of the plane. Therefore the trace has the following equation:

$$3x - 2y + 5 \cdot 0 = 4 \quad \Rightarrow \quad 3x - 2y = 4$$

We conclude that the trace of the plane in the xy-plane is the line $3x - 2y = 4$ in the xy-plane.

52. Find the intersection of the planes $x + y + z = 1$ and $3x - 2y + z = 5$.

SOLUTION The line of intersection of the planes $x + y + z = 1$ and $3x - 2y + z = 5$ consists of all points that satisfy the equations of the two planes. Therefore, we must solve the following equations:

$$x + y + z = 1$$
$$3x - 2y + z = 5$$

The first equation implies $y = 1 - x - z$. Substituting in the second equation and solving for x in terms of z, gives:

$$3x - 2(1 - x - z) + z = 5$$
$$3x - 2 + 2x + 2z + z = 5$$
$$5x + 3z = 7 \quad \Rightarrow \quad x = \frac{7}{5} - \frac{3}{5}z$$

We find y in terms of z using the relation $y = 1 - x - z$:

$$y = 1 - \left(\frac{7}{5} - \frac{3}{5}z\right) - z = -\frac{2}{5} - \frac{2}{5}z$$

Therefore the solution is:

$$x = \frac{7}{5} - \frac{3}{5}z, \quad y = -\frac{2}{5} - \frac{2}{5}z, \quad z = z$$

We find the vector form of the equation of the line of intersection, using $z = t$ as the parameter. This gives:

$$\mathbf{r}(t) = \left\langle \frac{7}{5} - \frac{3}{5}t, -\frac{2}{5} - \frac{2}{5}t, t \right\rangle = \left\langle \frac{7}{5}, -\frac{2}{5}, 0 \right\rangle + t\left\langle -\frac{3}{5}, -\frac{2}{5}, 1 \right\rangle$$

In Exercises 53–58, determine the type of the quadric surface.

53. $\left(\frac{x}{3}\right)^2 + \left(\frac{y}{4}\right)^2 + 2z^2 = 1$

SOLUTION Writing the equation in the form:

$$\left(\frac{x}{3}\right)^2 + \left(\frac{y}{4}\right)^2 + \left(\frac{z}{\frac{1}{\sqrt{2}}}\right)^2 = 1$$

we identify the quadric surface as an ellipsoid.

54. $\left(\frac{x}{3}\right)^2 - \left(\frac{y}{4}\right)^2 + 2z^2 = 1$

SOLUTION Writing the equation in the form:

$$\left(\frac{x}{3}\right)^2 - \left(\frac{y}{4}\right)^2 + \left(\frac{z}{\frac{1}{\sqrt{2}}}\right)^2 = 1$$

we identify the quadric surface as an hyperboloid of one sheet.

55. $\left(\frac{x}{3}\right)^2 + \left(\frac{y}{4}\right)^2 - 2z = 0$

SOLUTION We rewrite this equation as:

$$2z = \left(\frac{x}{3}\right)^2 + \left(\frac{y}{4}\right)^2$$

or

$$z = \left(\frac{x}{3\sqrt{2}}\right)^2 + \left(\frac{y}{4\sqrt{2}}\right)^2$$

This is the equation of an elliptic paraboloid.

56. $\left(\frac{x}{3}\right)^2 - \left(\frac{y}{4}\right)^2 - 2z = 0$

SOLUTION We rewrite this equation in the form:

$$2z = \left(\frac{x}{3}\right)^2 - \left(\frac{y}{4}\right)^2$$

or

$$z = \left(\frac{x}{3\sqrt{2}}\right)^2 - \left(\frac{y}{4\sqrt{2}}\right)^2$$

This is the equation of a hyperbolic paraboloid.

57. $\left(\frac{x}{3}\right)^2 - \left(\frac{y}{4}\right)^2 - 2z^2 = 0$

SOLUTION This equation may be rewritten in the form

$$\left(\frac{x}{3}\right)^2 - \left(\frac{y}{4}\right)^2 = \left(\frac{z}{\frac{1}{\sqrt{2}}}\right)^2$$

we identify the quadric surface as an elliptic cone.

58. $\left(\frac{x}{3}\right)^2 - \left(\frac{y}{4}\right)^2 - 2z^2 = 1$

SOLUTION We rewrite the equation in the form

$$\left(\frac{x}{3}\right)^2 - \left(\frac{y}{4}\right)^2 - \left(\frac{z}{\frac{1}{\sqrt{2}}}\right)^2 = 1$$

The corresponding quadric surface is a hyperboloid of two sheets.

59. Determine the type of the quadric surface $ax^2 + by^2 - z^2 = 1$ if:

(a) $a < 0, \quad b < 0$

(b) $a > 0, \quad b > 0$

(c) $a > 0, \quad b < 0$

SOLUTION

(a) If $a < 0$, $b < 0$ then for all x, y and z we have $ax^2 + by^2 - z^2 < 0$, hence there are no points that satisfy $ax^2 + by^2 - z^2 = 1$. Therefore it is the empty set.

(b) For $a > 0$ and $b > 0$ we rewrite the equation as

$$\left(\frac{x}{\frac{1}{\sqrt{a}}}\right)^2 + \left(\frac{y}{\frac{1}{\sqrt{b}}}\right)^2 - z^2 = 1$$

which is the equation of a hyperboloid of one sheet.

(c) For $a > 0$, $b < 0$ we rewrite the equation in the form

$$\left(\frac{x}{\frac{1}{\sqrt{a}}}\right)^2 - \left(\frac{y}{\frac{1}{\sqrt{|b|}}}\right)^2 - z^2 = 1$$

which is the equation of a hyperboloid of two sheets.

60. Describe the traces of the surface

$$\left(\frac{x}{2}\right)^2 - y^2 + \left(\frac{z}{2}\right)^2 = 1$$

in the three coordinate planes.

SOLUTION The xy-trace is obtained by setting $z = 0$ in the equation $\left(\frac{x}{2}\right)^2 - y^2 + \left(\frac{z}{2}\right)^2 = 1$ of the surface. This gives

$$\left(\frac{x}{2}\right)^2 - y^2 = 1$$

Therefore, the xy-trace is a hyperbola in the xy-plane. To find the xz-trace we set $y = 0$ in the equation of the surface, obtaining

$$\left(\frac{x}{2}\right)^2 + \left(\frac{z}{2}\right)^2 = 1$$

The xz-trace is a circle in the xz-plane. The yz-trace is obtained by setting $x = 0$. This gives

$$\left(\frac{z}{2}\right)^2 - y^2 = 1$$

which is a hyperbola in the yz-plane.

61. Convert $(x, y, z) = (3, 4, -1)$ from rectangular to cylindrical and spherical coordinates.

SOLUTION In cylindrical coordinates (r, θ, z) we have

$$r = \sqrt{x^2 + y^2}, \quad \tan\theta = \frac{y}{x}$$

Therefore, $r = \sqrt{3^2 + 4^2} = 5$ and $\tan\theta = \frac{4}{3}$. The projection of the point $(3, 4, -1)$ onto the xy-plane is the point $(3, 4)$, in the first quadrant. Therefore, the corresponding value of θ is $\tan^{-1}\frac{4}{3} \approx 0.93$ rad. The cylindrical coordinates are, thus,

$$(r, \theta, z) = \left(5, \tan^{-1}\frac{4}{3}, -1\right)$$

The spherical coordinates (ρ, θ, ϕ) satisfy

$$\rho = \sqrt{x^2 + y^2 + z^2}, \quad \tan\theta = \frac{y}{x}, \quad \cos\phi = \frac{z}{\rho}$$

Therefore,

$$\rho = \sqrt{3^2 + 4^2 + (-1)^2} = \sqrt{26}$$
$$\tan\theta = \frac{4}{3}$$
$$\cos\phi = \frac{-1}{\sqrt{26}}$$

The angle θ is the same as in the cylindrical coordinates, that is, $\theta = \tan^{-1}\frac{4}{3}$. The angle ϕ is the solution of $\cos\phi = \frac{-1}{\sqrt{26}}$ that satisfies $0 \le \phi \le \pi$, that is, $\phi = \cos^1\left(\frac{-1}{\sqrt{26}}\right) \approx 1.77$ rad. The spherical coordinates are, thus,

$$(\rho, \theta, \phi) = \left(\sqrt{26}, \tan^{-1}\frac{4}{3}, \cos^{-1}\left(\frac{-1}{\sqrt{26}}\right)\right).$$

62. Convert $(r, \theta, z) = \left(3, \frac{\pi}{6}, 4\right)$ from cylindrical to spherical coordinates.

SOLUTION By the given information, $r = 3$, $\theta = \frac{\pi}{6}$ and $z = 4$. We must determine the spherical coordinates (ρ, θ, ϕ). The angle θ is the same as in cylindrical coordinates. To find ρ we use the relation $\rho = \sqrt{x^2 + y^2 + z^2} = \sqrt{r^2 + z^2}$. This gives

$$\rho = \sqrt{r^2 + z^2} = \sqrt{3^2 + 4^2} = 5$$

The angle ϕ satisfies $\cos\phi = \frac{z}{\rho} = \frac{4}{5} = 0.8$ and $0 \le \phi \le \pi$. Therefore, $\phi = \cos^{-1}0.8$. In spherical coordinates, we obtain the following description:

$$(\rho, \theta, \phi) = \left(5, \frac{\pi}{6}, \cos^{-1}0.8\right).$$

63. Convert the point $(\rho, \theta, \phi) = \left(3, \frac{\pi}{6}, \frac{\pi}{3}\right)$ from spherical to cylindrical coordinates.

SOLUTION By the given information, $\rho = 3$, $\theta = \frac{\pi}{6}$, and $\phi = \frac{\pi}{3}$. We must determine the cylindrical coordinates (r, θ, z). The angle θ is the same as in spherical coordinates. We find z using the relation $\cos\phi = \frac{z}{\rho}$, or $z = \rho\cos\phi$. We obtain

$$z = \rho\cos\phi = 3\cos\frac{\pi}{3} = 3 \cdot \frac{1}{2} = \frac{3}{2}$$

We find r using the relation $\rho^2 = x^2 + y^2 + z^2 = r^2 + z^2$, or $r = \sqrt{\rho^2 - z^2}$, we get

$$r = \sqrt{3^2 - \left(\frac{3}{2}\right)^2} = \sqrt{\frac{27}{4}} = \frac{3\sqrt{3}}{2}$$

Hence, in cylindrical coordinates we obtain the following description:

$$(r, \theta, z) = \left(\frac{3\sqrt{3}}{2}, \frac{\pi}{6}, \frac{3}{2}\right).$$

64. Describe the set of all points $P = (x, y, z)$ satisfying $x^2 + y^2 \le 4$ in both cylindrical and spherical coordinates.

SOLUTION In cylindrical coordinates we have $x^2 + y^2 = r^2$, hence the inequality $x^2 + y^2 \le 4$ becomes

$$r^2 \le 4$$

or

$$r \le 2 \quad \text{and} \quad 0 \le \theta \le 2\pi.$$

That is,

$$\{(r, \theta, z) : r \le 2,\ 0 \le \theta \le 2\pi\}$$

This is a solid cylinder of radius 2. In spherical coordinates we have $x^2 + y^2 + z^2 = \rho^2$ and $z = \rho \cos \phi$. Therefore,

$$x^2 + y^2 = \rho^2 - z^2 = \rho^2 - \rho^2 \cos^2 \phi = \rho^2 \left(1 - \cos^2 \phi\right) = \rho^2 \sin^2 \phi$$

The inequality $x^2 + y^2 \le 4$ in spherical coordinates is, thus,

$$\rho^2 \sin^2 \phi \le 4 \tag{1}$$

Notice that since $0 \le \phi \le \pi$, we have $\sin \phi \ge 0$. Also $\rho \ge 0$, therefore $\rho \sin \phi \ge 0$, hence inequality (1) is equivalent to

$$\rho \sin \phi \le 2$$

We obtain the following description in spherical coordinates:

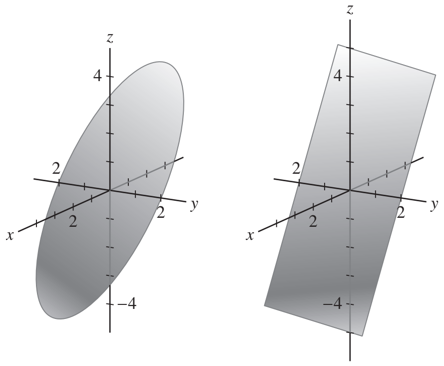
$$\{(\rho, \theta, \phi) : \rho \sin \phi \le 2,\ 0 \le \theta \le 2\pi, 0 \le \phi \le \pi\}$$

65. Sketch the graph of the cylindrical equation $z = 2r \cos \theta$ and write the equation in rectangular coordinates.

SOLUTION To obtain the equation in rectangular coordinates, we substitute $x = r \cos \theta$ in the equation $z = 2r \cos \theta$:

$$z = 2r \cos \theta = 2x \quad \Rightarrow \quad z = 2x$$

This is the equation of a plane normal to the xz-plane, whose intersection with the xz-plane is the line $z = 2x$. The graph of the plane is shown in the following figure (the same plane drawn twice, using the cylindrical coordinates' equation and using the rectangular coordinates' equation):



66. Write the surface $x^2 + y^2 - z^2 = 2(x + y)$ as an equation $r = f(\theta, z)$ in cylindrical coordinates.

SOLUTION In cylindrical coordinates, we have

$$r^2 = x^2 + y^2, \quad x = r \cos \theta, \quad y = r \sin \theta$$

Substituting in the equation of the surface $x^2 + y^2 - z^2 = 2(x + y)$ gives:

$$\begin{aligned} r^2 - z^2 &= 2(r\cos\theta + r\sin\theta) \\ r^2 &= z^2 + 2r(\cos\theta + \sin\theta) \\ r^2 - 2r(\cos\theta + \sin\theta) - z^2 &= 0 \end{aligned}$$

We solve the quadratic equation for r:

$$\begin{aligned} r &= (\cos\theta + \sin\theta) \pm \sqrt{(\cos\theta + \sin\theta)^2 + z^2} \\ &= (\cos\theta + \sin\theta) \pm \sqrt{\cos^2\theta + 2\cos\theta\sin\theta + \sin^2\theta + z^2} \end{aligned}$$

We use the identities $\cos^2\theta + \sin^2\theta = 1$ and $2\cos\theta\sin\theta = \sin 2\theta$ to obtain the following function:

$$r = \cos\theta + \sin\theta \pm \sqrt{1 + \sin 2\theta + z^2}$$

67. Show that the cylindrical equation

$$r^2(1 - 2\sin^2\theta) + z^2 = 1$$

is a hyperboloid of one sheet.

SOLUTION We rewrite the equation in the form

$$r^2 - 2(r\sin\theta)^2 + z^2 = 1$$

To write this equation in rectangular coordinates, we substitute $r^2 = x^2 + y^2$ and $r\sin\theta = y$. This gives

$$\begin{aligned} x^2 + y^2 - 2y^2 + z^2 &= 1 \\ x^2 - y^2 + z^2 &= 1 \end{aligned}$$

We now can identify the surface as a hyperboloid of one sheet.

68. Sketch the graph of the spherical equation $\rho = 2\cos\theta\sin\phi$ and write the equation in rectangular coordinates.

SOLUTION We multiply the equation by ρ and then substitute $x = \rho\cos\theta\sin\phi$. This gives

$$\rho^2 = 2\rho\cos\theta\sin\phi = 2x$$

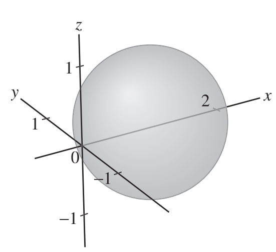
We now substitute $\rho^2 = x^2 + y^2 + z^2$ to obtain the following equation in terms of x, y, and z only:

$$x^2 + y^2 + z^2 = 2x$$

To identify the surface, we transfer sides and complete the square in x. This gives

$$\begin{aligned} x^2 - 2x + y^2 + z^2 &= 0 \\ (x-1)^2 - 1 + y^2 + z^2 &= 0 \\ (x-1)^2 + y^2 + z^2 &= 1 \end{aligned}$$

The surface is the sphere of radius 1 centered at $(1, 0, 0)$. This sphere is shown next:



$(x-1)^2 + y^2 + z^2 = 1$

69. Describe how the surface with spherical equation

$$\rho^2(1 + A\cos^2\phi) = 1$$

depends on the constant A.

SOLUTION To identify the surface we convert the equation to rectangular coordinates. We write

$$\rho^2 + A\rho^2 \cos^2\phi = 1$$

To obtain the following equation in terms of x, y, z only, we substitute $\rho^2 = x^2 + y^2 + z^2$ and $\rho\cos\phi = z$:

$$x^2 + y^2 + z^2 + Az^2 = 1$$
$$x^2 + y^2 + (1 + A)z^2 = 1 \qquad (1)$$

Case 1: $A < -1$. Then $A + 1 < 0$ and the equation can be rewritten in the form

$$x^2 + y^2 - \left(\frac{z}{|1 + A|^{-1/2}}\right)^2 = 1$$

The corresponding surface is a hyperboloid of one sheet.
Case 2: $A = -1$. Equation (1) becomes:

$$x^2 + y^2 = 1$$

In R^3, this equation describes a cylinder with the z-axis as its central axis.
Case 3: $A > -1$. Then equation (1) can be rewritten as

$$x^2 + y^2 + \left(\frac{z}{(1 + A)^{-1/2}}\right)^2 = 1$$

Then if $A = 0$ the equation $x^2 + y^2 + z^2 = 1$ describes the unit sphere in R^3. Otherwise, the surface is an ellipsoid.

70. Show that the spherical equation $\cot\phi = 2\cos\theta + \sin\theta$ defines a plane through the origin (with the origin excluded). Find a normal vector to this plane.

SOLUTION We multiply the equation by $\rho\sin\phi$, to obtain

$$\rho\sin\phi\cot\phi = 2\rho\sin\phi\cos\theta + \rho\sin\phi\sin\theta$$
$$\rho\cos\phi = 2\rho\sin\phi\cos\theta + \rho\sin\phi\sin\theta$$

We now convert to cartesian coordinates using the transition formula. We obtain

$$z = 2x + y$$
$$2x + y - z = 0$$

This is a standard representation of a plane and $n = \langle 2, 1, -1\rangle$ is orthogonal to this plane.

71. Let c be a scalar, let $\mathbf{a}$ and $\mathbf{b}$ be vectors, and let $\mathbf{X} = \langle x, y, z\rangle$. Show that the equation $(\mathbf{X} - \mathbf{a}) \cdot (\mathbf{X} - \mathbf{b}) = c^2$ defines a sphere with center $\mathbf{m} = \frac{1}{2}(\mathbf{a} + \mathbf{b})$ and radius R, where $R^2 = c^2 + \left\|\frac{1}{2}(\mathbf{a} - \mathbf{b})\right\|^2$.

SOLUTION We evaluate the following length:

$$\begin{aligned}
\|\mathbf{x} - \mathbf{m}\|^2 &= \left\|\mathbf{x} - \frac{1}{2}(\mathbf{a} + \mathbf{b})\right\|^2 = \left((\mathbf{x} - \mathbf{a}) + \frac{1}{2}(\mathbf{a} - \mathbf{b})\right) \cdot \left((\mathbf{x} - \mathbf{b}) - \frac{1}{2}(\mathbf{a} - \mathbf{b})\right) \\
&= (\mathbf{x} - \mathbf{a}) \cdot (\mathbf{x} - \mathbf{b}) - \frac{1}{2}(\mathbf{x} - \mathbf{a}) \cdot (\mathbf{a} - \mathbf{b}) + \frac{1}{2}(\mathbf{a} - \mathbf{b}) \cdot (\mathbf{x} - \mathbf{b}) - \frac{1}{4}(\mathbf{a} - \mathbf{b}) \cdot (\mathbf{a} - \mathbf{b}) \\
&= (\mathbf{x} - \mathbf{a}) \cdot (\mathbf{x} - \mathbf{b}) + \frac{1}{2}(\mathbf{a} - \mathbf{b}) \cdot (\mathbf{x} - \mathbf{b} - \mathbf{x} + \mathbf{a}) - \frac{1}{4}(\mathbf{a} - \mathbf{b}) \cdot (\mathbf{a} - \mathbf{b}) \\
&= (\mathbf{x} - \mathbf{a}) \cdot (\mathbf{x} - \mathbf{b}) + \frac{1}{2}(\mathbf{a} - \mathbf{b}) \cdot (\mathbf{a} - \mathbf{b}) - \frac{1}{4}(\mathbf{a} - \mathbf{b}) \cdot (\mathbf{a} - \mathbf{b}) \\
&= (\mathbf{x} - \mathbf{a}) \cdot (\mathbf{x} - \mathbf{b}) + \frac{1}{4}(\mathbf{a} - \mathbf{b}) \cdot (\mathbf{a} - \mathbf{b}) \\
&= (\mathbf{x} - \mathbf{a}) \cdot (\mathbf{x} - \mathbf{b}) + \left\|\frac{1}{2}(\mathbf{a} - \mathbf{b})\right\|^2
\end{aligned}$$

Since $R^2 = c^2 + \|\frac{1}{2}(\mathbf{a} - \mathbf{b})\|^2$ we get

$$\|\mathbf{x} - \mathbf{m}\|^2 = (\mathbf{x} - \mathbf{a}) \cdot (\mathbf{x} - \mathbf{b}) + R^2 - c^2$$

We conclude that if $(\mathbf{x} - \mathbf{a})(\mathbf{x} - \mathbf{b}) = c^2$ then $\|\mathbf{x} - \mathbf{m}\|^2 = R^2$. That is, the equation $(\mathbf{x} - \mathbf{a})(\mathbf{x} - \mathbf{b}) = c^2$ defines a sphere with center $\mathbf{m}$ and radius R.

13 CALCULUS OF VECTOR-VALUED FUNCTIONS

13.1 Vector-Valued Functions (LT Section 14.1)

Preliminary Questions

1. Which one of the following does *not* parametrize a line?

(a) $\mathbf{r}_1(t) = \langle 8-t, 2t, 3t \rangle$
(b) $\mathbf{r}_2(t) = t^3\mathbf{i} - 7t^3\mathbf{j} + t^3\mathbf{k}$
(c) $\mathbf{r}_3(t) = \left\langle 8-4t^3, 2+5t^2, 9t^3 \right\rangle$

SOLUTION

(a) This is a parametrization of the line passing through the point $(8, 0, 0)$ in the direction parallel to the vector $\langle -1, 2, 3 \rangle$, since:

$$\langle 8-t, 2t, 3t \rangle = \langle 8, 0, 0 \rangle + t \langle -1, 2, 3 \rangle$$

(b) Using the parameter $s = t^3$ we get:

$$\left\langle t^3, -7t^3, t^3 \right\rangle = \langle s, -7s, s \rangle = s \langle 1, -7, 1 \rangle$$

This is a parametrization of the line through the origin, with the direction vector $\mathbf{v} = \langle -1, 7, 1 \rangle$.
(c) The parametrization $\left\langle 8-4t^3, 2+5t^2, 9t^3 \right\rangle$ does not parametrize a line. In particular, the points $(8, 2, 0)$ (at $t = 0$), $(4, 7, 9)$ (at $t = 1$), and $(-24, 22, 72)$ (at $t = 2$) are not collinear.

2. What is the projection of $\mathbf{r}(t) = t\mathbf{i} + t^4\mathbf{j} + e^t\mathbf{k}$ onto the xz-plane?

SOLUTION The projection of the path onto the xz-plane is the curve traced by $t\mathbf{i} + e^t\mathbf{k} = \left\langle t, 0, e^t \right\rangle$. This is the curve $z = e^x$ in the xz-plane.

3. Which projection of $\langle \cos t, \cos 2t, \sin t \rangle$ is a circle?

SOLUTION The parametric equations are

$$x = \cos t, \quad y = \cos 2t, \quad z = \sin t$$

The projection onto the xz-plane is $\langle \cos t, 0, \sin t \rangle$. Since $x^2 + z^2 = \cos^2 t + \sin^2 t = 1$, the projection is a circle in the xz-plane. The projection onto the xy-plane is traced by the curve $\langle \cos t, \cos 2t, 0 \rangle$. Therefore, $x = \cos t$ and $y = \cos 2t$. We express y in terms of x:

$$y = \cos 2t = 2\cos^2 t - 1 = 2x^2 - 1$$

The projection onto the xy-plane is a parabola. The projection onto the yz-plane is the curve $\langle 0, \cos 2t, \sin t \rangle$. Hence $y = \cos 2t$ and $z = \sin t$. We find y as a function of z:

$$y = \cos 2t = 1 - 2\sin^2 t = 1 - 2z^2$$

The projection onto the yz-plane is again a parabola.

4. What is the center of the circle with parametrization

$$\mathbf{r}(t) = (-2 + \cos t)\mathbf{i} + 2\mathbf{j} + (3 - \sin t)\mathbf{k}?$$

SOLUTION The parametric equations are

$$x = -2 + \cos t, \quad y = 2, \quad z = 3 - \sin t$$

Therefore, the curve is contained in the plane $y = 2$, and the following holds:

$$(x+2)^2 + (z-3)^2 = \cos^2 t + \sin^2 t = 1$$

We conclude that the curve $\mathbf{r}(t)$ is the circle of radius 1 in the plane $y = 2$ centered at the point $(-2, 2, 3)$.

5. How do the paths $\mathbf{r}_1(t) = \langle \cos t, \sin t \rangle$ and $\mathbf{r}_2(t) = \langle \sin t, \cos t \rangle$ around the unit circle differ?

SOLUTION The two paths describe the unit circle. However, as t increases from 0 to 2π, the point on the path $\sin t\mathbf{i} + \cos t\mathbf{j}$ moves in a clockwise direction, whereas the point on the path $\cos t\mathbf{i} + \sin t\mathbf{j}$ moves in a counterclockwise direction.

6. Which three of the following vector-valued functions parametrize the same space curve?

(a) $(-2 + \cos t)\mathbf{i} + 9\mathbf{j} + (3 - \sin t)\mathbf{k}$

(b) $(2 + \cos t)\mathbf{i} - 9\mathbf{j} + (-3 - \sin t)\mathbf{k}$

(c) $(-2 + \cos 3t)\mathbf{i} + 9\mathbf{j} + (3 - \sin 3t)\mathbf{k}$

(d) $(-2 - \cos t)\mathbf{i} + 9\mathbf{j} + (3 + \sin t)\mathbf{k}$

(e) $(2 + \cos t)\mathbf{i} + 9\mathbf{j} + (3 + \sin t)\mathbf{k}$

SOLUTION All the curves except for (b) lie in the vertical plane $y = 9$. We identify each one of the curves (a), (c), (d) and (e).

(a) The parametric equations are:

$$x = -2 + \cos t, \quad y = 9, \quad z = 3 - \sin t$$

Hence,

$$(x+2)^2 + (z-3)^2 = (\cos t)^2 + (-\sin t)^2 = 1$$

This is the circle of radius 1 in the plane $y = 9$, centered at $(-2, 9, 3)$.

(c) The parametric equations are:

$$x = -2 + \cos 3t, \quad y = 9, \quad z = 3 - \sin 3t$$

Hence,

$$(x+2)^2 + (z-3)^2 = (\cos 3t)^2 + (-\sin 3t)^2 = 1$$

This is the circle of radius 1 in the plane $y = 9$, centered at $(-2, 9, 3)$.

(d) In this curve we have:

$$x = -2 - \cos t, \quad y = 9, \quad z = 3 + \sin t$$

Hence,

$$(x+2)^2 + (z-3)^2 = (-\cos t)^2 + (\sin t)^2 = 1$$

Again, the circle of radius 1 in the plane $y = 9$, centered at $(-2, 9, 3)$.

(e) In this parametrization we have:

$$x = 2 + \cos t, \quad y = 9, \quad z = 3 + \sin t$$

Hence,

$$(x-2)^2 + (z-3)^2 = (\cos t)^2 + (\sin t)^2 = 1$$

This is the circle of radius 1 in the plane $y = 9$, centered at $(2, 9, 3)$.

We conclude that (a), (c) and (d) parametrize the same circle whereas (b) and (e) are different curves.

Exercises

1. What is the domain of $\mathbf{r}(t) = e^t\mathbf{i} + \frac{1}{t}\mathbf{j} + (t+1)^{-3}\mathbf{k}$?

SOLUTION $\mathbf{r}(t)$ is defined for $t \neq 0$ and $t \neq -1$, hence the domain of $\mathbf{r}(t)$ is:

$$D = \{t \in \mathbf{R} : t \neq 0, t \neq -1\}$$

2. What is the domain of $\mathbf{r}(s) = e^s\mathbf{i} + \sqrt{s}\mathbf{j} + \cos s\mathbf{k}$?

SOLUTION $\mathbf{r}(s)$ is defined for $s \geq 0$, hence the domain of $\mathbf{r}(s)$ is:

$$D = \{s \in \mathbf{R} : s \geq 0\}.$$

3. Evaluate $\mathbf{r}(2)$ and $\mathbf{r}(-1)$ for $\mathbf{r}(t) = \left\langle \sin \frac{\pi}{2}t, t^2, (t^2+1)^{-1} \right\rangle$.

SOLUTION Since $\mathbf{r}(t) = \left\langle \sin \frac{\pi}{2}t, t^2, (t^2+1)^{-1} \right\rangle$, then

$$\mathbf{r}(2) = \left\langle \sin \pi, 4, 5^{-1} \right\rangle = \left\langle 0, 4, \frac{1}{5} \right\rangle$$

and

$$\mathbf{r}(-1) = \left\langle \sin \frac{-\pi}{2}, 1, 2^{-1} \right\rangle = \left\langle -1, 1, \frac{1}{2} \right\rangle$$

4. Does either of $P = (4, 11, 20)$ or $Q = (-1, 6, 16)$ lie on the path $\mathbf{r}(t) = \left\langle 1+t, 2+t^2, t^4 \right\rangle$?

SOLUTION The point $P = (4, 11, 20)$ lies on the path $\mathbf{r}(t) = \left\langle 1+t, 2+t^2, t^4 \right\rangle$ if there exists a value of t such that $\overrightarrow{OP} = \mathbf{r}(t)$. That is,

$$\left\langle 4, 11, 20 \right\rangle = \left\langle 1+t, 2+t^2, t^4 \right\rangle$$

Equating like components we get:

$$\begin{aligned} 1+t &= 4 \\ 2+t^2 &= 11 \\ t^4 &= 20 \end{aligned}$$

The first equation implies that $t = 3$, but this value does not satisfy the third equation. We conclude that P does not lie on the path. The point $Q = (-1, 6, 16)$ lies on the path if there exists a value of t such that:

$$\langle -1, 6, 16 \rangle = \left\langle 1+t, 2+t^2, t^4 \right\rangle$$

or equivalently:

$$\begin{aligned} 1+t &= -1 \\ 2+t^2 &= 6 \\ t^4 &= 16 \end{aligned}$$

These equations have the solution $t = -2$, hence $Q = (-1, 6, 16)$ lies on the path.

5. Find a vector parametrization of the line through $P = (3, -5, 7)$ in the direction $\mathbf{v} = \langle 3, 0, 1 \rangle$.

SOLUTION We use the vector parametrization of the line to obtain:

$$\mathbf{r}(t) = \overrightarrow{OP} + t\mathbf{v} = \langle 3, -5, 7 \rangle + t \langle 3, 0, 1 \rangle = \langle 3+3t, -5, 7+t \rangle$$

or in the form:

$$\mathbf{r}(t) = (3+3t)\mathbf{i} - 5\mathbf{j} + (7+t)\mathbf{k}, \quad -\infty < t < \infty$$

6. Find a direction vector for the line with parametrization $\mathbf{r}(t) = (4-t)\mathbf{i} + (2+5t)\mathbf{j} + \frac{1}{2}t\mathbf{k}$.

SOLUTION We rewrite the vector $\mathbf{r}(t)$ in the following form:

$$\mathbf{r}(t) = \left\langle 4-t, 2+5t, \frac{1}{2}t \right\rangle = \langle 4, 2, 0 \rangle + t \left\langle -1, 5, \frac{1}{2} \right\rangle$$

We identify $\mathbf{v} = \left\langle -1, 5, \frac{1}{2} \right\rangle$ as a direction vector for the line.

7. Match the space curves in Figure 8 with their projections onto the xy-plane in Figure 9.

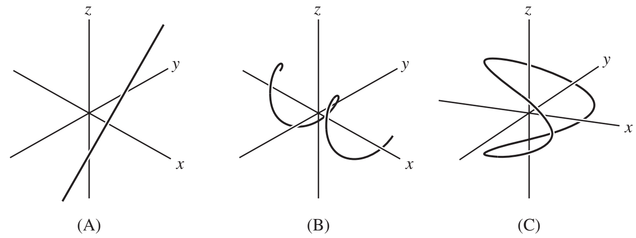


FIGURE 8

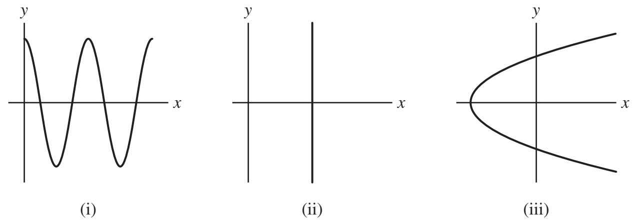

FIGURE 9

SOLUTION The projection of curve (C) onto the xy-plane is neither a segment nor a periodic wave. Hence, the correct projection is (iii), rather than the two other graphs. The projection of curve (A) onto the xy-plane is a vertical line, hence the corresponding projection is (ii). The projection of curve (B) onto the xy-plane is a periodic wave as illustrated in (i).

8. Match the space curves in Figure 8 with the following vector-valued functions:

(a) $\mathbf{r}_1(t) = \langle \cos 2t, \cos t, \sin t\rangle$

(b) $\mathbf{r}_2(t) = \langle t, \cos 2t, \sin 2t\rangle$

(c) $\mathbf{r}_3(t) = \langle 1, t, t\rangle$

SOLUTION

(a) This function traces the curve $\langle \cos 2t, \cos t\rangle$ on the xy-plane. Using the identity $\cos 2t = 2\cos^2 t - 1$, we have $x = 2y^2 - 1$. This equation corresponds to Figure 9(iii) which is the projection of curve (C), onto the xy-plane.

(b) The projection of this curve onto the xy-plane is traced by $\langle t, \cos 2t\rangle$ which is a wave moving in the x-direction as in Figure 9(i). By Exercise 7 it corresponds to curve (B).

(c) The projection of this curve onto the xy-plane is traced by $\langle 1, t\rangle$ which is a vertical line in the xy-plane, as in Figure 9(ii). By Exercise 7 it corresponds to curve (A).

9. Match the vector-valued functions (a)–(f) with the space curves (i)–(vi) in Figure 10.

(a) $\mathbf{r}(t) = \left\langle t + 15, e^{0.08t}\cos t, e^{0.08t}\sin t\right\rangle$

(b) $\mathbf{r}(t) = \left\langle \cos t, \sin t, \sin 12t\right\rangle$

(c) $\mathbf{r}(t) = \left\langle t, t, \dfrac{25t}{1+t^2}\right\rangle$

(d) $\mathbf{r}(t) = \left\langle \cos^3 t, \sin^3 t, \sin 2t\right\rangle$

(e) $\mathbf{r}(t) = \left\langle t, t^2, 2t\right\rangle$

(f) $\mathbf{r}(t) = \left\langle \cos t, \sin t, \cos t \sin 12t\right\rangle$

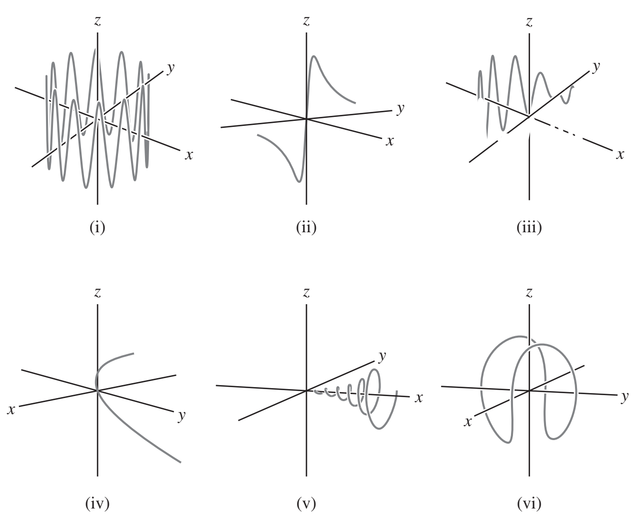

FIGURE 10

SOLUTION

(a) (v)	**(b)** (i)	**(c)** (ii)
(d) (vi)	**(e)** (iv)	**(f)** (iii)

10. Which of the following curves have the same projection onto the xy-plane?

(a) $\mathbf{r}_1(t) = \left\langle t, t^2, e^t\right\rangle$ **(b)** $\mathbf{r}_2(t) = \left\langle e^t, t^2, t\right\rangle$ **(c)** $\mathbf{r}_3(t) = \left\langle t, t^2, \cos t\right\rangle$

SOLUTION The projection onto the xy-plane is obtained by setting the z-component equal to zero. The curves $\left\langle t, t^2, e^t\right\rangle$ and $\left\langle t, t^2, \cos t\right\rangle$ have the same projection onto the xy-plane, traced by $\left\langle t, t^2, 0\right\rangle$.

11. Match the space curves (A)–(C) in Figure 11 with their projections (i)–(iii) onto the xy-plane.

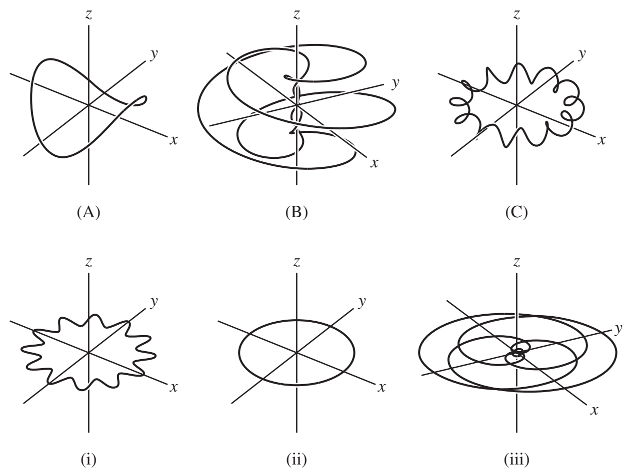

FIGURE 11

SOLUTION Observing the curves and the projections onto the xy-plane we conclude that: Projection (i) corresponds to curve (C); Projection (ii) corresponds to curve (A); Projection (iii) corresponds to curve (B).

12. Describe the projections of the circle $\mathbf{r}(t) = \langle \sin t, 0, 4 + \cos t \rangle$ onto the coordinate planes.

SOLUTION The projection onto the xy-plane is traced by $\langle \sin t, 0, 0 \rangle$, which is the segment $[-1, 1]$ on the x-axis (since $-1 \le \sin t \le 1$). The given circle is contained in the xz-plane, hence the projection on the xz-plane is the circle itself. We identify this circle. Since $x = \sin t$ and $z = 4 + \cos t$, we have:

$$x^2 + (z - 4)^2 = \sin^2 t + \cos^2 t = 1$$

This is the circle of radius 1 centered at $(0, 0, 4)$. The projection onto the yz-plane is traced by $\langle 0, 0, 4 + \cos t \rangle$, which is the segment $[3, 5]$ on the z-axis (since $3 = 4 - 1 \le 4 + \cos t \le 4 + 1 = 5$).

In Exercises 13–16, the function $\mathbf{r}(t)$ traces a circle. Determine the radius, center, and plane containing the circle.

13. $\mathbf{r}(t) = (9 \cos t)\mathbf{i} + (9 \sin t)\mathbf{j}$

SOLUTION Since $x(t) = 9 \cos t$, $y(t) = 9 \sin t$ we have:

$$x^2 + y^2 = 81 \cos^2 t + 81 \sin^2 t = 81(\cos^2 t + \sin^2 t) = 81$$

This is the equation of a circle with radius 9 centered at the origin. The circle lies in the xy-plane.

14. $\mathbf{r}(t) = 7\mathbf{i} + (12 \cos t)\mathbf{j} + (12 \sin t)\mathbf{k}$

SOLUTION We have:

$$x(t) = 7, \quad y(t) = 12 \cos t, \quad z(t) = 12 \sin t$$

Hence,

$$y(t)^2 + z(t)^2 = 144 \cos^2 t + 144 \sin^2 t = 144\left(\cos^2 t + \sin^2 t\right) = 144$$

This is the equation of a circle in the vertical plane $x = 7$. The circle is centered at the point $(7, 0, 0)$ and its radius is $\sqrt{144} = 12$.

15. $\mathbf{r}(t) = \langle \sin t, 0, 4 + \cos t \rangle$

SOLUTION $x(t) = \sin t$, $z(t) = 4 + \cos t$, hence:

$$x^2 + (z - 4)^2 = \sin^2 t + \cos^2 t = 1$$

$y = 0$ is the equation of the xz-plane. We conclude that the function traces the circle of radius 1, centered at the point $(0, 0, 4)$, and contained in the xz-plane.

16. $\mathbf{r}(t) = \langle 6 + 3\sin t, 9, 4 + 3\cos t\rangle$

SOLUTION Since $y(t) = 9$ the curve is contained in the vertical plane $y = 9$. By the given equations, $x(t) = 6 + 3\sin t$ and $z = 4 + 3\cos t$, hence:

$$\left(\frac{x-6}{3}\right)^2 + \left(\frac{z-4}{3}\right)^2 = \sin^2 t + \cos^2 t = 1$$

We conclude that the function traces a circle in the vertical plane $y = 9$, centered at the point $(6, 9, 4)$ and with radius 3.

17. Let $\mathcal{C}$ be the curve $\mathbf{r}(t) = \langle t\cos t, t\sin t, t\rangle$.

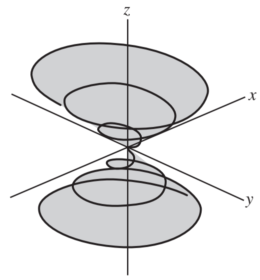
(a) Show that $\mathcal{C}$ lies on the cone $x^2 + y^2 = z^2$.

(b) Sketch the cone and make a rough sketch of $\mathcal{C}$ on the cone.

SOLUTION $x = t\cos t$, $y = t\sin t$ and $z = t$, hence:

$$x^2 + y^2 = t^2\cos^2 t + t^2\sin^2 t = t^2\left(\cos^2 t + \sin^2 t\right) = t^2 = z^2.$$

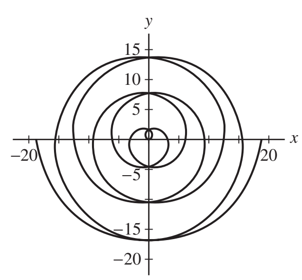
$x^2 + y^2 = z^2$ is the equation of a circular cone, hence the curve lies on a circular cone. As the height $z = t$ increases linearly with time, the x and y coordinates trace out points on the circles of increasing radius. We obtain the following curve:



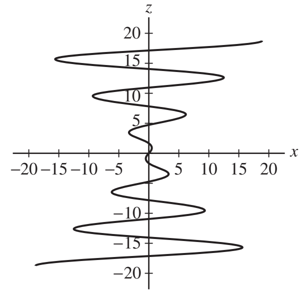
$\mathbf{r}(t) = \langle t\cos t, t\sin t, t\rangle$

18. CAS Use a computer algebra system to plot the projections onto the xy- and xz-planes of the curve $\mathbf{r}(t) = \langle t\cos t, t\sin t, t\rangle$ in Exercise 17.

SOLUTION The projection of the curve onto the xy-plane is traced by the function $\langle t\cos t, t\sin t, 0\rangle$. The curve is the following spiral:



The projection of the curve onto the xz-plane is traced by $\langle t\cos t, 0, t\rangle$, which is a wave with increasing amplitude moving in the z direction as shown in the following figure:



In Exercises 19 and 20, let

$$\mathbf{r}(t) = \langle \sin t, \cos t, \sin t \cos 2t \rangle$$

as shown in Figure 12.

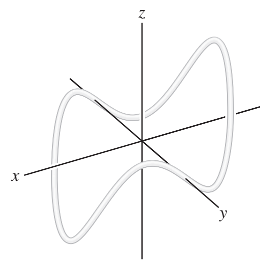


FIGURE 12

19. Find the points where $\mathbf{r}(t)$ intersects the xy-plane.

SOLUTION The curve intersects the xy-plane at the points where $z = 0$. That is, $\sin t \cos 2t = 0$ and so either $\sin t = 0$ or $\cos 2t = 0$. The solutions are, thus:

$$t = \pi k \text{ or } t = \frac{\pi}{4} + \frac{\pi k}{2}, \quad k = 0, \pm 1, \pm 2, \dots$$

The values $t = \pi k$ yield the points: $(\sin \pi k, \cos \pi k, 0) = \left(0, (-1)^k, 0\right)$. The values $t = \frac{\pi}{4} + \frac{\pi k}{2}$ yield the points:

$$k = 0 : \left(\sin \frac{\pi}{4}, \cos \frac{\pi}{4}, 0\right) = \left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 0\right)$$

$$k = 1 : \left(\sin \frac{3\pi}{4}, \cos \frac{3\pi}{4}, 0\right) = \left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, 0\right)$$

$$k = 2 : \left(\sin \frac{5\pi}{4}, \cos \frac{5\pi}{4}, 0\right) = \left(-\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, 0\right)$$

$$k = 3 : \left(\sin \frac{7\pi}{4}, \cos \frac{7\pi}{4}, 0\right) = \left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 0\right)$$

(Other values of k do not provide new points). We conclude that the curve intersects the xy-plane at the following points: $(0, 1, 0)$, $(0, -1, 0)$, $\left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 0\right)$, $\left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, 0\right)$, $\left(-\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, 0\right)$, $\left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 0\right)$

20. Show that the projection of $\mathbf{r}(t)$ onto the xz-plane is the curve

$$z = x - 2x^3 \quad \text{for} \quad -1 \le x \le 1$$

SOLUTION The xz-plane projection indicates that $y = 0$. We are given $x = \sin t$, so $-1 \le x \le 1$ and note that from trigonometry, $\cos 2t = 1 - 2\sin^2 t$. Thus

$$z = \sin t \cos 2t = \sin t(1 - 2\sin^2 t) = x(1 - 2x^2) = x - 2x^3, -1 \le x \le 1$$

21. Parametrize the intersection of the surfaces

$$y^2 - z^2 = x - 2, \qquad y^2 + z^2 = 9$$

using $t = y$ as the parameter (two vector functions are needed as in Example 3).

SOLUTION We solve for z and x in terms of y. From the equation $y^2 + z^2 = 9$ we have $z^2 = 9 - y^2$ or $z = \pm\sqrt{9 - y^2}$. From the second equation we have:

$$x = y^2 - z^2 + 2 = y^2 - \left(9 - y^2\right) + 2 = 2y^2 - 7$$

Taking $t = y$ as a parameter, we have $z = \pm\sqrt{9 - t^2}$, $x = 2t^2 - 7$, yielding the following vector parametrization:

$$\mathbf{r}(t) = \left\langle 2t^2 - 7, t, \pm\sqrt{9 - t^2} \right\rangle, \text{ for } -3 \le t \le 3.$$

22. Find a parametrization of the curve in Exercise 21 using trigonometric functions.

SOLUTION The curve in Exercise 21 is the intersection of the surfaces $y^2 - z^2 = x - 2$, $y^2 + z^2 = 9$. The circle $y^2 + z^2 = 9$ is parametrized by $y = 3\cos t$, $z = 3\sin t$. Substituting in the first equation and using the identity $\cos^2 t - \sin^2 t = \cos 2t$, gives:

$$x = 2 + y^2 - z^2 = 2 + (3\cos t)^2 - (3\sin t)^2 = 2 + 9\left(\cos^2 t - \sin^2 t\right) = 2 + 9\cos 2t$$

We obtain the following trigonometric parametrization:

$$\mathbf{r}(t) = \langle 2 + 9\cos 2t, 3\cos t, 3\sin t\rangle$$

23. Viviani's Curve $\mathcal{C}$ is the intersection of the surfaces (Figure 13)

$$x^2 + y^2 = z^2, \qquad y = z^2$$

(a) Parametrize each of the two parts of $\mathcal{C}$ corresponding to $x \geq 0$ and $x \leq 0$, taking $t = z$ as parameter.
(b) Describe the projection of $\mathcal{C}$ onto the xy-plane.
(c) Show that $\mathcal{C}$ lies on the sphere of radius 1 with center (0, 1, 0). This curve looks like a figure eight lying on a sphere [Figure 13(B)].

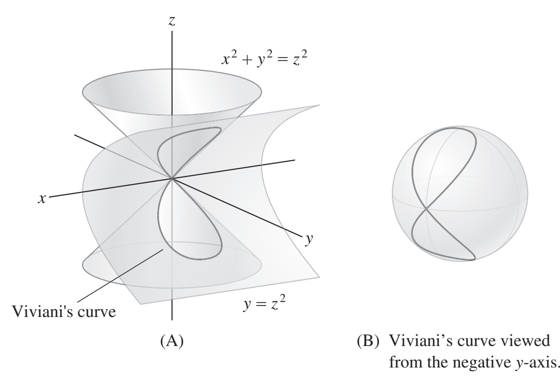

FIGURE 13 Viviani's curve is the intersection of the surfaces $x^2 + y^2 = z^2$ and $y = z^2$.

SOLUTION
(a) We must solve for y and x in terms of z (which is a parameter). We get:

$$y = z^2$$
$$x^2 = z^2 - y^2 \quad \Rightarrow \quad x = \pm\sqrt{z^2 - y^2} = \pm\sqrt{z^2 - z^4}$$

Here, the $\pm$ from $x = \pm\sqrt{z^2 - z^4}$ represents the two parts of the parametrization: $+$ for $x \geq 0$, and $-$ for $x \leq 0$. Substituting the parameter $z = t$ we get:

$$y = t^2, \quad x = \pm\sqrt{t^2 - t^4} = \pm t\sqrt{1 - t^2}.$$

We obtain the following parametrization:

$$\mathbf{r}(t) = \left\langle \pm t\sqrt{1 - t^2}, t^2, t\right\rangle \text{ for } -1 \leq t \leq 1 \tag{1}$$

(b) The projection of the curve onto the xy-plane is the curve on the xy-plane obtained by setting the z-coordinate of $\mathbf{r}(t)$ equal to zero. We obtain the following curve:

$$\left\langle \pm t\sqrt{1 - t^2}, t^2, 0\right\rangle, \quad -1 \leq t \leq 1$$

We also note that since $x = \pm t\sqrt{1 - t^2}$, then $x^2 = t^2(1 - t^2)$, but also $y = t^2$, so that gives us the equation $x^2 = y(1 - y)$ for the projection onto the xy plane. We rewrite this as follows.

$$x^2 = y(1 - y) \quad \Rightarrow \quad x^2 + y^2 - y = 0$$
$$x^2 + y^2 - y + 1/4 = 1/4$$
$$x^2 + (y - 1/2)^2 = (1/2)^2$$

We can now identify this projection as a circle in the xy plane, with radius $1/2$, centered at the xy point $(0, 1/2)$.

(c) The equation of the sphere of radius 1 with center (0, 1, 0) is:

$$x^2 + (y-1)^2 + z^2 = 1 \tag{2}$$

To show that $\mathcal{C}$ lies on this sphere, we show that the coordinates of the points on $\mathcal{C}$ (given in (1)) satisfy the equation of the sphere. Substituting the coordinates from (1) into the left side of (2) gives:

$$\begin{aligned} x^2 + (y-1)^2 + z^2 &= \left(\pm t\sqrt{1-t^2}\right)^2 + (t^2-1)^2 + t^2 = t^2(1-t^2) + (t^2-1)^2 + t^2 \\ &= (t^2-1)(t^2-1-t^2) + t^2 = 1 \end{aligned}$$

We conclude that the curve $\mathcal{C}$ lies on the sphere of radius 1 with center (0, 1, 0).

24. Show that any point on $x^2 + y^2 = z^2$ can be written in the form $(z\cos\theta, z\sin\theta, z)$ for some θ. Use this to find a parametrization of Viviani's curve (Exercise 23) with θ as parameter.

SOLUTION We first verify that $x = z\cos\theta$, $y = z\sin\theta$, and $z = z$ satisfy the equation of the surface:

$$x^2 + y^2 = z^2\cos^2\theta + z^2\sin^2\theta = z^2\left(\cos^2\theta + \sin^2\theta\right) = z^2$$

We now show that if (x, y, z) satisfies $x^2 + y^2 = z^2$, then there exists a value of θ such that $x = z\cos\theta$, $y = z\sin\theta$. Since $x^2 + y^2 = z^2$, we have $|x| \le |z|$ and $|y| \le |z|$. If $z = 0$, then also $x = y = 0$ and any value of θ is adequate. If $z \ne 0$ then $\|\frac{x}{z}\| \le 1$ and $\|\frac{y}{z}\| \le 1$, hence there exists θ_0 such that $\frac{x}{z} = \cos\theta_0$. Hence,

$$\frac{y}{z} = \pm\sqrt{\frac{z^2 - x^2}{z^2}} = \pm\sqrt{1 - \left(\frac{x}{z}\right)^2} = \pm\sqrt{1 - \cos^2\theta_0} = \pm\sin\theta_0$$

If $\frac{x}{z}$ and $\frac{y}{z}$ are both positive, we choose θ_0 such that $0 < \theta_0 < \frac{\pi}{2}$. If $\frac{x}{z} > 0$ and $\frac{y}{z} < 0$ we choose θ_0 such that $\frac{3\pi}{2} < \theta_0 < 2\pi$. If $\frac{x}{z} < 0$ and $\frac{y}{z} < 0$ we choose θ_0 such that $\pi < \theta_0 < \frac{3\pi}{2}$, and if $\frac{x}{z} < 0$ and $\frac{y}{z} > 0$ we choose θ_0 such that $\frac{\pi}{2} < \theta_0 < \pi$. In either case we can represent the points on the surface as required. Viviani's curve is the intersection of the surfaces $x^2 + y^2 = z^2$ and $x = z^2$. The points on these surfaces are of the form:

$$\begin{aligned} x^2 + y^2 = z^2: &\quad (z\cos\theta, z\sin\theta, z) \\ x = z^2: &\quad (z^2, y, z) \end{aligned} \tag{1}$$

The points (x, y, z) on the intersection curve must satisfy the following equations:

$$\begin{cases} z^2 = z\cos\theta \\ y = z\sin\theta \end{cases}$$

The first equation implies that $z = 0$ or $z = \cos\theta$. The second equation implies that $y = 0$ or $y = \cos\theta\sin\theta = \frac{1}{2}\sin 2\theta$. The x coordinate is obtained by substituting $z = \cos\theta$ in $x = z\cos\theta$ (or in $x = z^2$). That is, $x = \cos^2\theta$. We obtain the following vector parametrization of the curve:

$$\mathbf{r}(t) = \left\langle \cos^2\theta, \frac{1}{2}\sin 2\theta, \cos\theta \right\rangle$$

25. Use sine and cosine to parametrize the intersection of the cylinders $x^2 + y^2 = 1$ and $x^2 + z^2 = 1$ (use two vector-valued functions). Then describe the projections of this curve onto the three coordinate planes.

SOLUTION The circle $x^2 + z^2 = 1$ in the xz-plane is parametrized by $x = \cos t$, $z = \sin t$, and the circle $x^2 + y^2 = 1$ in the xy-plane is parametrized by $x = \cos s$, $y = \sin s$. Hence, the points on the cylinders can be written in the form:

$$\begin{aligned} x^2 + z^2 = 1: &\quad \langle \cos t, y, \sin t\rangle, \quad 0 \le t \le 2\pi \\ x^2 + y^2 = 1: &\quad \langle \cos s, \sin s, z\rangle, \quad 0 \le t \le 2\pi \end{aligned}$$

The points (x, y, z) on the intersection of the two cylinders must satisfy the following equations:

$$\cos t = \cos s$$

$$y = \sin s$$

$$z = \sin t$$

The first equation implies that $s = \pm t + 2\pi k$. Substituting in the second equation gives $y = \sin(\pm t + 2\pi k) = \sin(\pm t) = \pm\sin t$. Hence, $x = \cos t$, $y = \pm\sin t$, $z = \sin t$. We obtain the following vector parametrization of the intersection:

$$\mathbf{r}(t) = \langle \cos t, \pm\sin t, \sin t\rangle$$

The projection of the curve on the xy-plane is traced by $\langle \cos t, \pm \sin t, 0\rangle$ which is the unit circle in this plane. The projection of the curve on the xz-plane is traced by $\langle \cos t, 0, \sin t\rangle$ which is the unit circle in the xz-plane. The projection of the curve on the yz-plane is traced by $\langle 0, \pm \sin t, \sin t\rangle$ which is the two segments $z = y$ and $z = -y$ for $-1 \le y \le 1$.

26. Use hyperbolic functions to parametrize the intersection of the surfaces $x^2 - y^2 = 4$ and $z = xy$.

SOLUTION $x = 2\cosh t$ and $y = 2\sinh t$ satisfy the equation of the (hyperbolic) cylinder since:

$$x^2 - y^2 = 4\cosh^2 t - 4\sinh^2 t = 4(\cosh^2 t - \sinh^2 t) = 4 \cdot 1 = 4$$

To find a parametrization of the curve of intersection, we substitute $x = 2\cosh t$, $y = 2\sinh t$ in the equation of the surface $z = xy$ and solve for z. This gives $z = 4\cosh t \sinh t$. We obtain the following parametrization of the curve of intersection (valid for all values of t):

$$\mathbf{r}(t) = \langle 2\cosh t, 2\sinh t, 4\sinh t \cosh t\rangle .$$

27. Use sine and cosine to parametrize the intersection of the surfaces $x^2 + y^2 = 1$ and $z = 4x^2$ (Figure 14).

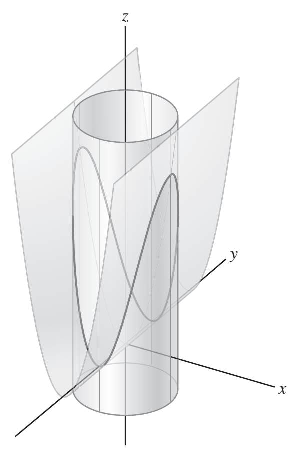

FIGURE 14 Intersection of the surfaces $x^2 + y^2 = 1$ and $z = 4x^2$.

SOLUTION The points on the cylinder $x^2 + y^2 = 1$ and on the parabolic cylinder $z = 4x^2$ can be written in the form:

$$\begin{aligned} x^2 + y^2 = 1: &\quad \langle \cos t, \sin t, z\rangle \\ z = 4x^2: &\quad \left\langle x, y, 4x^2\right\rangle \end{aligned}$$

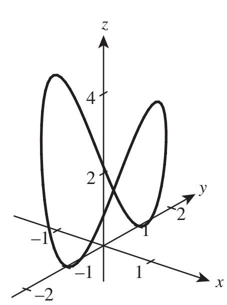
The points (x, y, z) on the intersection curve must satisfy the following equations:

$$\begin{aligned} x &= \cos t \\ y &= \sin t \\ z &= 4x^2 \end{aligned} \quad \Rightarrow \quad x = \cos t,\ y = \sin t,\ z = 4\cos^2 t$$

We obtain the vector parametrization:

$$\mathbf{r}(t) = \left\langle \cos t, \sin t, 4\cos^2 t\right\rangle, \quad 0 \le t \le 2\pi$$

Using the CAS we obtain the following curve:



$\mathbf{r}(t) = \left\langle \cos t, \sin t, 4\cos^2 t\right\rangle$

In Exercises 28–30, two paths $\mathbf{r}_1(t)$ *and* $\mathbf{r}_2(t)$ *intersect if there is a point* P *lying on both curves. We say that* $\mathbf{r}_1(t)$ *and* $\mathbf{r}_2(t)$ collide *if* $\mathbf{r}_1(t_0) = \mathbf{r}_2(t_0)$ *at some time* t_0.

28. Which of the following statements are true?

(a) If $\mathbf{r}_1$ and $\mathbf{r}_2$ intersect, then they collide.

(b) If $\mathbf{r}_1$ and $\mathbf{r}_2$ collide, then they intersect.

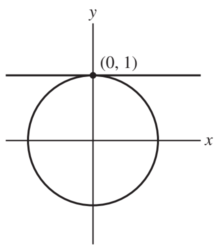
(c) Intersection depends only on the underlying curves traced by $\mathbf{r}_1$ and $\mathbf{r}_2$, but collision depends on the actual parametrizations.

SOLUTION

(a) This statement is wrong. $\mathbf{r}_1(t)$ and $\mathbf{r}_2(t)$ may intersect but the point of intersection may correspond to different values of the parameters in the two curves, as illustrated in the following example:

$$\mathbf{r}_1(t) = \langle \cos t, \sin t \rangle \text{ (the unit circle)}$$

$$\mathbf{r}_2(s) = \langle s, 1 \rangle \text{ (the horizontal line } y = 1\text{)}$$



The point of intersection (0, 1) corresponds to $t = \frac{\pi}{2}$ and $s = 0$.

(b) This statement is true. If $\mathbf{r}_1(t_0) = \mathbf{r}_2(t_0)$, then the head of the vector $\mathbf{r}_1(t_0)$ (or $\mathbf{r}_2(t_0)$) is a point of intersection of the two curves.

(c) The statement is true. Intersection is a geometric property of the curves and it is independent of the parametrization we choose for the curves. Collision depends on the actual parametrization. Notice that if we parametrize the line $y = 1$ in the example given in part (a) by $\mathbf{r}_3(s) = \left\langle s - \frac{\pi}{2}, 1 \right\rangle$, then $\mathbf{r}_1\left(\frac{\pi}{2}\right) = \mathbf{r}_3\left(\frac{\pi}{2}\right)$ hence the two paths collide.

29. Determine whether $\mathbf{r}_1$ and $\mathbf{r}_2$ collide or intersect:

$$\mathbf{r}_1(t) = \left\langle t^2 + 3, t + 1, 6t^{-1} \right\rangle$$

$$\mathbf{r}_2(t) = \left\langle 4t, 2t - 2, t^2 - 7 \right\rangle$$

SOLUTION To determine if the paths collide, we must examine whether the following equations have a solution:

$$\begin{cases} t^2 + 3 = 4t \\ t + 1 = 2t - 2 \\ \dfrac{6}{t} = t^2 - 7 \end{cases}$$

We simplify to obtain:

$$t^2 - 4t + 3 = (t - 3)(t - 1) = 0$$

$$t = 3$$

$$t^3 - 7t - 6 = 0$$

The solution of the second equation is $t = 3$. This is also a solution of the first and the third equations. It follows that $\mathbf{r}_1(3) = \mathbf{r}_2(3)$ so the curves collide. The curves also intersect at the point where they collide. We now check if there are other points of intersection by solving the following equation:

$$\mathbf{r}_1(t) = \mathbf{r}_2(s)$$

$$\left\langle t^2 + 3, t + 1, \frac{6}{t} \right\rangle = \left\langle 4s, 2s - 2, s^2 - 7 \right\rangle$$

Equating coordinates we get:

$$\begin{cases} t^2 + 3 = 4s \\ t + 1 = 2s - 2 \\ \dfrac{6}{t} = s^2 - 7 \end{cases}$$

By the second equation, $t = 2s - 3$. Substituting into the first equation yields:

$$\begin{aligned}(2s-3)^2 + 3 &= 4s\\ 4s^2 - 12s + 9 + 3 &= 4s\\ s^2 - 4s + 3 &= 0 \quad \Rightarrow \quad s_1 = 1, \quad s_2 = 3\end{aligned}$$

Substituting $s_1 = 1$ and $s_2 = 3$ into the second equation gives:

$$\begin{aligned}t_1 + 1 = 2 \cdot 1 - 2 \quad &\Rightarrow \quad t_1 = -1\\ t_2 + 1 = 2 \cdot 3 - 2 \quad &\Rightarrow \quad t_2 = 3\end{aligned}$$

The solutions of the first two equations are:

$$t_1 = -1, \quad s_1 = 1; \qquad t_2 = 3, \quad s_2 = 3$$

We check if these solutions satisfy the third equation:

$$\begin{aligned}\frac{6}{t_1} = \frac{6}{-1} = -6, \quad s_1^2 - 7 = 1^2 - 7 = -6 \quad &\Rightarrow \quad \frac{6}{t_1} = s_1^2 - 7\\ \frac{6}{t_2} = \frac{6}{3} = 2, \quad s_2^2 - 7 = 3^2 - 7 = 2 \quad &\Rightarrow \quad \frac{6}{t^2} = s_2^2 - 7\end{aligned}$$

We conclude that the paths intersect at the endpoints of the vectors $\mathbf{r}_1(-1)$ and $\mathbf{r}_1(3)$ (or equivalently $\mathbf{r}_2(1)$ and $\mathbf{r}_2(3)$). That is, at the points $(4, 0, -6)$ and $(12, 4, 2)$.

30. Determine whether $\mathbf{r}_1$ and $\mathbf{r}_2$ collide or intersect:

$$\mathbf{r}_1(t) = \left\langle t, t^2, t^3 \right\rangle, \qquad \mathbf{r}_2(t) = \left\langle 4t + 6, 4t^2, 7 - t \right\rangle$$

SOLUTION The two paths collide if there exists a value of t such that:

$$\left\langle t, t^2, t^3 \right\rangle = \left\langle 4t + 6, 4t^2, 7 - t \right\rangle$$

Equating corresponding components we obtain the following equations:

$$\begin{aligned}t &= 4t + 6\\ t^2 &= 4t^2\\ t^3 &= 7 - t\end{aligned}$$

The second equation implies that $t = 0$, but this value does not satisfy the other equations. Therefore, the equations have no solution, which means that the paths do not collide. The two paths intersect if there exist values of t and s such that:

$$\left\langle t, t^2, t^3 \right\rangle = \left\langle 4s + 6, 4s^2, 7 - s \right\rangle$$

Or equivalently:

$$\begin{aligned}t &= 4s + 6\\ t^2 &= 4s^2\\ t^3 &= 7 - s\end{aligned} \tag{1}$$

The second equation implies that $t_1 = 2s$ or $t_2 = -2s$. Substituting $t_1 = 2s$ and $t_2 = -2s$ in the first equation gives:

$$\begin{aligned}t_1 = 2s : 2s = 4s + 6 \quad &\Rightarrow \quad 2s = -6 \quad \Rightarrow \quad s_1 = -3\\ t_2 = -2s : -2s = 4s + 6 \quad &\Rightarrow \quad 6s = -6 \quad \Rightarrow \quad s_2 = -1\end{aligned}$$

The solutions of the first two equations are thus

$$(t_1, s_1) = (-6, -3); \qquad (t_2, s_2) = (2, -1)$$

(t_1, s_1) does not satisfy the third equation whereas (t_2, s_2) does. We conclude that the equations in (1) have a solution $t = 2$, $s = -1$, hence the two paths intersect.

In Exercises 31–40, find a parametrization of the curve.

31. The vertical line passing through the point $(3, 2, 0)$

SOLUTION The points of the vertical line passing through the point $(3, 2, 0)$ can be written as $(3, 2, z)$. Using $z = t$ as parameter we get the following parametrization:

$$\mathbf{r}(t) = \langle 3, 2, t \rangle, \quad -\infty < t < \infty$$

32. The line passing through $(1, 0, 4)$ and $(4, 1, 2)$

SOLUTION We use the vector parametrization of the line passing through the point $(x_0, y_0, z_0) = (1, 0, 4)$ in the direction of $\mathbf{v} = \langle 4 - 1, 1 - 0, 2 - 4 \rangle = \langle 3, 1, -2 \rangle$. We obtain:

$$\mathbf{r}(t) = \langle 1, 0, 4 \rangle + t \langle 3, 1, -2 \rangle = \langle 1 + 3t, t, 4 - 2t \rangle$$

33. The line through the origin whose projection on the xy-plane is a line of slope 3 and whose projection on the yz-plane is a line of slope 5 (i.e., $\Delta z/\Delta y = 5$)

SOLUTION We denote by (x, y, z) the points on the line. The projection of the line on the xy-plane is the line through the origin having slope 3, that is the line $y = 3x$ in the xy-plane. The projection of the line on the yz-plane is the line through the origin with slope 5, that is the line $z = 5y$. Thus, the points on the desired line satisfy the following equalities:

$$\begin{matrix} y = 3x \\ z = 5y \end{matrix} \quad \Rightarrow \quad y = 3x, \ z = 5 \cdot 3x = 15x$$

We conclude that the points on the line are all the points in the form $(x, 3x, 15x)$. Using $x = t$ as parameter we obtain the following parametrization:

$$\mathbf{r}(t) = \langle t, 3t, 15t \rangle, \quad -\infty < t < \infty.$$

34. The horizontal circle of radius 1 with center $(2, -1, 4)$

SOLUTION The projection of the circle on the xy-plane is the circle of radius 1 centered at the point $(2, -1)$. This circle has the parametrization:

$$x = 2 + \cos t, \quad y = -1 + \sin t$$

Since the circle is contained in the horizontal plane $z = 4$, the z-coordinates of the points on the circle is $z = 4$. We obtain the following parametrization:

$$\mathbf{r}(t) = \langle 2 + \cos t, -1 + \sin t, 4 \rangle, \quad 0 \le t \le 2\pi.$$

35. The circle of radius 2 with center $(1, 2, 5)$ in a plane parallel to the yz-plane

SOLUTION The circle is parallel to the yz-plane and centered at $(1, 2, 5)$, hence the x-coordinates of the points on the circle are $x = 1$. The projection of the circle on the yz-plane is a circle of radius 2 centered at $(2, 5)$. This circle is parametrized by:

$$y = 2 + 2\cos t, \quad z = 5 + 2\sin t$$

We conclude that the points on the required circle can be written as $(1, 2 + 2\cos t, 5 + 2\sin t)$. This gives the following parametrization:

$$\mathbf{r}(t) = \langle 1, 2 + 2\cos t, 5 + 2\sin t \rangle, \quad 0 \le t \le 2\pi.$$

36. The ellipse $\left(\frac{x}{2}\right)^2 + \left(\frac{y}{3}\right)^2 = 1$ in the xy-plane, translated to have center $(9, -4, 0)$

SOLUTION We first parametrize the ellipse $\left(\frac{x}{2}\right)^2 + \left(\frac{y}{3}\right)^2 = 1$ by:

$$x = 2\cos t, \quad y = 3\sin t, \quad 0 \le t \le 2\pi; \quad \text{or} \quad \mathbf{r}_1(t) = \langle 2\cos t, 3\sin t \rangle, \quad 0 \le t \le 2\pi$$

We verify that the above is a parametrization of the ellipse by showing that $x = 2\cos t$, $y = 3\sin t$ satisfy the equation of the ellipse:

$$\left(\frac{x}{2}\right)^2 + \left(\frac{y}{3}\right)^2 = \left(\frac{2\cos t}{2}\right)^2 + \left(\frac{3\sin t}{3}\right)^2 = \cos^2 t + \sin^2 t = 1$$

We now translate the ellipse so that it remains in the xy-plane, with a center at $(9, -4, 0)$. This is done by translating along the vector $\langle 9, -4, 0 \rangle$, considering the ellipse as a curve in R^3. We get:

$$\mathbf{r}(t) = \langle 2\cos t, 3\sin t, 0 \rangle + \langle 9, -4, 0 \rangle = \langle 9 + 2\cos t, -4 + 3\sin t, 0 \rangle$$

which holds for $0 \le t \le 2\pi$.

37. The intersection of the plane $y = \frac{1}{2}$ with the sphere $x^2 + y^2 + z^2 = 1$

SOLUTION Substituting $y = \frac{1}{2}$ in the equation of the sphere gives:

$$x^2 + \left(\frac{1}{2}\right)^2 + z^2 = 1 \quad \Rightarrow \quad x^2 + z^2 = \frac{3}{4}$$

This circle in the horizontal plane $y = \frac{1}{2}$ has the parametrization $x = \frac{\sqrt{3}}{2}\cos t$, $z = \frac{\sqrt{3}}{2}\sin t$. Therefore, the points on the intersection of the plane $y = \frac{1}{2}$ and the sphere $x^2 + y^2 + z^2 = 1$, can be written in the form $\left(\frac{\sqrt{3}}{2}\cos t, \frac{1}{2}, \frac{\sqrt{3}}{2}\sin t\right)$, yielding the following parametrization:

$$\mathbf{r}(t) = \left\langle \frac{\sqrt{3}}{2}\cos t, \frac{1}{2}, \frac{\sqrt{3}}{2}\sin t \right\rangle, \quad 0 \le t \le 2\pi.$$

38. The intersection of the surfaces

$$z = x^2 - y^2 \qquad \text{and} \qquad z = x^2 + xy - 1$$

SOLUTION We solve for x and z in terms of y. Equating the two equations and solving for x gives:

$$\begin{aligned} x^2 - y^2 &= x^2 + xy - 1 \\ -y^2 &= xy - 1 \\ xy &= 1 - y^2 \end{aligned}$$

Notice that on the intersection curve, $y \ne 0$ (since $y = 0$ gives $z = x^2$ and $z = x^2 - 1$, which are not equal for any z). Dividing by y we get:

$$x = \frac{1 - y^2}{y} = -y + \frac{1}{y}$$

We now substitute x in terms of y in the equation $z = x^2 - y^2$, to obtain:

$$z = \left(\frac{1 - y^2}{y}\right)^2 - y^2 = \frac{(1 - y^2)^2 - y^4}{y^2} = \frac{1 - 2y^2}{y^2} = -2 + \frac{1}{y^2}$$

Therefore the points of the intersection can be written in the form $\left(-y + \frac{1}{y}, y, -2 + \frac{1}{y^2}\right)$. Choosing $y = t$ as parameter we get the following parametrization:

$$\mathbf{r}(t) = \left\langle -t + \frac{1}{t}, t, -2 + \frac{1}{t^2} \right\rangle.$$

39. The ellipse $\left(\frac{x}{2}\right)^2 + \left(\frac{z}{3}\right)^2 = 1$ in the xz-plane, translated to have center $(3, 1, 5)$ [Figure 15(A)]

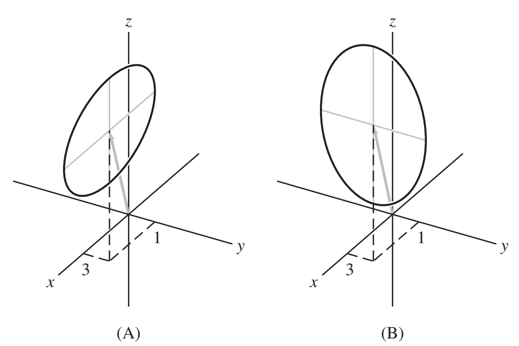


FIGURE 15 The ellipses described in Exercises 39 and 40.

SOLUTION The translated ellipse is in the vertical plane $y = 1$, hence the y-coordinate of the points on this ellipse is $y = 1$. The x and z coordinates satisfy the equation of the ellipse:

$$\left(\frac{x - 3}{2}\right)^2 + \left(\frac{z - 5}{3}\right)^2 = 1.$$

This ellipse is parametrized by the following equations:

$$x = 3 + 2\cos t, \quad z = 5 + 3\sin t.$$

Therefore, the points on the translated ellipse can be written as $(3 + 2\cos t, 1, 5 + 3\sin t)$. This gives the following parametrization:

$$\mathbf{r}(t) = \langle 3 + 2\cos t, 1, 5 + 3\sin t \rangle, \quad 0 \le t \le 2\pi.$$

40. The ellipse $\left(\frac{y}{2}\right)^2 + \left(\frac{z}{3}\right)^2 = 1$, translated to have center (3, 1, 5) [Figure 15(B)]

SOLUTION The translated ellipse is contained in the plane $x = 3$, hence the x-coordinate of the points on the ellipse is $x = 3$. The y and z coordinates satisfy the equation of the ellipse:

$$\left(\frac{y-1}{2}\right)^2 + \left(\frac{z-5}{3}\right)^2 = 1$$

This ellipse is parametrized by the equations:

$$y = 1 + 2\cos t, \quad z = 5 + 3\sin t$$

We conclude that the points on the translated ellipse can be written as $(3,\, 1 + 2\cos t,\, 5 + 3\sin t)$, which gives the following parametrization:

$$\mathbf{r}(t) = \langle 3, 1 + 2\cos t, 5 + 3\sin t\rangle, \quad 0 \le t \le 2\pi.$$

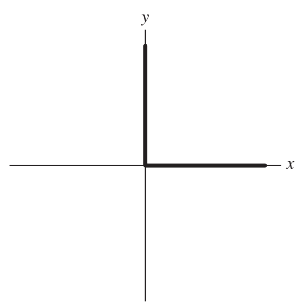
Further Insights and Challenges

41. Sketch the curve parametrized by $\mathbf{r}(t) = \langle |t| + t, |t| - t\rangle$.

SOLUTION We have:

$$|t| + t = \begin{cases} 0 & t \le 0 \\ 2t & t > 0 \end{cases}; \qquad |t| - t = \begin{cases} 2t & t \le 0 \\ 0 & t > 0 \end{cases}$$

As t increases from $-\infty$ to 0, the x-coordinate is zero and the y-coordinate is positive and decreasing to zero. As t increases from 0 to $+\infty$, the y-coordinate is zero and the x-coordinate is positive and increasing to $+\infty$. We obtain the following curve:



$\mathbf{r}(t) = \langle |t| + t, |t| - t\rangle$

42. Find the maximum height above the xy-plane of a point on $\mathbf{r}(t) = \left\langle e^t, \sin t, t(4-t)\right\rangle$.

SOLUTION The height of a point is the value of the z-coordinate of the point. Therefore we need to maximize the function $z = t\,(4 - t)$. $z(t)$ is a quadratic function having the roots $t = 0$ and $t = 4$, hence the maximum value is obtained at the midpoint of the interval $0 \le t \le 4$, that is at $t = 2$. The corresponding value of z is:

$$z_{\max} = z(2) = 2\,(4-2) = 4$$

The point of maximum height is, thus,

$$(e^2, \sin 2, 4) \approx (7.39, 0.91, 4)$$

43. Let $\mathcal{C}$ be the curve obtained by intersecting a cylinder of radius r and a plane. Insert two spheres of radius r into the cylinder above and below the plane, and let F_1 and F_2 be the points where the plane is tangent to the spheres [Figure 16(A)]. Let K be the vertical distance between the equators of the two spheres. Rediscover Archimedes's proof that $\mathcal{C}$ is an ellipse by showing that every point P on $\mathcal{C}$ satisfies

$$PF_1 + PF_2 = K \qquad \boxed{2}$$

Hint: If two lines through a point P are tangent to a sphere and intersect the sphere at Q_1 and Q_2 as in Figure 16(B), then the segments $\overline{PQ_1}$ and $\overline{PQ_2}$ have equal length. Use this to show that $PF_1 = PR_1$ and $PF_2 = PR_2$.

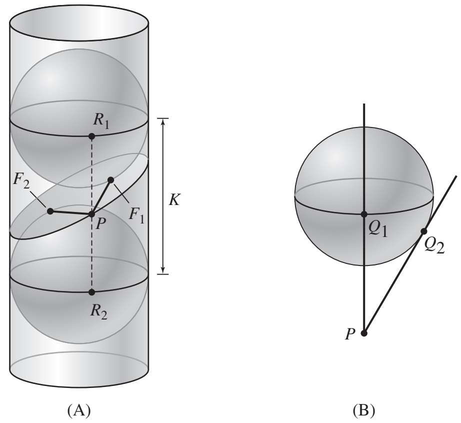


FIGURE 16

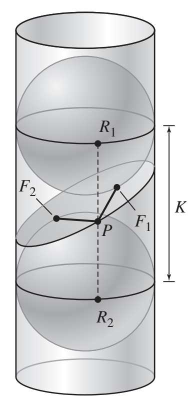
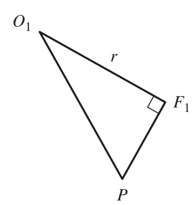
SOLUTION To show that $\mathcal{C}$ is an ellipse, we show that every point P on $\mathcal{C}$ satisfies:

$$\overline{F_1 P} + \overline{F_2 P} = K$$

We denote the points of intersection of the vertical line through P with the equators of the two spheres by R_1 and R_2 (see figure).



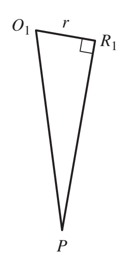
We denote by O_1 and O_2 the centers of the spheres.



Since F_1 is the tangency point, the radius $\overline{O_1 F_1}$ is perpendicular to the plane of the curve $\mathcal{C}$, and therefore it is orthogonal to the segment $\overline{PF_1}$ on this plane. Hence, $\Delta O_1 F_1 P$ is a right triangle and by Pythagoras' Theorem we have:

$$\overline{O_1 F_1}^2 + \overline{PF_1}^2 = \overline{O_1 P}^2$$

$$r^2 + \overline{PF_1}^2 = \overline{O_1 P}^2 \quad \Rightarrow \quad \overline{PF_1} = \sqrt{\overline{O_1 P}^2 - r^2} \tag{1}$$



$\Delta O_1 R_1 P$ is also a right triangle, hence by Pythagoras' Theorem we have:

$$\overline{O_1 R_1}^2 + \overline{R_1 P}^2 = \overline{O_1 P}^2$$

$$r^2 + \overline{R_1P}^2 = \overline{O_1P}^2 \quad \Rightarrow \quad \overline{PR_1} = \sqrt{\overline{O_1P}^2 - r^2} \tag{2}$$

Combining (1) and (2) we get:

$$\overline{PF_1} = \overline{PR_1} \tag{3}$$

Similarly we have:

$$\overline{PF_2} = \overline{PR_2} \tag{4}$$

We now combine (3), (4) and the equality $\overline{PR_1} + \overline{PR_2} = K$ to obtain:

$$\overline{F_1P} + \overline{F_2P} = \overline{PR_1} + \overline{PR_2} = K$$

Thus, the sum of the distances of the points P on $\mathcal{C}$ to the two fixed points F_1 and F_2 is a constant $K > 0$, hence $\mathcal{C}$ is an ellipse.

44. Assume that the cylinder in Figure 16 has equation $x^2 + y^2 = r^2$ and the plane has equation $z = ax + by$. Find a vector parametrization $\mathbf{r}(t)$ of the curve of intersection using the trigonometric functions $\cos t$ and $\sin t$.

SOLUTION Since $x^2 + y^2 = r^2$, it is convenient to make $x = r\cos t$ and $y = r\sin t$ with $0 \le t \le 2\pi$. Then the curve of intersection using these trigonometric functions will be $z = ar\cos t + br\sin t$ and one vector parameterization for this curve is

$$\mathbf{r}(t) = \langle r\cos t, r\sin t, ar\cos t + br\sin t\rangle, 0 \le t \le 2\pi.$$

45. CAS Now reprove the result of Exercise 43 using vector geometry. Assume that the cylinder has equation $x^2 + y^2 = r^2$ and the plane has equation $z = ax + by$.

(a) Show that the upper and lower spheres in Figure 16 have centers

$$C_1 = \left(0, 0, r\sqrt{a^2 + b^2 + 1}\right)$$
$$C_2 = \left(0, 0, -r\sqrt{a^2 + b^2 + 1}\right)$$

(b) Show that the points where the plane is tangent to the sphere are

$$F_1 = \frac{r}{\sqrt{a^2 + b^2 + 1}}\left(a, b, a^2 + b^2\right)$$
$$F_2 = \frac{-r}{\sqrt{a^2 + b^2 + 1}}\left(a, b, a^2 + b^2\right)$$

Hint: Show that $\overline{C_1F_1}$ and $\overline{C_2F_2}$ have length r and are orthogonal to the plane.

(c) Verify, with the aid of a computer algebra system, that Eq. (2) holds with

$$K = 2r\sqrt{a^2 + b^2 + 1}$$

To simplify the algebra, observe that since a and b are arbitrary, it suffices to verify Eq. (2) for the point $P = (r, 0, ar)$.

SOLUTION

(a) and (b) Since F_1 is the tangency point of the sphere and the plane, the radius to F_1 is orthogonal to the plane. Therefore to show that the center of the sphere is at C_1 and the tangency point is the given point we must show that:

$$\|\overrightarrow{C_1F_1}\| = r \tag{1}$$

$$\overrightarrow{C_1F_1} \text{ is orthogonal to the plane.} \tag{2}$$

We compute the vector $\overrightarrow{C_1F_1}$:

$$\overrightarrow{C_1F_1} = \left\langle \frac{ra}{\sqrt{a^2 + b^2 + 1}}, \frac{rb}{\sqrt{a^2 + b^2 + 1}}, \frac{r(a^2 + b^2)}{\sqrt{a^2 + b^2 + 1}} - r\sqrt{a^2 + b^2 + 1}\right\rangle = \frac{r}{\sqrt{a^2 + b^2 + 1}}\langle a, b, -1\rangle$$

Hence,

$$\|\overrightarrow{C_1F_1}\| = \frac{r}{\sqrt{a^2 + b^2 + 1}}\|\langle a, b, -1\rangle\| = \frac{r}{\sqrt{a^2 + b^2 + 1}}\sqrt{a^2 + b^2 + (-1)^2} = r$$

We, thus, proved that (1) is satisfied. To show (2) we must show that $\overrightarrow{C_1F_1}$ is parallel to the normal vector $\langle a, b, -1\rangle$ to the plane $z = ax + by$ (i.e., $ax + by - z = 0$). The two vectors are parallel since by (1) $\overrightarrow{C_1F_1}$ is a constant multiple of $\langle a, b, -1\rangle$. In a similar manner one can show (1) and (2) for the vector $\overrightarrow{C_2F_2}$.

(c) This is an extremely challenging problem. As suggested in the book, we use $P = (r, 0, ar)$, and we also use the expressions for F_1 and F_2 as given above. This gives us:

$$PF_1 = \sqrt{\left(1 + 2a^2 + b^2 - 2a\sqrt{1 + a^2 + b^2}\right) r^2}$$

$$PF_2 = \sqrt{\left(1 + 2a^2 + b^2 + 2a\sqrt{1 + a^2 + b^2}\right) r^2}$$

Their sum is not very inspiring:

$$PF_1 + PF_2 = \sqrt{\left(1 + 2a^2 + b^2 - 2a\sqrt{1 + a^2 + b^2}\right) r^2} + \sqrt{\left(1 + 2a^2 + b^2 + 2a\sqrt{1 + a^2 + b^2}\right) r^2}$$

Let us look, instead, at $(PF_1 + PF_2)^2$, and show that this is equal to K^2. Since everything is positive, this will imply that $PF_1 + PF_2 = K$, as desired.

$$\begin{aligned}(PF_1 + PF_2)^2 &= 2r^2 + 4a^2r^2 + 2b^2r^2 + 2\sqrt{r^4 + 2b^2r^4 + b^4r^4} \\ &= 2r^2 + 4a^2r^2 + 2b^2r^2 + 2(1 + b^2)r^2 = 4r^2(1 + a^2 + b^2) = K^2\end{aligned}$$

13.2 Calculus of Vector-Valued Functions (LT Section 14.2)

Preliminary Questions

1. State the three forms of the Product Rule for vector-valued functions.

SOLUTION The Product Rule for scalar multiple $f(t)$ of a vector-valued function $\mathbf{r}(t)$ states that:

$$\frac{d}{dt} f(t)\mathbf{r}(t) = f(t)\mathbf{r}'(t) + f'(t)\mathbf{r}(t)$$

The Product Rule for dot products states that:

$$\frac{d}{dt}\mathbf{r}_1(t) \cdot \mathbf{r}_2(t) = \mathbf{r}_1(t) \cdot \mathbf{r}_2'(t) + \mathbf{r}_1'(t) \cdot \mathbf{r}_2(t)$$

Finally, the Product Rule for cross product is

$$\frac{d}{dt}\mathbf{r}_1(t) \times \mathbf{r}_2(t) = \mathbf{r}_1(t) \times \mathbf{r}_2'(t) + \mathbf{r}_1'(t) \times \mathbf{r}_2(t).$$

In Questions 2–6, indicate whether the statement is true or false, and if it is false, provide a correct statement.

2. The derivative of a vector-valued function is defined as the limit of the difference quotient, just as in the scalar-valued case.

SOLUTION The statement is true. The derivative of a vector-valued function $\mathbf{r}(t)$ is defined a limit of the difference quotient:

$$\mathbf{r}'(t) = \lim_{t \to 0} \frac{\mathbf{r}(t + h) - \mathbf{r}(t)}{h}$$

in the same way as in the scalar-valued case.

3. There are two Chain Rules for vector-valued functions: one for the composite of two vector-valued functions and one for the composite of a vector-valued and a scalar-valued function.

SOLUTION This statement is false. A vector-valued function $\mathbf{r}(t)$ is a function whose domain is a set of real numbers and whose range consists of position vectors. Therefore, if $\mathbf{r}_1(t)$ and $\mathbf{r}_2(t)$ are vector-valued functions, the composition "$(\mathbf{r}_1 \cdot \mathbf{r}_2)(t) = \mathbf{r}_1(\mathbf{r}_2(t))$" has no meaning since $\mathbf{r}_2(t)$ is a vector and not a real number. However, for a scalar-valued function $f(t)$, the composition $\mathbf{r}(f(t))$ has a meaning, and there is a Chain Rule for differentiability of this vector-valued function.

4. The terms "velocity vector" and "tangent vector" for a path $\mathbf{r}(t)$ mean one and the same thing.

SOLUTION This statement is true.

5. The derivative of a vector-valued function is the slope of the tangent line, just as in the scalar case.

SOLUTION The statement is false. The derivative of a vector-valued function is again a vector-valued function, hence it cannot be the slope of the tangent line (which is a scalar). However, the derivative, $\mathbf{r}'(t_0)$ is the direction vector of the tangent line to the curve traced by $\mathbf{r}(t)$, at $\mathbf{r}(t_0)$.

6. The derivative of the cross product is the cross product of the derivatives.

SOLUTION The statement is false, since usually,

$$\frac{d}{dt}\mathbf{r}_1(t)\times\mathbf{r}_2(t)\neq\mathbf{r}_1'(t)\times\mathbf{r}_2'(t)$$

The correct statement is the Product Rule for Cross Products. That is,

$$\frac{d}{dt}\mathbf{r}_1(t)\times\mathbf{r}_2(t)=\mathbf{r}_1(t)\times\mathbf{r}_2'(t)+\mathbf{r}_1'(t)\times\mathbf{r}_2(t)$$

7. State whether the following derivatives of vector-valued functions $\mathbf{r}_1(t)$ and $\mathbf{r}_2(t)$ are scalars or vectors:

(a) $\frac{d}{dt}\mathbf{r}_1(t)$ **(b)** $\frac{d}{dt}\big(\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)\big)$ **(c)** $\frac{d}{dt}\big(\mathbf{r}_1(t)\times\mathbf{r}_2(t)\big)$

SOLUTION (a) vector, (b) scalar, (c) vector.

Exercises

In Exercises 1–6, evaluate the limit.

1. $\lim_{t\to 3}\left\langle t^2, 4t, \frac{1}{t}\right\rangle$

SOLUTION By the theorem on vector-valued limits we have:

$$\lim_{t\to 3}\left\langle t^2, 4t, \frac{1}{t}\right\rangle=\left\langle \lim_{t\to 3}t^2, \lim_{t\to 3}4t, \lim_{t\to 3}\frac{1}{t}\right\rangle=\left\langle 9, 12, \frac{1}{3}\right\rangle.$$

2. $\lim_{t\to\pi}\sin 2t\,\mathbf{i}+\cos t\,\mathbf{j}+\tan 4t\,\mathbf{k}$

SOLUTION We compute the limit of each component. That is:

$$\begin{aligned}\lim_{t\to\pi}(\sin 2t\,\mathbf{i}+\cos t\,\mathbf{j}+\tan 4t\,\mathbf{k})&=\left(\lim_{t\to\pi}\sin 2t\right)\mathbf{i}+\left(\lim_{t\to\pi}\cos t\right)\mathbf{j}+\left(\lim_{t\to\pi}\tan 4t\right)\mathbf{k}\\&=(\sin 2\pi)\,\mathbf{i}+(\cos\pi)\,\mathbf{j}+(\tan 4\pi)\,\mathbf{k}=-\mathbf{j}.\end{aligned}$$

3. $\lim_{t\to 0}e^{2t}\mathbf{i}+\ln(t+1)\mathbf{j}+4\mathbf{k}$

SOLUTION Computing the limit of each component, we obtain:

$$\lim_{t\to 0}\left(e^{2t}\mathbf{i}+\ln(t+1)\,\mathbf{j}+4\mathbf{k}\right)=\left(\lim_{t\to 0}e^{2t}\right)\mathbf{i}+\left(\lim_{t\to 0}\ln(t+1)\right)\mathbf{j}+\left(\lim_{t\to 0}4\right)\mathbf{k}=e^0\mathbf{i}+(\ln 1)\mathbf{j}+4\mathbf{k}=\mathbf{i}+4\mathbf{k}$$

4. $\lim_{t\to 0}\left\langle\frac{1}{t+1}, \frac{e^t-1}{t}, 4t\right\rangle$

SOLUTION We use the theorem on vector-valued limits and L'Hôpital's rule to write:

$$\lim_{t\to 0}\left\langle\frac{1}{t+1}, \frac{e^t-1}{t}, 4t\right\rangle=\left\langle\lim_{t\to 0}\frac{1}{t+1}, \lim_{t\to 0}\frac{e^t-1}{t}, \lim_{t\to 0}4t\right\rangle=\left\langle 1, \lim_{t\to 0}\frac{e^t}{1}, 0\right\rangle=\langle 1,1,0\rangle.$$

5. Evaluate $\lim_{h\to 0}\frac{\mathbf{r}(t+h)-\mathbf{r}(t)}{h}$ for $\mathbf{r}(t)=\left\langle t^{-1}, \sin t, 4\right\rangle$.

SOLUTION This limit is the derivative $\frac{d\mathbf{r}}{dt}$. Using componentwise differentiation yields:

$$\lim_{h\to 0}\frac{\mathbf{r}(t+h)-\mathbf{r}(t)}{h}=\frac{d\mathbf{r}}{dt}=\left\langle\frac{d}{dt}\left(t^{-1}\right), \frac{d}{dt}(\sin t), \frac{d}{dt}(4)\right\rangle=\left\langle-\frac{1}{t^2}, \cos t, 0\right\rangle.$$

6. Evaluate $\lim_{t\to 0} \frac{\mathbf{r}(t)}{t}$ for $\mathbf{r}(t) = \langle \sin t, 1 - \cos t, -2t \rangle$.

SOLUTION Since $\mathbf{r}(0) = \langle \sin 0, 1 - \cos 0, -2 \cdot 0 \rangle = \langle 0, 0, 0 \rangle$ we may think of the limit $\lim_{t\to 0} \frac{\mathbf{r}(t)}{t}$ as a derivative and compute it using componentwise differentiation. That is,

$$\lim_{t\to 0} \frac{\mathbf{r}(t)}{t} = \lim_{t\to 0} \frac{\mathbf{r}(t) - \mathbf{r}(0)}{t} = \lim_{h\to 0} \frac{\mathbf{r}\,(0+h) - \mathbf{r}(0)}{h} = \left.\frac{d\mathbf{r}}{dt}\right|_{t=0} = \left.\left\langle \frac{d}{dt}\,(\sin t)\,, \frac{d}{dt}\,(1 - \cos t)\,, \frac{d}{dt}\,(-2t) \right\rangle\right|_{t=0}$$

$$= \left.\langle \cos t, \sin t, -2 \rangle\right|_{t=0} = \langle \cos 0, \sin 0, -2 \rangle = \langle 1, 0, -2 \rangle$$

In Exercises 7–12, compute the derivative.

7. $\mathbf{r}(t) = \langle t, t^2, t^3 \rangle$

SOLUTION Using componentwise differentiation we get:

$$\frac{d\mathbf{r}}{dt} = \left\langle \frac{d}{dt}(t), \frac{d}{dt}(t^2), \frac{d}{dt}(t^3) \right\rangle = \left\langle 1, 2t, 3t^2 \right\rangle$$

8. $\mathbf{r}(t) = \langle 7 - t, 4\sqrt{t}, 8 \rangle$

SOLUTION Using componentwise differentiation we get:

$$\frac{d\mathbf{r}}{dt} = \left\langle \frac{d}{dt}(7 - t), \frac{d}{dt}(4\sqrt{t}), \frac{d}{dt}(8) \right\rangle = \left\langle -1, 2t^{-1/2}, 0 \right\rangle = \left\langle -1, \frac{2}{\sqrt{t}}, 0 \right\rangle$$

9. $\mathbf{r}(s) = \langle e^{3s}, e^{-s}, s^4 \rangle$

SOLUTION Using componentwise differentiation we get:

$$\frac{d\mathbf{r}}{ds} = \left\langle \frac{d}{ds}(e^{3s}), \frac{d}{ds}(e^{-s}), \frac{d}{ds}(s^4) \right\rangle = \left\langle 3e^{3s}, -e^{-s}, 4s^3 \right\rangle$$

10. $\mathbf{b}(t) = \left\langle e^{3t-4}, e^{6-t}, (t+1)^{-1} \right\rangle$

SOLUTION Using componentwise differentiation we get:

$$\frac{d\mathbf{b}}{dt} = \left\langle \frac{d}{dt}(e^{3t-4}), \frac{d}{dt}(e^{6-t}), \frac{d}{dt}((t+1)^{-1}) \right\rangle = \left\langle 3e^{3t-4}, -e^{6-t}, \frac{-1}{(t+1)^2} \right\rangle$$

11. $\mathbf{c}(t) = t^{-1}\mathbf{i} - e^{2t}\mathbf{k}$

SOLUTION Using componentwise differentiation we get:

$$\mathbf{c}'(t) = \left(t^{-1}\right)'\mathbf{i} - \left(e^{2t}\right)'\mathbf{k} = -t^{-2}\mathbf{i} - 2e^{2t}\mathbf{k}$$

12. $\mathbf{a}(\theta) = (\cos 3\theta)\mathbf{i} + (\sin^2\theta)\mathbf{j} + (\tan\theta)\mathbf{k}$

SOLUTION Using componentwise differentiation we get:

$$\mathbf{a}'(\theta) = -3\sin 3\theta\mathbf{i} + 2\sin\theta\cos\theta\mathbf{j} + \sec^2\theta\mathbf{k}$$

13. Calculate $\mathbf{r}'(t)$ and $\mathbf{r}''(t)$ for $\mathbf{r}(t) = \langle t, t^2, t^3 \rangle$.

SOLUTION We perform the differentiation componentwise to obtain:

$$\mathbf{r}'(t) = \left\langle (t)', (t^2)', (t^3)' \right\rangle = \left\langle 1, 2t, 3t^2 \right\rangle$$

We now differentiate the derivative vector to find the second derivative:

$$\mathbf{r}''(t) = \frac{d}{dt}\left\langle 1, 2t, 3t^2 \right\rangle = \langle 0, 2, 6t \rangle\,.$$

14. Sketch the curve $\mathbf{r}(t) = \langle 1 - t^2, t \rangle$ for $-1 \le t \le 1$. Compute the tangent vector at $t = 1$ and add it to the sketch.

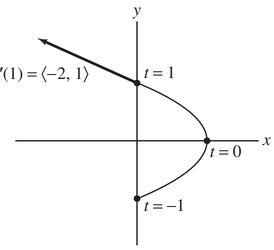
SOLUTION We find that

$$\mathbf{r}'(t) = \frac{d}{dt}\langle 1 - t^2, t \rangle = \langle -2t, 1 \rangle$$

and so at $t = 1$, we have

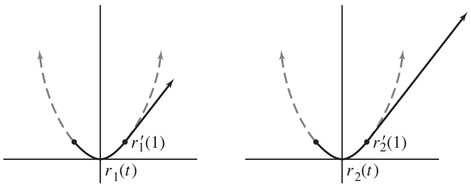
$$\mathbf{r}'(1) = \langle -2, 1 \rangle$$

To graph $\mathbf{r}(t)$, we note that it satisfies $x = 1 - y^2$. The sketch is shown here, along with the tangent vector at $t = 1$.



15. Sketch the curve $\mathbf{r}_1(t) = \langle t, t^2 \rangle$ together with its tangent vector at $t = 1$. Then do the same for $\mathbf{r}_2(t) = \langle t^3, t^6 \rangle$.

SOLUTION Note that $\mathbf{r}_1{}'(t) = \langle 1, 2t \rangle$ and so $\mathbf{r}_1{}'(1) = \langle 1, 2 \rangle$. The graph of $\mathbf{r}_1(t)$ satisfies $y = x^2$. Likewise, $\mathbf{r}_2{}'(t) = \langle 3t^2, 6t^5 \rangle$ and so $\mathbf{r}_2{}'(1) = \langle 3, 6 \rangle$. The graph of $\mathbf{r}_2(t)$ also satisfies $y = x^2$. Both graphs and tangent vectors are given here.



16. Sketch the cycloid $\mathbf{r}(t) = \langle t - \sin t, 1 - \cos t \rangle$ together with its tangent vectors at $t = \frac{\pi}{3}$ and $\frac{3\pi}{4}$.

SOLUTION The tangent vector $\mathbf{r}'(t)$ is the following vector:

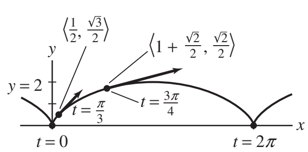
$$\mathbf{r}'(t) = \frac{d}{dt}\langle t - \sin t, 1 - \cos t \rangle = \langle 1 - \cos t, \sin t \rangle$$

Substituting the given values gives the following vectors:

$$\mathbf{r}'\left(\frac{\pi}{3}\right) = \left\langle 1 - \cos\frac{\pi}{3}, \sin\frac{\pi}{3} \right\rangle = \left\langle \frac{1}{2}, \frac{\sqrt{3}}{2} \right\rangle$$

$$\mathbf{r}'\left(\frac{3\pi}{4}\right) = \left\langle 1 - \cos\frac{3\pi}{4}, \sin\frac{3\pi}{4} \right\rangle = \left\langle 1 + \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle$$

The cycloid $\mathbf{r}(t) = \langle t - \sin t, 1 - \cos t \rangle$ and the two tangent vectors are shown in the following figure:



In Exercises 17–20, evaluate the derivative by using the appropriate Product Rule, where

$$\mathbf{r}_1(t) = \langle t^2, t^3, t \rangle, \qquad \mathbf{r}_2(t) = \langle e^{3t}, e^{2t}, e^t \rangle$$

17. $\frac{d}{dt}\big(\mathbf{r}_1(t) \cdot \mathbf{r}_2(t)\big)$

SOLUTION

$$\frac{d}{dt}(\mathbf{r}_1(t) \cdot \mathbf{r}_2(t)) = \mathbf{r}_1(t) \cdot \mathbf{r}_2'(t) + \mathbf{r}_1'(t) \cdot \mathbf{r}_2(t)$$

$$= \left\langle t^2, t^3, t\right\rangle \cdot \left\langle 3e^{3t}, 2e^{2t}, e^t\right\rangle + \left\langle 2t, 3t^2, 1\right\rangle \cdot \left\langle e^{3t}, e^{2t}, e^t\right\rangle$$
$$= 3t^2e^{3t} + 2t^3e^{2t} + te^t + 2te^{3t} + 3t^2e^{2t} + e^t$$
$$= (3t^2+2t)e^{3t} + (2t^3+3t^2)e^{2t} + (t+1)e^t$$

18. $\dfrac{d}{dt}\left(t^4\mathbf{r}_1(t)\right)$

SOLUTION

$$\begin{aligned}\frac{d}{dt}(t^4\mathbf{r}_1(t)) &= t^4\mathbf{r}_1'(t) + \frac{d}{dt}(t^4)\mathbf{r}_1(t)\\ &= t^4\left\langle 2t, 3t^2, 1\right\rangle + (4t^3)\left\langle t^2, t^3, t\right\rangle\\ &= \left\langle 2t^5, 3t^6, t^4\right\rangle + \left\langle 4t^5, 4t^6, 4t^4\right\rangle\\ &= \left\langle 6t^5, 7t^6, 5t^4\right\rangle\end{aligned}$$

19. $\dfrac{d}{dt}\left(\mathbf{r}_1(t)\times\mathbf{r}_2(t)\right)$

SOLUTION

$$\begin{aligned}\frac{d}{dt}(\mathbf{r}_1(t)\times\mathbf{r}_2(t)) &= \mathbf{r}_1(t)\times\mathbf{r}_2'(t) + \mathbf{r}_1'(t)\times\mathbf{r}_2(t)\\ &= \left\langle t^2, t^3, t\right\rangle \times \left\langle 3e^{3t}, 2e^{2t}, e^t\right\rangle + \left\langle 2t, 3t^2, 1\right\rangle \times \left\langle e^{3t}, e^{2t}, e^t\right\rangle\\ &= \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ t^2 & t^3 & t\\ 3e^{3t} & 2e^{2t} & e^t\end{vmatrix} + \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 2t & 3t^2 & 1\\ e^{3t} & e^{2t} & e^t\end{vmatrix}\\ &= (t^3e^t - 2te^{2t})\mathbf{i} + (3te^{3t} - t^2e^t)\mathbf{j} + (2t^2e^{2t} - 3t^3e^{3t})\mathbf{k}\\ &\quad + (3t^2e^t - e^{2t})\mathbf{i} + (e^{3t} - 2te^t)\mathbf{j} + (2te^{2t} - 3t^2e^{3t})\mathbf{k}\\ &= [(t^3+3t^2)e^t - (2t+1)e^{2t}]\mathbf{i} + [(3t+1)e^{3t} - (t^2+2t)e^t]\mathbf{j}\\ &\quad + [(2t^2+2t)e^{2t} - (3t^3+3t^2)e^{3t}]\mathbf{k}\end{aligned}$$

20. $\dfrac{d}{dt}\left(\mathbf{r}(t)\cdot\mathbf{r}_1(t)\right)\Big|_{t=2}$, assuming that

$$\mathbf{r}(2) = \langle 2, 1, 0\rangle, \qquad \mathbf{r}'(2) = \langle 1, 4, 3\rangle$$

SOLUTION

$$\begin{aligned}\frac{d}{dt}(\mathbf{r}(t)\cdot)\mathbf{r}_1(t))\Big|_{t=2} &= \mathbf{r}(t)\cdot\mathbf{r}_1'(t)\Big|_{t=2} + \mathbf{r}'(t)\cdot\mathbf{r}_1'(t)\Big|_{t=2}\\ &= \mathbf{r}(t)\cdot\left\langle 2t, 3t^2, 1\right\rangle\Big|_{t=2} + \mathbf{r}'(t)\cdot\left\langle t^2, t^3, t\right\rangle\Big|_{t=2}\\ &= \mathbf{r}(2)\cdot\langle 4, 12, 1\rangle + \mathbf{r}'(2)\cdot\langle 4, 8, 2\rangle\\ &= \langle 2, 1, 0\rangle\cdot\langle 4, 12, 1\rangle + \langle 1, 4, 3\rangle\cdot\langle 4, 8, 2\rangle\\ &= (8+12+0) + (4+32+6) = 62\end{aligned}$$

In Exercises 21 and 22, let

$$\mathbf{r}_1(t) = \langle t^2, 1, 2t\rangle, \qquad \mathbf{r}_2(t) = \left\langle 1, 2, e^t\right\rangle$$

21. Compute $\dfrac{d}{dt}\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)\Big|_{t=1}$ in two ways:

(a) Calculate $\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)$ and differentiate.

(b) Use the Product Rule.

SOLUTION

(a) First we will calculate $\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)$:

$$\begin{aligned}\mathbf{r}_1(t)\cdot\mathbf{r}_2(t) &= \left\langle t^2, 1, 2t\right\rangle\cdot\left\langle 1, 2, e^t\right\rangle\\ &= t^2 + 2 + 2te^t\end{aligned}$$

And then differentiating we get:

$$\frac{d}{dt}(\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)) = \frac{d}{dt}(t^2+2+2te^t) = 2t+2te^t+2e^t$$
$$\frac{d}{dt}(\mathbf{r}_1(t)\cdot\mathbf{r}_2(t))\Big|_{t=1} = 2+2e+2e = 2+4e$$

(b) First we differentiate:

$$\mathbf{r}_1(t) = \left\langle t^2, 1, 2t\right\rangle, \qquad \mathbf{r}_1'(t) = \langle 2t, 0, 2\rangle$$
$$\mathbf{r}_2(t) = \left\langle 1, 2, e^t\right\rangle, \qquad \mathbf{r}_2'(t) = \left\langle 0, 0, e^t\right\rangle$$

Using the Product Rule we see:

$$\begin{aligned}\frac{d}{dt}(\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)) &= \mathbf{r}_1(t)\cdot\mathbf{r}_2'(t)+\mathbf{r}_1'(t)\cdot\mathbf{r}_2(t)\\ &= \left\langle t^2,1,2t\right\rangle\cdot\left\langle 0,0,e^t\right\rangle + \langle 2t,0,2\rangle\cdot\left\langle 1,2,e^t\right\rangle\\ &= 2te^t+2t+2e^t\\ \frac{d}{dt}(\mathbf{r}_1(t)\cdot\mathbf{r}_2(t))\Big|_{t=1} &= 2e+2+2e = 2+4e\end{aligned}$$

22. Compute $\frac{d}{dt}\mathbf{r}_1(t)\times\mathbf{r}_2(t)\Big|_{t=1}$ in two ways:
(a) Calculate $\mathbf{r}_1(t)\times\mathbf{r}_2(t)$ and differentiate.
(b) Use the Product Rule.

SOLUTION
(a) First we will calculate $\mathbf{r}_1(t)\times\mathbf{r}_2(t)$:

$$\mathbf{r}_1(t)\times\mathbf{r}_2(t) = \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ t^2 & 1 & 2t\\ 1 & 2 & e^t\end{vmatrix} = (e^t-4t)\mathbf{i}+(2t-t^2e^t)\mathbf{j}+(2t^2-1)\mathbf{k}$$

And then differentiating we get:

$$\begin{aligned}\frac{d}{dt}(\mathbf{r}_1(t)\times\mathbf{r}_2(t))\Big|_{t=1} &= \frac{d}{dt}((e^t-4t)\mathbf{i}+(2t-t^2e^t)\mathbf{j}+(2t^2-1)\mathbf{k})\Big|_{t=1}\\ &= (e^t-4)\mathbf{i}+(2-t^2e^t-2te^t)\mathbf{j}+(4t)\mathbf{k}\Big|_{t=1}\\ &= (e-4)\mathbf{i}+(2-3e)\mathbf{j}+4\mathbf{k}\end{aligned}$$

(b) First we differentiate:

$$\mathbf{r}_1(t) = \left\langle t^2, 1, 2t\right\rangle \quad\Rightarrow\quad \mathbf{r}_1(1) = \langle 1,1,2\rangle$$
$$\mathbf{r}_1'(1) = \langle 2t, 0, 2\rangle\Big|_{t=1} = \langle 2,0,2\rangle$$
$$\mathbf{r}_2(t) = \left\langle 1,2,e^t\right\rangle \quad\Rightarrow\quad \mathbf{r}_2(1) = \langle 1,2,e\rangle$$
$$\mathbf{r}_2' = \left\langle 0,0,e^t\right\rangle\Big|_{t=1} = \langle 0,0,e\rangle$$

Using the Product Rule we see:

$$\begin{aligned}\frac{d}{dt}(\mathbf{r}_1(1)\times\mathbf{r}_2(1)) &= \mathbf{r}_1(1)\times\mathbf{r}_2'(1)+\mathbf{r}_1'(1)\times\mathbf{r}_2(1)\\ &= \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 1 & 1 & 2\\ 0 & 0 & e\end{vmatrix} + \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 2 & 0 & 2\\ 1 & 2 & e\end{vmatrix}\\ &= [e\mathbf{i}-e\mathbf{j}+0\mathbf{k}]+[-4\mathbf{i}+(2-2e)\mathbf{j}+4\mathbf{k}]\\ &= (e-4)\mathbf{i}+(2-e-2e)\mathbf{j}+4\mathbf{k} = (e-4)\mathbf{i}+(2-3e)\mathbf{j}+4\mathbf{k}\end{aligned}$$

In Exercises 23–26, evaluate $\frac{d}{dt}\mathbf{r}(g(t))$ *using the Chain Rule.*

23. $\mathbf{r}(t) = \langle t^2, 1-t \rangle, \quad g(t) = e^t$

SOLUTION We first differentiate the two functions:

$$\mathbf{r}'(t) = \frac{d}{dt}\left\langle t^2, 1-t \right\rangle = \langle 2t, -1 \rangle$$

$$g'(t) = \frac{d}{dt}(e^t) = e^t$$

Using the Chain Rule we get:

$$\frac{d}{dt}\mathbf{r}(g(t)) = g'(t)\mathbf{r}'(g(t)) = e^t \left\langle 2e^t, -1 \right\rangle = \left\langle 2e^{2t}, -e^t \right\rangle$$

24. $\mathbf{r}(t) = \langle t^2, t^3 \rangle, \quad g(t) = \sin t$

SOLUTION We first differentiate the two functions:

$$\mathbf{r}'(t) = \frac{d}{dt}\left\langle t^2, t^3 \right\rangle = \left\langle 2t, 3t^2 \right\rangle$$

$$g'(t) = \cos t$$

Using the Chain Rule we get:

$$\frac{d}{dt}\mathbf{r}(g(t)) = g'(t)\mathbf{r}'(g(t)) = \cos t \left\langle 2\sin t, 3\sin^2 t \right\rangle = \left\langle 2\sin t\cos t, 3\sin^2 t\cos t \right\rangle$$

25. $\mathbf{r}(t) = \langle e^t, e^{2t}, 4 \rangle, \quad g(t) = 4t+9$

SOLUTION We first differentiate the two functions:

$$\mathbf{r}'(t) = \frac{d}{dt}\langle e^t, e^{2t}, 4 \rangle = \langle e^t, 2e^{2t}, 0 \rangle$$

$$g'(t) = \frac{d}{dt}(4t+9) = 4$$

Using the Chain Rule we get:

$$\frac{d}{dt}\mathbf{r}\,(g(t)) = g'(t)\mathbf{r}'(g(t)) = 4\langle e^{4t+9}, 2e^{2(4t+9)}, 0 \rangle = \langle 4e^{4t+9}, 8e^{8t+18}, 0 \rangle$$

26. $\mathbf{r}(t) = \langle 4\sin 2t, 6\cos 2t \rangle, \quad g(t) = t^2$

SOLUTION We differentiate the two functions:

$$\mathbf{r}'(t) = \frac{d}{dt}\langle 4\sin 2t, 6\cos 2t \rangle = \langle 8\cos 2t, -12\sin 2t \rangle$$

$$g'(t) = 2t$$

Using the Chain Rule we obtain:

$$\frac{d}{dt}\mathbf{r}(g(t)) = g'(t)\mathbf{r}'(g(t)) = 2t\langle 8\cos 2t^2, -12\sin 2t^2 \rangle = 8t\langle 2\cos 2t^2, -3\sin 2t^2 \rangle$$

27. Let $\mathbf{r}(t) = \langle t^2, 1-t, 4t \rangle$. Calculate the derivative of $\mathbf{r}(t)\cdot\mathbf{a}(t)$ at $t=2$, assuming that $\mathbf{a}(2) = \langle 1, 3, 3 \rangle$ and $\mathbf{a}'(2) = \langle -1, 4, 1 \rangle$.

SOLUTION By the Product Rule for dot products we have

$$\frac{d}{dt}\mathbf{r}(t)\cdot\mathbf{a}(t) = \mathbf{r}(t)\cdot\mathbf{a}'(t) + \mathbf{r}'(t)\cdot\mathbf{a}(t)$$

At $t=2$ we have

$$\left.\frac{d}{dt}\mathbf{r}(t)\cdot\mathbf{a}(t)\right|_{t=2} = \mathbf{r}(2)\cdot\mathbf{a}'(2) + \mathbf{r}'(2)\cdot\mathbf{a}(2) \tag{1}$$

We compute the derivative $\mathbf{r}'(2)$:

$$\mathbf{r}'(t) = \frac{d}{dt}\left\langle t^2, 1-t, 4t\right\rangle = \langle 2t, -1, 4\rangle \quad \Rightarrow \quad \mathbf{r}'(2) = \langle 4, -1, 4\rangle \tag{2}$$

Also, $\mathbf{r}(2) = \left\langle 2^2, 1-2, 4\cdot 2\right\rangle = \langle 4, -1, 8\rangle$. Substituting the vectors in the equation above, we obtain:

$$\frac{d}{dt}\mathbf{r}(t)\cdot\mathbf{a}(t)\bigg|_{t=2} = \langle 4, -1, 8\rangle\cdot\langle -1, 4, 1\rangle + \langle 4, -1, 4\rangle\cdot\langle 1, 3, 3\rangle = (-4-4+8)+(4-3+12) = 13$$

The derivative of $\mathbf{r}(t)\cdot\mathbf{a}(t)$ at $t=2$ is 13.

28. Let $\mathbf{v}(s) = s^2\mathbf{i} + 2s\mathbf{j} + 9s^{-2}\mathbf{k}$. Evaluate $\frac{d}{ds}\mathbf{v}(g(s))$ at $s=4$, assuming that $g(4)=3$ and $g'(4)=-9$.

SOLUTION Applying the Chain Rule we have

$$\frac{d}{ds}\mathbf{v}\left(g(s)\right) = g'(s)\mathbf{v}'\left(g(s)\right)$$

The derivative at $s=4$ is, thus,

$$\frac{d}{ds}\mathbf{v}\left(g(s)\right)\bigg|_{s=4} = g'(4)\mathbf{v}'\left(g(4)\right) = -9\mathbf{v}'(3) \tag{1}$$

We differentiate $\mathbf{v}(s)$:

$$\mathbf{v}'(s) = 2s\mathbf{i} + 2\mathbf{j} - 18s^{-3}\mathbf{k} \quad \Rightarrow \quad \mathbf{v}'(3) = 6\mathbf{i} + 2\mathbf{j} - \frac{2}{3}\mathbf{k} \tag{2}$$

Combining (1) and (2) gives:

$$\frac{d}{ds}\mathbf{v}\left(g(s)\right)\bigg|_{s=4} = -9\left(6\mathbf{i} + 2\mathbf{j} - \frac{2}{3}\mathbf{k}\right) = -54\mathbf{i} - 18\mathbf{j} + 6\mathbf{k}$$

In Exercises 29–34, find a parametrization of the tangent line at the point indicated.

29. $\mathbf{r}(t) = \left\langle t^2, t^4\right\rangle, \quad t=-2$

SOLUTION The tangent line has the following parametrization:

$$\ell(t) = \mathbf{r}(-2) + t\mathbf{r}'(-2) \tag{1}$$

We compute the vectors $\mathbf{r}(-2)$ and $\mathbf{r}'(-2)$:

$$\mathbf{r}(-2) = \left\langle (-2)^2, (-2)^4\right\rangle = \langle 4, 16\rangle$$
$$\mathbf{r}'(t) = \frac{d}{dt}\left\langle t^2, t^4\right\rangle = \left\langle 2t, 4t^3\right\rangle \quad \Rightarrow \quad \mathbf{r}'(-2) = \langle -4, -32\rangle$$

Substituting in (1) gives:

$$\ell(t) = \langle 4, 16\rangle + t\,\langle -4, -32\rangle = \langle 4-4t, 16-32t\rangle$$

The parametrization for the tangent line is, thus,

$$x = 4-4t, \quad y = 16-32t, \quad -\infty < t < \infty.$$

To find a direct relation between y and x, we express t in terms of x and substitute in $y = 16-32t$. This gives:

$$x = 4-4t \Rightarrow t = \frac{x-4}{-4}.$$

Hence,

$$y = 16-32t = 16-32\cdot\frac{x-4}{-4} = 16+8(x-4) = 8x-16.$$

The equation of the tangent line is $y = 8x-16$.

30. $\mathbf{r}(t) = \langle \cos 2t, \sin 3t \rangle, \quad t = \frac{\pi}{4}$

SOLUTION The tangent line is parametrized by:

$$\ell(t) = \mathbf{r}\left(\frac{\pi}{4}\right) + t\mathbf{r}'\left(\frac{\pi}{4}\right) \tag{1}$$

We compute the vectors in the above parametrization:

$$\mathbf{r}\left(\frac{\pi}{4}\right) = \langle \cos\frac{\pi}{2}, \sin\frac{3\pi}{4} \rangle = \left\langle 0, \frac{1}{\sqrt{2}} \right\rangle$$

$$\mathbf{r}'(t) = \frac{d}{dt}\langle \cos 2t, \sin 3t \rangle = \langle -2\sin 2t, 3\cos 3t \rangle$$

$$\Rightarrow \quad \mathbf{r}'\left(\frac{\pi}{4}\right) = \left\langle -2\sin\frac{\pi}{2}, 3\cos\frac{3\pi}{4} \right\rangle = \left\langle -2, \frac{-3}{\sqrt{2}} \right\rangle$$

Substituting the vectors in (1) we obtain the following parametrization:

$$\ell(t) = \left\langle 0, \frac{1}{\sqrt{2}} \right\rangle + t\left\langle -2, \frac{-3}{\sqrt{2}} \right\rangle = \left\langle -2t, \frac{1}{\sqrt{2}}(1-3t) \right\rangle$$

31. $\mathbf{r}(t) = \langle 1 - t^2, 5t, 2t^3 \rangle, \quad t = 2$

SOLUTION The tangent line is parametrized by:

$$\ell(t) = \mathbf{r}(2) + t\mathbf{r}'(2) \tag{1}$$

We compute the vectors in the above parametrization:

$$\mathbf{r}(2) = \langle 1 - 2^2, 5 \cdot 2, 2 \cdot 2^3 \rangle = \langle -3, 10, 16 \rangle$$

$$\mathbf{r}'(t) = \frac{d}{dt}\langle 1 - t^2, 5t, 2t^3 \rangle = \langle -2t, 5, 6t^2 \rangle \quad \Rightarrow \quad \mathbf{r}'(2) = \langle -4, 5, 24 \rangle$$

Substituting the vectors in (1) we obtain the following parametrization:

$$\ell(t) = \langle -3, 10, 16 \rangle + t\langle -4, 5, 24 \rangle = \langle -3 - 4t, 10 + 5t, 16 + 24t \rangle$$

32. $\mathbf{r}(t) = \langle 4t, 5t, 9t \rangle, \quad t = -4$

SOLUTION The tangent line is parametrized by:

$$\ell(t) = \mathbf{r}(-4) + t\mathbf{r}'(-4) \tag{1}$$

We compute the vectors in the above parametrization:

$$\mathbf{r}(-4) = \langle 4(-4), 5(-4), 9(-4) \rangle = \langle -16, -20, -36 \rangle$$

$$\mathbf{r}'(t) = \frac{d}{dt}\langle 4t, 5t, 9t \rangle = \langle 4, 5, 9 \rangle \quad \Rightarrow \quad \mathbf{r}'(-4) = \langle 4, 5, 9 \rangle$$

Substituting the vectors in (1) we obtain the following parametrization:

$$\ell(t) = \langle -16, -20, -36 \rangle + t\langle 4, 5, 9 \rangle = \langle -16 + 4t, -20 + 5t, -36 + 9t \rangle$$

33. $\mathbf{r}(s) = 4s^{-1}\mathbf{i} - \frac{8}{3}s^{-3}\mathbf{k}, \quad s = 2$

SOLUTION The tangent line is parametrized by:

$$\ell(s) = \mathbf{r}(2) + s\mathbf{r}'(2) \tag{1}$$

We compute the vectors in the above parametrization:

$$\mathbf{r}(2) = 4(2)^{-1}\mathbf{i} - \frac{8}{3}(2)^{-3}\mathbf{k} = 2\mathbf{i} - \frac{1}{3}\mathbf{k}$$

$$\mathbf{r}'(s) = \frac{d}{ds}\left(4s^{-1}\mathbf{i} - \frac{8}{3}s^{-3}\mathbf{k}\right) = -4s^{-2}\mathbf{i} + 8s^{-4}\mathbf{k} \quad \Rightarrow \quad \mathbf{r}'(2) = -\mathbf{i} + \frac{1}{2}\mathbf{k}$$

Substituting the vectors in (1) we obtain the following parametrization:

$$\ell(t) = \left(2\mathbf{i} - \frac{1}{3}\mathbf{k}\right) + s\left(-\mathbf{i} + \frac{1}{2}\mathbf{k}\right) = (2 - s)\mathbf{i} + \left(\frac{1}{2}s - \frac{1}{3}\right)\mathbf{k}$$

34. $\mathbf{r}(s) = (\ln s)\mathbf{i} + s^{-1}\mathbf{j} + 9s\mathbf{k}, \quad s = 1$

SOLUTION The tangent line has the following parametrization:

$$\ell(s) = \mathbf{r}(1) + s\mathbf{r}'(1) \tag{1}$$

We compute the vectors $\mathbf{r}(1)$ and $\mathbf{r}'(1)$:

$$\mathbf{r}(1) = \ln 1\mathbf{i} + 1^{-1}\mathbf{j} + 9 \cdot 1\mathbf{k} = \mathbf{j} + 9\mathbf{k}$$

$$\mathbf{r}'(s) = \frac{d}{ds}(\ln s\mathbf{i} + s^{-1}\mathbf{j} + 9s\mathbf{k}) = \frac{1}{s}\mathbf{i} - s^{-2}\mathbf{j} + 9\mathbf{k} \quad \Rightarrow \quad \mathbf{r}'(1) = \mathbf{i} - \mathbf{j} + 9\mathbf{k}$$

We substitute the vectors in (1) to obtain the following parametrization:

$$\ell(s) = \mathbf{j} + 9\mathbf{k} + s(\mathbf{i} - \mathbf{j} + 9\mathbf{k}) = s\mathbf{i} + (1 - s)\mathbf{j} + (9 + 9s)\mathbf{k}$$

or in scalar form:

$$x = s, \quad y = 1 - s, \quad z = 9 + 9s.$$

35. Use Example 4 to calculate $\frac{d}{dt}(\mathbf{r} \times \mathbf{r}')$, where $\mathbf{r}(t) = \langle t, t^2, e^t \rangle$.

SOLUTION In Example 4 it is proved that:

$$\frac{d}{dt}\mathbf{r} \times \mathbf{r}' = \mathbf{r} \times \mathbf{r}'' \tag{1}$$

We compute the derivatives $\mathbf{r}'(t)$ and $\mathbf{r}''(t)$:

$$\mathbf{r}'(t) = \frac{d}{dt}\langle t, t^2, e^t \rangle = \langle 1, 2t, e^t \rangle$$

$$\mathbf{r}''(t) = \frac{d}{dt}\langle 1, 2t, e^t \rangle = \langle 0, 2, e^t \rangle$$

Using (1) we get

$$\frac{d}{dt}\mathbf{r} \times \mathbf{r}' = \mathbf{r} \times \mathbf{r}'' = \langle t, t^2, e^t \rangle \times \langle 0, 2, e^t \rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ t & t^2 & e^t \\ 0 & 2 & e^t \end{vmatrix} = \left(t^2e^t - 2e^t\right)\mathbf{i} - \left(0 - te^t\right)\mathbf{j} + \left(2t - 0\right)\mathbf{k}$$

$$= \left(t^2 - 2\right)e^t\mathbf{i} + te^t\mathbf{j} + 2t\mathbf{k} = \left\langle \left(t^2 - 2t\right)e^t, te^t, 2t \right\rangle$$

36. Let $\mathbf{r}(t) = \langle 3\cos t, 5\sin t, 4\cos t \rangle$. Show that $\|\mathbf{r}(t)\|$ is constant and conclude, using Example 7, that $\mathbf{r}(t)$ and $\mathbf{r}'(t)$ are orthogonal. Then compute $\mathbf{r}'(t)$ and verify directly that $\mathbf{r}'(t)$ is orthogonal to $\mathbf{r}(t)$.

SOLUTION First let us compute $||\mathbf{r}(t)||$:

$$||\mathbf{r}(t)|| = \sqrt{9\cos^2 t + 25\sin^2 t + 16\cos^2 t} = \sqrt{25(\cos^2 t + \sin^2 t)} = \sqrt{25} = 5$$

Therefore, $||\mathbf{r}(t)||$ is constant. Using Example 7, we see:

$$\frac{d}{dt}||\mathbf{r}(t)||^2 = 2\mathbf{r}(t) \cdot \mathbf{r}'(t)$$

Since $||\mathbf{r}(t)||$ is constant, its derivative is 0, therefore we get:

$$2\mathbf{r}(t) \cdot \mathbf{r}'(t) = 0 \quad \Rightarrow \quad \mathbf{r}(t) \cdot \mathbf{r}'(t) = 0$$

and we can conclude that $\mathbf{r}(t)$ and $\mathbf{r}'(t)$ are orthogonal.

Now, computing in a different way, we know:

$$\mathbf{r}'(t) = \langle -3\sin t, 5\cos t, -4\sin t \rangle$$

and

$$\begin{aligned} \mathbf{r}(t) \cdot \mathbf{r}'(t) &= \langle 3\cos t, 5\sin t, 4\cos t \rangle \cdot \langle -3\sin t, 5\cos t, -4\sin t \rangle \\ &= -9\cos t\sin t + 25\sin t\cos t - 16\cos t\sin t \\ &= 0 \end{aligned}$$

Hence we can conclude that $\mathbf{r}(t)$ and $\mathbf{r}'(t)$ are orthogonal.

37. Show that the *derivative of the norm* is not equal to the *norm of the derivative* by verifying that $\|\mathbf{r}(t)\|' \neq \|\mathbf{r}'(t)\|$ for $\mathbf{r}(t) = \langle t, 1, 1\rangle$.

SOLUTION First let us compute $\|\mathbf{r}(t)\|'$ for $\mathbf{r}(t) = \langle t, 1, 1\rangle$:

$$\|\mathbf{r}(t)\|' = \frac{d}{dt}(\sqrt{t^2+2}) = \frac{t}{\sqrt{t^2+2}}$$

Now, first let us compute the derivative, $\mathbf{r}'(t)$:

$$\mathbf{r}'(t) = \langle 1, 0, 0\rangle$$

and then computing the norm:

$$\|\mathbf{r}'(t)\| = \|\langle 1, 0, 0\rangle\| = \sqrt{1} = 1$$

It is clear in this example, that $\|\mathbf{r}(t)\|' \neq \|\mathbf{r}'(t)\|$.

38. Show that $\frac{d}{dt}(\mathbf{a} \times \mathbf{r}) = \mathbf{a} \times \mathbf{r}'$ for any constant vector $\mathbf{a}$.

SOLUTION We use the Product Rule for cross products and the derivative $\frac{d}{dt}(\mathbf{a}) = \mathbf{0}$ of the constant vector $\mathbf{a}$, to write:

$$\frac{d}{dt}\mathbf{a} \times \mathbf{r} = \mathbf{a} \times \mathbf{r}' + \mathbf{a}' \times \mathbf{r} = \mathbf{a} \times \mathbf{r}' + \mathbf{0} \times \mathbf{r} = \mathbf{a} \times \mathbf{r}' + \mathbf{0} = \mathbf{a} \times \mathbf{r}'$$

In Exercises 39–46, evaluate the integrals.

39. $\int_{-1}^{3} \left\langle 8t^2 - t, 6t^3 + t \right\rangle dt$

SOLUTION Vector-valued integration is defined via componentwise integration. Thus, we first compute the integral of each component.

$$\int_{-1}^{3} 8t^2 - t\,dt = \frac{8}{3}t^3 - \frac{t^2}{2}\bigg|_{-1}^{3} = \left(72 - \frac{9}{2}\right) - \left(-\frac{8}{3} - \frac{1}{2}\right) = \frac{212}{3}$$

$$\int_{-1}^{3} 6t^3 + t\,dt = \frac{3}{2}t^4 + \frac{t^2}{2}\bigg|_{-1}^{3} = \left(\frac{243}{2} + \frac{9}{2}\right) - \left(\frac{3}{2} + \frac{1}{2}\right) = 124$$

Therefore,

$$\int_{-1}^{3} \left\langle 8t^2 - t, 6t^3 + t \right\rangle dt = \left\langle \int_{-1}^{3} 8t^2 - t\,dt, \int_{-1}^{3} 6t^3 + t\,dt \right\rangle = \left\langle \frac{212}{3}, 124 \right\rangle$$

40. $\int_{0}^{1} \left\langle \frac{1}{1+s^2}, \frac{s}{1+s^2} \right\rangle ds$

SOLUTION The vector-valued integration is defined via componentwise integration. Thus, we first compute the integral of each component. For the second integral we use the substitution $t = 1 + s^2$, $dt = 2s\,ds$. We get:

$$\int_0^1 \frac{ds}{1+s^2} = \tan^{-1}(s)\bigg|_0^1 = \tan^{-1}(1) - \tan^1(0) = \frac{\pi}{4} - 0 = \frac{\pi}{4}$$

$$\int_0^1 \frac{s}{1+s^2}\,ds = \int_1^2 \frac{1}{t}\left(\frac{dt}{2}\right) = \frac{1}{2}\int_1^2 \frac{dt}{t} = \frac{1}{2}\ln t\bigg|_1^2 = \frac{1}{2}(\ln 2 - \ln 1) = \frac{1}{2}\ln 2$$

Therefore,

$$\int_0^1 \left\langle \frac{1}{1+s^2}, \frac{s}{1+s^2} \right\rangle ds = \left\langle \int_0^1 \frac{ds}{1+s^2}, \int_0^1 \frac{s\,ds}{1+s^2} \right\rangle = \left\langle \frac{\pi}{4}, \frac{1}{2}\ln 2 \right\rangle$$

41. $\int_{-2}^{2} \left(u^3\mathbf{i} + u^5\mathbf{j}\right) du$

SOLUTION The vector-valued integration is defined via componentwise integration. Thus, we first compute the integral of each component.

$$\int_{-2}^{2} u^3\, du = \frac{u^4}{4}\bigg|_{-2}^{2} = \frac{16}{4} - \frac{16}{4} = 0$$

$$\int_{-2}^{2} u^5\, du = \frac{u^6}{6}\bigg|_{-2}^{2} = \frac{64}{6} - \frac{64}{6} = 0$$

Therefore,

$$\int_{-2}^{2} \left(u^3\mathbf{i} + u^5\mathbf{j}\right) du = \left(\int_{-2}^{2} u^3\, du\right)\mathbf{i} + \left(\int_{-2}^{2} u^5\, du\right)\mathbf{j} = 0\mathbf{i} + 0\mathbf{j}$$

42. $\int_{0}^{1} \left(te^{-t^2}\mathbf{i} + t\ln(t^2+1)\mathbf{j}\right) dt$

SOLUTION We compute the integral of each component. The integral of the first component is computed using the substitution $s = -t^2$, $ds = -2t\,dt$. This gives

$$\int_0^1 te^{-t^2}\, dt = \int_0^{-1} e^s \left(-\frac{ds}{2}\right) = \frac{1}{2}\int_{-1}^{0} e^s\, ds = \frac{1}{2}e^s\bigg|_{-1}^{0} = \frac{1}{2}\left(e^0 - e^{-1}\right) = \frac{1}{2}\left(1 - e^{-1}\right)$$

For the integral of the second component we use the substitution $s = t^2 + 1$, $ds = 2t\,dt$. This gives:

$$\int_0^1 t\ln(t^2+1)\, dt = \int_1^2 \ln s \frac{ds}{2} = \frac{1}{2}\int_1^2 \ln s\, ds = \frac{1}{2}s(\ln s - 1)\bigg|_1^2 = \frac{1}{2}\left(2(\ln 2 - 1) - 1(\ln 1 - 1)\right)$$
$$= \ln 2 - 1 + \frac{1}{2} = \ln 2 - \frac{1}{2}$$

Hence,

$$\int_0^1 \left\langle te^{-t^2}, t\ln(t^2+1)\right\rangle dt = \left\langle \frac{1}{2}\left(1 - e^{-1}\right), -\frac{1}{2} + \ln 2\right\rangle.$$

43. $\int_0^1 \langle 2t, 4t, -\cos 3t\rangle\, dt$

SOLUTION The vector valued integration is defined via componentwise integration. Therefore,

$$\int_0^1 \langle 2t, 4t, -\cos 3t\rangle\, dt = \left\langle \int_0^1 2t\, dt, \int_0^1 4t\, dt, \int_0^1 -\cos 3t\, dt\right\rangle = \left\langle t^2\bigg|_0^1, 2t^2\bigg|_0^1, -\frac{\sin 3t}{3}\bigg|_0^1\right\rangle = \left\langle 1, 2, -\frac{\sin 3}{3}\right\rangle$$

44. $\int_{1/2}^{1} \left\langle \frac{1}{u^2}, \frac{1}{u^4}, \frac{1}{u^5}\right\rangle du$

SOLUTION The vector valued integration is defined via componentwise integration. Computing the integral of each component we get:

$$\int_{1/2}^{1} \frac{1}{u^2}\, du = \frac{-1}{u}\bigg|_{1/2}^{1} = -1 - (-2) = 1$$

$$\int_{1/2}^{1} \frac{1}{u^4}\, du = \frac{-1}{3u^3}\bigg|_{1/2}^{1} = \frac{-1}{3} - \frac{-8}{3} = \frac{7}{3}$$

$$\int_{1/2}^{1} \frac{1}{u^5}\, du = \frac{-1}{4u^4}\bigg|_{1/2}^{1} = \frac{-1}{4} - \frac{-16}{4} = \frac{15}{4}$$

Therefore,

$$\int_{1/2}^{1} \left\langle \frac{1}{u^2}, \frac{1}{u^4}, \frac{1}{u^5}\right\rangle du = \left\langle \int_{1/2}^{1} \frac{1}{u^2}\, du, \int_{1/2}^{1} \frac{1}{u^4}\, du, \int_{1/2}^{1} \frac{1}{u^5}\, du\right\rangle = \left\langle 1, \frac{7}{3}, \frac{15}{4}\right\rangle$$

45. $\int_1^4 \left(t^{-1}\mathbf{i} + 4\sqrt{t}\,\mathbf{j} - 8t^{3/2}\mathbf{k}\right) dt$

SOLUTION We perform the integration componentwise. Computing the integral of each component we get:

$$\int_1^4 t^{-1}\,dt = \ln t\Big|_1^4 = \ln 4 - \ln 1 = \ln 4$$

$$\int_1^4 4\sqrt{t}\,dt = 4\cdot\frac{2}{3}t^{3/2}\Big|_1^4 = \frac{8}{3}\left(4^{3/2}-1\right) = \frac{56}{3}$$

$$\int_1^4 -8t^{3/2}\,dt = -\frac{16}{5}t^{5/2}\Big|_1^4 = -\frac{16}{5}\left(4^{5/2}-1\right) = -\frac{496}{5}$$

Hence,

$$\int_1^4 \left(t^{-1}\mathbf{i} + 4\sqrt{t}\mathbf{j} - 8t^{3/2}\mathbf{k}\right) dt = (\ln 4)\,\mathbf{i} + \frac{56}{3}\mathbf{j} - \frac{496}{5}\mathbf{k}$$

46. $\int_0^t \left(3s\mathbf{i} + 6s^2\mathbf{j} + 9\mathbf{k}\right) ds$

SOLUTION We first compute the integral of each component:

$$\int_0^t 3s\,ds = \frac{3}{2}s^2\Big|_0^t = \frac{3}{2}t^2$$

$$\int_0^t 6s^2\,ds = \frac{6}{3}s^3\Big|_0^t = 2t^3$$

$$\int_0^t 9\,ds = 9s\Big|_0^t = 9t$$

Hence,

$$\int_0^t \left(3s\mathbf{i} + 6s^2\mathbf{j} + 9\mathbf{k}\right) dt = \left(\int_0^t 3s\,ds\right)\mathbf{i} + \left(\int_0^t 6s^2\,ds\right)\mathbf{j} + \left(\int_0^t 9\,ds\right)\mathbf{k} = \left(\frac{3}{2}t^2\right)\mathbf{i} + \left(2t^3\right)\mathbf{j} + (9t)\mathbf{k}$$

In Exercises 47–54, find both the general solution of the differential equation and the solution with the given initial condition.

47. $\frac{d\mathbf{r}}{dt} = \langle 1-2t, 4t\rangle, \quad \mathbf{r}(0) = \langle 3, 1\rangle$

SOLUTION We first find the general solution by integrating $\frac{d\mathbf{r}}{dt}$:

$$\mathbf{r}(t) = \int \langle 1-2t, 4t\rangle\,dt = \left\langle \int (1-2t)\,dt, \int 4t\,dt\right\rangle = \left\langle t-t^2, 2t^2\right\rangle + \mathbf{c} \tag{1}$$

Since $\mathbf{r}(0) = \langle 3, 1\rangle$, we have:

$$\mathbf{r}(0) = \left\langle 0-0^2, 2\cdot 0^2\right\rangle + \mathbf{c} = \langle 3, 1\rangle \Rightarrow \mathbf{c} = \langle 3, 1\rangle$$

Substituting in (1) gives the solution:

$$\mathbf{r}(t) = \left\langle t-t^2, 2t^2\right\rangle + \langle 3, 1\rangle = \left\langle -t^2+t+3, 2t^2+1\right\rangle$$

48. $\mathbf{r}'(t) = \mathbf{i} - \mathbf{j}, \quad \mathbf{r}(0) = 2\mathbf{i} + 3\mathbf{k}$

SOLUTION The general solution is obtained by integrating $\mathbf{r}'(t)$:

$$\mathbf{r}(t) = \int (\mathbf{i}-\mathbf{j})\,dt = \left(\int 1\,dt\right)\mathbf{i} - \left(\int 1\,dt\right)\mathbf{j} = t\mathbf{i} - t\mathbf{j} + \mathbf{c} \tag{1}$$

Hence,

$$\mathbf{r}(0) = 0\mathbf{i} - 0\mathbf{j} + \mathbf{c} = \mathbf{c}$$

The solution with the initial condition $\mathbf{r}(0) = 2\mathbf{i} + 3\mathbf{k}$ must satisfy:

$$\mathbf{r}(0) = \mathbf{c} = 2\mathbf{i} + 3\mathbf{k}$$

Substituting in (1) yields the solution:

$$\mathbf{r}(t) = t\mathbf{i} - t\mathbf{j} + 2\mathbf{i} + 3\mathbf{k} = (t+2)\,\mathbf{i} - t\mathbf{j} + 3\mathbf{k}$$

49. $\mathbf{r}'(t) = t^2\mathbf{i} + 5t\mathbf{j} + \mathbf{k}, \quad \mathbf{r}(1) = \mathbf{j} + 2\mathbf{k}$

SOLUTION We first find the general solution by integrating $\mathbf{r}'(t)$:

$$\mathbf{r}(t) = \int \left(t^2\mathbf{i} + 5t\mathbf{j} + \mathbf{k}\right) dt = \left(\int t^2\,dt\right)\mathbf{i} + \left(\int 5t\,dt\right)\mathbf{j} + \left(\int 1\,dt\right)\mathbf{k} = \left(\frac{1}{3}t^3\right)\mathbf{i} + \left(\frac{5}{2}t^2\right)\mathbf{j} + t\mathbf{k} + \mathbf{c} \qquad (1)$$

The solution which satisfies the initial condition must satisfy:

$$\mathbf{r}(1) = \left(\frac{1}{3}\cdot 1^3\right)\mathbf{i} + \left(\frac{5}{2}\cdot 1^2\right)\mathbf{j} + 1\cdot\mathbf{k} + \mathbf{c} = \mathbf{j} + 2\mathbf{k}$$

That is,

$$\mathbf{c} = -\frac{1}{3}\mathbf{i} - \frac{3}{2}\mathbf{j} + 1\mathbf{k}$$

Substituting in (1) gives the following solution:

$$\mathbf{r}(t) = \left(\frac{1}{3}t^3\right)\mathbf{i} + \left(\frac{5}{2}t^2\right)\mathbf{j} + t\mathbf{k} - \frac{1}{3}\mathbf{i} - \frac{3}{2}\mathbf{j} + \mathbf{k} = \left(\frac{1}{3}t^3 - \frac{1}{3}\right)\mathbf{i} + \left(\frac{5t^2}{2} - \frac{3}{2}\right)\mathbf{j} + (t+1)\,\mathbf{k}$$

50. $\mathbf{r}'(t) = \langle \sin 3t, \sin 3t, t\rangle, \quad \mathbf{r}\left(\frac{\pi}{2}\right) = \left\langle 2, 4, \frac{\pi^2}{4}\right\rangle$

SOLUTION We first integrate the vector $\mathbf{r}'(t)$ to find the general solution:

$$\mathbf{r}(t) = \int \langle \sin 3t, \sin 3t, t\rangle\; dt = \left\langle \int \sin 3t\,dt, \int \sin 3t\,dt, \int t\,dt\right\rangle \qquad (1)$$

$$= \left\langle -\frac{1}{3}\cos 3t, -\frac{1}{3}\cos 3t, \frac{1}{2}t^2\right\rangle + \mathbf{c} \qquad (2)$$

Substituting the initial condition we obtain:

$$\mathbf{r}(\pi/2) = \left\langle -\frac{1}{3}\cos\frac{\pi}{2}, -\frac{1}{3}\cos\frac{\pi}{2}, \frac{1}{2}\cdot\left(\frac{\pi}{2}\right)^2\right\rangle + \mathbf{c} = \left\langle 0, 0, \frac{\pi^2}{8}\right\rangle + \mathbf{c} = \left\langle 2, 4, \frac{\pi^2}{4}\right\rangle$$

Hence,

$$\mathbf{c} = \left\langle 2, 4, \frac{\pi^2}{4}\right\rangle - \left\langle 0, 0, \frac{\pi^2}{8}\right\rangle = \left\langle 2, 4, \frac{\pi^2}{8}\right\rangle$$

Substituting in (2) we obtain the solution:

$$\mathbf{r}(t) = \left\langle -\frac{1}{3}\cos 3t, -\frac{1}{3}\cos 3t, \frac{1}{2}t^2\right\rangle + \left\langle 2, 4, \frac{\pi^2}{8}\right\rangle = \left\langle -\frac{1}{3}\cos 3t + 2, -\frac{1}{3}\cos 3t + 4, \frac{1}{2}t^2 + \frac{\pi^2}{8}\right\rangle$$

51. $\mathbf{r}''(t) = 16\mathbf{k}, \quad \mathbf{r}(0) = \langle 1, 0, 0\rangle, \quad \mathbf{r}'(0) = \langle 0, 1, 0\rangle$

SOLUTION To find the general solution we first find $\mathbf{r}'(t)$ by integrating $\mathbf{r}''(t)$:

$$\mathbf{r}'(t) = \int \mathbf{r}''(t)\,dt = \int 16\mathbf{k}\,dt = (16t)\,\mathbf{k} + \mathbf{c}_1 \qquad (1)$$

We now integrate $\mathbf{r}'(t)$ to find the general solution $\mathbf{r}(t)$:

$$\mathbf{r}(t) = \int \mathbf{r}'(t)\,dt = \int ((16t)\,\mathbf{k} + \mathbf{c}_1)\; dt = \left(\int 16(t)\,dt\right)\mathbf{k} + \mathbf{c}_1 t + \mathbf{c}_2 = (8t^2)\mathbf{k} + \mathbf{c}_1 t + \mathbf{c}_2 \qquad (2)$$

We substitute the initial conditions in (1) and (2). This gives:

$$\mathbf{r}'(0) = \mathbf{c}_1 = \langle 0, 1, 0\rangle = \mathbf{j}$$

$$\mathbf{r}(0) = 0\mathbf{k} + \mathbf{c}_1\cdot 0 + \mathbf{c}_2 = \langle 1, 0, 0\rangle \quad\Rightarrow\quad \mathbf{c}_2 = \langle 1, 0, 0\rangle = \mathbf{i}$$

Combining with (2) we obtain the following solution:

$$\mathbf{r}(t) = (8t^2)\mathbf{k} + t\mathbf{j} + \mathbf{i} = \mathbf{i} + t\mathbf{j} + (8t^2)\mathbf{k}$$

52. $\mathbf{r}''(t) = \left\langle e^{2t-2}, t^2-1, 1\right\rangle, \mathbf{r}(1) = \langle 0,0,1\rangle, \mathbf{r}'(1) = \langle 2,0,0\rangle$

SOLUTION To find the general solution we first find $\mathbf{r}'(t)$ by integrating $\mathbf{r}''(t)$:

$$\mathbf{r}'(t) = \int \mathbf{r}''(t)\,dt = \int \left\langle e^{2t-2}, t^2-1, 1\right\rangle\,dt = \left\langle \frac{1}{2}e^{2t-2}, \frac{t^3}{3}-t, t\right\rangle + \mathbf{c}_1 \tag{1}$$

We now integrate $\mathbf{r}'(t)$ to find the general solution $\mathbf{r}(t)$:

$$\mathbf{r}(t) = \int \mathbf{r}'(t)\,dt = \int \left(\left\langle \frac{1}{2}e^{2t-2}, \frac{t^3}{3}-t, t\right\rangle + \mathbf{c}_1\right)\,dt = \left\langle \frac{1}{4}e^{2t-2}, \frac{t^4}{12}-\frac{t^2}{2}, \frac{t^2}{2}\right\rangle + \mathbf{c}_1 t + \mathbf{c}_2 \tag{2}$$

We substitute the initial conditions in (1) and (2). This gives:

$$\begin{aligned}
\mathbf{r}'(1) &= \left\langle \frac{1}{2}, -\frac{2}{3}, 1\right\rangle + \mathbf{c}_1 = \langle 2,0,0\rangle \quad \Rightarrow \quad \mathbf{c}_1 = \left\langle \frac{3}{2}, \frac{2}{3}, -1\right\rangle \\
\mathbf{r}(1) &= \left\langle \frac{1}{4}, -\frac{5}{12}, \frac{1}{2}\right\rangle + \mathbf{c}_1(1) + \mathbf{c}_2 = < 0,0,1 > \\
&\left\langle \frac{1}{4}, -\frac{5}{12}, \frac{1}{2}\right\rangle + \left\langle \frac{3}{2}, \frac{2}{3}, -1\right\rangle + \mathbf{c}_2 = < 0,0,1 > \\
&\Rightarrow \quad \mathbf{c}_2 = \left\langle -\frac{7}{4}, -\frac{1}{4}, \frac{3}{2}\right\rangle
\end{aligned}$$

Combining with (2) we obtain the following solution:

$$\begin{aligned}
\mathbf{r}(t) &= \left\langle \frac{1}{4}e^{2t-2}, \frac{t^4}{12}-\frac{t^2}{2}, \frac{t^2}{2}\right\rangle + t\left\langle \frac{3}{2}, \frac{2}{3}, -1\right\rangle + \left\langle -\frac{7}{4}, -\frac{1}{4}, \frac{3}{2}\right\rangle \\
&= \left\langle \frac{1}{4}e^{2t-2} + \frac{3}{2}t - \frac{7}{4}, \frac{t^4}{12} - \frac{t^2}{2} + \frac{2}{3}t - \frac{1}{4}, \frac{t^2}{2} - t + \frac{3}{2}\right\rangle
\end{aligned}$$

53. $\mathbf{r}''(t) = \langle 0,2,0\rangle, \mathbf{r}(3) = \langle 1,1,0\rangle, \mathbf{r}'(3) = \langle 0,0,1\rangle$

SOLUTION To find the general solution we first find $\mathbf{r}'(t)$ by integrating $\mathbf{r}''(t)$:

$$\mathbf{r}'(t) = \int \mathbf{r}''(t)\,dt = \int \langle 0,2,0\rangle\,dt = \langle 0,2t,0\rangle + \mathbf{c}_1 \tag{1}$$

We now integrate $\mathbf{r}'(t)$ to find the general solution $\mathbf{r}(t)$:

$$\mathbf{r}(t) = \int \mathbf{r}'(t)\,dt = \int (\langle 0,2t,0\rangle + \mathbf{c}_1)\,dt = \left\langle 0, t^2, 0\right\rangle + \mathbf{c}_1 t + \mathbf{c}_2 \tag{2}$$

We substitute the initial conditions in (1) and (2). This gives:

$$\begin{aligned}
\mathbf{r}'(3) &= \langle 0,6,0\rangle + \mathbf{c}_1 = \langle 0,0,1\rangle \quad \Rightarrow \quad \mathbf{c}_1 = \langle 0,-6,1\rangle \\
\mathbf{r}(3) &= \langle 0,9,0\rangle + \mathbf{c}_1(3) + \mathbf{c}_2 = < 1,1,0 > \\
&\langle 0,9,0\rangle + \langle 0,-18,3\rangle + \mathbf{c}_2 = < 1,1,0 > \\
&\Rightarrow \quad \mathbf{c}_2 = \langle 1,10,-3\rangle
\end{aligned}$$

Combining with (2) we obtain the following solution:

$$\begin{aligned}
\mathbf{r}(t) &= \left\langle 0, t^2, 0\right\rangle + t\,\langle 0,-6,1\rangle + \langle 1,10,-3\rangle \\
&= \left\langle 1, t^2 - 6t + 10, t - 3\right\rangle
\end{aligned}$$

54. $\mathbf{r}''(t) = \left\langle e^t, \sin t, \cos t\right\rangle, \quad \mathbf{r}(0) = \langle 1,0,1\rangle, \quad \mathbf{r}'(0) = \langle 0,2,2\rangle$

SOLUTION We perform integration componentwise on $\mathbf{r}''(t)$ to obtain:

$$\mathbf{r}'(t) = \int \left\langle e^t, \sin t, \cos t\right\rangle\,dt = \left\langle e^t, -\cos t, \sin t\right\rangle + \mathbf{c}_1 \tag{1}$$

We now integrate $\mathbf{r}'(t)$ to obtain the general solution:

$$\mathbf{r}(t) = \int \left(\left\langle e^t, -\cos t, \sin t\right\rangle + \mathbf{c}_1\right) dt = \left\langle e^t, -\sin t, -\cos t\right\rangle + \mathbf{c}_1 t + \mathbf{c}_2 \tag{2}$$

Now, we substitute the initial conditions $\mathbf{r}(0) = \langle 1, 0, 1\rangle$ and $\mathbf{r}'(0) = \langle 0, 2, 2\rangle$ into (1) and (2) and solve for the vectors $\mathbf{c}_1$ and $\mathbf{c}_2$. We obtain:

$$\mathbf{r}'(0) = \langle 1, -1, 0\rangle + \mathbf{c}_1 = \langle 0, 2, 2\rangle \quad \Rightarrow \quad \mathbf{c}_1 = \langle -1, 3, 2\rangle$$
$$\mathbf{r}(0) = \langle 1, 0, -1\rangle + \mathbf{c}_2 = \langle 1, 0, 1\rangle \quad \Rightarrow \quad \mathbf{c}_2 = \langle 0, 0, 2\rangle$$

Finally we combine the above to obtain the solution:

$$\mathbf{r}(t) = \left\langle e^t, -\sin t, -\cos t\right\rangle + \langle -1, 3, 2\rangle\, t + \langle 0, 0, 2\rangle = \left\langle e^t - t, -\sin t + 3t, -\cos t + 2t + 2\right\rangle$$

55. Find the location at $t = 3$ of a particle whose path (Figure 8) satisfies

$$\frac{d\mathbf{r}}{dt} = \left\langle 2t - \frac{1}{(t+1)^2}, 2t - 4\right\rangle, \qquad \mathbf{r}(0) = \langle 3, 8\rangle$$

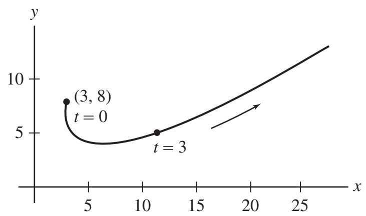


FIGURE 8 Particle path.

SOLUTION To determine the position of the particle in general, we perform integration componentwise on $\mathbf{r}'(t)$ to obtain:

$$\begin{aligned}\mathbf{r}(t) &= \int \mathbf{r}'(t)\, dt \\ &= \int \left\langle 2t - \frac{1}{(t+1)^2}, 2t - 4\right\rangle dt \\ &= \left\langle t^2 + \frac{1}{t+1}, t^2 - 4t\right\rangle + \mathbf{c}_1\end{aligned}$$

Using the initial condition, observe the following:

$$\mathbf{r}(0) = \langle 1, 0\rangle + \mathbf{c}_1 = \langle 3, 8\rangle$$
$$\Rightarrow \quad \mathbf{c}_1 = \langle 2, 8\rangle$$

Therefore,

$$\mathbf{r}(t) = \left\langle t^2 + \frac{1}{t+1}, t^2 - 4t\right\rangle + \langle 2, 8\rangle = \left\langle t^2 + \frac{1}{t+1} + 2, t^2 - 4t + 8\right\rangle$$

and thus, the location of the particle at $t = 3$ is $\mathbf{r}(3) = \langle 45/4, 5\rangle = \langle 11.25, 5\rangle$

56. Find the location and velocity at $t = 4$ of a particle whose path satisfies

$$\frac{d\mathbf{r}}{dt} = \left\langle 2t^{-1/2}, 6, 8t\right\rangle, \qquad \mathbf{r}(1) = \langle 4, 9, 2\rangle$$

SOLUTION The velocity of this particle at $t = 4$ is exactly:

$$\mathbf{r}'(4) = \left\langle 2(4)^{-1/2}, 6, 8(4)\right\rangle = \langle 1, 6, 32\rangle$$

To determine the location of the particle at any general t, we will perform integration componentwise on $\mathbf{r}'(t)$:

$$\begin{aligned}\mathbf{r}(t) &= \int \mathbf{r}'(t)\, dt = \int \left\langle 2t^{-1/2}, 6, 8t\right\rangle dt \\ &= \left\langle 4\sqrt{t}, 6t, 4t^2\right\rangle + \mathbf{c}_1\end{aligned}$$

Using the initial condition, observe the following:

$$\mathbf{r}(1) = \langle 4, 6, 4\rangle + \mathbf{c}_1 = \langle 4, 9, 2\rangle$$
$$\Rightarrow \quad \mathbf{c}_1 = \langle 0, 3, -2\rangle$$

Therefore,

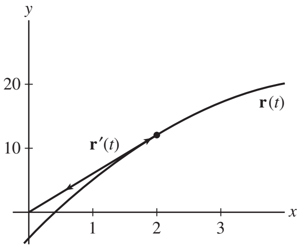
$$\mathbf{r}(t) = \left\langle 4\sqrt{t}, 6t, 4t^2\right\rangle + \langle 0, 3, -2\rangle = \left\langle 4\sqrt{t}, 6t+3, 4t^2-2\right\rangle$$

Then the location of this particle at $t = 4$ is:

$$\mathbf{r}(4) = \langle 8, 27, 62\rangle$$

57. A fighter plane, which can shoot a laser beam straight ahead, travels along the path $\mathbf{r}(t) = \left\langle 5-t, 21-t^2, 3-t^3/27\right\rangle$. Show that there is precisely one time t at which the pilot can hit a target located at the origin.

SOLUTION By the given information the laser beam travels in the direction of $\mathbf{r}'(t)$. The pilot hits a target located at the origin at the time t when $\mathbf{r}'(t)$ points towards the origin, that is, when $\mathbf{r}(t)$ and $\mathbf{r}'(t)$ are parallel and point to opposite directions.



We find $\mathbf{r}'(t)$:

$$\mathbf{r}'(t) = \frac{d}{dt}\left\langle 5-t, 21-t^2, 3-\frac{t^3}{27}\right\rangle = \left\langle -1, -2t, -\frac{t^2}{9}\right\rangle$$

We first find t such that $\mathbf{r}(t)$ and $\mathbf{r}'(t)$ are parallel, that is, we find t such that the cross product of the two vectors is zero. We obtain:

$$\mathbf{0} = \mathbf{r}'(t) \times \mathbf{r}(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -1 & -2t & -\frac{t^2}{9} \\ 5-t & 21-t^2 & 3-\frac{t^3}{27} \end{vmatrix}$$
$$= \left(-2t\left(3-\frac{t^3}{27}\right) + \frac{t^2}{9}(21-t^2)\right)\mathbf{i} - \left(-\left(3-\frac{t^3}{27}\right) + \frac{t^2}{9}(5-t)\right)\mathbf{j} + \left(-\left(21-t^2\right) + 2t(5-t)\right)\mathbf{k}$$
$$= \left(\frac{-t^4}{27} + \frac{7t^2}{3} - 6t\right)\mathbf{i} - \left(-\frac{2t^3}{27} + \frac{5t^2}{9} - 3\right)\mathbf{j} + \left(-t^2 + 10t - 21\right)\mathbf{k}$$

Equating each component to zero we obtain the following equations:

$$-\frac{t^4}{27} + \frac{7}{3}t^2 - 6t = 0$$
$$-\frac{2t^3}{27} + \frac{5t^2}{9} - 3 = 0$$
$$-t^2 + 10t - 21 = -(t-7)(t-3) = 0$$

The third equation implies that $t = 3$ or $t = 7$. Only $t = 3$ satisfies the other two equations as well. We now must verify that $\mathbf{r}(3)$ and $\mathbf{r}'(3)$ point in opposite directions. We find these vectors:

$$\mathbf{r}(3) = \left\langle 5-3, 21-3^2, 3-\frac{3^3}{27}\right\rangle = \langle 2, 12, 2\rangle$$
$$\mathbf{r}'(3) = \left\langle -1, -2\cdot 3, -\frac{3^2}{9}\right\rangle = \langle -1, -6, -1\rangle$$

Since $\mathbf{r}(3) = -2\mathbf{r}'(3)$, the vectors point in opposite direction. We conclude that only at time $t = 3$ can the pilot hit a target located at the origin.

58. The fighter plane of Exercise 57 travels along the path $\mathbf{r}(t) = \left\langle t - t^3, 12 - t^2, 3 - t\right\rangle$. Show that the pilot cannot hit any target on the x-axis.

SOLUTION First we will compute the tangent line to the given path of the plane at any time t . The tangent line will be

$$\ell(t) = \mathbf{r}(t_0) + t\mathbf{r}'(t_0)$$

Computing the derivatives we get:

$$\mathbf{r}'(t) = \left\langle 1 - 3t^2, -2t, -1\right\rangle$$

Therefore, the tangent line at time t is

$$\begin{aligned}\ell(t) &= \mathbf{r}(0) + t\mathbf{r}'(0)\\ &= \langle 0, 12, 3\rangle + t\,\langle 1, 0, -1\rangle\\ &= \langle t, 12, 3 - t\rangle\end{aligned}$$

The tangent line always lies on the plane $y = 12$, so it can never hit the x-axis.

59. Find all solutions to $\mathbf{r}'(t) = \mathbf{v}$ with initial condition $\mathbf{r}(1) = \mathbf{w}$, where $\mathbf{v}$ and $\mathbf{w}$ are constant vectors in $\mathbf{R}^3$.

SOLUTION We denote the components of the constant vector $\mathbf{v}$ by $\mathbf{v} = \langle v_1, v_2, v_3\rangle$ and integrate to find the general solution. This gives:

$$\begin{aligned}\mathbf{r}(t) &= \int \mathbf{v}\,dt = \int \langle v_1, v_2, v_3\rangle\,dt = \left\langle \int v_1\,dt, \int v_2\,dt, \int v_3\,dt\right\rangle\\ &= \langle v_1t + c_1, v_2t + c_2, v_3t + c_3\rangle = t\,\langle v_1, v_2, v_3\rangle + \langle c_1, c_2, c_3\rangle\end{aligned}$$

We let $\mathbf{c} = \langle c_1, c_2, c_3\rangle$ and obtain:

$$\mathbf{r}(t) = t\mathbf{v} + \mathbf{c} = \mathbf{c} + t\mathbf{v}$$

Notice that the solutions are the vector parametrizations of all the lines with direction vector $\mathbf{v}$.

We are also given the initial condition that $\mathbf{r}(1) = \mathbf{w}$, using this information we can determine:

$$\mathbf{r}(1) = (1)\mathbf{v} + \mathbf{c} = \mathbf{w}$$

Therefore $\mathbf{c} = \mathbf{w} - \mathbf{v}$ and we get:

$$\mathbf{r}(t) = (\mathbf{w} - \mathbf{v}) + t\mathbf{v} = (t - 1)\mathbf{v} + \mathbf{w}$$

60. Let $\mathbf{u}$ be a constant vector in $\mathbf{R}^3$. Find the solution of the equation $\mathbf{r}'(t) = (\sin t)\mathbf{u}$ satisfying $\mathbf{r}'(0) = \mathbf{0}$.

SOLUTION We first integrate to find the general solution. Denoting $\mathbf{u} = \langle u_1, u_2, u_3\rangle$ we get:

$$\begin{aligned}\mathbf{r}(t) &= \int (\sin t)\,\mathbf{u}\,dt = \int \langle u_1 \sin t, u_2 \sin t, u_3 \sin t\rangle\,dt\\ &= \left\langle \int u_1 \sin t\,dt, \int u_2 \sin t\,dt, \int u_3 \sin t\,dt\right\rangle = \left\langle u_1 \int \sin t\,dt, u_2 \int \sin t\,dt, u_3 \int \sin t\,dt\right\rangle\\ &= \langle -u_1 \cos t + c_1, -u_2 \cos t + c_2, -u_3 \cos t + c_3\rangle = -\cos t\,\langle u_1, u_2, u_3\rangle + \langle c_1, c_2, c_3\rangle\end{aligned}$$

Letting $\mathbf{c} = \langle c_1, c_2, c_3\rangle$ we obtain the following solutions:

$$\mathbf{r}(t) = (-\cos t)\,\mathbf{u} + \mathbf{c}$$

Since $\mathbf{r}'(0) = 0$ we have $\mathbf{r}'(0) = \sin 0 \cdot \mathbf{u} = 0$.

61. Find all solutions to $\mathbf{r}'(t) = 2\mathbf{r}(t)$ where $\mathbf{r}(t)$ is a vector-valued function in three-space.

SOLUTION We denote the components of $\mathbf{r}(t)$ by $\mathbf{r}(t) = \langle x(t), y(t), z(t)\rangle$. Then, $\mathbf{r}'(t) = \left\langle x'(t), y'(t), z'(t)\right\rangle$. Substituting in the differential equation we get:

$$\left\langle x'(t), y'(t), z'(t)\right\rangle = 2\,\langle x(t), y(t), z(t)\rangle$$

Equating corresponding components gives:

$$\begin{array}{lcl} x'(t) = 2x(t) & & x(t) = c_1e^{2t}\\ y'(t) = 2y(t) & \Rightarrow & y(t) = c_2e^{2t}\\ z'(t) = 2z(t) & & z(t) = c_3e^{2t}\end{array}$$

We denote the constant vector by $\mathbf{c} = \langle c_1, c_2, c_3 \rangle$ and obtain the following solutions:

$$\mathbf{r}(t) = \left\langle c_1 e^{2t}, c_2 e^{2t}, c_3 e^{2t} \right\rangle = e^{2t} \langle c_1, c_2, c_3 \rangle = e^{2t}\mathbf{c}$$

62. Show that $\mathbf{w}(t) = \langle \sin(3t+4), \sin(3t-2), \cos 3t \rangle$ satisfies the differential equation $\mathbf{w}''(t) = -9\mathbf{w}(t)$.

SOLUTION We differentiate the vector $\mathbf{w}(t)$ twice:

$$\begin{aligned}
\mathbf{w}'(t) &= \langle 3\cos(3t+4), 3\cos(3t-2), -3\sin 3t \rangle \\
\mathbf{w}''(t) &= \frac{d}{dt}\left(\mathbf{w}'(t)\right) = \langle -9\sin(3t+4), -9\sin(3t-2), -9\cos 3t \rangle \\
&= -9 \langle \sin(3t+4), \sin(3t-2), \cos 3t \rangle = -9\mathbf{w}(t)
\end{aligned}$$

We thus showed that $\mathbf{w}''(t) = -9\mathbf{w}(t)$

63. Prove that the **Bernoulli spiral** (Figure 9) with parametrization $\mathbf{r}(t) = \left\langle e^t \cos 4t, e^t \sin 4t \right\rangle$ has the property that the angle ψ between the position vector and the tangent vector is constant. Find the angle ψ in degrees.

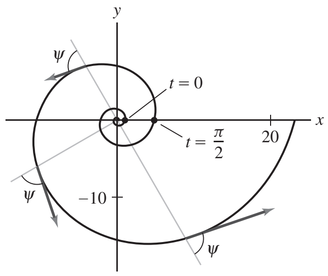


FIGURE 9 Bernoulli spiral.

SOLUTION First, let us compute the tangent vector, $\mathbf{r}'(t)$:

$$\mathbf{r}(t) = \left\langle e^t \cos 4t, e^t \sin 4t \right\rangle, \quad \Rightarrow \quad \mathbf{r}'(t) = \left\langle -4e^t \sin 4t + e^t \cos 4t, 4e^t \cos 4t + e^t \sin 4t \right\rangle$$

Then recall the identity that $\mathbf{a} \cdot \mathbf{b} = \|\mathbf{a}\| \cdot \|\mathbf{b}\| \cos\theta$, where θ is the angle between $\mathbf{a}$ and $\mathbf{b}$, so then,

$$\begin{aligned}
\mathbf{r}(t) \cdot \mathbf{r}'(t) &= \left\langle e^t \cos 4t, e^t \sin 4t \right\rangle \cdot \left\langle -4e^t \sin 4t + e^t \cos 4t, 4e^t \cos 4t + e^t \sin 4t \right\rangle \\
&= -4e^{2t} \sin 4t \cos 4t + e^{2t} \cos^2 4t + 4e^{2t} \sin 4t \cos 4t + e^{2t} \sin^2 4t \\
&= e^{2t}(\cos^2 4t + \sin^2 4t) \\
&= e^{2t}
\end{aligned}$$

Then, computing norms, we get:

$$\begin{aligned}
\|\mathbf{r}(t)\| &= \sqrt{e^{2t}\cos^2 4t + e^{2t}\sin^2 4t} = \sqrt{e^{2t}(\cos^2 4t + \sin^2 4t)} = e^t \\
\|\mathbf{r}'(t)\| &= \sqrt{(-4e^t \sin 4t + e^t \cos 4t)^2 + (4e^t \cos 4t + e^t \sin 4t)^2} \\
&= \sqrt{16e^{2t}\sin^2 4t - 4e^{2t}\sin 4t \cos 4t + e^{2t}\cos^2 4t + 16e^{2t}\cos^2 4t + 4e^{2t}\sin 4t\cos 4t + e^{2t}\sin^2 4t} \\
&= \sqrt{16e^{2t}(\sin^2 4t + \cos^2 4t) + e^{2t}(\cos^2 4t + \sin^2 4t)} \\
&= \sqrt{16e^{2t} + e^{2t}} \\
&= \sqrt{17}e^t
\end{aligned}$$

Then using the dot product relation listed above we get:

$$e^{2t} = e^t(\sqrt{17}e^t)\cos\theta = \sqrt{17}e^{2t}\cos\theta$$

Hence

$$\cos\theta = \frac{1}{\sqrt{17}}, \quad \Rightarrow \quad \theta \approx 75.96^\circ$$

Therefore, the angle between the position vector and the tangent vector is constant.

64. A curve in polar form $r = f(\theta)$ has parametrization

$$\mathbf{r}(\theta) = f(\theta)\langle \cos\theta, \sin\theta\rangle$$

Let ψ be the angle between the radial and tangent vectors (Figure 10). Prove that

$$\tan\psi = \frac{r}{dr/d\theta} = \frac{f(\theta)}{f'(\theta)}$$

Hint: Compute $\mathbf{r}(\theta) \times \mathbf{r}'(\theta)$ and $\mathbf{r}(\theta) \cdot \mathbf{r}'(\theta)$.

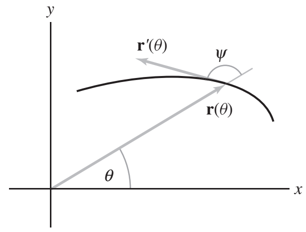

FIGURE 10 Curve with polar parametrization $\mathbf{r}(\theta) = f(\theta)\langle \cos\theta, \sin\theta\rangle$.

SOLUTION First we will compute $\mathbf{r}(\theta)$ and $\mathbf{r}'(\theta)$:

$$\mathbf{r}(\theta) = f(\theta)\langle \cos\theta, \sin\theta\rangle = \langle f(\theta)\cos\theta, f(\theta)\sin\theta\rangle$$

$$\mathbf{r}'(\theta) = f(\theta)\langle -\sin\theta, \cos\theta\rangle + f'(\theta)\langle \cos\theta, \sin\theta\rangle$$

$$= \left\langle f'(\theta)\cos\theta - f(\theta)\sin\theta, f'(\theta)\sin\theta + f(\theta)\cos\theta\right\rangle$$

Now we will compute both $\mathbf{r}(\theta) \cdot \mathbf{r}'(\theta)$ and $\mathbf{r}(\theta) \times \mathbf{r}'(\theta)$.

$$\mathbf{r}(\theta) \cdot \mathbf{r}'(\theta) = f(\theta)\cos\theta[f'(\theta)\cos\theta - f(\theta)\sin\theta] + f(\theta)\sin\theta[f'(\theta)\sin\theta + f(\theta)\cos\theta]$$

$$= f(\theta)f'(\theta)\cos^2\theta - [f(\theta)]^2\cos\theta\sin\theta + f(\theta)f'(\theta)\sin\theta + [f(\theta)]^2\sin\theta\cos\theta$$

$$= f(\theta)f'(\theta)[\cos^2\theta + \sin^2\theta]$$

$$= f(\theta)f'(\theta)$$

$$\mathbf{r}(\theta) \times \mathbf{r}'(\theta) = \langle f(\theta)\cos\theta, f(\theta)\sin\theta\rangle \times \left\langle f'(\theta)\cos\theta - f(\theta)\sin\theta, f'(\theta)\sin\theta + f(\theta)\cos\theta\right\rangle$$

$$= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ f(\theta)\cos\theta & f(\theta)\sin\theta & 0 \\ f'(\theta)\cos\theta - f(\theta)\sin\theta & f'(\theta)\sin\theta + f(\theta)\cos\theta) & 0 \end{vmatrix}$$

$$= 0\mathbf{i} + 0\mathbf{j} + [f(\theta)\cos\theta(f'(\theta)\sin\theta + f(\theta)\cos\theta) - f(\theta)\sin\theta(f'(\theta)\cos\theta - f(\theta)\sin\theta)]\mathbf{k}$$

$$= 0\mathbf{i} + 0\mathbf{j} + [f(\theta)]^2\mathbf{k}$$

Recall that $\mathbf{a} \cdot \mathbf{b} = \|\mathbf{a}\|\|\mathbf{b}\|\cos\psi$ and $\|\mathbf{a} \times \mathbf{b}\| = \|\mathbf{a}\|\|\mathbf{b}\|\sin\psi$ so then:

$$\tan\psi = \frac{\sin\psi}{\cos\psi} = \frac{\frac{\|\mathbf{r}(\theta)\times\mathbf{r}'(\theta)\|}{\|\mathbf{r}(\theta)\|\|\mathbf{r}'(\theta)\|}}{\frac{\mathbf{r}(\theta)\cdot\mathbf{r}'(\theta)}{\|\mathbf{r}(\theta)\|\|\mathbf{r}'(\theta)\|}} = \frac{\|\mathbf{r}(\theta) \times \mathbf{r}'(\theta)\|}{\mathbf{r}(\theta) \cdot \mathbf{r}'(\theta)} = \frac{\sqrt{[f(\theta)]^4}}{f(\theta)f'(\theta)} = \frac{|[f(\theta)]^2|}{f(\theta)f'(\theta)} = \frac{f(\theta)}{f'(\theta)} = \frac{r}{dr/d\theta}$$

65. Prove that if $\|\mathbf{r}(t)\|$ takes on a local minimum or maximum value at t_0, then $\mathbf{r}(t_0)$ is orthogonal to $\mathbf{r}'(t_0)$. Explain how this result is related to Figure 11. *Hint:* Observe that if $\|\mathbf{r}(t_0)\|$ is a minimum, then $\mathbf{r}(t)$ is tangent at t_0 to the sphere of radius $\|\mathbf{r}(t_0)\|$ centered at the origin.

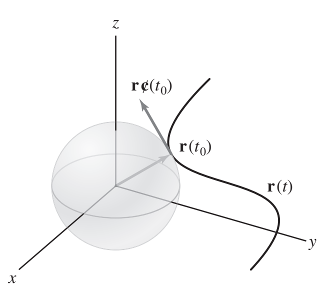

FIGURE 11

SOLUTION Suppose that $\|\mathbf{r}(t)\|$ takes on a minimum or maximum value at $t = t_0$. Hence, $\|\mathbf{r}(t)\|^2$ also takes on a minimum or maximum value at $t = t_0$, therefore $\frac{d}{dt}\|\mathbf{r}(t)\|^2\big|_{t=t_0} = 0$. Using the Product Rule for dot products we get

$$\frac{d}{dt}\|\mathbf{r}(t)\|^2\bigg|_{t=t_0} = \frac{d}{dt}\mathbf{r}(t)\cdot\mathbf{r}(t)\bigg|_{t=t_0} = \mathbf{r}(t_0)\cdot\mathbf{r}'(t_0) + \mathbf{r}'(t_0)\cdot\mathbf{r}(t_0) = 2\mathbf{r}(t_0)\cdot\mathbf{r}'(t_0) = 0$$

Thus $\mathbf{r}(t_0)\cdot\mathbf{r}'(t_0) = 0$, which implies the orthogonality of $\mathbf{r}(t_0)$ and $\mathbf{r}'(t_0)$. In Figure 11, $\|\mathbf{r}(t_0)\|$ is a minimum and the path intersects the sphere of radius $\|\mathbf{r}(t_0)\|$ at a single point. Therefore, the point of intersection is a tangency point which implies that $\mathbf{r}'(t_0)$ is tangent to the sphere at t_0. We conclude that $\mathbf{r}(t_0)$ and $\mathbf{r}'(t_0)$ are orthogonal.

66. Newton's Second Law of Motion in vector form states that $\mathbf{F} = \frac{d\mathbf{p}}{dt}$ where $\mathbf{F}$ is the force acting on an object of mass m and $\mathbf{p} = m\mathbf{r}'(t)$ is the object's momentum. The analogs of force and momentum for rotational motion are the **torque** $\boldsymbol{\tau} = \mathbf{r}\times\mathbf{F}$ and **angular momentum**

$$\mathbf{J} = \mathbf{r}(t)\times\mathbf{p}(t)$$

Use the Second Law to prove that $\boldsymbol{\tau} = \frac{d\mathbf{J}}{dt}$.

SOLUTION We differentiate $\mathbf{J} = \mathbf{r}(t)\times m\mathbf{r}'(t)$ using the Product Rule for cross products. Using $\mathbf{r}'(t)\times\mathbf{r}'(t) = \mathbf{0}$ we get:

$$\begin{aligned}\frac{d\mathbf{J}}{dt} &= \frac{d}{dt}\left(\mathbf{r}(t)\times m\mathbf{r}'(t)\right) = m\frac{d}{dt}\left(\mathbf{r}(t)\times\mathbf{r}'(t)\right) = m\left(\mathbf{r}(t)\times\mathbf{r}''(t) + \mathbf{r}'(t)\times\mathbf{r}'(t)\right)\\ &= m\mathbf{r}(t)\times\mathbf{r}''(t) = \mathbf{r}(t)\times m\mathbf{r}''(t) \qquad (1)\end{aligned}$$

Since $\mathbf{p} = m\mathbf{r}'(t)$, we have $\frac{d\mathbf{p}}{dt} = m\mathbf{r}''(t)$. Combining with (1) we obtain:

$$\frac{d\mathbf{J}}{dt} = \mathbf{r}(t)\times\frac{d\mathbf{p}}{dt} \qquad (2)$$

Finally, we use Newton's Second Law of Motion, $\mathbf{F} = \frac{d\mathbf{p}}{dt}$. Substituting in (2) we obtain the required equality:

$$\frac{d\mathbf{J}}{dt} = \mathbf{r}(t)\times\mathbf{F}(t) = \tau$$

Further Insights and Challenges

67. Let $\mathbf{r}(t) = \langle x(t), y(t)\rangle$ trace a plane curve $\mathcal{C}$. Assume that $x'(t_0) \neq 0$. Show that the slope of the tangent vector $\mathbf{r}'(t_0)$ is equal to the slope dy/dx of the curve at $\mathbf{r}(t_0)$.

SOLUTION

(a) By the Chain Rule we have

$$\frac{dy}{dt} = \frac{dy}{dx}\cdot\frac{dx}{dt}$$

Hence, at the points where $\frac{dx}{dt} \neq 0$ we have:

$$\frac{dy}{dx} = \frac{\frac{dy}{dt}}{\frac{dx}{dt}} = \frac{y'(t)}{x'(t)}$$

(b) The line $\ell(t) = \langle a, b\rangle + t\mathbf{r}'(t_0)$ passes through (a, b) at $t = 0$. It holds that:

$$\ell(0) = \langle a, b\rangle + 0\mathbf{r}'(t_0) = \langle a, b\rangle$$

That is, (a, b) is the terminal point of the vector $\ell(0)$, hence the line passes through (a, b). The line has the direction vector $\mathbf{r}'(t_0) = \left\langle x'(t_0), y'(t_0)\right\rangle$, therefore the slope of the line is $\frac{y'(t_0)}{x'(t_0)}$ which is equal to $\frac{dy}{dx}\big|_{t=t_0}$ by part (a).

68. Prove that $\frac{d}{dt}(\mathbf{r}\cdot(\mathbf{r}'\times\mathbf{r}'')) = \mathbf{r}\cdot(\mathbf{r}'\times\mathbf{r}''')$.

SOLUTION We use the Product Rule for dot products to obtain:

$$\frac{d}{dt}\left(\mathbf{r}\cdot\left(\mathbf{r}'\times\mathbf{r}''\right)\right) = \mathbf{r}\cdot\frac{d}{dt}\left(\mathbf{r}'\times\mathbf{r}''\right) + \mathbf{r}'\cdot\left(\mathbf{r}'\times\mathbf{r}''\right) \qquad (1)$$

By the Product Rule for cross products and properties of cross products, we have:

$$\frac{d}{dt}\left(\mathbf{r}' \times \mathbf{r}''\right) = \mathbf{r}' \times \mathbf{r}''' + \mathbf{r}'' \times \mathbf{r}'' = \mathbf{r}' \times \mathbf{r}''' + \mathbf{0} = \mathbf{r}' \times \mathbf{r}''' \qquad (2)$$

Substituting (2) into (1) yields:

$$\frac{d}{dt}\left(\mathbf{r} \cdot \left(\mathbf{r}' \times \mathbf{r}''\right)\right) = \mathbf{r} \cdot \left(\mathbf{r}' \times \mathbf{r}'''\right) + \mathbf{r}' \cdot \left(\mathbf{r}' \times \mathbf{r}''\right) \qquad (3)$$

Since $\mathbf{r}' \times \mathbf{r}''$ is orthogonal to $\mathbf{r}'$, the dot product $\mathbf{r}' \cdot \left(\mathbf{r}' \times \mathbf{r}''\right) = 0$. So (3) gives:

$$\frac{d}{dt}\left(\mathbf{r} \cdot \left(\mathbf{r}' \times \mathbf{r}''\right)\right) = \mathbf{r} \cdot \left(\mathbf{r}' \times \mathbf{r}'''\right) + 0 = \mathbf{r} \cdot \left(\mathbf{r}' \times \mathbf{r}'''\right)$$

69. Verify the Sum and Product Rules for derivatives of vector-valued functions.

SOLUTION We first verify the Sum Rule stating:

$$(\mathbf{r}_1(t) + \mathbf{r}_2(t))' = \mathbf{r}_1'(t) + \mathbf{r}_2'(t)$$

Let $\mathbf{r}_1(t) = \langle x_1(t), y_1(t), z_1(t)\rangle$ and $\mathbf{r}_2(t) = \langle x_2(t), y_2(t), z_2(t)\rangle$. Then,

$$\begin{aligned}
(\mathbf{r}_1(t) + \mathbf{r}_2(t))' &= \frac{d}{dt}\langle x_1(t) + x_2(t), y_1(t) + y_2(t), z_1(t) + z_2(t)\rangle \\
&= \left\langle (x_1(t) + x_2(t))', (y_1(t) + y_2(t))', (z_1(t) + z_2(t))'\right\rangle \\
&= \left\langle x_1'(t) + x_2'(t), y_1'(t) + y_2'(t), z_1'(t) + z_2'(t)\right\rangle \\
&= \left\langle x_1'(t), y_1'(t), z_1'(t)\right\rangle + \left\langle x_2'(t), y_2'(t), z_2'(t)\right\rangle = \mathbf{r}_1'(t) + \mathbf{r}_2'(t)
\end{aligned}$$

The Product Rule states that for any differentiable scalar-valued function $f(t)$ and differentiable vector-valued function $\mathbf{r}(t)$, it holds that:

$$\frac{d}{dt} f(t)\mathbf{r}(t) = f(t)\mathbf{r}'(t) + f'(t)\mathbf{r}(t)$$

To verify this rule, we denote $\mathbf{r}(t) = \langle x(t), y(t), z(t)\rangle$. Then,

$$\frac{d}{df} f(t)\mathbf{r}(t) = \frac{d}{dt}\langle f(t)x(t), f(t)y(t), f(t)z(t)\rangle$$

Applying the Product Rule for scalar functions for each component we get:

$$\begin{aligned}
\frac{d}{dt} f(t)\mathbf{r}(t) &= \left\langle f(t)x'(t) + f'(t)x(t), f(t)y'(t) + f'(t)y(t), f(t)z'(t) + f'(t)z(t)\right\rangle \\
&= \left\langle f(t)x'(t), f(t)y'(t), f(t)z'(t)\right\rangle + \left\langle f'(t)x(t), f'(t)y(t), f'(t)z(t)\right\rangle \\
&= f(t)\left\langle x'(t), y'(t), z'(t)\right\rangle + f'(t)\langle x(t), y(t), z(t)\rangle = f(t)\mathbf{r}'(t) + f'(t)\mathbf{r}(t)
\end{aligned}$$

70. Verify the Chain Rule for vector-valued functions.

SOLUTION Let $g(t)$ and $\mathbf{r}(t) = \langle x(t), y(t), z(t)\rangle$ be differentiable scalar and vector valued functions respectively. We must show that:

$$\frac{d}{dt}\mathbf{r}(g(t)) = g'(t)\mathbf{r}'(g(t)).$$

We have

$$\mathbf{r}(g(t)) = \langle x(g(t)), y(g(t)), z(g(t))\rangle$$

We differentiate the vector componentwise, using the Chain Rule for scalar functions. This gives:

$$\begin{aligned}
\frac{d}{dt}\mathbf{r}(g(t)) &= \left\langle \frac{d}{dt}(x(g(t))), \frac{d}{dt}(y(g(t))), \frac{d}{dt}(z(g(t)))\right\rangle = \left\langle g'(t)x'(g(t)), g'(t)y'(g(t)), g'(t)z'(g(t))\right\rangle \\
&= g'(t)\left\langle x'(g(t)), y'(g(t)), z'(g(t))\right\rangle = g'(t)\mathbf{r}'(g(t))
\end{aligned}$$

71. Verify the Product Rule for cross products [Eq. (5)].

SOLUTION Let $\mathbf{r}_1(t) = \langle a_1(t), a_2(t), a_3(t)\rangle$ and $\mathbf{r}_2(t) = \langle b_1(t), b_2(t), b_3(t)\rangle$. Then (we omit the independent variable t for simplicity):

$$\mathbf{r}_1(t) \times \mathbf{r}_2(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix} = (a_2b_3 - a_3b_2)\,\mathbf{i} - (a_1b_3 - a_3b_1)\,\mathbf{j} + (a_1b_2 - a_2b_1)\,\mathbf{k}$$

Differentiating this vector componentwise we get:

$$\begin{aligned}\frac{d}{dt}\mathbf{r}_1 \times \mathbf{r}_2 &= \left(a_2b_3' + a_2'b_3 - a_3b_2' - a_3'b_2\right)\mathbf{i} - \left(a_1b_3' + a_1'b_3 - a_3b_1' - a_3'b_1\right)\mathbf{j} + \left(a_1b_2' + a_1'b_2 - a_2b_1' - a_2'b_1\right)\mathbf{k} \\ &= \left(\left(a_2b_3' - a_3b_2'\right)\mathbf{i} - \left(a_1b_3' - a_3b_1'\right)\mathbf{j} + \left(a_1b_2' - a_2b_1'\right)\mathbf{k}\right) \\ &\quad + \left(\left(a_2'b_3 - a_3'b_2\right)\mathbf{i} - \left(a_1'b_3 - a_3'b_1\right)\mathbf{j} + \left(a_1'b_2 - a_2'b_1\right)\mathbf{k}\right)\end{aligned}$$

Notice that the vectors in each of the two brackets can be written as the following formal determinants:

$$\begin{aligned}\frac{d}{dt}\mathbf{r}_1 \times \mathbf{r}_2 &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ b_1' & b_2' & b_3' \end{vmatrix} + \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1' & a_2' & a_3' \\ b_1 & b_2 & b_3 \end{vmatrix} = \langle a_1, a_2, a_3\rangle \times \langle b_1', b_2', b_3'\rangle + \langle a_1', a_2', a_3'\rangle \times \langle b_1, b_2, b_3\rangle \\ &= \mathbf{r}_1 \times \mathbf{r}_2' + \mathbf{r}_1' \times \mathbf{r}_2\end{aligned}$$

72. Verify the linearity properties

$$\int c\mathbf{r}(t)\,dt = c\int \mathbf{r}(t)\,dt \qquad (c \text{ any constant})$$

$$\int \left(\mathbf{r}_1(t) + \mathbf{r}_2(t)\right)dt = \int \mathbf{r}_1(t)\,dt + \int \mathbf{r}_2(t)\,dt$$

SOLUTION We denote the components of the vectors by $\mathbf{r}(t) = \langle x(t), y(t), z(t)\rangle$; $\mathbf{r}_1(t) = \langle x_1(t), y_1(t), z_1(t)\rangle$; $\mathbf{r}_2(t) = \langle x_2(t), y_2(t), z_2(t)\rangle$. Using vector operations, componentwise integration and the linear properties for scalar functions, we obtain:

$$\begin{aligned}\int c\mathbf{r}(t)\,dt &= \int \langle cx(t), cy(t), cz(t)\rangle\,dt = \left\langle \int cx(t)\,dt, \int cy(t)\,dt, \int cz(t)\,dt\right\rangle \\ &= \left\langle c\int x(t)\,dt, c\int y(t)\,dt, c\int z(t)\,dt\right\rangle = c\left\langle \int x(t)\,dt, \int y(t)\,dt, \int z(t)\,dt\right\rangle \\ &= c\int \langle x(t), y(t), z(t)\rangle\,dt = c\int \mathbf{r}(t)\,dt\end{aligned}$$

Next we prove the second linear property:

$$\begin{aligned}\int (\mathbf{r}_1(t) + \mathbf{r}_2(t))\,dt &= \int \langle x_1(t) + x_2(t), y_1(t) + y_2(t), z_1(t) + z_2(t)\rangle\,dt \\ &= \left\langle \int (x_1(t) + x_2(t))\,dt, \int (y_1(t) + y_2(t))\,dt, \int (z_1(t) + z_2(t))\,dt\right\rangle \\ &= \left\langle \int x_1(t)\,dt + \int x_2(t)\,dt, \int y_1(t)\,dt + \int y_2(t)\,dt, \int z_1(t)\,dt + \int z_2(t)\,dt\right\rangle \\ &= \left\langle \int x_1(t)\,dt, \int y_1(t)\,dt, \int z_1(t)\,dt\right\rangle + \left\langle \int x_2(t)\,dt, \int y_2(t)\,dt, \int z_2(t)\,dt\right\rangle \\ &= \int \langle x_1(t), y_1(t), z_1(t)\rangle\,dt + \int \langle x_2(t), y_2(t), z_2(t)\rangle\,dt = \int \mathbf{r}_1(t)\,dt + \int \mathbf{r}_2(t)\,dt\end{aligned}$$

73. Prove the Substitution Rule (where $g(t)$ is a differentiable scalar function):

$$\int_a^b \mathbf{r}(g(t))g'(t)\,dt = \int_{g^{-1}(a)}^{g^{-1}(b)} \mathbf{r}(u)\,du$$

SOLUTION (Note that an early edition of the textbook had the integral limits as $g(a)$ and $g(b)$; they should actually be $g^{-1}(a)$ and $g^{-1}(b)$.) We denote the components of the vector-valued function by $\mathbf{r}(t)\,dt = \langle x(t), y(t), z(t)\rangle$. Using componentwise integration we have:

$$\int_a^b \mathbf{r}(t)\,dt = \left\langle \int_a^b x(t)\,dt, \int_a^b y(t)\,dt, \int_a^b z(t)\,dt \right\rangle$$

Write $\int_a^b x(t)\,dt$ as $\int_a^b x(s)\,ds$. Let $s = g(t)$, so $ds = g'(t)\,dt$. The substitution gives us $\int_{g^{-1}(a)}^{g^{-1}(b)} x(g(t))g'(t)\,dt$. A similar procedure for the other two integrals gives us:

$$\begin{aligned}\int_a^b \mathbf{r}(t)\,dt &= \left\langle \int_{g^{-1}(a)}^{g^{-1}(b)} x\left(g(t)\right) g'(t)\,dt, \int_{g^{-1}(a)}^{g^{-1}(b)} y\left(g(t)\right) g'(t)\,dt, \int_{g^{-1}(a)}^{g^{-1}(b)} z\left(g(t)\right) g'(t)\,dt \right\rangle \\ &= \int_{g^{-1}(a)}^{g^{-1}(b)} \left\langle x\left(g(t)\right) g'(t), y\left(g(t)\right) g'(t), z\left(g(t)\right) g'(t) \right\rangle dt \\ &= \int_{g^{-1}(a)}^{g^{-1}(b)} \left\langle x\left(g(t)\right), y\left(g(t)\right), z\left(g(t)\right) \right\rangle g'(t)\,dt = \int_{g^{-1}(a)}^{g^{-1}(b)} \mathbf{r}\left(g(t)\right) g'(t)\,dt\end{aligned}$$

74. Prove that if $\|\mathbf{r}(t)\| \le K$ for $t \in [a, b]$, then

$$\left\| \int_a^b \mathbf{r}(t)\,dt \right\| \le K(b-a)$$

SOLUTION Think of $\mathbf{r}(t)$ as a velocity vector. Then, $\int_a^b \mathbf{r}(t)\,dt$ gives the displacement vector from the location at time $t = a$ to the time $t = b$, and so $\left\| \int_a^b \mathbf{r}(t)\,dt \right\|$ gives the length of this displacement vector. But, since speed is $\|\mathbf{r}(t)\|$ which is less than or equal to K, then in the interval $a \le t \le b$, the object can move a total distance not more than $K(b-a)$. Thus, the length of the displacement vector is $\le K(b-a)$, which gives us $\left\| \int_a^b \mathbf{r}(t)\,dt \right\| \le K(b-a)$, as desired.

13.3 Arc Length and Speed (LT Section 14.3)

Preliminary Questions

1. At a given instant, a car on a roller coaster has velocity vector $\mathbf{r}' = \langle 25, -35, 10 \rangle$ (in miles per hour). What would the velocity vector be if the speed were doubled? What would it be if the car's direction were reversed but its speed remained unchanged?

SOLUTION The speed is doubled but the direction is unchanged, hence the new velocity vector has the form:

$$\lambda \mathbf{r}' = \lambda \langle 25, -35, 10 \rangle \ \text{ for } \lambda > 0$$

We use $\lambda = 2$, and so the new velocity vector is $\langle 50, -70, 20 \rangle$. If the direction is reversed but the speed is unchanged, the new velocity vector is:

$$-\mathbf{r}' = \langle -25, 35, -10 \rangle .$$

2. Two cars travel in the same direction along the same roller coaster (at different times). Which of the following statements about their velocity vectors at a given point P on the roller coaster is/are true?

(a) The velocity vectors are identical.

(b) The velocity vectors point in the same direction but may have different lengths.

(c) The velocity vectors may point in opposite directions.

SOLUTION

(a) The length of the velocity vector is the speed of the particle. Therefore, if the speeds of the cars are different the velocities are not identical. The statement is false.

(b) The velocity vector is tangent to the curve. Since the cars travel in the same direction, their velocity vectors point in the same direction. The statement is true.

(c) Since the cars travel in the same direction, the velocity vectors point in the same direction. The statement is false.

3. A mosquito flies along a parabola with speed $v(t) = t^2$. Let $s(t)$ be the total distance traveled at time t.

(a) How fast is $s(t)$ changing at $t = 2$?

(b) Is $s(t)$ equal to the mosquito's distance from the origin?

SOLUTION

(a) By the Arc Length Formula, we have:

$$s(t) = \int_{t_0}^{t} \|\mathbf{r}'(t)\|\, dt = \int_{t_0}^{t} v(t)\, dt$$

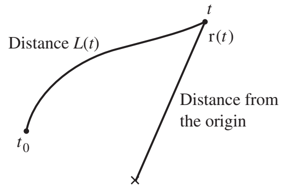
Therefore,

$$s'(t) = v(t)$$

To find the rate of change of $s(t)$ at $t = 2$ we compute the derivative of $s(t)$ at $t = 2$, that is,

$$s'(2) = v(2) = 2^2 = 4$$

(b) $s(t)$ is the distance along the path traveled by the mosquito. This distance is usually different from the mosquito's distance from the origin, which is the length of $\mathbf{r}(t)$.



4. What is the length of the path traced by $\mathbf{r}(t)$ for $4 \le t \le 10$ if $\mathbf{r}(t)$ is an arc length parametrization?

SOLUTION Since $\mathbf{r}(t)$ is an arc length parametrization, the length of the path for $4 \le t \le 10$ is equal to the length of the time interval $4 \le t \le 10$, which is 6.

Exercises

In Exercises 1–6, compute the length of the curve over the given interval.

1. $\mathbf{r}(t) = \langle 3t, 4t - 3, 6t + 1\rangle, \quad 0 \le t \le 3$

SOLUTION We have $x(t) = 3t$, $y(t) = 4t - 3$, $z(t) = 6t + 1$ hence

$$x'(t) = 3, \quad y'(t) = 4, \quad z'(t) = 6.$$

We use the Arc Length Formula to obtain:

$$s = \int_0^3 \|\mathbf{r}'(t)\|\, dt = \int_0^3 \sqrt{x'(t)^2 + y'(t)^2 + z'(t)^2}\, dt = \int_0^3 \sqrt{3^2 + 4^2 + 6^2}\, dt = 3\sqrt{61}$$

2. $\mathbf{r}(t) = 2t\mathbf{i} - 3t\mathbf{k}, \quad 11 \le t \le 15$

SOLUTION We have, $x(t) = 2t$, $y(t) = 0$, $z(t) = -3t$. Hence

$$x'(t) = 2, \quad y'(t) = 0, \quad z'(t) = -3$$

Using the Arc Length Formula we get:

$$\begin{aligned} s &= \int_{11}^{15} \|\mathbf{r}'(t)\|\, dt \\ &= \int_{11}^{15} \sqrt{x'(t)^2 + y'(t)^2 + z'(t)^2}\, dt \\ &= \int_{11}^{15} \sqrt{2^2 + 0^2 + (-3)^2}\, dt \\ &= \sqrt{13}(15 - 11) = 4\sqrt{13}. \end{aligned}$$

3. $\mathbf{r}(t) = \left\langle 2t, \ln t, t^2 \right\rangle, \quad 1 \le t \le 4$

SOLUTION The derivative of $\mathbf{r}(t)$ is $\mathbf{r}'(t) = \left\langle 2, \frac{1}{t}, 2t \right\rangle$. We use the Arc Length Formula to obtain:

$$\begin{aligned} s &= \int_1^4 \|\mathbf{r}'(t)\|\, dt = \int_1^4 \sqrt{2^2 + \left(\frac{1}{t}\right)^2 + (2t)^2}\, dt = \int_1^4 \sqrt{4t^2 + 4 + \frac{1}{t^2}}\, dt = \int_1^4 \sqrt{\left(2t + \frac{1}{t}\right)^2}\, dt \\ &= \int_1^4 \left(2t + \frac{1}{t}\right) dt = t^2 + \ln t \Big|_1^4 = (16 + \ln 4) - (1 + \ln 1) = 15 + \ln 4 \end{aligned}$$

4. $\mathbf{r}(t) = \left\langle 2t^2+1, 2t^2-1, t^3 \right\rangle, \quad 0 \le t \le 2$

SOLUTION The derivative of $\mathbf{r}(t)$ is $\mathbf{r}'(t) = \left\langle 4t, 4t, 3t^2 \right\rangle$. Using the Arc Length Formula we have:

$$s = \int_0^2 \|\mathbf{r}'(t)\|\,dt = \int_0^2 \sqrt{(4t)^2+(4t)^2+(3t^2)^2}\,dt = \int_0^2 \sqrt{32t^2+9t^4}\,dt = \int_0^2 t\sqrt{32+9t^2}\,dt$$

We compute the integral using the substitution $u = 32+9t^2$, $du = 18t\,dt$. This gives:

$$s = \int_{32}^{68} \sqrt{u}\frac{du}{18} = \frac{1}{18}\cdot\frac{2}{3}u^{3/2}\Big|_{32}^{68} = \frac{1}{27}\left(68^{3/2}-32^{3/2}\right) \approx 14.063$$

5. $\mathbf{r}(t) = \langle t\cos t, t\sin t, 3t \rangle, \quad 0 \le t \le 2\pi$

SOLUTION The derivative of $\mathbf{r}(t)$ is $\mathbf{r}'(t) = \langle \cos t - t\sin t, \sin t + t\cos t, 3\rangle$. The length of $\mathbf{r}'(t)$ is, thus,

$$\begin{aligned}\|\mathbf{r}'(t)\| &= \sqrt{(\cos t - t\sin t)^2 + (\sin t + t\cos t)^2 + 9}\\ &= \sqrt{\cos^2 t - 2t\cos t\sin t + t^2\sin^2 t + \sin^2 t + 2t\sin t\cos t + t^2\cos^2 t + 9}\\ &= \sqrt{\left(\cos^2 t + \sin^2 t\right) + t^2\left(\sin^2 t + \cos^2 t\right) + 9} = \sqrt{t^2+10}\end{aligned}$$

Using the Arc Length Formula and the integration formula given in Exercise 6, we obtain:

$$\begin{aligned}s &= \int_0^{2\pi} \|\mathbf{r}'(t)\|\,dt = \int_0^{2\pi} \sqrt{t^2+10}\,dt = \frac{1}{2}t\sqrt{t^2+10} + \frac{1}{2}\cdot 10\ln\left(t+\sqrt{t^2+10}\right)\Big|_0^{2\pi}\\ &= \pi\sqrt{4\pi^2+10} + 5\ln\left(2\pi+\sqrt{4\pi^2+10}\right) - 5\ln\sqrt{10} = \pi\sqrt{4\pi^2+10} + 5\ln\frac{2\pi+\sqrt{4\pi^2+10}}{\sqrt{10}} \approx 29.3\end{aligned}$$

6. $\mathbf{r}(t) = t\mathbf{i} + 2t\mathbf{j} + (t^2-3)\mathbf{k}, \quad 0 \le t \le 2$. Use the formula:

$$\int \sqrt{t^2+a^2}\,dt = \frac{1}{2}t\sqrt{t^2+a^2} + \frac{1}{2}a^2\ln\left(t+\sqrt{t^2+a^2}\right)$$

SOLUTION The derivative of $\mathbf{r}(t)$ is $\mathbf{r}'(t) = \mathbf{i} + 2\mathbf{j} + 2t\mathbf{k}$. Using the Arc Length Formula we get:

$$s = \int_0^2 \|\mathbf{r}'(t)\|\,dt = \int_0^2 \sqrt{1^2+(2)^2+(2t)^2}\,dt = \int_0^2 \sqrt{4t^2+5}\,dt$$

We substitute $u = 2t$, $du = 2\,dt$ and use the given integration formula. This gives:

$$\begin{aligned}s &= \frac{1}{2}\int_0^4 \sqrt{u^2+5}\,du = \frac{1}{4}u\sqrt{u^2+5} + \frac{1}{4}\cdot 5\ln\left(u+\sqrt{u^2+5}\right)\Big|_0^4\\ &= \frac{1}{4}\cdot 4\sqrt{4^2+5} + \frac{5}{4}\ln\left(4+\sqrt{4^2+5}\right) - \frac{5}{4}\ln\sqrt{5} = \sqrt{21} + \frac{5}{4}\ln\left(4+\sqrt{21}\right) - \frac{5}{4}\ln\sqrt{5}\\ &= \sqrt{21} + \frac{5}{4}\ln\frac{4+\sqrt{21}}{\sqrt{5}} \approx 6.26\end{aligned}$$

In Exercises 7 and 8, compute the arc length function $s(t) = \int_a^t \|\mathbf{r}'(u)\|\,du$ *for the given value of* a.

7. $\mathbf{r}(t) = \left\langle t^2, 2t^2, t^3 \right\rangle, \quad a = 0$

SOLUTION The derivative of $\mathbf{r}(t)$ is $\mathbf{r}'(t) = \left\langle 2t, 4t, 3t^2 \right\rangle$. Hence,

$$\|\mathbf{r}'(t)\| = \sqrt{(2t)^2+(4t)^2+(3t^2)^2} = \sqrt{4t^2+16t^2+9t^4} = t\sqrt{20+9t^2}$$

Hence,

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\,du = \int_0^t u\sqrt{20+9u^2}\,du$$

We compute the integral using the substitution $v = 20+9u^2$, $dv = 18u\,du$. This gives:

$$s(t) = \frac{1}{18}\int_{20}^{20+9t^2} v^{1/2}\,dv = \frac{1}{18}\cdot\frac{2}{3}v^{3/2}\Big|_{20}^{20+9t^2} = \frac{1}{27}\left((20+9t^2)^{3/2} - 20^{3/2}\right).$$

8. $\mathbf{r}(t) = \langle 4t^{1/2}, \ln t, 2t\rangle, \quad a = 1$

SOLUTION The derivative of $\mathbf{r}(t)$ is $\mathbf{r}'(t) = \left\langle 2t^{-1/2}, 1/t, 2\right\rangle$ Hence,

$$\|\mathbf{r}'(t)\| = \sqrt{(2t^{-1/2})^2 + (1/t)^2 + 2^2} = \sqrt{\frac{4}{t} + \frac{1}{t^2} + 4} = \sqrt{\frac{4t^2 + 4t + 1}{t^2}} = \sqrt{\frac{(2t+1)^2}{t^2}} = \frac{2t+1}{t} = 2 + \frac{1}{t}$$

Therefore,

$$s(t) = \int_1^t \|\mathbf{r}'(u)\|\, du = \int_1^t 2 + \frac{1}{u}\, du = 2u + \ln u\Big|_1^t = 2t + \ln t - (2 + \ln 1) = 2t + \ln t - 2$$

In Exercises 9–12, find the speed at the given value of t.

9. $\mathbf{r}(t) = \langle 2t+3, 4t-3, 5-t\rangle, \quad t = 4$

SOLUTION The speed is the magnitude of the derivative $\mathbf{r}'(t) = \langle 2, 4, -1\rangle$. That is,

$$v(t) = \|\mathbf{r}'(t)\| = \sqrt{2^2 + 4^2 + (-1)^2} = \sqrt{21} \approx 4.58$$

10. $\mathbf{r}(t) = \langle e^{t-3}, 12, 3t^{-1}\rangle, \quad t = 3$

SOLUTION The velocity vector is $\mathbf{r}'(t) = \langle e^{t-3}, 0, -3t^{-2}\rangle$ and at $t = 3$, $\mathbf{r}'(3) = \langle e^{3-3}, 0, -3\cdot 3^{-2}\rangle = \langle 1, 0, -\frac{1}{3}\rangle$. The speed is the magnitude of the velocity vector, that is,

$$v(3) = \|\mathbf{r}'(3)\| = \sqrt{1^2 + 0^2 + \left(-\frac{1}{3}\right)^2} = \sqrt{\frac{10}{9}} \approx 1.05$$

11. $\mathbf{r}(t) = \langle \sin 3t, \cos 4t, \cos 5t\rangle, \quad t = \frac{\pi}{2}$

SOLUTION The velocity vector is $\mathbf{r}'(t) = \langle 3\cos 3t, -4\sin 4t, -5\sin 5t\rangle$. At $t = \frac{\pi}{2}$ the velocity vector is $\mathbf{r}'\left(\frac{\pi}{2}\right) = \left\langle 3\cos\frac{3\pi}{2}, -4\sin 2\pi, -5\sin\frac{5\pi}{2}\right\rangle = \langle 0, 0, -5\rangle$. The speed is the magnitude of the velocity vector:

$$v\left(\frac{\pi}{2}\right) = \|\langle 0, 0, -5\rangle\| = 5.$$

12. $\mathbf{r}(t) = \langle \cosh t, \sinh t, t\rangle, \quad t = 0$

SOLUTION The velocity vector is $\mathbf{r}'(t) = \langle \sinh t, \cosh t, 1\rangle$. At $t = 0$ the velocity is $\mathbf{r}'(0) = \langle \sinh(0), \cosh(0), 1\rangle = \langle 0, 1, 1\rangle$, hence the speed is

$$v(0) = \|\mathbf{r}'(0)\| = \sqrt{0^2 + 1^2 + 1^2} = \sqrt{2}.$$

13. What is the velocity vector of a particle traveling to the right along the hyperbola $y = x^{-1}$ with constant speed 5 cm/s when the particle's location is $\left(2, \frac{1}{2}\right)$?

SOLUTION The position of the particle is given as $\mathbf{r}(t) = t^{-1}$. The magnitude of the velocity vector $\mathbf{r}'(t)$ is the speed of the particle. Hence,

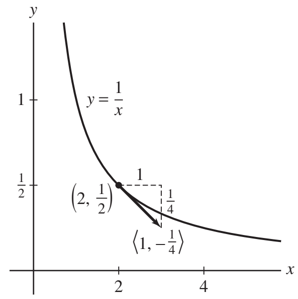
$$\|\mathbf{r}'(t)\| = 5 \tag{1}$$

The velocity vector points in the direction of motion, hence it is parallel to the tangent line to the curve $y = x^{-1}$ and points to the right. We find the slope of the tangent line at $x = 2$:

$$m = \frac{dy}{dx}\Big|_{x=2} = \frac{d}{dx}(x^{-1})\Big|_{x=2} = -x^{-2}\Big|_{x=2} = -\frac{1}{4}$$

We conclude that the vector $\left\langle 1, -\frac{1}{4}\right\rangle$ is a direction vector of the tangent line at $x = 2$, and for some $\lambda > 0$ we have at the given instance:

$$\mathbf{r}' = \lambda\left\langle 1, -\frac{1}{4}\right\rangle \tag{2}$$



To satisfy (1) we must have:

$$\|\mathbf{r}'\| = \lambda\sqrt{1^2 + \left(-\frac{1}{4}\right)^2} = \lambda\frac{\sqrt{17}}{4} = 5 \quad \Rightarrow \quad \lambda = \frac{20}{\sqrt{17}}$$

Substituting in (2) we obtain the following velocity vector at $\left(2, \frac{1}{2}\right)$:

$$\mathbf{r}' = \frac{20}{\sqrt{17}}\left\langle 1, -\frac{1}{4}\right\rangle = \left\langle \frac{20}{\sqrt{17}}, \frac{-5}{\sqrt{17}}\right\rangle$$

14. A bee with velocity vector $\mathbf{r}'(t)$ starts out at the origin at $t = 0$ and flies around for T seconds. Where is the bee located at time T if $\int_0^T \mathbf{r}'(u)\,du = \mathbf{0}$? What does the quantity $\int_0^T \|\mathbf{r}'(u)\|\,du$ represent?

SOLUTION By the Fundamental Theorem for vector-valued functions, $\int_0^T \mathbf{r}'(u)\,du = \mathbf{r}(T) - \mathbf{r}(0)$, hence by the given information $\mathbf{r}(T) = \mathbf{r}(0)$. It follows that at time T the bee is located at the starting point which is at the origin. The integral $\int_0^T \|\mathbf{r}'(u)\|\,du$ is the length of the path traveled by the bee in the time interval $0 \le t \le T$. Notice that there is a difference between the displacement and the actual length traveled.

15. Let

$$\mathbf{r}(t) = \left\langle R\cos\left(\frac{2\pi Nt}{h}\right), R\sin\left(\frac{2\pi Nt}{h}\right), t\right\rangle, \qquad 0 \le t \le h$$

(a) Show that $\mathbf{r}(t)$ parametrizes a helix of radius R and height h making N complete turns.

(b) Guess which of the two springs in Figure 5 uses more wire.

(c) Compute the lengths of the two springs and compare.

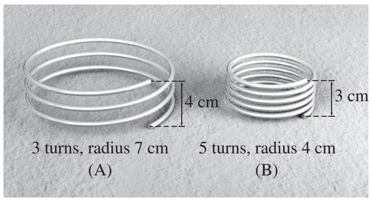


FIGURE 5 Which spring uses more wire?

SOLUTION We first verify that the projection $\mathbf{p}(t) = \left\langle R\cos\left(\frac{2\pi Nt}{h}\right), R\sin\left(\frac{2\pi Nt}{h}\right), 0\right\rangle$ onto the xy-plane describes a point moving around the circle of radius R. We have:

$$x(t)^2 + y(t)^2 = R^2\cos^2\left(\frac{2\pi Nt}{h}\right) + R^2\sin^2\left(\frac{2\pi Nt}{h}\right) = R^2\left(\cos^2\left(\frac{2\pi Nt}{h}\right) + \sin^2\left(\frac{2\pi Nt}{h}\right)\right) = R^2$$

This is the equation of the circle of radius R in the xy-plane. As t changes in the interval $0 \le t \le h$ the argument $\frac{2\pi Nt}{h}$ changes from 0 to $2\pi N$, that is, it covers N periods of the cos and sin functions. It follows that the projection onto the xy-plane describes a point moving around the circle of radius R, making N complete turns. The height of the helix is the maximum value of the z-component, which is $t = h$.

(a) The second wire seems to use more wire than the first one.

(b) Setting $R = 7$, $h = 4$ and $N = 3$ in the parametrization in Exercise 15 gives:

$$\mathbf{r}_1(t) = \left\langle 7\cos\frac{2\pi\cdot 3t}{4}, 7\sin\frac{2\pi\cdot 3t}{4}, t\right\rangle = \left\langle 7\cos\frac{3\pi t}{2}, 7\sin\frac{3\pi t}{2}, t\right\rangle, \quad 0 \le t \le 4$$

Setting $R = 4$, $h = 3$ and $N = 5$ in this parametrization we get:

$$\mathbf{r}_2(t) = \left\langle 4\cos\frac{2\pi\cdot 5t}{3}, 4\sin\frac{2\pi\cdot 5t}{3}, t\right\rangle = \left\langle 4\cos\frac{10\pi t}{3}, 4\sin\frac{10\pi t}{3}, t\right\rangle, \quad 0 \le t \le 3$$

We find the derivatives of the two vectors and their lengths:

$$\mathbf{r}_1'(t) = \left\langle -\frac{21\pi}{2}\sin\frac{3\pi t}{2}, \frac{21\pi}{2}\cos\frac{3\pi t}{2}, 1\right\rangle \quad\Rightarrow\quad \|\mathbf{r}_1'(t)\| = \sqrt{\frac{441\pi^2}{4}+1} = \frac{1}{2}\sqrt{441\pi^2+4}$$

$$\mathbf{r}_2'(t) = \left\langle -\frac{40\pi}{3}\sin\frac{10\pi t}{3}, \frac{40\pi}{3}\cos\frac{10\pi t}{3}, 1\right\rangle \quad\Rightarrow\quad \|\mathbf{r}_2'(t)\| = \sqrt{\frac{1600\pi^2}{9}+1} = \frac{1}{3}\sqrt{1600\pi^2+9}$$

Using the Arc Length Formula we obtain the following lengths:

$$s_1 = \int_0^4 \frac{1}{2}\sqrt{441\pi^2+4}\,dt = 2\sqrt{441\pi^2+4} \approx 132$$

$$s_2 = \int_0^3 \frac{1}{3}\sqrt{1600\pi^2+9}\,dt = \sqrt{1600\pi^2+9} \approx 125.7$$

We see that the first spring uses more wire than the second one.

16. Use Exercise 15 to find a general formula for the length of a helix of radius R and height h that makes N complete turns.

SOLUTION In Exercise 15 it is shown that the helix has the following parametrization:

$$\mathbf{r}(t) = \left\langle R\cos\frac{2\pi Nt}{h}, R\sin\frac{2\pi Nt}{h}, t\right\rangle; \quad 0 \le t \le h$$

We compute the derivative vector and its length:

$$\mathbf{r}'(t) = \left\langle -\frac{R\cdot 2\pi N}{h}\sin\frac{2\pi Nt}{h}, \frac{R\cdot 2\pi N}{h}\cos\frac{2\pi Nt}{h}, 1\right\rangle$$

$$\|\mathbf{r}'(t)\| = \sqrt{\left(\frac{R\cdot 2\pi N}{h}\sin\frac{2\pi Nt}{h}\right)^2 + \left(\frac{R\cdot 2\pi N}{h}\cos\frac{2\pi Nt}{h}\right)^2 + 1^2}$$

$$= \sqrt{\frac{4\pi^2N^2R^2}{h^2}\left(\sin^2\frac{2\pi Nt}{h} + \cos^2\frac{2\pi Nt}{h}\right) + 1} = \sqrt{\frac{4\pi^2N^2R^2}{h^2}+1} = \frac{1}{h}\sqrt{4\pi^2N^2R^2+h^2}$$

We now apply the Arc Length Formula to compute the length of the helix:

$$s = \int_0^h \|\mathbf{r}'(t)\|\,dt = \int_0^h \frac{1}{h}\sqrt{4\pi^2N^2R^2+h^2}\,dt = \frac{\sqrt{4\pi^2N^2R^2+h^2}}{h}\cdot h = \sqrt{4\pi^2N^2R^2+h^2}$$

17. The cycloid generated by the unit circle has parametrization

$$\mathbf{r}(t) = \langle t - \sin t, 1 - \cos t\rangle$$

(a) Find the value of t in $[0, 2\pi]$ where the speed is at a maximum.

(b) Show that one arch of the cycloid has length 8. Recall the identity $\sin^2(t/2) = (1-\cos t)/2$.

SOLUTION One arch of the cycloid is traced as $0 \le t \le 2\pi$. By the Arc Length Formula we have:

$$s = \int_0^{2\pi} \|\mathbf{r}'(t)\|\,dt \tag{1}$$

We compute the derivative and its length:

$$\mathbf{r}'(t) = \langle 1-\cos t, \sin t\rangle$$

$$\|\mathbf{r}'(t)\| = \sqrt{(1-\cos t)^2 + (\sin t)^2} = \sqrt{1 - 2\cos t + \cos^2 t + \sin^2 t}$$

$$= \sqrt{2-2\cos t} = \sqrt{2(1-\cos t)} = \sqrt{2\cdot 2\sin^2\frac{t}{2}} = 2\left|\sin\frac{t}{2}\right|.$$

For $0 \le t \le 2\pi$, we have $0 \le \frac{t}{2} \le \pi$, so $\sin \frac{t}{2} \ge 0$. Therefore we may omit the absolute value sign and write:

$$\|\mathbf{r}'(t)\| = 2\sin\frac{t}{2}$$

Substituting in (1) and computing the integral using the substitution $u = \frac{t}{2}$, $du = \frac{1}{2}\,dt$, gives:

$$s = \int_0^{2\pi} 2\sin\frac{t}{2}\,dt = \int_0^{\pi} 2\sin u \cdot (2\,du) = 4\int_0^{\pi} \sin u\,du$$
$$= 4(-\cos u)\Big|_0^{\pi} = 4\left(-\cos\pi - (-\cos 0)\right) = 4(1+1) = 8$$

The length of one arc of the cycloid is $s = 8$. The speed is given by the function:

$$v(t) = \|\mathbf{r}'(t)\| = 2\sin\frac{t}{2}, \quad 0 \le t \le \pi$$

To find the value of t in $[0, 2\pi]$ where the speed is at maximum, we first find the critical point in this interval:

$$v'(t) = 2 \cdot \frac{1}{2}\cos\frac{t}{2} = \cos\frac{t}{2}$$
$$\cos\frac{t}{2} = 0 \quad \Rightarrow \quad \frac{t}{2} = \frac{\pi}{2} \quad \Rightarrow \quad t = \pi$$

Since $v''(t) = -\frac{1}{2}\sin\frac{t}{2}$, we have $v''(\pi) = -\frac{1}{2}\sin\frac{\pi}{2} = -\frac{1}{2} < 0$, hence the speed $v(t)$ has a maximum value at $t = \pi$.

18. Which of the following is an arc length parametrization of a circle of radius 4 centered at the origin?

(a) $\mathbf{r}_1(t) = \langle 4\sin t, 4\cos t\rangle$

(b) $\mathbf{r}_2(t) = \langle 4\sin 4t, 4\cos 4t\rangle$

(c) $\mathbf{r}_3(t) = \left\langle 4\sin\frac{t}{4}, 4\cos\frac{t}{4}\right\rangle$

SOLUTION The arc length parametrization is defined by the condition $\|\mathbf{r}'(t)\| = 1$ for all t. We thus must check whether this condition is satisfied.

(a) The derivative vector is $\mathbf{r}_1'(t) = \langle 4\cos t, -4\sin t\rangle$. We compute the length of this vector:

$$\|\mathbf{r}_1'(t)\| = \sqrt{(4\cos t)^2 + (-4\sin t)^2} = \sqrt{16\left(\cos^2 t + \sin^2 t\right)} = \sqrt{16} = 4 \ne 1$$

We conclude that this parametrization is not the arc length parametrization of the circle.

(b) We compute the derivative vector and its length:

$$\mathbf{r}_2'(t) = \langle 16\cos 4t, -16\sin 4t\rangle$$
$$\|\mathbf{r}_2'(t)\| = \sqrt{(16\cos 4t)^2 + (-16\sin 4t)^2} = \sqrt{16^2\left(\cos^2 4t + \sin^2 4t\right)} = \sqrt{16^2 \cdot 1} = 16 \ne 1$$

Hence, this parametrization is not the arc length parametrization of the circle.

(c) We find the derivative vector and its length:

$$\mathbf{r}_3'(t) = \left\langle 4 \cdot \frac{1}{4}\cos\frac{t}{4}, -4 \cdot \frac{1}{4}\sin\frac{t}{4}\right\rangle = \left\langle \cos\frac{t}{4}, -\sin\frac{t}{4}\right\rangle$$
$$\|\mathbf{r}_3'(t)\| = \sqrt{\left(\cos\frac{t}{4}\right)^2 + \left(-\sin\frac{t}{4}\right)^2} = 1$$

Hence, this parametrization is the arc length parametrization of the circle.

19. Let $\mathbf{r}(t) = \langle 3t+1, 4t-5, 2t\rangle$.

(a) Evaluate the arc length integral $s(t) = \int_0^t \|\mathbf{r}'(u)\|\,du$.

(b) Find the inverse $g(s)$ of $s(t)$.

(c) Verify that $\mathbf{r}_1(s) = \mathbf{r}(g(s))$ is an arc length parametrization.

SOLUTION

(a) We differentiate $\mathbf{r}(t)$ componentwise and then compute the norm of the derivative vector. This gives:

$$\mathbf{r}'(t) = \langle 3, 4, 2\rangle$$
$$\|\mathbf{r}'(t)\| = \sqrt{3^2 + 4^2 + 2^2} = \sqrt{29}$$

We compute $s(t)$:

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\, du = \int_0^t \sqrt{29}\, du = \sqrt{29}\, u\Big|_0^t = \sqrt{29}t$$

(b) We find the inverse $g(s) = t(s)$ by solving $s = \sqrt{29}t$ for t. We obtain:

$$s = \sqrt{29}t \quad \Rightarrow \quad t = g(s) = \frac{s}{\sqrt{29}}$$

We obtain the following arc length parametrization:

$$\mathbf{r}_1(s) = \mathbf{r}\left(\frac{s}{\sqrt{29}}\right) = \left\langle \frac{3s}{\sqrt{29}} + 1, \frac{4s}{\sqrt{29}} - 5, \frac{2s}{\sqrt{29}} \right\rangle$$

To verify that $\mathbf{r}_1(s)$ is an arc length parametrization we must show that $\|\mathbf{r}_1'(s)\| = 1$. We compute $\mathbf{r}_1'(s)$:

$$\mathbf{r}_1'(s) = \frac{d}{ds}\left\langle \frac{3s}{\sqrt{29}} + 1, \frac{4s}{\sqrt{29}} - 5, \frac{2s}{\sqrt{29}} \right\rangle = \left\langle \frac{3}{\sqrt{29}}, \frac{4}{\sqrt{29}}, \frac{2}{\sqrt{29}} \right\rangle = \frac{1}{\sqrt{29}}\langle 3, 4, 2\rangle$$

Thus,

$$\|\mathbf{r}_1'(s)\| = \frac{1}{\sqrt{29}}\|\langle 3, 4, 2\rangle\| = \frac{1}{\sqrt{29}}\sqrt{3^2 + 4^2 + 2^2} = \frac{1}{\sqrt{29}} \cdot \sqrt{29} = 1$$

20. Find an arc length parametrization of the line $y = 4x + 9$.

SOLUTION First, let $\mathbf{r}(t) = \langle t, 4t + 9\rangle$. Then we know $\mathbf{r}'(t) = \langle 1, 4\rangle$ and $\|\mathbf{r}'(t)\| = \sqrt{17}$. We now compute $s(t)$:

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\, du = \int_0^t \sqrt{17}\, du = t\sqrt{17}$$

We find the inverse $g(s) = t(s)$ by solving $s = t\sqrt{17}$ for t:

$$s = t\sqrt{17}, \quad \Rightarrow \quad t = \frac{1}{\sqrt{17}}s$$

We obtain the following arc length parametrization:

$$\mathbf{r}_1(s) = \mathbf{r}\left(\frac{s}{\sqrt{17}}\right) = \left\langle \frac{s}{\sqrt{17}}, \frac{4s}{\sqrt{17}} + 9 \right\rangle$$

21. Let $\mathbf{r}(t) = \mathbf{w} + t\mathbf{v}$ be the parametrization of a line.

(a) Show that the arc length function $s(t) = \int_0^t \|\mathbf{r}'(u)\|\, du$ is given by $s(t) = t\|\mathbf{v}\|$. This shows that $\mathbf{r}(t)$ is an arc length parametrizaton if and only if $\mathbf{v}$ is a unit vector.

(b) Find an arc length parametrization of the line with $\mathbf{w} = \langle 1, 2, 3\rangle$ and $\mathbf{v} = \langle 3, 4, 5\rangle$.

SOLUTION

(a) Since $\mathbf{r}(t) = \mathbf{w} + t\mathbf{v}$, then $\mathbf{r}'(t) = \mathbf{v}$ and $\|\mathbf{r}'(t)\| = \|\mathbf{v}\|$. Then computing $s(t)$ we get:

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\, du = \int_0^t \|\mathbf{v}\|\, du = t\|\mathbf{v}\|$$

If we consider $s(t)$,

$$s(t) = t \text{ if and only if } \|\mathbf{v}\| = 1$$

(b) Since $\mathbf{v} = \langle 3, 4, 5\rangle$, then from part (a) we get:

$$s(t) = t\|\mathbf{v}\| = t\sqrt{3^2 + 4^2 + 5^2} = t\sqrt{50}, \quad \Rightarrow t = g(s) = \frac{s}{\sqrt{50}}$$

Therefore, since we are given $\mathbf{r}(t) = \mathbf{w} + t\mathbf{v}$, the arc length parametrization is:

$$\mathbf{r}_1(s) = \langle 1, 2, 3\rangle + \frac{s}{\sqrt{50}}\langle 3, 4, 5\rangle = \left\langle 1 + \frac{3s}{\sqrt{50}}, 2 + \frac{4s}{\sqrt{50}}, 3 + \frac{5s}{\sqrt{50}} \right\rangle$$

22. Find an arc length parametrization of the circle in the plane $z = 9$ with radius 4 and center $(1, 4, 9)$.

SOLUTION We start with the following parametrization of the circle:

$$\mathbf{r}(t) = \langle 1, 4, 9\rangle + 4\langle \cos t, \sin t, 0\rangle = \langle 1 + 4\cos t, 4 + 4\sin t, 9\rangle$$

We now follow two steps:

Step 1. Find the inverse of the arc length function. The arc length function is $s(t) = \int_0^t \|\mathbf{r}'(l)\|\, dl$. We compute $\mathbf{r}'(t)$ and its length:

$$\mathbf{r}(t) = \langle -4\sin t, 4\cos t, 0\rangle$$
$$\|\mathbf{r}'(t)\| = \sqrt{(-4\sin t)^2 + (4\cos t)^2 + 0^2} = \sqrt{16(\sin^2 t + \cos^2 t)} = \sqrt{16\cdot 1} = 4$$

Hence,

$$s(t) = \int_0^t 4\, dl = 4t$$

The inverse of $s = 4t$ is $t = g(s) = \frac{s}{4}$.

Step 2. Reparametrize the curve. The arc length parametrization is

$$\mathbf{r}_1(s) = \mathbf{r}\,(g(s)) = \mathbf{r}\left(\frac{s}{4}\right) = \left\langle 1 + 4\cos\frac{s}{4}, 4 + 4\sin\frac{s}{4}, 9\right\rangle$$

23. Find a path that traces the circle in the plane $y = 10$ with radius 4 and center $(2, 10, -3)$ with constant speed 8.

SOLUTION We start with the following parametrization of the circle:

$$\mathbf{r}(t) = \langle 2, 10, -3\rangle + 4\langle \cos t, 0, \sin t\rangle = \langle 2 + 4\cos t, 10, -3 + 4\sin t\rangle$$

We need to reparametrize the curve by making a substitution $t = g(s)$, so that the new parametrization $\mathbf{r}_1(s) = \mathbf{r}\,(g(s))$ satisfies $\|\mathbf{r}_1'(s)\| = 8$ for all s. We find $\mathbf{r}_1'(s)$ using the Chain Rule:

$$\mathbf{r}_1'(s) = \frac{d}{ds}\mathbf{r}\,(g(s)) = g'(s)\mathbf{r}'\,(g(s)) \qquad (1)$$

Next, we differentiate $\mathbf{r}(t)$ and then replace t by $g(s)$:

$$\mathbf{r}'(t) = \langle -4\sin t, 0, 4\cos t\rangle$$
$$\mathbf{r}'\,(g(s)) = \langle -4\sin g(s), 0, 4\cos g(s)\rangle$$

Substituting in (1) we get:

$$\mathbf{r}_1'(s) = g'(s)\langle -4\sin g(s), 0, 4\cos g(s)\rangle = -4g'(s)\langle \sin g(s), 0, -\cos g(s)\rangle$$

Hence,

$$\|\mathbf{r}_1'(s)\| = 4|g'(s)|\sqrt{(\sin g(s))^2 + (-\cos g(s))^2} = 4|g'(s)|$$

To satisfy $\|\mathbf{r}_1'(s)\| = 8$ for all s, we choose $g'(s) = 2$. We may take the antiderivative $g(s) = 2\cdot s$, and obtain the following parametrization:

$$\mathbf{r}_1(s) = \mathbf{r}\,(g(s)) = \mathbf{r}(2s) = \langle 2 + 4\cos(2s), 10, -3 + 4\sin(2s)\rangle\,.$$

This is a parametrization of the given circle, with constant speed 8.

24. Find an arc length parametrization of $\mathbf{r}(t) = \langle e^t \sin t, e^t \cos t, e^t\rangle$.

SOLUTION An arc length parametrization is $\mathbf{r}_1(s) = \mathbf{r}\,(g(s))$ where $t = g(s)$ is the inverse of the arc length function. We compute the arc length function:

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\, du \qquad (1)$$

Differentiating $\mathbf{r}(t)$ and computing the norm of $\mathbf{r}'(t)$ gives:

$$\mathbf{r}'(t) = \langle e^t \sin t + e^t \cos t, e^t \cos t - e^t \sin t, e^t\rangle = e^t\langle \sin t + \cos t, \cos t - \sin t, 1\rangle$$
$$\|\mathbf{r}'(t)\| = e^t\sqrt{(\sin t + \cos t)^2 + (\cos t - \sin t)^2 + 1^2}$$

$$= e^t\left(\sin^2 t + 2\sin t\cos t + \cos^2 t + \cos^2 t - 2\sin t\cos t + \sin^2 t + 1\right)^{1/2}$$

$$= e^t\sqrt{2(\sin^2 t + \cos^2 t) + 1} = e^t\sqrt{2\cdot 1 + 1} = \sqrt{3}\,e^t \tag{2}$$

Substituting (2) into (1) gives:

$$s(t) = \int_0^t \sqrt{3}\,e^u\,du = \sqrt{3}\,e^u\Big|_0^t = \sqrt{3}(e^t - e^0) = \sqrt{3}(e^t - 1)$$

We find the inverse function of $s(t)$ by solving $s = \sqrt{3}\left(e^t - 1\right)$ for t. We obtain:

$$s = \sqrt{3}(e^t - 1)$$

$$\frac{s}{\sqrt{3}} = e^t - 1$$

$$e^t = 1 + \frac{s}{\sqrt{3}} \quad\Rightarrow\quad t = g(s) = \ln\left(1 + \frac{s}{\sqrt{3}}\right)$$

An arc length parametrization for $\mathbf{r}_1(s) = \mathbf{r}\,(g(s))$ is:

$$\left\langle e^{\ln(1+s/(\sqrt{3}))}\sin\left(\ln\left(1+\frac{s}{\sqrt{3}}\right)\right), e^{\ln(1+s/(\sqrt{3}))}\cos\left(\ln\left(1+\frac{s}{\sqrt{3}}\right)\right), e^{\ln(1+s/(\sqrt{3}))}\right\rangle$$

$$= \left(1+\frac{s}{\sqrt{3}}\right)\left\langle \sin\left(\ln\left(1+\frac{s}{\sqrt{3}}\right)\right), \cos\left(\ln\left(1+\frac{s}{\sqrt{3}}\right)\right), 1\right\rangle$$

25. Find an arc length parametrization of $\mathbf{r}(t) = \left\langle t^2, t^3\right\rangle$.

SOLUTION We follow two steps.

Step 1. Find the inverse of the arc length function. The arc length function is the following function:

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\,du \tag{1}$$

In our case $\mathbf{r}'(t) = \left\langle 2t, 3t^2\right\rangle$ hence $\|\mathbf{r}'(t)\| = \sqrt{4t^2 + 9t^4} = \sqrt{4 + 9t^2}\,t$. We substitute in (1) and compute the resulting integral using the substitution $v = 4 + 9u^2$, $dv = 18u\,du$. This gives:

$$s(t) = \int_0^t \sqrt{4 + 9u^2}\,u\,du = \frac{1}{18}\int_4^{4+9t^2} v^{1/2}\,dv = \frac{1}{18}\cdot\frac{2}{3}v^{3/2}\Big|_4^{4+9t^2} = \frac{1}{27}\left((4+9t^2)^{3/2} - 4^{3/2}\right)$$

$$= \frac{1}{27}\left(\left(4 + 9t^2\right)^{3/2} - 8\right)$$

We find the inverse of $t = s(t)$ by solving for t in terms of s. This function is invertible for $t \ge 0$ and for $t \le 0$.

$$s = \frac{1}{27}\left((4+9t^2)^{3/2} - 8\right)$$

$$27s + 8 = (4 + 9t^2)^{3/2}$$

$$(27s + 8)^{2/3} - 4 = 9t^2$$

$$t^2 = \frac{1}{9}\left((27s+8)^{2/3} - 4\right) = \frac{1}{9}(27s+8)^{2/3} - \frac{4}{9}$$

$$t = \pm\frac{1}{3}\sqrt{(27s+8)^{2/3} - 4} \tag{2}$$

Step 2. Reparametrize the curve. The arc length parametrization is obtained by replacing t by (2) in $\mathbf{r}(t)$:

$$\mathbf{r}_1(s) = \left\langle \frac{1}{9}(27s+8)^{2/3} - \frac{4}{9}, \pm\frac{1}{27}\left((27s+8)^{2/3} - 4\right)^{3/2}\right\rangle$$

26. Find an arc length parametrization of the cycloid with parametrization $\mathbf{r}(t) = \langle t - \sin t, 1 - \cos t\rangle$.

SOLUTION

Step 1. Find the inverse of the arc length function. We are given $\mathbf{r}(t) = \langle t - \sin t, 1 - \cos t\rangle$, so then $\mathbf{r}'(t) = \langle 1 - \cos t, \sin t\rangle$ and

$$\|\mathbf{r}'(t)\| = \sqrt{(1 - \cos t)^2 + \sin^2 t} = \sqrt{1 - 2\cos t + \cos^2 t + \sin^2 t}$$

$$= \sqrt{2 - 2\cos t} = \sqrt{4\sin^2(t/2)} = 2\sin(t/2)$$

We then compute $s(t)$:

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\,du = \int_0^t 2\sin\frac{u}{2}\,du$$
$$= -4\cos\frac{u}{2}\Big|_0^t = -4\cos\frac{t}{2} + 4 = 4\left(1 - \cos\frac{t}{2}\right)$$

Then solve $s(t) = 4\left(1 - \cos\frac{t}{2}\right)$ for t:

$$s = 4\left(1 - \cos\frac{t}{2}\right) \quad \Rightarrow \frac{s}{4} = 1 - \cos\frac{t}{2} \quad \Rightarrow 1 - \frac{s}{4} = \cos\frac{t}{2} \quad \Rightarrow t = 2\arccos\left(1 - \frac{s}{4}\right)$$

Step 2. Reparametrize the curve using the t we just found. We will write this as $t = 2\arccos\left(\frac{4-s}{4}\right)$ and solving, let us first note that:

$$\sin t = 2\sin\frac{t}{2}\cos\frac{t}{2} = 2\left(\frac{\sqrt{8s - s^2}}{4}\right)\left(\frac{4-s}{4}\right) = \frac{(4-s)\sqrt{8s-s^2}}{8}$$
$$\cos t = 2\cos^2\frac{t}{2} - 1 = 2\left(\frac{4-s}{4}\right)^2 - 1$$

So then, rewriting

$$\mathbf{r}(t) = \langle t - \sin t, 1 - \cos t\rangle$$
$$\mathbf{r}_1(s) = \left\langle 2\arccos\left(\frac{4-s}{4}\right) - \frac{(4-s)\sqrt{8s-s^2}}{8}, 1 - \left(2\left(\frac{4-s}{4}\right)^2 - 1\right)\right\rangle$$
$$= \left\langle 2\arccos\left(\frac{4-s}{4}\right) - \frac{(4-s)\sqrt{8s-s^2}}{8}, 1 - \frac{1}{8}(4-s)^2 + 1\right\rangle$$
$$= \left\langle 2\arccos\left(\frac{4-s}{4}\right) - \frac{(4-s)\sqrt{8s-s^2}}{8}, 2 - \frac{1}{8}(4-s)^2\right\rangle$$

27. Find an arc length parametrization of the line $y = mx$ for an arbitrary slope m.

SOLUTION

Step 1. Find the inverse of the arc length function. We are given the line $y = mx$ and a parametrization of this line is $\mathbf{r}(t) = \langle t, mt\rangle$, thus $\mathbf{r}'(t) = \langle 1, m\rangle$ and

$$\|\mathbf{r}'(t)\| = \sqrt{1 + m^2}$$

We then compute $s(t)$:

$$s(t) = \int_0^t \sqrt{1+m^2}\,du = t\sqrt{1+m^2}$$

Solving $s = t\sqrt{1+m^2}$ for t we get:

$$t = \frac{s}{\sqrt{1+m^2}}$$

Step 2. Reparametrize the curve using the t we just found.

$$\mathbf{r}_1(s) = \left\langle \frac{s}{\sqrt{1+m^2}}, \frac{sm}{\sqrt{1+m^2}}\right\rangle$$

28. Express the arc length s of $y = x^3$ for $0 \le x \le 8$ as an integral in two ways, using the parametrizations $\mathbf{r}_1(t) = \langle t, t^3\rangle$ and $\mathbf{r}_2(t) = \langle t^3, t^9\rangle$. Do not evaluate the integrals, but use substitution to show that they yield the same result.

SOLUTION For $\mathbf{r}_1(t) = \langle t, t^3\rangle$ we have $\mathbf{r}_1'(t) = \langle 1, 3t^2\rangle$ hence $\|\mathbf{r}_1'(t)\| = \sqrt{1 + 9t^4}$. For $\mathbf{r}_2(t) = \langle t^3, t^9\rangle$ we have $\mathbf{r}_2'(t) = \langle 3t^2, 9t^8\rangle$ hence $\|\mathbf{r}_2'(t)\| = \sqrt{9t^4 + 81t^{16}}$. The length s may be computed using the two parametrizations by the following integrals (notice that in the second parametrization $0 \le t^3 \le 8$ hence $0 \le t \le 2$).

$$s = \int_0^8 \|\mathbf{r}_1'(t)\|\,dt = \int_0^8 \sqrt{1+9t^4}\,dt \tag{1}$$

$$s = \int_0^2 \|\mathbf{r}_2'(t)\|\,dt = \int_0^2 \sqrt{1+9t^{12}}\,3t^2\,dt \tag{2}$$

We use the substitution $u = t^3$, $du = 3t^2\,dt$ in the second integral to obtain:

$$\int_0^2 \sqrt{1+9t^{12}}\,3t^2\,dt = \int_0^8 \sqrt{1+9u^4}\,du$$

This integral is the same as the integral in (1), in accordance with the well known property: the arc length is independent of the parametrization we choose for the curve.

29. The curve known as the **Bernoulli spiral** (Figure 6) has parametrization $\mathbf{r}(t) = \langle e^t\cos 4t, e^t\sin 4t\rangle$.

(a) Evaluate $s(t) = \int_{-\infty}^{t} \|\mathbf{r}'(u)\|\,du$. It is convenient to take lower limit $-\infty$ because $\mathbf{r}(-\infty) = \langle 0, 0\rangle$.

(b) Use (a) to find an arc length parametrization of $\mathbf{r}(t)$.

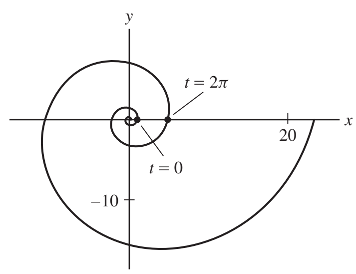

FIGURE 6 Bernoulli spiral.

SOLUTION

(a) We differentiate $\mathbf{r}(t)$ and compute the norm of the derivative vector. This gives:

$$\mathbf{r}'(t) = \langle e^t\cos 4t - 4e^t\sin 4t, e^t\sin 4t + 4e^t\cos 4t\rangle = e^t\,\langle \cos 4t - 4\sin 4t, \sin 4t + 4\cos 4t\rangle$$

$$\begin{aligned}\|\mathbf{r}'(t)\| &= e^t\sqrt{(\cos 4t - 4\sin 4t)^2 + (\sin 4t + 4\cos 4t)^2}\\ &= e^t\left(\cos^2 4t - 8\cos 4t\sin 4t + 16\sin^2 4t + \sin^2 4t + 8\sin 4t\cos 4t + 16\cos^2 4t\right)^{1/2}\\ &= e^t\sqrt{\cos^2 4t + \sin^2 4t + 16\left(\sin^2 4t + \cos^2 4t\right)} = e^t\sqrt{1+16\cdot 1} = \sqrt{17}e^t\end{aligned}$$

We now evaluate the improper integral:

$$\begin{aligned}s(t) &= \int_{-\infty}^{t} \|\mathbf{r}'(u)\|\,du = \lim_{R\to-\infty}\int_R^t \sqrt{17}e^u\,du = \lim_{R\to-\infty} \sqrt{17}e^u\Big|_R^t = \lim_{R\to-\infty}\sqrt{17}(e^t - e^R)\\ &= \sqrt{17}(e^t - 0) = \sqrt{17}e^t\end{aligned}$$

(b) An arc length parametrization of $\mathbf{r}(t)$ is $\mathbf{r}_1(s) = \mathbf{r}\,(g(s))$ where $t = g(s)$ is the inverse function of $s(t)$. We find $t = g(s)$ by solving $s = \sqrt{17}e^t$ for t:

$$s = \sqrt{17}e^t \quad\Rightarrow\quad e^t = \frac{s}{\sqrt{17}} \Rightarrow t = g(s) = \ln\frac{s}{\sqrt{17}}$$

An arc length parametrization of $\mathbf{r}(t)$ is:

$$\begin{aligned}\mathbf{r}_1(s) = \mathbf{r}\,(g(s)) &= \left\langle e^{\ln(s/(\sqrt{17}))}\cos\left(4\ln\frac{s}{\sqrt{17}}\right), e^{\ln(s/(\sqrt{17}))}\sin\left(4\ln\frac{s}{\sqrt{17}}\right)\right\rangle\\ &= \frac{s}{\sqrt{17}}\left\langle\cos\left(4\ln\frac{s}{\sqrt{17}}\right), \sin\left(4\ln\frac{s}{\sqrt{17}}\right)\right\rangle\end{aligned} \tag{1}$$

Further Insights and Challenges

30. Prove that the length of a curve as computed using the arc length integral does not depend on its parametrization. More precisely, let $\mathcal{C}$ be the curve traced by $\mathbf{r}(t)$ for $a \le t \le b$. Let $f(s)$ be a differentiable function such that $f'(s) > 0$ and that $f(c) = a$ and $f(d) = b$. Then $\mathbf{r}_1(s) = \mathbf{r}(f(s))$ parametrizes $\mathcal{C}$ for $c \le s \le d$. Verify that

$$\int_a^b \|\mathbf{r}'(t)\|\,dt = \int_c^d \|\mathbf{r}_1'(s)\|\,ds$$

SOLUTION By the Chain Rule we have:

$$\mathbf{r}_1'(t) = g'(t)\mathbf{r}'(g(t)) \quad \Rightarrow \quad \|\mathbf{r}_1'(t)\| = |g'(t)|\|\mathbf{r}'(g(t))\| = g'(t)\|\mathbf{r}'(g(t))\|$$

Hence,

$$\int_c^d \|\mathbf{r}_1'(t)\|\,dt = \int_c^d g'(t)\|\mathbf{r}'(g(t))\|dt \qquad (1)$$

We use the substitution $u = g(t)$, $du = g'(t)\,dt$. We are given that $g(c) = a$ and $g(d) = b$, hence the new limits of integration are $g(c) = a$ and $\varphi(d) = b$. Thus, by (1):

$$\int_c^d \|\mathbf{r}_1'(t)\|\,dt = \int_{g(c)}^{g(d)} \|\mathbf{r}'(u)\|\,du = \int_a^b \|\mathbf{r}'(u)\|\,du = \int_a^b \|\mathbf{r}'(t)\|\,dt$$

31. The unit circle with the point $(-1, 0)$ removed has parametrization (see Exercise 73 in Section 11.1)

$$\mathbf{r}(t) = \left\langle \frac{1-t^2}{1+t^2}, \frac{2t}{1+t^2} \right\rangle, \qquad -\infty < t < \infty$$

Use this parametrization to compute the length of the unit circle as an improper integral. *Hint:* The expression for $\|\mathbf{r}'(t)\|$ simplifies.

SOLUTION We have $x(t) = \frac{1-t^2}{1+t^2}$, $y(t) = \frac{2t}{1+t^2}$. Hence,

$$x^2(t) + y^2(t) = \left(\frac{1-t^2}{1+t^2}\right)^2 + \left(\frac{2t}{1+t^2}\right)^2 = \frac{1 - 2t^2 + t^4 + 4t^2}{\left(1+t^2\right)^2} = \frac{1 + 2t^2 + t^4}{\left(1+t^2\right)^2} = \frac{\left(1+t^2\right)^2}{\left(1+t^2\right)^2} = 1$$

It follows that the path $\mathbf{r}(t)$ lies on the unit circle. We now show that the entire circle is indeed parametrized by $\mathbf{r}(t)$ as t moves from $-\infty$ to ∞. First, note that $x'(t)$ can be written as $\left[-2t(1+t^2) - 2t(1-t^2)\right]/(1+t^2)^2$ which is $-4t/(1+t^2)^2$. So, for t negative, $x(t)$ is an increasing function, $y(t)$ is negative, and since $\lim_{t\to-\infty} x(t) = -1$ and $\lim_{t\to 0} x(t) = 1$, we conclude that $\mathbf{r}(t)$ does indeed parametrize the lower half of the circle for negative t. A similar argument proves that we get the upper half of the circle for positive t. We now compute $\mathbf{r}'(t)$ and its length:

$$\begin{aligned}
\mathbf{r}'(t) &= \left\langle \frac{-2t(1+t^2) - 2t(1-t^2)}{(1+t^2)^2}, \frac{2(1+t^2) - 2t\cdot 2t}{(1+t^2)^2} \right\rangle \\
&= \left\langle -\frac{4t}{(1+t^2)^2}, \frac{2-2t^2}{(1+t^2)^2} \right\rangle = \frac{1}{\left(1+t^2\right)^2}\left\langle -4t, 2(1-t^2)\right\rangle \\
\|\mathbf{r}'(t)\| &= \frac{1}{(1+t^2)^2}\sqrt{16t^2 + 4(1-t^2)^2} = \frac{2}{(1+t^2)^2}\sqrt{t^4 + 2t^2 + 1} \\
&= \frac{2}{(1+t^2)^2}\sqrt{(t^2+1)^2} = \frac{2(t^2+1)}{\left(1+t^2\right)^2} = \frac{2}{1+t^2}
\end{aligned}$$

That is,

$$\|\mathbf{r}'(t)\| = \frac{2}{1+t^2}$$

We now use the Arc Length Formula to compute the length of the circle:

$$s = \int_{-\infty}^{\infty} \|\mathbf{r}'(t)\|\,dt = 2\int_{-\infty}^{\infty} \frac{dt}{1+t^2} = 2\left(\lim_{R\to\infty} \tan^{-1} R - \lim_{R\to-\infty} \tan^{-1} R\right) = 2\left(\frac{\pi}{2} - \left(-\frac{\pi}{2}\right)\right) = 2\pi$$

32. The involute of a circle (Figure 7), traced by a point at the end of a thread unwinding from a circular spool of radius R, has parametrization (see Exercise 26 in Section 12.2)

$$\mathbf{r}(\theta) = \left\langle R(\cos\theta + \theta\sin\theta),\ R(\sin\theta - \theta\cos\theta)\right\rangle$$

Find an arc length parametrization of the involute.

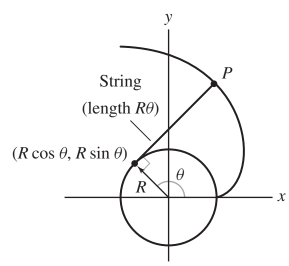

FIGURE 7 The involute of a circle.

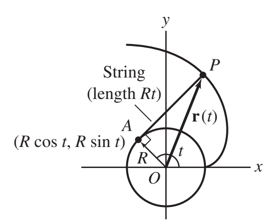
SOLUTION We have:

$$\mathbf{r}(t) = \overrightarrow{OP} = \overrightarrow{OA} + \overrightarrow{AP} \tag{1}$$

We find the vectors in the right-hand side of the equation.



A is a point on the circle of radius R. Hence:

$$\overrightarrow{OA} = \langle R\cos t,\ R\sin t\rangle = R\,\langle\cos t, \sin t\rangle$$

The vector $\overrightarrow{AP}$ is orthogonal to $\overrightarrow{OA}$, hence $\overrightarrow{OA}\cdot\overrightarrow{AP} = 0$. It has length Rt and points in the opposite direction to the tangent vector, hence:

$$\overrightarrow{AP} = R\,\langle t\sin t, -t\cos t\rangle$$

Substituting in (1) gives:

$$\mathbf{r}(t) = R\,\langle\cos t + t\sin t, \sin t - t\cos t\rangle \tag{2}$$

To find the arc length function we first must compute the derivative vector $\mathbf{r}'(t)$ and its length. We get:

$$\mathbf{r}'(t) = R\,\langle -\sin t + \sin t + t\cos t, \cos t - \cos t + t\sin t\rangle = Rt\,\langle\cos t, \sin t\rangle$$

$$\|\mathbf{r}'(t)\| = Rt\sqrt{\cos^2 t + \sin^2 t} = Rt$$

Using the Arc Length Formula we obtain:

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\,du = \int_0^t Ru\,du = \left.\frac{Ru^2}{2}\right|_0^t = \frac{Rt^2}{2}$$

That is:

$$s(t) = \frac{Rt^2}{2}$$

We now find the arc length parametrization. The inverse of the arc length function for $t \ge 0$ is $t = \sqrt{\frac{2s}{R}}$. Substituting in (2) we obtain the following arc length parametrization:

$$\mathbf{r}_1(s) = \mathbf{r}\left(\sqrt{\frac{2s}{R}}\right) = R\left\langle\cos\sqrt{\frac{2s}{R}} + \sqrt{\frac{2s}{R}}\sin\sqrt{\frac{2s}{R}}, \sin\sqrt{\frac{2s}{R}} - \sqrt{\frac{2s}{R}}\cos\sqrt{\frac{2s}{R}}\right\rangle$$

33. The curve $\mathbf{r}(t) = \langle t - \tanh t, \operatorname{sech} t\rangle$ is called a **tractrix** (see Exercise 92 in Section 11.1).

(a) Show that $s(t) = \int_0^t \|\mathbf{r}'(u)\|\, du$ is equal to $s(t) = \ln(\cosh t)$.

(b) Show that $t = g(s) = \ln(e^s + \sqrt{e^{2s} - 1})$ is an inverse of $s(t)$ and verify that

$$\mathbf{r}_1(s) = \left\langle \tanh^{-1}\left(\sqrt{1 - e^{-2s}}\right) - \sqrt{1 - e^{-2s}}, e^{-s}\right\rangle$$

is an arc length parametrization of the tractrix.

SOLUTION

(a) We compute the derivative vector and its length:

$$\mathbf{r}'(t) = \left\langle 1 - \operatorname{sech}^2 t, -\operatorname{sech} t \tanh t\right\rangle$$

$$\|\mathbf{r}'(t)\| = \sqrt{(1 - \operatorname{sech}^2 t) + \operatorname{sech}^2 t \tanh^2 t} = \sqrt{1 - 2\operatorname{sech}^2 t + \operatorname{sech}^4 t + \operatorname{sech}^2 t \tanh^2 t}$$
$$= \sqrt{-\operatorname{sech}^2 t(2 - \tanh^2 t) + 1 + \operatorname{sech}^4 t}$$

We use the identity $1 - \tanh^2 t = \operatorname{sech}^2 t$ to write:

$$\|\mathbf{r}'(t)\| = \sqrt{-\operatorname{sech}^2 t(1 + \operatorname{sech}^2 t) + 1 + \operatorname{sech}^4 t} = \sqrt{-\operatorname{sech}^2 t - \operatorname{sech}^4 t + 1 + \operatorname{sech}^4 t}$$
$$= \sqrt{1 - \operatorname{sech}^2 t} = \sqrt{\tanh^2 t} = |\tanh t|$$

For $t \ge 0$, $\tanh t \ge 0$ hence, $\|\mathbf{r}'(t)\| = \tanh t$. We now apply the Arc Length Formula to obtain:

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\, du = \int_0^t (\tanh u)\, du = \ln(\cosh u)\Big|_0^t = \ln(\cosh t) - \ln(\cosh 0)$$
$$= \ln(\cosh t) - \ln 1 = \ln(\cosh t)$$

That is:

$$s(t) = \ln(\cosh t)$$

(b) We show that the function $t = g(s) = \ln\left(e^s + \sqrt{e^{2s} - 1}\right)$ is an inverse of $s(t)$. First we note that $s'(t) = \tanh t$, hence $s'(t) > 0$ for $t > 0$, which implies that $s(t)$ has an inverse function for $t \ge 0$. Therefore, it suffices to verify that $g(s(t)) = t$. We have:

$$g(s(t)) = \ln\left(e^{\ln(\cosh t)} + \sqrt{e^{2\ln(\cosh t)} - 1}\right) = \ln\left(\cosh t + \sqrt{\cosh^2 t - 1}\right)$$

Since $\cosh^2 t - 1 = \sinh^2 t$ we obtain (for $t \ge 0$):

$$g\left(s(t)\right) = \ln\left(\cosh t + \sqrt{\sinh^2 t}\right) = \ln\left(\cosh t + \sinh t\right) = \ln\left(\frac{e^t + e^{-t}}{2} + \frac{e^t - e^{-t}}{2}\right) = \ln\left(e^t\right) = t$$

We thus proved that $t = g(s)$ is an inverse of $s(t)$. Therefore, the arc length parametrization is obtained by substituting $t = g(s)$ in $\mathbf{r}(t) = \langle t - \tanh t, \operatorname{sech} t\rangle$. We compute t, $\tanh t$ and $\operatorname{sech} t$ in terms of s. We have:

$$s = \ln\left(\cosh t\right) \quad \Rightarrow \quad e^s = \cosh t \quad \Rightarrow \quad \operatorname{sech} t = e^{-s}$$

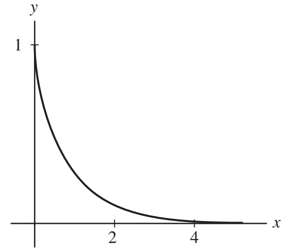
Also:

$$\tanh^2 t = 1 - \operatorname{sech}^2 t = 1 - e^{-2s} \quad \Rightarrow \quad \tanh t = \sqrt{1 - e^{-2s}} \quad \Rightarrow \quad t = \tanh^{-1}\sqrt{1 - e^{-2s}}$$

Substituting in $\mathbf{r}(t)$ gives:

$$\mathbf{r}_1(s) = \langle t - \tanh t, \operatorname{sech} t\rangle = \left\langle \tanh^{-1}\sqrt{1 - e^{-2s}} - \sqrt{1 - e^{-2s}}, e^{-s}\right\rangle$$

(c) The tractrix is shown in the following figure:



13.4 Curvature (LT Section 14.4)

Preliminary Questions

1. What is the unit tangent vector of a line with direction vector $\mathbf{v} = \langle 2, 1, -2 \rangle$?

SOLUTION A line with direction vector $\mathbf{v}$ has the parametrization:

$$\mathbf{r}(t) = \overrightarrow{OP_0} + t\mathbf{v}$$

hence, since $\overrightarrow{OP_0}$ and $\mathbf{v}$ are constant vectors, we have:

$$\mathbf{r}'(t) = \mathbf{v}$$

Therefore, since $\|\mathbf{v}\| = 3$, the unit tangent vector is:

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \langle 2/3, 1/3, -2/3 \rangle$$

2. What is the curvature of a circle of radius 4?

SOLUTION The curvature of a circle of radius R is $\frac{1}{R}$, hence the curvature of a circle of radius 4 is $\frac{1}{4}$.

3. Which has larger curvature, a circle of radius 2 or a circle of radius 4?

SOLUTION The curvature of a circle of radius 2 is $\frac{1}{2}$, and it is larger than the curvature of a circle of radius 4, which is $\frac{1}{4}$.

4. What is the curvature of $\mathbf{r}(t) = \langle 2 + 3t, 7t, 5 - t \rangle$?

SOLUTION $\mathbf{r}(t)$ parametrizes the line $\langle 2, 0, 5 \rangle + t \langle 3, 7, -1 \rangle$, and a line has zero curvature.

5. What is the curvature at a point where $\mathbf{T}'(s) = \langle 1, 2, 3 \rangle$ in an arc length parametrization $\mathbf{r}(s)$?

SOLUTION The curvature is given by the formula:

$$\kappa(t) = \frac{\|\mathbf{T}'(t)\|}{\|\mathbf{r}'(t)\|}$$

In an arc length parametrization, $\|\mathbf{r}'(t)\| = 1$ for all t, hence the curvature is $\kappa(t) = \|\mathbf{T}'(t)\|$. Using the given information we obtain the following curvature:

$$\kappa = \| \langle 1, 2, 3 \rangle \| = \sqrt{1^2 + 2^2 + 3^2} = \sqrt{14}$$

6. What is the radius of curvature of a circle of radius 4?

SOLUTION The definition of the osculating circle implies that the osculating circles at the points of a circle, is the circle itself. Therefore, the radius of curvature is the radius of the circle, that is, 4.

7. What is the radius of curvature at P if $\kappa_P = 9$?

SOLUTION The radius of curvature is the reciprocal of the curvature, hence the radius of curvature at P is:

$$R = \frac{1}{\kappa_P} = \frac{1}{9}$$

Exercises

In Exercises 1–6, calculate $\mathbf{r}'(t)$ and $\mathbf{T}(t)$, and evaluate $\mathbf{T}(1)$.

1. $\mathbf{r}(t) = \left\langle 4t^2, 9t \right\rangle$

SOLUTION We differentiate $\mathbf{r}(t)$ to obtain:

$$\mathbf{r}'(t) = \langle 8t, 9 \rangle \quad \Rightarrow \quad \|\mathbf{r}'(t)\| = \sqrt{(8t)^2 + 9^2} = \sqrt{64t^2 + 81}$$

We now find the unit tangent vector:

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \frac{1}{\sqrt{64t^2 + 81}} \langle 8t, 9 \rangle$$

For $t = 1$ we obtain the vector:

$$\mathbf{T}(t) = \frac{1}{\sqrt{64 + 81}} \langle 8, 9 \rangle = \left\langle \frac{8}{\sqrt{145}}, \frac{9}{\sqrt{145}} \right\rangle.$$

2. $\mathbf{r}(t) = \langle e^t, t^2 \rangle$

SOLUTION We find $\mathbf{r}'(t)$ and its length:

$$\mathbf{r}'(t) = \langle e^t, 2t \rangle \quad \Rightarrow \quad \|\mathbf{r}'(t)\| = \sqrt{\left(e^t\right)^2 + (2t)^2} = \sqrt{e^{2t} + 4t^2}$$

The unit tangent vector is, thus,

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \frac{1}{\sqrt{e^{2t} + 4t^2}} \langle e^t, 2t \rangle$$

For $t = 1$ we get:

$$\mathbf{T}(1) = \left\langle \frac{e}{\sqrt{e^2 + 4}}, \frac{2}{\sqrt{e^2 + 4}} \right\rangle.$$

3. $\mathbf{r}(t) = \langle 3 + 4t, 3 - 5t, 9t \rangle$

SOLUTION We first find the vector $\mathbf{r}'(t)$ and its length:

$$\mathbf{r}'(t) = \langle 4, -5, 9 \rangle \quad \Rightarrow \quad \|\mathbf{r}'(t)\| = \sqrt{4^2 + (-5)^2 + 9^2} = \sqrt{122}$$

The unit tangent vector is therefore:

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \frac{1}{\sqrt{122}} \langle 4, -5, 9 \rangle = \left\langle \frac{4}{\sqrt{122}}, -\frac{5}{\sqrt{122}}, \frac{9}{\sqrt{122}} \right\rangle$$

We see that the unit tangent vector is constant, since the curve is a straight line.

4. $\mathbf{r}(t) = \langle 1 + 2t, t^2, 3 - t^2 \rangle$

SOLUTION We compute the derivative vector and its length:

$$\mathbf{r}'(t) = \langle 2, 2t, -2t \rangle$$

$$\|\mathbf{r}'(t)\| = \sqrt{2^2 + (2t)^2 + (-2t)^2} = \sqrt{4 + 8t^2}$$

The unit tangent vector is thus:

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \frac{1}{2\sqrt{1 + 2t^2}} \langle 2, 2t, -2t \rangle = \frac{1}{\sqrt{1 + 2t^2}} \langle 1, t, -t \rangle$$

For $t = 1$ we have:

$$\mathbf{T}(1) = \frac{1}{\sqrt{1 + 2}} \langle 1, 1, -1 \rangle = \left\langle \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{3}} \right\rangle.$$

5. $\mathbf{r}(t) = \langle \cos \pi t, \sin \pi t, t \rangle$

SOLUTION We compute the derivative vector and its length:

$$\mathbf{r}'(t) = \langle -\pi \sin \pi t, \pi \cos \pi t, 1 \rangle$$

$$\|\mathbf{r}'(t)\| = \sqrt{(-\pi \sin \pi t)^2 + (\pi \cos \pi t)^2 + 1^2} = \sqrt{\pi^2(\sin^2 \pi t + \cos^2 \pi t) + 1} = \sqrt{\pi^2 + 1}$$

The unit tangent vector is thus:

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \frac{1}{\sqrt{\pi^2 + 1}} \langle -\pi \sin \pi t, \pi \cos \pi t, 1 \rangle$$

For $t = 1$ we get:

$$\mathbf{T}(1) = \frac{1}{\sqrt{\pi^2 + 1}} \langle -\pi \sin \pi, \pi \cos \pi, 1 \rangle = \frac{1}{\sqrt{\pi^2 + 1}} \langle 0, -\pi, 1 \rangle = \left\langle 0, -\frac{\pi}{\sqrt{\pi^2 + 1}}, \frac{1}{\sqrt{\pi^2 + 1}} \right\rangle.$$

6. $\mathbf{r}(t) = \langle e^t, e^{-t}, t^2 \rangle$

SOLUTION We compute the tangent vector and its length:

$$\mathbf{r}'(t) = \langle e^t, -e^{-t}, 2t \rangle$$

$$\|\mathbf{r}'(t)\| = \sqrt{(e^t)^2 + (-e^{-t})^2 + (2t)^2} = \sqrt{2e^{2t} + 4t^2}$$

The unit tangent vector is:

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \frac{1}{\sqrt{2e^{2t} + 4t^2}} \left\langle e^t, -e^{-t}, 2t \right\rangle$$

For $t = 1$ we get:

$$\mathbf{T}(1) = \frac{1}{\sqrt{2e^2 + 4}} \left\langle e, -\frac{1}{e}, 2 \right\rangle$$

In Exercises 7–10, use Eq. (3) to calculate the curvature function $\kappa(t)$.

7. $\mathbf{r}(t) = \left\langle 1, e^t, t \right\rangle$

SOLUTION We compute the first and the second derivatives of $\mathbf{r}(t)$:

$$\mathbf{r}'(t) = \left\langle 0, e^t, 1 \right\rangle, \quad \mathbf{r}''(t) = \left\langle 0, e^t, 0 \right\rangle.$$

Next, we find the cross product $\mathbf{r}'(t) \times \mathbf{r}''(t)$:

$$\mathbf{r}'(t) \times \mathbf{r}''(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & e^t & 1 \\ 0 & e^t & 0 \end{vmatrix} = \begin{vmatrix} e^t & 1 \\ e^t & 0 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 0 & 1 \\ 0 & 0 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 0 & e^t \\ 0 & e^t \end{vmatrix} \mathbf{k} = -e^t \mathbf{i} = \left\langle -e^t, 0, 0 \right\rangle$$

We need to find the lengths of the following vectors:

$$\|\mathbf{r}'(t) \times \mathbf{r}''(t)\| = \left| \left\langle -e^t, 0, 0 \right\rangle \right| = e^t$$

$$\|\mathbf{r}'(t)\| = \sqrt{0^2 + (e^t)^2 + 1^2} = \sqrt{1 + e^{2t}}$$

We now use the formula for curvature to calculate $\kappa(t)$:

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{e^t}{\left(\sqrt{1 + e^{2t}}\right)^3} = \frac{e^t}{\left(1 + e^{2t}\right)^{3/2}}$$

8. $\mathbf{r}(t) = \left\langle 4\cos t, t, 4\sin t \right\rangle$

SOLUTION By the formula for curvature we have:

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} \tag{1}$$

First we find $\mathbf{r}'(t)$ and $\mathbf{r}''(t)$:

$$\mathbf{r}'(t) = \langle -4\sin t, 1, 4\cos t \rangle$$

$$\mathbf{r}''(t) = \langle -4\cos t, 0, -4\sin t \rangle$$

We compute the cross product:

$$\begin{aligned} \mathbf{r}'(t) \times \mathbf{r}''(t) &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -4\sin t & 1 & 4\cos t \\ -4\cos t & 0 & -4\sin t \end{vmatrix} \\ &= \begin{vmatrix} 1 & 4\cos t \\ 0 & -4\sin t \end{vmatrix} \mathbf{i} - \begin{vmatrix} -4\sin t & 4\cos t \\ -4\cos t & -4\sin t \end{vmatrix} \mathbf{j} + \begin{vmatrix} -4\sin t & 1 \\ -4\cos t & 0 \end{vmatrix} \mathbf{k} \\ &= -4\sin t\,\mathbf{i} - \left(16\sin^2 t + 16\cos^2 t\right)\mathbf{j} + 4\cos t\,\mathbf{k} \\ &= -4\sin t\,\mathbf{i} - 16\mathbf{j} + 4\cos t\,\mathbf{k} = 4\,\langle -\sin t, -4, \cos t \rangle \end{aligned}$$

We compute the lengths of the following vectors:

$$\|\mathbf{r}'(t) \times \mathbf{r}''(t)\| = 4\sqrt{(-\sin t)^2 + (-4)^2 + \cos^2 t} = 4\sqrt{\sin^2 t + 16 + \cos^2 t} = 4\sqrt{17}\|\mathbf{r}'(t)\|$$

$$= \sqrt{(-4\sin t)^2 + 1^2 + (4\cos t)^2} = \sqrt{16\sin^2 t + 1 + 16\cos^2 t} = \sqrt{17}$$

Substituting in (1) gives the following curvature:

$$\kappa(t) = \frac{4\sqrt{17}}{\left(\sqrt{17}\right)^3} = \frac{4\sqrt{17}}{17\sqrt{17}} = \frac{4}{17}$$

We see that this curve has constant curvature.

9. $\mathbf{r}(t) = \langle 4t+1, 4t-3, 2t\rangle$

SOLUTION By Formula (3) we have:

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3}$$

We compute $\mathbf{r}'(t)$ and $\mathbf{r}''(t)$:

$$\mathbf{r}'(t) = \langle 4, 4, 2\rangle, \quad \mathbf{r}''(t) = \langle 0, 0, 0\rangle$$

Thus $\mathbf{r}'(t) \times \mathbf{r}''(t) = \langle 0, 0, 0\rangle$, $\|\mathbf{r}'(t) \times \mathbf{r}''(t)\| = 0$, and $\kappa(t) = 0$, as expected.

10. $\mathbf{r}(t) = \langle t^{-1}, 1, t\rangle$

SOLUTION By the formula for curvature we have:

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} \tag{1}$$

We now find $\mathbf{r}'(t)$, $\mathbf{r}''(t)$ and their cross product. This gives:

$$\mathbf{r}'(t) = \langle -t^{-2}, 0, 1\rangle, \quad \mathbf{r}''(t) = \langle 2t^{-3}, 0, 0\rangle$$
$$\mathbf{r}'(t) \times \mathbf{r}''(t) = \left(-t^{-2}\mathbf{i} + \mathbf{k}\right) \times 2t^{-3}\mathbf{i} = 2t^{-3}\mathbf{k} \times \mathbf{i} = 2t^{-3}\mathbf{j}$$

We compute the lengths of the vector in (1):

$$\|\mathbf{r}'(t) \times \mathbf{r}''(t)\| = \|2t^{-3}\mathbf{j}\| = 2|t^{-3}|$$
$$\|\mathbf{r}'(t)\| = \sqrt{\left((-t)^{-2}\right)^2 + 0^2 + 1^2} = \sqrt{t^{-4}+1}$$

Substituting in (1) we obtain the following curvature:

$$\kappa(t) = \frac{2|t|^{-3}}{\left(\sqrt{t^{-4}+1}\right)^3} = \frac{2|t|^{-3}}{\left(t^{-4}+1\right)^{3/2}}$$

We multiply through by $|t|^{4\cdot 3/2} = |t|^6$ to obtain:

$$\kappa(t) = \frac{2|t|^3}{\left(1+|t|^4\right)^{3/2}}$$

In Exercises 11–14, use Eq. (3) to evaluate the curvature at the given point.

11. $\mathbf{r}(t) = \langle 1/t, 1/t^2, t^2\rangle, \quad t = -1$

SOLUTION By the formula for curvature we know:

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3}$$

We now find $\mathbf{r}'(t)$, $\mathbf{r}''(t)$ and the cross product. These give:

$$\mathbf{r}'(t) = \left\langle -t^{-2}, -2t^{-3}, 2t\right\rangle, \quad \Rightarrow \mathbf{r}'(-1) = \langle -1, 2, -2\rangle$$
$$\mathbf{r}''(t) = \left\langle 2t^{-3}, 6t^{-4}, 2\right\rangle, \quad \Rightarrow \mathbf{r}''(-1) = \langle -2, 6, 2\rangle$$
$$\mathbf{r}'(-1) \times \mathbf{r}''(-1) = \langle 16, 6, -2\rangle$$

Now finding the norms, we get:

$$\|\mathbf{r}'(-1)\| = \sqrt{(-1)^2 + 2^2 + (-2)^2} = 3$$
$$\|\mathbf{r}'(-1) \times \mathbf{r}''(-1)\| = \sqrt{16^2 + 6^2 + (-2)^2} = \sqrt{296} = 2\sqrt{74}$$

Therefore,

$$\kappa(-1) = \frac{\|\mathbf{r}'(-1) \times \mathbf{r}''(-1)\|}{\|\mathbf{r}'(-1)\|^3} = \frac{2\sqrt{74}}{3^3} = \frac{2\sqrt{74}}{27}$$

12. $\mathbf{r}(t) = \left\langle 3-t, e^{t-4}, 8t-t^2 \right\rangle, \quad t = 4$

SOLUTION By the formula for curvature we know:

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3}$$

We now find $\mathbf{r}'(t)$, $\mathbf{r}''(t)$ and the cross product. These give:

$$\begin{aligned} \mathbf{r}'(t) &= \left\langle -1, e^{t-4}, 8-2t \right\rangle \quad \Rightarrow \mathbf{r}'(4) = \langle -1, 1, 0 \rangle \\ \mathbf{r}''(t) &= \left\langle 0, e^{t-4}, -2 \right\rangle \quad \Rightarrow \mathbf{r}''(4) = \langle 0, 1, -2 \rangle \\ \mathbf{r}'(4) \times \mathbf{r}''(4) &= \langle -2, -2, -1 \rangle \end{aligned}$$

Now finding norms we get:

$$\|\mathbf{r}'(4)\| = \sqrt{(-1)^2 + 1^2 + 0^2} = \sqrt{2}$$

$$\|\mathbf{r}'(4) \times \mathbf{r}''(4)\| = \sqrt{(-2)^2 + (-2)^2 + (-1)^2} = 3$$

Therefore,

$$\kappa(4) = \frac{\|\mathbf{r}'(4) \times \mathbf{r}''(4)\|}{\|\mathbf{r}'(4)\|^3} = \frac{3}{(\sqrt{2})^3} = \frac{3}{2^{3/2}}$$

13. $\mathbf{r}(t) = \left\langle \cos t, \sin t, t^2 \right\rangle, \quad t = \frac{\pi}{2}$

SOLUTION By the formula for curvature we know:

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3}$$

We now find $\mathbf{r}'(t)$, $\mathbf{r}''(t)$ and the cross product. These give:

$$\begin{aligned} \mathbf{r}'(t) &= \langle -\sin t, \cos t, 2t \rangle \quad \Rightarrow \mathbf{r}'(\pi/2) = \langle -1, 0, \pi \rangle \\ \mathbf{r}''(t) &= \langle -\cos t, -\sin t, 2 \rangle \quad \Rightarrow \mathbf{r}''(\pi/2) = \langle 0, -1, 2 \rangle \\ \mathbf{r}'(\pi/2) \times \mathbf{r}''(\pi/2) &= \langle \pi, 2, 1 \rangle \end{aligned}$$

Now finding norms we get:

$$\|\mathbf{r}'(\pi/2)\| = \sqrt{(-1)^2 + 0^2 + \pi^2} = \sqrt{1+\pi^2}$$

$$\|\mathbf{r}'(\pi/2) \times \mathbf{r}''(\pi/2)\| = \sqrt{\pi^2 + (-1)^2 + 2^2} = \sqrt{\pi^2 + 5}$$

Therefore,

$$\kappa(\pi/2) = \frac{\|\mathbf{r}'(\pi/2) \times \mathbf{r}''(\pi/2)\|}{\|\mathbf{r}'(\pi/2)\|^3} = \frac{\sqrt{\pi^2+5}}{(\sqrt{1+\pi^2})^3} = \frac{\sqrt{\pi^2+5}}{(1+\pi^2)^{3/2}} \approx 0.108$$

14. $\mathbf{r}(t) = \left\langle \cosh t, \sinh t, t \right\rangle, \quad t = 0$

SOLUTION We compute the values needed to use the formula for curvature:

$$\mathbf{r}'(t) = \langle \sinh t, \cosh t, 1 \rangle, \quad \mathbf{r}''(t) = \langle \cosh t, \sinh t, 0 \rangle$$

$$\begin{aligned} \mathbf{r}'(t) \times \mathbf{r}''(t) &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \sinh t & \cosh t & 1 \\ \cosh t & \sinh t & 0 \end{vmatrix} = \begin{vmatrix} \cosh t & 1 \\ \sinh t & 0 \end{vmatrix} \mathbf{i} - \begin{vmatrix} \sinh t & 1 \\ \cosh t & 0 \end{vmatrix} \mathbf{j} + \begin{vmatrix} \sinh t & \cosh t \\ \cosh t & \sinh t \end{vmatrix} \mathbf{k} \\ &= -\sinh t\,\mathbf{i} + \cosh t\,\mathbf{j} + \left(\sinh^2 t - \cosh^2 t\right)\mathbf{k} = -\sinh t\,\mathbf{i} + \cosh t\,\mathbf{j} - \mathbf{k} \end{aligned}$$

We find the lengths of the following vectors:

$$\|\mathbf{r}'(t) \times \mathbf{r}''(t)\| = \sqrt{(-\sinh t)^2 + (\cosh t)^2 + (-1)^2} = \sqrt{\sinh^2 t + \cosh^2 t + 1}$$

$$= \sqrt{\cosh^2 t - 1 + \cosh^2 t + 1} = \sqrt{2\cosh^2 t} = \sqrt{2}\cosh t$$

$$\|\mathbf{r}'(t)\| = \sqrt{\sinh^2 t + \cosh^2 t + 1^2} = \sqrt{\sinh^2 t + 1 + \sinh^2 t + 1} = \sqrt{2 + 2\sinh^2 t} = \sqrt{2}\cosh t$$

Substituting in the formula for the curvature we get:

$$\kappa(t) = \frac{\sqrt{2}\cosh t}{\left(\sqrt{2}\cosh t\right)^3} = \frac{1}{2\cosh^2 t}$$

and

$$\kappa(0) = \frac{1}{2(1)^2} = \frac{1}{2}$$

In Exercises 15–18, find the curvature of the plane curve at the point indicated.

15. $y = e^t, \quad t = 3$

SOLUTION We use the curvature of a graph in the plane:

$$\kappa(t) = \frac{|f''(t)|}{\left(1 + f'(t)^2\right)^{3/2}}$$

In our case $f(t) = e^t$, hence $f'(t) = f''(t) = e^t$ and we obtain:

$$\kappa(t) = \frac{e^t}{\left(1 + e^{2t}\right)^{3/2}} \quad \Rightarrow \quad \kappa(3) = \frac{e^3}{\left(1 + e^6\right)^{3/2}} \approx 0.0025$$

16. $y = \cos x, \quad x = 0$

SOLUTION We have $f(x) = \cos x$, hence $f'(x) = -\sin x$ and $f''(x) = -\cos x$. By the curvature of a graph in the plane we have:

$$\kappa(x) = \frac{|f''(x)|}{(1 + f'(x)^2)^{3/2}} = \frac{|-\cos x|}{(1 + (-\sin x)^2)^{3/2}} = \frac{|\cos x|}{(1 + \sin^2 x)^{3/2}}$$

At $x = 0$ we obtain the following curvature:

$$\kappa(0) = \frac{\cos 0}{(1 + \sin^2 0)^{3/2}} = 1$$

17. $y = t^4, \quad t = 2$

SOLUTION By the curvature of a graph in the plane, we have:

$$\kappa(t) = \frac{|f''(t)|}{\left(1 + f'(t)^2\right)^{3/2}}$$

In this case $f(t) = t^4$, $f'(t) = 4t^3$, $f''(t) = 12t^2$. Hence,

$$\kappa(t) = \frac{12t^2}{\left(1 + \left(4t^3\right)^2\right)^{3/2}} = \frac{12t^2}{\left(1 + 16t^6\right)^{3/2}}$$

At $t = 2$ we obtain the following curvature:

$$\kappa(2) = \frac{12 \cdot 2^2}{(1 + 16 \cdot 2^6)^{3/2}} = \frac{48}{(1025)^{3/2}} \approx 0.0015.$$

18. $y = t^n, \quad t = 1$

SOLUTION In this case $f(t) = t^n$, hence $f'(t) = nt^{n-1}$ and $f''(t) = n\,(n-1)\,t^{n-2}$. Using the curvature of a graph in the plane we get:

$$\kappa(t) = \frac{|f''(t)|}{\left(1 + f'(t)^2\right)^{3/2}} = \frac{|n(n-1)t^{n-2}|}{\left(1 + n^2 t^{2(n-1)}\right)^{3/2}} = \frac{n\,(n-1)\,|t|^{n-2}}{\left(1 + n^2 t^{2(n-1)}\right)^{3/2}}$$

At the point $t = 1$ we have the following curvature:

$$\kappa(1) = \frac{n(n-1)\cdot 1}{\left(1+n^2\cdot 1\right)^{3/2}} = \frac{n(n-1)}{\left(n^2+1\right)^{3/2}}$$

19. Find the curvature of $\mathbf{r}(t) = \langle 2\sin t, \cos 3t, t\rangle$ at $t = \frac{\pi}{3}$ and $t = \frac{\pi}{2}$ (Figure 16).

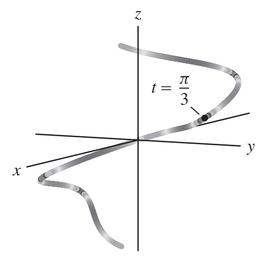


FIGURE 16 The curve $\mathbf{r}(t) = \langle 2\sin t, \cos 3t, t\rangle$.

SOLUTION By the formula for curvature we have:

$$\kappa(t) = \frac{\|\mathbf{r}'(t)\times\mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} \tag{1}$$

We compute the first and second derivatives:

$$\mathbf{r}'(t) = \langle 2\cos t, -3\sin 3t, 1\rangle, \quad \mathbf{r}''(t) = \langle -2\sin t, -9\cos 3t, 0\rangle$$

At the points $t = \frac{\pi}{3}$ and $t = \frac{\pi}{2}$ we have:

$$\mathbf{r}'\left(\frac{\pi}{3}\right) = \left\langle 2\cos\frac{\pi}{3}, -3\sin\frac{3\pi}{3}, 1\right\rangle = \left\langle 2\cos\frac{\pi}{3}, -3\sin\pi, 1\right\rangle = \langle 1, 0, 1\rangle$$

$$\mathbf{r}''\left(\frac{\pi}{3}\right) = \left\langle -2\sin\frac{\pi}{3}, -9\cos\frac{3\pi}{3}, 0\right\rangle = \left\langle -\sqrt{3}, 9, 0\right\rangle$$

$$\mathbf{r}'\left(\frac{\pi}{2}\right) = \left\langle 2\cos\frac{\pi}{2}, -3\sin\frac{3\pi}{2}, 1\right\rangle = \langle 0, 3, 1\rangle$$

$$\mathbf{r}''\left(\frac{\pi}{2}\right) = \left\langle -2\sin\frac{\pi}{2}, -9\cos\frac{3\pi}{2}, 0\right\rangle = \langle -2, 0, 0\rangle$$

We compute the cross products required to use (1):

$$\mathbf{r}'\left(\frac{\pi}{3}\right)\times\mathbf{r}''\left(\frac{\pi}{3}\right) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 1 \\ -\sqrt{3} & 9 & 0 \end{vmatrix} = \begin{vmatrix} 0 & 1 \\ 9 & 0 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 1 \\ -\sqrt{3} & 0 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 0 \\ -\sqrt{3} & 9 \end{vmatrix}\mathbf{k} = -9\mathbf{i} - \sqrt{3}\mathbf{j} + 9\mathbf{k}$$

$$\mathbf{r}'\left(\frac{\pi}{2}\right)\times\mathbf{r}''\left(\frac{\pi}{2}\right) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 3 & 1 \\ -2 & 0 & 0 \end{vmatrix} = \begin{vmatrix} 3 & 1 \\ 0 & 0 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 0 & 1 \\ -2 & 0 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 0 & 3 \\ -2 & 0 \end{vmatrix}\mathbf{k} = -2\mathbf{j} + 6\mathbf{k}$$

Hence,

$$\left\|\mathbf{r}'\left(\frac{\pi}{3}\right)\times\mathbf{r}''\left(\frac{\pi}{3}\right)\right\| = \sqrt{(-9)^2 + \left(-\sqrt{3}\right)^2 + 9^2} = \sqrt{165}$$

$$\left\|\mathbf{r}'\left(\frac{\pi}{3}\right)\right\| = \sqrt{1^2+0^2+1^2} = \sqrt{2}$$

At $t = \frac{\pi}{2}$ we have:

$$\left\|\mathbf{r}'\left(\frac{\pi}{2}\right)\times\mathbf{r}''\left(\frac{\pi}{2}\right)\right\| = \sqrt{(-2)^2+6^2} = \sqrt{40} = 2\sqrt{10}$$

$$\left\|\mathbf{r}'\left(\frac{\pi}{2}\right)\right\| = \sqrt{0^2+3^2+1^2} = \sqrt{10}$$

Substituting the values for $t = \frac{\pi}{3}$ and $t = \frac{\pi}{2}$ in (1) we obtain the following curvatures:

$$\kappa\left(\frac{\pi}{3}\right) = \frac{\sqrt{165}}{\left(\sqrt{2}\right)^3} = \frac{\sqrt{165}}{2\sqrt{2}} \approx 4.54$$

$$\kappa\left(\frac{\pi}{2}\right) = \frac{2\sqrt{10}}{\left(\sqrt{10}\right)^3} = \frac{2\sqrt{10}}{10\sqrt{10}} = 0.2$$

20. $\boxed{\text{GU}}$ Find the curvature function $\kappa(x)$ for $y = \sin x$. Use a computer algebra system to plot $\kappa(x)$ for $0 \le x \le 2\pi$. Prove that the curvature takes its maximum at $x = \frac{\pi}{2}$ and $\frac{3\pi}{2}$. *Hint:* As a shortcut to finding the max, observe that the maximum of the numerator and the minimum of the denominator of $\kappa(x)$ occur at the same points.

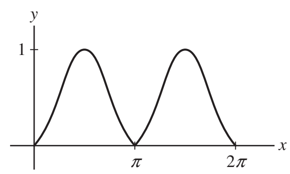
SOLUTION The curvature function is the following function:

$$\kappa(x) = \frac{|f''(x)|}{\left(1 + f'(x)^2\right)^{3/2}} \tag{1}$$

In our case $f(x) = \sin x$, hence $f'(x) = \cos x$ and $f''(x) = -\sin x$. Substituting in (1) gives:

$$\kappa(x) = \frac{|\sin x|}{\left(1 + \cos^2 x\right)^{3/2}}$$

The graph of $\kappa(x)$ for $0 \le x \le \pi$ is shown in the following figure:



To find the points where $\kappa(x)$ takes its maximum on the interval $0 \le x \le 2\pi$, we notice that $\kappa(x)$ and $\kappa^2(x)$ take maximum values at the same points, hence we may maximize $\kappa^2(x)$. Moreover, since $\kappa^2(x) \ge 0$ and $\kappa^2(0) = \kappa^2(2\pi) = 0$, we may maximize the function in the open interval $0 < x < 2\pi$. We find the stationary points of

$$g(x) = \kappa^2(x) = \frac{\sin^2 x}{(1 + \cos^2 x)^3}$$

on $0 < x < 2\pi$:

$$g'(x) = \frac{2\sin x \cos x\left(1 + \cos^2 x\right)^3 - \sin^2 x \cdot 3\left(1 + \cos^2 x\right)^2 \cdot 2\cos x\,(-\sin x)}{\left(1 + \cos^2 x\right)^6} = 0$$

Using $2\sin x \cos x = \sin 2x$ we get:

$$\left(1 + \cos^2 x\right)^2 \sin 2x\left(1 + \cos^2 x + 3\sin^2 x\right) = 0$$

Since $1 + \cos^2 x \ne 0$ and $\sin^2 x = 1 - \cos^2 x$ we get:

$$\sin 2x\left(4 - 2\cos^2 x\right) = 0$$

We know that $0 \le \cos^2 x \le 1$, hence $4 - 2\cos^2 x \ne 0$. Therefore:

$$\sin 2x = 0 \quad \Rightarrow \quad 2x = \pi\kappa \quad \Rightarrow \quad x = \frac{\pi}{2}\kappa, \quad \kappa = 0, \pm 1, \ldots$$

The solutions in the interval $(0, 2\pi)$ are:

$$x_1 = \frac{\pi}{2}, \quad x_2 = \pi, \quad x_3 = \frac{3\pi}{2}.$$

Now, $x_2 = \pi$ is a minimum point since $g(\pi) = 0$. We compute $g\left(\frac{\pi}{2}\right)$ and $g\left(\frac{3\pi}{2}\right)$:

$$g\left(\frac{\pi}{2}\right) = \frac{\sin^2 \frac{\pi}{2}}{\left(1 + \cos^2 \frac{\pi}{2}\right)^{3/2}} = 1$$

$$g\left(\frac{3\pi}{2}\right) = \frac{\sin^2 \frac{3\pi}{2}}{\left(1 + \cos^2 \frac{3\pi}{2}\right)^{3/2}} = 1$$

Since $g(x) \le 1$ it follows that $x_1 = \frac{\pi}{2}$ and $x_2 = \frac{3\pi}{2}$ are the points where $g(x) = \kappa^2(x)$ (hence also the curvature $\kappa(x)$) takes its maximum value.

21. Show that the tractrix $\mathbf{r}(t) = \langle t - \tanh t, \operatorname{sech} t\rangle$ has the curvature function $\kappa(t) = \operatorname{sech} t$.

SOLUTION Writing $\mathbf{r}(t) = \langle x(t), y(t)\rangle$, we have $x(t) = t - \tanh t$ and $y(t) = \operatorname{sech} t$. We compute the first and second derivatives of these functions. We use $\tanh^2 t = 1 - \operatorname{sech}^2 t$ to obtain:

$$\begin{aligned}
x'(t) &= 1 - \operatorname{sech}^2 t = \tanh^2 t \\
x''(t) &= -2 \operatorname{sech} t\,(-\operatorname{sech} t \tanh t) = 2\operatorname{sech}^2 t \tanh t \\
y'(t) &= -\operatorname{sech} t \tanh t \\
y''(t) &= -\left(-\operatorname{sech} t \tanh^2 t + \operatorname{sech}^3 t\right) = \operatorname{sech} t\left(\tanh^2 t - \operatorname{sech}^2 t\right) = \operatorname{sech} t\left(1 - 2\operatorname{sech}^2 t\right)
\end{aligned}$$

We compute the cross product $\|\mathbf{r}' \times \mathbf{r}''\|$:

$$\begin{aligned}
x'(t)y''(t) - x''(t)y'(t) &= \tanh^2 t \operatorname{sech} t(1 - 2\operatorname{sech}^2 t) + 2\operatorname{sech}^3 t \tanh^2 t \\
&= \tanh^2 t\left[\operatorname{sech} t - 2\operatorname{sech}^3 t + 2\operatorname{sech}^3 t\right] = \tanh^2 t \operatorname{sech} t
\end{aligned}$$

We compute the length of $\mathbf{r}'$:

$$x'(t)^2 + y'(t)^2 = \tanh^4 t + \operatorname{sech}^2 t \tanh^2 t = \tanh^2 t(\tanh^2 t + \operatorname{sech}^2 t) = \tanh^2 t$$

Hence

$$\|\mathbf{r}'\|^3 = \left(\tanh^2 t\right)^{3/2} = \tanh^3 t$$

Substituting, we obtain

$$\kappa(t) = \frac{|\operatorname{sech} t \tanh^2 t|}{\tanh^3 t} = \frac{\operatorname{sech} t \tanh^2 t}{\tanh^3 t} = \frac{\operatorname{sech} t}{\tanh t}$$

22. Show that curvature at an inflection point of a plane curve $y = f(x)$ is zero.

SOLUTION The curvature of the graph $y = f(x)$ in the plane is the following function:

$$\kappa(x) = \frac{|f''(x)|}{\left(1 + f'(x)^2\right)^{3/2}} \tag{1}$$

At an inflection point the second derivative changes its sign. Therefore, if f'' is continuous at the inflection point, it is zero at this point, hence by (1) the curvature at this point is zero.

23. Find the value of α such that the curvature of $y = e^{\alpha x}$ at $x = 0$ is as large as possible.

SOLUTION Using the curvature of a graph in the plane we have:

$$\kappa(x) = \frac{|y''(x)|}{\left(1 + y'(x)^2\right)^{3/2}} \tag{1}$$

In our case $y'(x) = \alpha e^{\alpha x}$, $y''(x) = \alpha^2 e^{\alpha x}$. Substituting in (1) we obtain

$$\kappa(x) = \frac{\alpha^2 e^{\alpha x}}{\left(1 + \alpha^2 e^{2\alpha x}\right)^{3/2}}$$

The curvature at the origin is thus

$$\kappa(0) = \frac{\alpha^2 e^{\alpha \cdot 0}}{\left(1 + \alpha^2 e^{2\alpha \cdot 0}\right)^{3/2}} = \frac{\alpha^2}{\left(1 + \alpha^2\right)^{3/2}}$$

Since $\kappa(0)$ and $\kappa^2(0)$ have their maximum values at the same values of α, we may maximize the function:

$$g(\alpha) = \kappa^2(0) = \frac{\alpha^4}{(1 + \alpha^2)^3}$$

We find the stationary points:

$$g'(\alpha) = \frac{4\alpha^3(1 + \alpha^2)^3 - \alpha^4(3)(1 + \alpha^2)^2 2\alpha}{(1 + \alpha^2)^6} = \frac{2\alpha^3(1 + \alpha^2)^2(2 - \alpha^2)}{(1 + \alpha^2)^6} = 0$$

The stationary points are the solutions of the following equation:

$$2\alpha^3(1+\alpha^2)^2(2-\alpha^2)=0$$

$$\alpha^3 = 0 \quad \text{or} \quad 2-\alpha^2=0$$
$$\alpha = 0 \qquad\qquad \alpha = \pm\sqrt{2}$$

Since $g(\alpha) \geq 0$ and $g(0)=0$, $\alpha = 0$ is a minimum point. Also, $g'(\alpha)$ is positive immediately to the left of $\sqrt{2}$ and negative to the right. Hence, $\alpha = \sqrt{2}$ is a maximum point. Since $g(\alpha)$ is an even function, $\alpha = -\sqrt{2}$ is a maximum point as well. Conclusion: $\kappa(x)$ takes its maximum value at the origin when $\alpha = \pm\sqrt{2}$.

24. Find the point of maximum curvature on $y = e^x$.

SOLUTION We substitute $y'(x) = y''(x) = e^x$ in the curvature of a graph in the plane, to obtain the following curvature:

$$\kappa(x) = \frac{|y''(x)|}{\left(1+y'(x)^2\right)^{3/2}} = \frac{e^x}{(1+e^{2x})^{3/2}}$$

The functions $\kappa(x)$ and $g(x) = \kappa^2(x) = \frac{e^{2x}}{(1+e^{2x})^3}$ take maximum values at the same points, hence we may maximize the function $g(x)$. We find the stationary points of $g(x)$:

$$g'(x) = \frac{2e^{2x}(1+e^{2x})^3 - e^{2x}\cdot 3(1+e^{2x})^2\cdot 2e^{2x}}{(1+e^{2x})^6} = \frac{2(1+e^{2x})^2 e^{2x}(1-2e^{2x})}{(1+e^{2x})^6} = 0 \tag{1}$$

We obtain the following equation:

$$(1+e^{2x})^2 e^{2x}(1-2e^{2x}) = 0$$

Since $(1+e^{2x})^2 e^{2x} > 0$ for all x, we get:

$$1-2e^{2x} = 0 \quad\Rightarrow\quad e^{2x} = \frac{1}{2} \quad\Rightarrow\quad 2x = \ln\frac{1}{2} \quad\Rightarrow\quad x = \ln\sqrt{\frac{1}{2}}$$

If $x < \ln\sqrt{\frac{1}{2}}$, then since $1-2e^{2x}$ is decreasing we have:

$$1-2e^{2x} > 1-2e^{2\ln\sqrt{1/2}} = 1-2e^{\ln(1/2)} = 1-1 = 0$$

Likewise, if $x > \ln\sqrt{\frac{1}{2}}$ then:

$$1-2e^{2x} < 1-2e^{2\ln\sqrt{1/2}} = 1-2e^{\ln(1/2)} = 1-2\cdot\frac{1}{2} = 0$$

It follows by (1) that $g'(x) > 0$ left of $x = \ln\sqrt{\frac{1}{2}}$ and $g'(x) < 0$ right of this point. Therefore, $x = \ln\sqrt{\frac{1}{2}} \approx -0.347$ is the point where $g(x)$ (hence also $\kappa(x)$) takes its maximum value.

25. Show that the curvature function of the parametrization $\mathbf{r}(t) = \langle a\cos t, b\sin t\rangle$ of the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$ is

$$\kappa(t) = \frac{ab}{(b^2\cos^2 t + a^2\sin^2 t)^{3/2}} \tag{9}$$

SOLUTION The curvature is the following function:

$$\kappa(t) = \frac{\|\mathbf{r}'(t)\times\mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} \tag{1}$$

We compute the derivatives and their cross product:

$$\mathbf{r}'(t) = \langle -a\sin t, b\cos t\rangle, \ \mathbf{r}''(t) = \langle -a\cos t, -b\sin t\rangle$$
$$\mathbf{r}'(t)\times\mathbf{r}''(t) = (-a\sin t\mathbf{i} + b\cos t\mathbf{j})\times(-a\cos t\mathbf{i} - b\sin t\mathbf{j})$$
$$= ab\sin^2 t\mathbf{k} + ab\cos^2 t\mathbf{k} = ab\left(\sin^2 t + \cos^2 t\right)\mathbf{k} = ab\mathbf{k}$$

Thus,

$$\|\mathbf{r}'(t)\times\mathbf{r}''(t)\| = \|ab\mathbf{k}\| = ab$$

$$\|\mathbf{r}'(t)\| = \sqrt{(-a\sin t)^2 + (b\cos t)^2} = \sqrt{a^2\sin^2 t + b^2\cos^2 t}$$

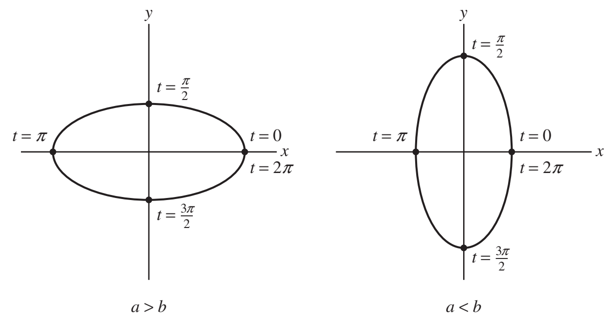
Substituting in (1) we obtain the following curvature:

$$\kappa(t) = \frac{ab}{\left(\sqrt{a^2\sin^2 t + b^2\cos^2 t}\right)^3} = \frac{ab}{\left(a^2\sin^2 t + b^2\cos^2 t\right)^{3/2}}$$

26. Use a sketch to predict where the points of minimal and maximal curvature occur on an ellipse. Then use Eq. (9) to confirm or refute your prediction.

SOLUTION As suggested by the graphs, for $a > b$ the maximal curvature seems to occur at the points $t = 0, \pi$ and the minimal curvature at $t = \frac{\pi}{2}, \frac{3\pi}{2}$, and vice versa for $a < b$.

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$$



In Exercise 25 we showed that the curvature of the ellipse $\mathbf{r}(t) = \langle a\cos t, b\sin t\rangle$ is:

$$\kappa(t) = \frac{ab}{\left(b^2\cos^2 t + a^2\sin^2 t\right)^{3/2}} \tag{1}$$

$\kappa(t)$ has minimal (maximal) value, where the denominator has maximal (minimal) value. Since the function $y = x^{3/2}$ is increasing, the minimal and maximal values of the denominator in (1) occur at the points where $g(t) = b^2\cos^2 t + a^2\sin^2 t$ has minimal and maximal values respectively. We find these points. We first find the critical points of $g(t)$:

$$g'(t) = b^2 \cdot 2\cos t(-\sin t) + a^2 \cdot 2\sin t\cos t = 2\sin t\cos t(a^2 - b^2) = (a^2 - b^2)\sin 2t$$

The critical points are the solutions of $g'(t) = 0$ in the interval $0 \le t \le 2\pi$. That is:

$$(a^2 - b^2)\sin 2t = 0$$

If $a = b$ then the ellipse is a circle, hence it has a constant curvature. For $a \ne b$ we have:

$$\sin 2t = 0 \quad \Rightarrow \quad 2t = \pi\kappa \quad \Rightarrow \quad t = \frac{\pi}{2}\kappa, \quad \kappa = 0, \pm 1, \ldots$$

The solutions in the interval $0 \le t \le 2\pi$ are

$$t_1 = 0, \quad t_2 = \frac{\pi}{2}, \quad t_3 = \pi, \quad t_4 = \frac{3\pi}{2}, \quad t_5 = 2\pi$$

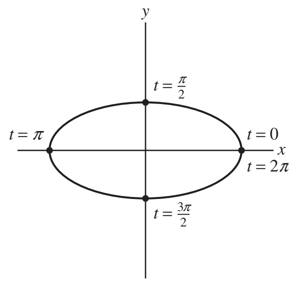
We compute the second derivative and substitute the stationary points:

$$\begin{aligned}
g''(t) &= 2(a^2 - b^2)\cdot\cos 2t \\
g''(0) &= 2(a^2 - b^2)\cdot\cos 0 = 2(a^2 - b^2) \\
g''\left(\frac{\pi}{2}\right) &= 2(a^2 - b^2)\cdot\cos\pi = 2(b^2 - a^2) \\
g''(\pi) &= 2(a^2 - b^2)\cdot\cos 2\pi = 2\left(a^2 - b^2\right) \\
g''\left(\frac{3\pi}{2}\right) &= 2(a^2 - b^2)\cdot\cos 3\pi = 2(b^2 - a^2) \\
g''(2\pi) &= 2(a^2 - b^2)\cdot\cos 4\pi = 2(a^2 - b^2)
\end{aligned}$$

We summarize the conclusions in the following table:

a > b

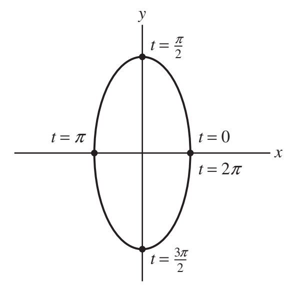
t	$g(t)$	$\kappa(t)$
0	min	max
$\frac{\pi}{2}$	max	min
π	min	max
$\frac{3\pi}{2}$	max	min
2π	min	max



$a > b$

a < b

t	$g(t)$	$\kappa(t)$
0	max	min
$\frac{\pi}{2}$	min	max
π	max	min
$\frac{3\pi}{2}$	min	max
2π	max	min



$a < b$

27. In the notation of Exercise 25, assume that $a \geq b$. Show that $b/a^2 \leq \kappa(t) \leq a/b^2$ for all t.

SOLUTION In Exercise 25 we showed that the curvature of the ellipse $\mathbf{r}(t) = \langle a\cos t, b\sin t\rangle$ is the following function:

$$\kappa(t) = \frac{ab}{\left(b^2\cos^2 t + a^2\sin^2 t\right)^{3/2}}$$

Since $a \geq b > 0$ the quotient becomes greater if we replace a by b in the denominator, and it becomes smaller if we replace b by a in the denominator. We use the identity $\cos^2 t + \sin^2 t = 1$ to obtain:

$$\frac{ab}{\left(a^2\cos^2 t + a^2\sin^2 t\right)^{3/2}} \leq \kappa(t) \leq \frac{ab}{\left(b^2\cos^2 t + b^2\sin^2 t\right)^{3/2}}$$

$$\frac{ab}{\left(a^2\left(\cos^2 t + \sin^2 t\right)\right)^{3/2}} \leq \kappa(t) \leq \frac{ab}{\left(b^2\left(\cos^2 t + \sin^2 t\right)\right)^{3/2}}$$

$$\frac{ab}{a^3} = \frac{ab}{(a^2)^{3/2}} \leq \kappa(t) \leq \frac{ab}{(b^2)^{3/2}} = \frac{ab}{b^3}$$

$$\frac{b}{a^2} \leq \kappa(t) \leq \frac{a}{b^2}$$

28. Use Eq. (3) to prove that for a plane curve $\mathbf{r}(t) = \langle x(t), y(t)\rangle$,

$$\kappa(t) = \frac{|x'(t)y''(t) - x''(t)y'(t)|}{\left(x'(t)^2 + y'(t)^2\right)^{3/2}} \qquad \boxed{10}$$

SOLUTION By the formula for curvature we have

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} \tag{1}$$

We compute the cross product of $\mathbf{r}'(t) = \left\langle x'(t), y'(t)\right\rangle$ and $\mathbf{r}''(t) = \left\langle x''(t), y''(t)\right\rangle$. Actually, since the cross product is only defined for three-dimensional vectors, we will think of these two vectors as follows: $\mathbf{r}'(t) = x'(t)\mathbf{i} + y'(t)\mathbf{j}$ and $\mathbf{r}''(t) = x''(t)\mathbf{i} + y''(t)\mathbf{j}$. Thus, the cross product is:

$$\mathbf{r}'(t) \times \mathbf{r}''(t) = \left(x'(t)\mathbf{i} + y'(t)\mathbf{j}\right) \times \left(x''(t)\mathbf{i} + y''(t)\mathbf{j}\right) = x'(t)y''(t)\mathbf{i} \times \mathbf{j} + y'(t)x''(t)\mathbf{j} \times \mathbf{i}$$

$$= x'(t)y''(t)\mathbf{k} - y'(t)x''(t)\mathbf{k} = \left(x'(t)y''(t) - y'(t)x''(t)\right)\mathbf{k}$$

We compute the lengths of the following vectors:

$$\|\mathbf{r}'(t) \times \mathbf{r}''(t)\| = \|\left(x'(t)y''(t) - y'(t)x''(t)\right)\mathbf{k}\| = |x'(t)y''(t) - y'(t)x''(t)|$$

$$\|\mathbf{r}'(t)\| = \|\langle x'(t), y'(t)\rangle\| = \sqrt{x'(t)^2 + y'(t)^2}$$

Substituting in (1) we get:

$$\kappa(t) = \frac{|x'(t)y''(t) - y'(t)x''(t)|}{\left(x'(t)^2 + y'(t)^2\right)^{3/2}}$$

In Exercises 29–32, use Eq. (10) to compute the curvature at the given point.

29. $\langle t^2, t^3\rangle, \quad t = 2$

SOLUTION For the given parametrization, $x(t) = t^2$, $y(t) = t^3$, hence

$$x'(t) = 2t$$
$$x''(t) = 2$$
$$y'(t) = 3t^2$$
$$y''(t) = 6t$$

At the point $t = 2$ we have

$$x'(2) = 4, \quad x''(2) = 2, \quad y'(2) = 3 \cdot 2^2 = 12, \quad y''(2) = 12$$

Substituting in Eq. (10) we get

$$\kappa(2) = \frac{|x'(2)y''(2) - x''(2)y'(2)|}{\left(x'(2)^2 + y'(2)^2\right)^{3/2}} = \frac{|4 \cdot 12 - 2 \cdot 12|}{\left(4^2 + 12^2\right)^{3/2}} = \frac{24}{160^{3/2}} \approx 0.012$$

30. $\langle \cosh s, s\rangle, \quad s = 0$

SOLUTION For this parametrization $x(s) = \cosh s$, $y(s) = s$, hence $x'(s) = \sinh s$, $x''(s) = \cosh s$, $y'(s) = 1$, $y''(s) = 0$. At the point $s = 0$ we have

$$x'(0) = \sinh 0 = 0, \quad x''(0) = \cosh 0 = 1, \quad y'(0) = 1, \quad y''(0) = 0$$

Substituting in Eq. (10) we obtain the following curvature:

$$\kappa(0) = \frac{|x'(0)y''(0) - y'(0)x''(0)|}{\left(x'(0)^2 + y'(0)^2\right)^{3/2}} = \frac{|0 \cdot 0 - 1 \cdot 1|}{\left(0^2 + 1^2\right)^{3/2}} = \frac{1}{1} = 1$$

31. $\langle t\cos t, \sin t\rangle, \quad t = \pi$

SOLUTION We have $x(t) = t\cos t$ and $y(t) = \sin t$, hence:

$$x'(t) = \cos t - t\sin t \quad \Rightarrow \quad x'(\pi) = \cos\pi - \pi\sin\pi = -1$$
$$x''(t) = -\sin t - (\sin t + t\cos t) = -2\sin t - t\cos t \quad \Rightarrow \quad x''(\pi) = -2\sin\pi - \pi\cos\pi = \pi$$
$$y'(t) = \cos t \quad \Rightarrow \quad y'(\pi) = \cos\pi = -1$$
$$y''(t) = -\sin t \quad \Rightarrow \quad y''(\pi) = -\sin\pi = 0$$

Substituting in Eq. (10) gives the following curvature:

$$\kappa(\pi) = \frac{|x'(\pi)y''(\pi) - x''(\pi)y'(\pi)|}{\left(x'(\pi)^2 + y'(\pi)^2\right)^{3/2}} = \frac{|-1 \cdot 0 - \pi \cdot (-1)|}{\left((-1)^2 + (-1)^2\right)^{3/2}} = \frac{\pi}{2\sqrt{2}} \approx 1.11$$

32. $\langle \sin 3s, 2\sin 4s\rangle, \quad s = \frac{\pi}{2}$

SOLUTION We have $x(s) = \sin 3s$, $y(s) = 2\sin 4s$. Hence

$$x'(s) = 3\cos 3s \quad \Rightarrow \quad x'\left(\frac{\pi}{2}\right) = 3\cos\frac{3\pi}{2} = 0$$

$$x''(s) = -9\sin 3s \quad \Rightarrow \quad x''\left(\frac{\pi}{2}\right) = -9\sin\frac{3\pi}{2} = 9$$

$$y'(s) = 8\cos 4s \quad \Rightarrow \quad y'\left(\frac{\pi}{2}\right) = 8\cos 2\pi = 8$$

$$y''(s) = -32\sin 4s \quad \Rightarrow \quad y''\left(\frac{\pi}{2}\right) = -32\sin 2\pi = 0$$

Substituting in Eq. (10) we get

$$\kappa\left(\frac{\pi}{2}\right) = \frac{\left|x'\left(\frac{\pi}{2}\right)y''\left(\frac{\pi}{2}\right) - x''\left(\frac{\pi}{2}\right)y'\left(\frac{\pi}{2}\right)\right|}{\left(x'\left(\frac{\pi}{2}\right)^2 + y'\left(\frac{\pi}{2}\right)^2\right)^{3/2}} = \frac{|0\cdot 0 - 9\cdot 8|}{\left(0^2+8^2\right)^{3/2}} = \frac{72}{8^3} = \frac{9}{64}$$

33. Let $s(t) = \int_{-\infty}^{t} \|\mathbf{r}'(u)\|\,du$ for the Bernoulli spiral $\mathbf{r}(t) = \langle e^t\cos 4t, e^t\sin 4t\rangle$ (see Exercise 29 in Section 13.3). Show that the radius of curvature is proportional to $s(t)$.

SOLUTION The radius of curvature is the reciprocal of the curvature:

$$R(t) = \frac{1}{\kappa(t)}$$

We compute the curvature using the equality given in Exercise 29 in Section 3:

$$\kappa(t) = \frac{|x'(t)y''(t) - x''(t)y'(t)|}{\left(x'(t)^2 + y'(t)^2\right)^{3/2}} \tag{1}$$

In our case, $x(t) = e^t\cos 4t$ and $y(t) = e^t\sin 4t$. Hence:

$$\begin{aligned}
x'(t) &= e^t\cos 4t - 4e^t\sin 4t = e^t(\cos 4t - 4\sin 4t)\\
x''(t) &= e^t(\cos 4t - 4\sin 4t) + e^t(-4\sin 4t - 16\cos 4t) = -e^t(15\cos 4t + 8\sin 4t)\\
y'(t) &= e^t\sin 4t + 4e^t\cos 4t = e^t(\sin 4t + 4\cos 4t)\\
y''(t) &= e^t(\sin 4t + 4\cos 4t) + e^t(4\cos 4t - 16\sin 4t) = e^t(8\cos 4t - 15\sin 4t)
\end{aligned}$$

We compute the numerator in (1):

$$\begin{aligned}
x'(t)y''(t) - x''(t)y'(t) &= e^{2t}(\cos 4t - 4\sin 4t)\cdot(8\cos 4t - 15\sin 4t)\\
&\quad + e^{2t}(15\cos 4t + 8\sin 4t)\cdot(\sin 4t + 4\cos 4t)\\
&= e^{2t}\left(68\cos^2 4t + 68\sin^2 4t\right) = 68e^{2t}
\end{aligned}$$

We compute the denominator in (1):

$$\begin{aligned}
x'(t)^2 + y'(t)^2 &= e^{2t}(\cos 4t - 4\sin 4t)^2 + e^{2t}(\sin 4t + 4\cos 4t)^2\\
&= e^{2t}\left(\cos^2 4t - 8\cos 4t\sin 4t + 16\sin^2 4t + \sin^2 4t + 8\sin 4t\cos 4t + 16\cos^2 4t\right)\\
&= e^{2t}\left(\cos^2 4t + \sin^2 4t + 16\left(\sin^2 4t + \cos^2 4t\right)\right)\\
&= e^{2t}(1 + 16\cdot 1) = 17e^{2t}
\end{aligned} \tag{2}$$

Hence

$$\left(x'(t)^2 + y'(t)^2\right)^{3/2} = 17^{3/2}e^{3t}$$

Substituting in (2) we have

$$\kappa(t) = \frac{68e^{2t}}{17^{3/2}e^{3t}} = \frac{4}{\sqrt{17}}e^{-t} \quad \Rightarrow \quad R = \frac{\sqrt{17}}{4}e^t \tag{3}$$

On the other hand, by the Fundamental Theorem and (2) we have

$$s'(t) = \|\mathbf{r}'(t)\| = \sqrt{x'(t)^2 + y'(t)^2} = \sqrt{17e^{2t}} = \sqrt{17}e^t$$

We integrate to obtain

$$s(t) = \int \sqrt{17}\, e^t\, dt = \sqrt{17}\, e^t + C \tag{4}$$

Since $s(t) = \int_{-\infty}^{t} \|\mathbf{r}'(u)\|\, du$, we have $\lim_{t\to-\infty} s(t) = 0$, hence by (4):

$$0 = \lim_{t\to-\infty}\left(\sqrt{17}e^t + C\right) = 0 + C = C.$$

Substituting $C = 0$ in (4) we get:

$$s(t) = \sqrt{17}e^t \tag{5}$$

Combining (3) and (5) gives:

$$R(t) = \frac{1}{4}s(t)$$

which means that the radius of curvature is proportional to $s(t)$.

34. The **Cornu spiral** is the plane curve $\mathbf{r}(t) = \langle x(t), y(t)\rangle$, where

$$x(t) = \int_0^t \sin\frac{u^2}{2}\, du, \qquad y(t) = \int_0^t \cos\frac{u^2}{2}\, du$$

Verify that $\kappa(t) = |t|$. Since the curvature increases linearly, the Cornu spiral is used in highway design to create transitions between straight and curved road segments (Figure 17).

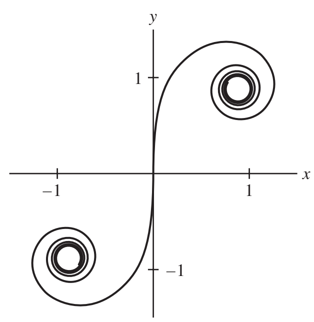


FIGURE 17 Cornu spiral.

SOLUTION We use the formula for the curvature given earlier:

$$\kappa(t) = \frac{|x'(t)y''(t) - x''(t)y'(t)|}{\left(x'(t)^2 + y'(t)^2\right)^{3/2}} \tag{1}$$

We compute the first and second derivatives of $x(t)$ and $y(t)$:

$$x'(t) = \frac{d}{dt}\left(\int_0^t \sin\frac{u^2}{2} du\right) = \sin\frac{t^2}{2}$$

$$x''(t) = \frac{d}{dt}\left(\sin\frac{t^2}{2}\right) = \frac{2t}{2}\cos\frac{t^2}{2} = t\cos\frac{t^2}{2}$$

$$y'(t) = \frac{d}{dt}\left(\int_0^t \cos\frac{u^2}{2} du\right) = \cos\frac{t^2}{2}$$

$$y''(t) = \frac{d}{dt}\left(\cos\frac{t^2}{2}\right) = \frac{2t}{2}\left(-\sin\frac{t^2}{2}\right) = -t\sin\frac{t^2}{2}$$

We compute the numerator in (1):

$$x'(t)y''(t) - x''(t)y'(t) = \sin\frac{t^2}{2}\left(-t\sin\frac{t^2}{2}\right) - t\cos\frac{t^2}{2}\cos\frac{t^2}{2}$$

$$= -t\left(\sin^2\left(\frac{t^2}{2}\right) + \cos^2\left(\frac{t^2}{2}\right)\right) = -t\cdot 1 = -t \tag{2}$$

We compute the denominator in (1):

$$x'(t)^2 + y'(t)^2 = \left(\sin \frac{t^2}{2}\right)^2 + \left(\cos \frac{t^2}{2}\right)^2 = 1$$

Hence:

$$\left(x'(t)^2 + y'(t)^2\right)^{3/2} = (1)^{3/2} = 1 \tag{3}$$

Substituting (2) and (3) in (1) gives the following curvature:

$$\kappa(t) = \frac{|-t|}{1} = |t|.$$

35. CAS Plot and compute the curvature $\kappa(t)$ of the **clothoid** $\mathbf{r}(t) = \langle x(t), y(t)\rangle$, where

$$x(t) = \int_0^t \sin \frac{u^3}{3}\, du, \qquad y(t) = \int_0^t \cos \frac{u^3}{3}\, du$$

SOLUTION We use the following formula for the curvature (given earlier):

$$\kappa(t) = \frac{|x'(t)y''(t) - x''(t)y'(t)|}{\left(x'(t)^2 + y'(t)^2\right)^{3/2}} \tag{1}$$

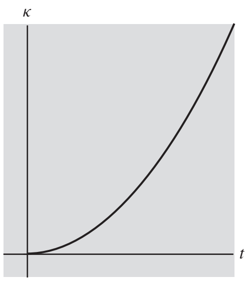
We compute the first and second derivatives of $x(t)$ and $y(t)$. Using the Fundamental Theorem and the Chain Rule we get:

$$\begin{aligned}
x'(t) &= \sin \frac{t^3}{3} \\
x''(t) &= \frac{3t^2}{3} \cos \frac{t^3}{3} = t^2 \cos \frac{t^3}{3} \\
y'(t) &= \cos \frac{t^3}{3} \\
y''(t) &= \frac{3t^2}{3}\left(-\sin \frac{t^3}{3}\right) = -t^2 \sin \frac{t^3}{3}
\end{aligned}$$

Substituting in (1) gives the following curvature function:

$$\kappa(t) = \frac{\left|\sin \frac{t^3}{3}\left(-t^2 \sin \frac{t^3}{3}\right) - t^2 \cos \frac{t^3}{3} \cos \frac{t^3}{3}\right|}{\left(\left(\sin \frac{t^3}{3}\right)^2 + \left(\cos \frac{t^3}{3}\right)^2\right)^{3/2}} = \frac{t^2\left(\sin^2 \frac{t^3}{3} + \cos^2 \frac{t^3}{3}\right)}{1^{3/2}} = t^2$$

That is, $\kappa(t) = t^2$. Here is a plot of the curvature as a function of t:



$\kappa(t) = t^2$

36. Find the unit normal vector $\mathbf{N}(\theta)$ to $\mathbf{r}(\theta) = R\langle \cos\theta, \sin\theta\rangle$, the circle of radius R. Does $\mathbf{N}(\theta)$ point inside or outside the circle? Draw $\mathbf{N}(\theta)$ at $\theta = \frac{\pi}{4}$ with $R = 4$.

SOLUTION We first find the unit tangent vector:

$$\mathbf{T}(\theta) = \frac{\mathbf{r}'(\theta)}{\|\mathbf{r}'(\theta)\|}$$

We have:

$$\mathbf{r}'(\theta) = R\langle -\sin\theta, \cos\theta\rangle \quad \Rightarrow \quad \|\mathbf{r}'(\theta)\| = R\|\langle -\sin\theta, \cos\theta\rangle\| = R\sqrt{\sin^2\theta + \cos^2\theta} = R$$

Hence:

$$\mathbf{T}(\theta) = \frac{R\langle -\sin\theta, \cos\theta\rangle}{R} = \langle -\sin\theta, \cos\theta\rangle$$

The unit normal vector is the following vector:

$$\mathbf{N}(\theta) = \frac{\mathbf{T}'(\theta)}{\|\mathbf{T}'(\theta)\|} \tag{1}$$

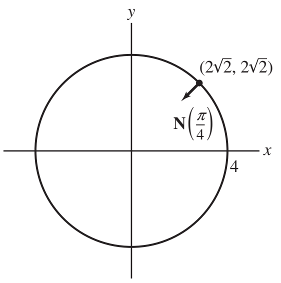
We compute $\mathbf{T}'(\theta)$ and its length:

$$\mathbf{T}'(\theta) = \langle -\cos\theta, -\sin\theta\rangle \quad \Rightarrow \quad \|\mathbf{T}'(\theta)\| = \sqrt{(-\cos\theta)^2 + (-\sin\theta)^2} = \sqrt{1} = 1$$

Substituting in (1) we get:

$$\mathbf{N}(\theta) = \langle -\cos\theta, -\sin\theta\rangle = -\langle\cos\theta, \sin\theta\rangle$$

The unit normal vector points to the "inside" of the curve, in this case it points inside the circle. For $\theta = \frac{\pi}{4}$, $\mathbf{N}\left(\frac{\pi}{4}\right) = -\left\langle\cos\frac{\pi}{4}, \sin\frac{\pi}{4}\right\rangle = \left\langle -\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right\rangle$. We plot the vector for $R = 4$:



37. Find the unit normal vector $\mathbf{N}(t)$ to $\mathbf{r}(t) = \langle 4, \sin 2t, \cos 2t\rangle$.

SOLUTION We first find the unit tangent vector:

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} \tag{1}$$

We have

$$\mathbf{r}'(t) = \frac{d}{dt}\langle 4, \sin 2t, \cos 2t\rangle = \langle 0, 2\cos 2t, -2\sin 2t\rangle = 2\langle 0, \cos 2t, -\sin 2t\rangle$$

$$\|\mathbf{r}'(t)\| = 2\sqrt{0^2 + \cos^2 2t + (-\sin 2t)^2} = 2\sqrt{0+1} = 2$$

Substituting in (1) gives:

$$\mathbf{T}(t) = \frac{2\langle 0, \cos 2t, -\sin 2t\rangle}{2} = \langle 0, \cos 2t, -\sin 2t\rangle$$

The normal vector is the following vector:

$$\mathbf{N}(t) = \frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|} \tag{2}$$

We compute the derivative of the unit tangent vector and its length:

$$\mathbf{T}'(t) = \frac{d}{dt}\langle 0, \cos 2t, -\sin 2t\rangle = \langle 0, -2\sin 2t, -2\cos 2t\rangle = -2\langle 0, \sin 2t, \cos 2t\rangle$$

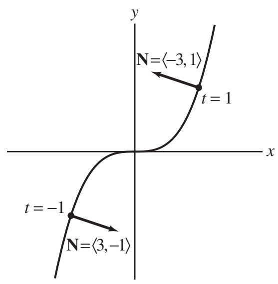
$$\|\mathbf{T}'(t)\| = 2\sqrt{0^2 + \sin^2 2t + \cos^2 2t} = 2\sqrt{0+1} = 2$$

Substituting in (2) we obtain:

$$\mathbf{N}(t) = \frac{-2\langle 0, \sin 2t, \cos 2t\rangle}{2} = \langle 0, -\sin 2t, -\cos 2t\rangle$$

38. Sketch the graph of $\mathbf{r}(t) = \langle t, t^3 \rangle$. Since $\mathbf{r}'(t) = \langle 1, 3t^2 \rangle$, the unit normal $\mathbf{N}(t)$ points in one of the two directions $\pm\langle -3t^2, 1 \rangle$. Which sign is correct at $t = 1$? Which is correct at $t = -1$?

SOLUTION The graph $\mathbf{r}(t) = \langle t, t^3 \rangle$ is shown in the following figure:



$\mathbf{r}(t) = \langle t, t^3 \rangle$

Since the unit normal vector points to the "inside" of the curve, the unit normal vector at $t = 1$ is along the direction $\langle -3, 1 \rangle$ rather than $\langle 3, -1 \rangle$. At $t = -1$ the unit normal vector is along the direction $\langle 3, -1 \rangle$ rather than $\langle -3, 1 \rangle$.

39. Find the normal vectors to $\mathbf{r}(t) = \langle t, \cos t \rangle$ at $t = \frac{\pi}{4}$ and $t = \frac{3\pi}{4}$.

SOLUTION The normal vector to $\mathbf{r}(t) = \langle t, \cos t \rangle$ is $\mathbf{T}'(t)$, where $\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|}$ is the unit tangent vector. We have

$$\mathbf{r}'(t) = \langle 1, -\sin t \rangle \quad \Rightarrow \quad \|\mathbf{r}'(t)\| = \sqrt{1^2 + (\sin t)^2} = \sqrt{1 + \sin^2 t}$$

Hence,

$$\mathbf{T}(t) = \frac{1}{\sqrt{1 + \sin^2 t}} \langle 1, -\sin t \rangle$$

We compute the derivative of $\mathbf{T}(t)$ to find the normal vector.We use the Product Rule and the Chain Rule to obtain:

$$\begin{aligned}
\mathbf{T}'(t) &= \frac{1}{\sqrt{1 + \sin^2 t}} \frac{d}{dt} \langle 1, -\sin t \rangle + \left(\frac{1}{\sqrt{1 + \sin^2 t}} \right)' \langle 1, -\sin t \rangle \\
&= \frac{1}{\sqrt{1 + \sin^2 t}} \langle 0, -\cos t \rangle - \frac{1}{1 + \sin^2 t} \cdot \frac{2 \sin t \cos t}{2\sqrt{1 + \sin^2 t}} \langle 1, -\sin t \rangle \\
&= \frac{1}{\sqrt{1 + \sin^2 t}} \langle 0, -\cos t \rangle - \frac{\sin 2t}{2\left(1 + \sin^2 t\right)^{3/2}} \langle 1, -\sin t \rangle
\end{aligned}$$

At $t = \frac{\pi}{4}$ we obtain the normal vector:

$$\mathbf{T}'\left(\frac{\pi}{4}\right) = \frac{1}{\sqrt{1 + \frac{1}{2}}} \left\langle 0, -\frac{1}{\sqrt{2}} \right\rangle - \frac{1}{2\left(1 + \frac{1}{2}\right)^{3/2}} \left\langle 1, -\frac{1}{\sqrt{2}} \right\rangle = \left\langle 0, -\frac{1}{\sqrt{3}} \right\rangle - \left\langle \frac{\sqrt{2}}{3\sqrt{3}}, \frac{-1}{3\sqrt{3}} \right\rangle = \left\langle \frac{-\sqrt{2}}{3\sqrt{3}}, \frac{-2}{3\sqrt{3}} \right\rangle$$

At $t = \frac{3\pi}{4}$ we obtain:

$$\mathbf{T}'\left(\frac{3\pi}{4}\right) = \frac{1}{\sqrt{1 + \frac{1}{2}}} \left\langle 0, \frac{1}{\sqrt{2}} \right\rangle - \frac{-1}{2\left(1 + \frac{1}{2}\right)^{3/2}} \left\langle 1, -\frac{1}{\sqrt{2}} \right\rangle = \left\langle 0, \frac{1}{\sqrt{3}} \right\rangle + \left\langle \frac{\sqrt{2}}{3\sqrt{3}}, \frac{-1}{3\sqrt{3}} \right\rangle = \left\langle \frac{\sqrt{2}}{3\sqrt{3}}, \frac{2}{3\sqrt{3}} \right\rangle$$

40. Find the unit normal to the Cornu spiral (Exercise 34) at $t = \sqrt{\pi}$.

SOLUTION The Cornu Spiral is the plane curve $\mathbf{r}(t) = \langle x(t), y(t) \rangle$ with

$$x(t) = \int_0^t \sin \frac{u^2}{2} du, \quad y(t) = \int_0^t \cos \frac{u^2}{2} du$$

The unit normal is the following vector:

$$\mathbf{N}(t) = \frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|} \tag{1}$$

We find the vector $\mathbf{T}'(t)$ and its length. By the Fundamental Theorem we have

$$\mathbf{r}'(t) = \langle x'(t), y'(t)\rangle = \left\langle \sin\frac{t^2}{2}, \cos\frac{t^2}{2}\right\rangle$$

$$\|\mathbf{r}'(t)\| = \sqrt{\sin^2\frac{t^2}{2} + \cos^2\frac{t^2}{2}} = \sqrt{1} = 1$$

Hence,

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \left\langle \sin\frac{t^2}{2}, \cos\frac{t^2}{2}\right\rangle$$

Differentiating $\mathbf{T}(t)$, using the Chain Rule, gives

$$\mathbf{T}'(t) = \left\langle \frac{2t}{2}\cos\frac{t^2}{2}, \frac{2t}{2}\left(-\sin\frac{t^2}{2}\right)\right\rangle = t\left\langle \cos\frac{t^2}{2}, -\sin\frac{t^2}{2}\right\rangle$$

$$\|\mathbf{T}'(t)\| = |t|\sqrt{\cos^2\frac{t^2}{2} + \left(-\sin\frac{t^2}{2}\right)^2} = |t|\sqrt{1} = |t|$$

Substituting in (1) gives the following unit normal:

$$\mathbf{N}(t) = \frac{t}{|t|}\left\langle \cos\frac{t^2}{2}, -\sin\frac{t^2}{2}\right\rangle \quad\Rightarrow\quad \mathbf{N}\left(\sqrt{\pi}\right) = \left\langle \cos\frac{\pi}{2}, -\sin\frac{\pi}{2}\right\rangle = \langle 0, -1\rangle$$

41. Find the unit normal to the clothoid (Exercise 35) at $t = \pi^{1/3}$.

SOLUTION The Clothoid is the plane curve $\mathbf{r}(t) = \langle x(t), y(t)\rangle$ with

$$x(t) = \int_0^t \sin\frac{u^3}{3}\,du, \quad y(t) = \int_0^t \cos\frac{u^3}{3}\,du$$

The unit normal is the following vector:

$$\mathbf{N}(t) = \frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|} \tag{1}$$

We first find the unit tangent vector $\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|}$. By the Fundamental Theorem we have

$$\mathbf{r}'(t) = \left\langle \sin\frac{t^3}{3}, \cos\frac{t^3}{3}\right\rangle \quad\Rightarrow\quad \|\mathbf{r}'(t)\| = \sqrt{\sin^2\frac{t^3}{3} + \cos^2\frac{t^3}{3}} = \sqrt{1} = 1$$

Hence,

$$\mathbf{T}(t) = \left\langle \sin\frac{t^3}{3}, \cos\frac{t^3}{3}\right\rangle$$

We now differentiate $\mathbf{T}(t)$ using the Chain Rule to obtain:

$$\mathbf{T}'(t) = \left\langle \frac{3t^2}{3}\cos\frac{t^3}{3}, \frac{-3t^2}{3}\sin\frac{t^3}{3}\right\rangle = t^2\left\langle \cos\frac{t^3}{3}, -\sin\frac{t^3}{3}\right\rangle$$

Hence,

$$\|\mathbf{T}'(t)\| = t^2\sqrt{\cos^2\frac{t^3}{3} + \left(-\sin\frac{t^3}{3}\right)^2} = t^2$$

Substituting in (1) we obtain the following unit normal:

$$\mathbf{N}(t) = \left\langle \cos\frac{t^3}{3}, -\sin\frac{t^3}{3}\right\rangle$$

At the point $T = \pi^{1/3}$ the unit normal is

$$\mathbf{N}(\pi^{1/3}) = \left\langle \cos\frac{(\pi^{1/3})^3}{3}, -\sin\frac{(\pi^{1/3})^3}{3}\right\rangle = \left\langle \cos\frac{\pi}{3}, -\sin\frac{\pi}{3}\right\rangle = \left\langle \frac{1}{2}, -\frac{\sqrt{3}}{2}\right\rangle$$

42. Method for Computing N Let $v(t) = \|\mathbf{r}'(t)\|$. Show that

$$\mathbf{N}(t) = \frac{v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)}{\|v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)\|} \qquad \boxed{11}$$

Hint: $\mathbf{N}$ is the unit vector in the direction $\mathbf{T}'(t)$. Differentiate $\mathbf{T}(t) = \mathbf{r}'(t)/v(t)$ to show that $v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)$ is a positive multiple of $\mathbf{T}'(t)$.

SOLUTION Since $v(t) = \|\mathbf{r}'(t)\|$ and $\mathbf{T}(t)$ is a unit vector in the direction at $\mathbf{r}'(t)$, we may write:

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{v(t)}$$

Differentiating this vector, using the Quotient Rule, we get

$$\mathbf{T}'(t) = \frac{v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)}{(v(t))^2}$$

thus,

$$(v(t))^2\mathbf{T}'(t) = v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)$$

Now, $\mathbf{N}(t)$ is a unit vector in the direction of $\mathbf{T}'(t)$, hence we can find it by dividing the vector $(v(t))^2\mathbf{T}'(t)$ by its length. Therefore,

$$\mathbf{N}(t) = \frac{v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)}{\|v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)\|}$$

In Exercises 43–48, use Eq. (11) to find $\mathbf{N}$ *at the point indicated.*

43. $\langle t^2, t^3 \rangle$, $\quad t = 1$

SOLUTION We use the equality

$$\mathbf{N}(t) = \frac{v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)}{\|v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)\|}$$

For $\mathbf{r}(t) = \langle t^2, t^3 \rangle$ we have

$$\begin{aligned}
\mathbf{r}'(t) &= \langle 2t, 3t^2 \rangle \\
\mathbf{r}''(t) &= \langle 2, 6t \rangle \\
v(t) &= \|\mathbf{r}'(t)\| = \sqrt{(2t)^2 + (3t^2)^2} = \sqrt{4t^2 + 9t^4} \\
v'(t) &= \frac{8t + 36t^3}{2\sqrt{4t^2 + 9t^4}} = \frac{4t + 18t^3}{\sqrt{4t^2 + 9t^4}}
\end{aligned}$$

At the point $t = 1$ we get

$$\mathbf{r}''(1) = \langle 2, 6 \rangle, \quad v'(1) = \frac{4 + 18}{\sqrt{4 + 9}} = \frac{22}{\sqrt{13}},$$

and also

$$\mathbf{r}'(1) = \langle 2, 3 \rangle, \quad v(1) = \sqrt{4 + 9} = \sqrt{13}$$

Hence,

$$\begin{aligned}
v(1)\mathbf{r}''(1) - v'(1)\mathbf{r}'(1) &= \sqrt{13}\,\langle 2, 6 \rangle - \frac{22}{\sqrt{13}} \cdot \langle 2, 3 \rangle = \left\langle \frac{26 - 44}{\sqrt{13}}, \frac{78 - 66}{\sqrt{13}} \right\rangle = \frac{1}{\sqrt{13}}\langle -18, 12 \rangle \\
\left\|v(1)\mathbf{r}''(1) - v'(1)\mathbf{r}'(1)\right\| &= \left\| \frac{1}{\sqrt{13}}\langle -18, 12 \rangle \right\| = \frac{1}{\sqrt{13}}\sqrt{(-18)^2 + 12^2} = \sqrt{\frac{468}{13}} = 6
\end{aligned}$$

Substituting in (1) gives the following unit normal:

$$\mathbf{N}(1) = \frac{\frac{1}{\sqrt{13}}\langle -18, 12 \rangle}{6} = \frac{1}{\sqrt{13}}\langle -3, 2 \rangle$$

44. $\left\langle t-\sin t, 1-\cos t\right\rangle, \quad t=\pi$

SOLUTION We use the following equality:

$$\mathbf{N}(t)=\frac{v(t)\mathbf{r}''(t)-v'(t)\mathbf{r}'(t)}{\|v(t)\mathbf{r}''(t)-v'(t)\mathbf{r}'(t)\|}$$

We compute the vectors in the above equality. For $\mathbf{r}(t)=\langle t-\sin t, 1-\cos t\rangle$ we have

$$\begin{aligned}
\mathbf{r}'(t)&=\langle 1-\cos t, \sin t\rangle\\
\mathbf{r}''(t)&=\langle \sin t, \cos t\rangle\\
v(t)=\|\mathbf{r}'(t)\|&=\sqrt{(1-\cos t)^2+\sin^2 t}=\sqrt{1-2\cos t+\cos^2 t+\sin^2 t}\\
&=\sqrt{1-2\cos t+1}=\sqrt{2(1-\cos t)}=\sqrt{2\cdot 2\sin^2\frac{t}{2}}=2\left|\sin\frac{t}{2}\right|
\end{aligned}$$

For $0\le t\le 2\pi$, $\sin\frac{t}{2}\ge 0$, hence $v(t)=2\sin\frac{t}{2}$. Therefore,

$$v'(t)=2\cdot\frac{1}{2}\cos\frac{t}{2}=\cos\frac{t}{2}, \quad 0\le t\le 2\pi$$

At the point $t=\pi$ we have

$$\begin{aligned}
\mathbf{r}''(\pi)&=\langle \sin\pi, \cos\pi\rangle=\langle 0,-1\rangle\\
v'(\pi)&=\cos\frac{\pi}{2}=0\\
\mathbf{r}'(\pi)&=\langle 1-\cos\pi, \sin\pi\rangle=\langle 2,0\rangle\\
v(\pi)&=2\left|\sin\frac{\pi}{2}\right|=2
\end{aligned}$$

We now substitute these values in (1) to obtain the following unit normal:

$$\mathbf{N}(\pi)=\frac{v(\pi)\mathbf{r}''(\pi)-v'(\pi)\mathbf{r}'(\pi)}{\|v(\pi)\mathbf{r}''(\pi)-v'(\pi)\mathbf{r}'(\pi)\|}=\frac{2\langle 0,-1\rangle-0\langle 2,0\rangle}{\|v(\pi)\mathbf{r}''(\pi)-v'(\pi)\mathbf{r}'(\pi)\|}=\frac{\langle 0,-2\rangle}{\sqrt{0^2+(-2)^2}}=\langle 0,-1\rangle$$

45. $\left\langle t^2/2, t^3/3, t\right\rangle, \quad t=1$

SOLUTION We use the following equality:

$$\mathbf{N}(t)=\frac{v(t)\mathbf{r}''(t)-v'(t)\mathbf{r}'(t)}{\|v(t)\mathbf{r}''(t)-v'(t)\mathbf{r}'(t)\|}$$

We compute the vectors in the equality above. For $\mathbf{r}(t)=\left\langle t^2/2, t^3/3, t\right\rangle$ we get:

$$\begin{aligned}
\mathbf{r}'(t)&=\left\langle t, t^2, 1\right\rangle\\
\mathbf{r}''(t)&=\langle 1, 2t, 0\rangle\\
v(t)=\|\mathbf{r}'(t)\|&=\sqrt{t^2+t^4+1}\\
v'(t)&=\frac{1}{2}(t^2+t^4+1)^{-1/2}(4t^3+2t)=\frac{4t^3+2t}{2\sqrt{t^2+t^4+1}}
\end{aligned}$$

At the point $t=1$ we get:

$$\begin{aligned}
\mathbf{r}'(1)&=\langle 1,1,1\rangle\\
\mathbf{r}''(1)&=\langle 1,2,0\rangle\\
v'(1)&=\frac{6}{2\sqrt{3}}=\frac{3}{\sqrt{3}}=\sqrt{3}\\
v(1)&=\sqrt{3}
\end{aligned}$$

Hence,

$$v(1)\mathbf{r}''(1) - v'(1)\mathbf{r}'(1) = \sqrt{3}\,\langle 1, 2, 0\rangle - \sqrt{3}\,\langle 1, 1, 1\rangle = \left\langle 0, \sqrt{3}, -\sqrt{3}\right\rangle$$

$$\|v(1)\mathbf{r}''(1) - v'(1)\mathbf{r}'(1)\| = \sqrt{0^2 + (\sqrt{3})^2 + (-\sqrt{3})^2} = \sqrt{6}$$

We now substitute these values in (1) to obtain the following unit normal:

$$\mathbf{N}(1) = \frac{v(1)\mathbf{r}''(1) - v'(1)\mathbf{r}'(1)}{\|v(1)\mathbf{r}''(1) - v'(1)\mathbf{r}'(1)\|} = \frac{\left\langle 0, \sqrt{3}, -\sqrt{3}\right\rangle}{\sqrt{6}} = \left\langle 0, \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right\rangle$$

46. $\left\langle t^{-1}, t, t^2\right\rangle, \quad t = -1$

SOLUTION We use the equality

$$\mathbf{N}(t) = \frac{v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)}{\|v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)\|}$$

We compute the vectors in the above equality. For $\mathbf{r}(t) = \left\langle t^{-1}, t, t^2\right\rangle$ we have

$$\begin{aligned}
\mathbf{r}'(t) &= \left\langle -t^{-2}, 1, 2t\right\rangle \\
\mathbf{r}''(t) &= \left\langle 2t^{-3}, 0, 2\right\rangle \\
v(t) &= \|\mathbf{r}'(t)\| = \sqrt{t^{-4} + 1 + 4t^2} \\
v'(t) &= \frac{-4t^{-5} + 8t}{2\sqrt{t^{-4} + 1 + 4t^2}} = \frac{-2t^{-5} + 4t}{\sqrt{t^{-4} + 1 + 4t^2}}
\end{aligned}$$

At the point $t = -1$ we get

$$\mathbf{r}'(-1) = \langle -1, 1, -2\rangle, \quad \mathbf{r}''(-1) = \langle -2, 0, 2\rangle, \quad v'(-1) = \frac{2-4}{\sqrt{1+1+4}} = \frac{-2}{\sqrt{6}},$$

$$v(-1) = \sqrt{(-1)^{-4} + 1 + 4(-1)^2} = \sqrt{6}$$

Hence,

$$\begin{aligned}
v(-1)\mathbf{r}''(-1) - v'(-1)\mathbf{r}'(-1) &= \sqrt{6}\,\langle -2, 0, 2\rangle + \frac{2}{\sqrt{6}}\,\langle -1, 1, -2\rangle \\
&= \left\langle \frac{-12-2}{\sqrt{6}}, \frac{2}{\sqrt{6}}, \frac{12-4}{\sqrt{6}}\right\rangle \\
&= \left\langle -\frac{14}{\sqrt{6}}, \frac{2}{\sqrt{6}}, \frac{8}{\sqrt{6}}\right\rangle \\
&= \sqrt{\frac{2}{3}}\,\langle -7, 1, 4\rangle \\
\|v(-1)\mathbf{r}''(-1) - v'(-1)\mathbf{r}'(-1)\| &= \sqrt{\frac{2}{3}}\sqrt{49 + 1 + 16} = \sqrt{44}
\end{aligned}$$

Substituting in (1) gives the following unit normal:

$$\mathbf{N}(-1) = \frac{\sqrt{\frac{2}{3}}\,\langle -7, 1, 4\rangle}{\sqrt{44}} = \frac{1}{\sqrt{66}}\,\langle -7, 1, 4\rangle$$

47. $\left\langle t, e^t, t\right\rangle, \quad t = 0$

SOLUTION We use the equality

$$\mathbf{N}(t) = \frac{v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)}{\|v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)\|}$$

For $\mathbf{r}(t) = \left\langle t, e^t, t\right\rangle$ we have

$$\mathbf{r}'(t) = \left\langle 1, e^t, 1\right\rangle$$

$$\mathbf{r}''(t) = \left\langle 0, e^t, 0 \right\rangle$$
$$v(t) = \|\mathbf{r}'(t)\| = \sqrt{1^2 + (e^t)^2 + 1^2} = \sqrt{e^{2t} + 2}$$
$$v'(t) = \frac{2e^{2t}}{2\sqrt{e^{2t}+2}} = \frac{e^{2t}}{\sqrt{e^{2t}+2}}$$

At the point $t = 0$ we have

$$\mathbf{r}'(0 = \langle 1, 1, 1 \rangle, \quad \mathbf{r}''(0) = \left\langle 0, 1, 0 \right\rangle, \quad v(0) = \sqrt{3}, \quad v'(0) = \frac{1}{\sqrt{3}},$$

Hence,

$$v(0)\mathbf{r}''(0) - v'(0)\mathbf{r}'(0) = \sqrt{3}\,\langle 0, 1, 0\rangle - \frac{1}{\sqrt{3}}\,\langle 1, 1, 1\rangle$$
$$= \left\langle -\frac{1}{\sqrt{3}}, \frac{2}{\sqrt{3}}, -\frac{1}{\sqrt{3}} \right\rangle$$
$$= \frac{1}{\sqrt{3}}\,\langle -1, 2, -1\rangle$$
$$\|v(0)\mathbf{r}''(0) - v'(0)\mathbf{r}'(0)\| = \frac{1}{\sqrt{3}}\sqrt{1+4+1} = \sqrt{2}$$

Substituting in (1) we obtain the following unit normal:

$$\mathbf{N}(0) = \frac{\frac{1}{\sqrt{3}}\,\langle -1, 2, -1\rangle}{\sqrt{2}} = \frac{1}{\sqrt{6}}\,\langle -1, 2, -1\rangle$$

48. $\left\langle \cosh t, \sinh t, t^2 \right\rangle, \quad t = 0$

SOLUTION We use the following equality:

$$\mathbf{N}(t) = \frac{v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)}{\|v(t)\mathbf{r}''(t) - v'(t)\mathbf{r}'(t)\|}$$

For $\mathbf{r}(t) = \left\langle \cosh t, \sinh t, t^2 \right\rangle$ we have

$$\mathbf{r}'(t) = \langle \sinh t, \cosh t, 2t\rangle$$
$$\mathbf{r}''(t) = \langle \cosh t, \sinh t, 2\rangle$$
$$v(t) = \|\mathbf{r}'(t)\| = \sqrt{\sinh^2 t + \cosh^2 t + (2t)^2}$$
$$= \sqrt{\left(\cosh^2 t - 1\right) + \cosh^2 t + 4t^2}$$
$$= \sqrt{2\cosh^2 t + 4t^2 - 1}$$
$$v'(t) = \frac{1}{2}(2\cosh^2 t + 4t^2 - 1)^{-1/2}(4\cosh t \sinh t + 8t) = \frac{4\cosh t \sinh t}{2\sqrt{2\cosh^2 t + 4t^2 - 1}}$$

At the point $t = 0$ we get

$$\mathbf{r}'(0) = \langle \sinh 0, \cosh 0, 0\rangle = \langle 0, 1, 0\rangle$$
$$\mathbf{r}''(0) = \langle \cosh 0, \sinh 0, 2\rangle = \langle 1, 0, 2\rangle$$
$$v(0) = \sqrt{2(1)^2 + 4(0)^2 - 1} = 1$$
$$v'(0) = \frac{0}{2(1)} = 0$$

Hence,

$$v(0)\mathbf{r}''(0) - v'(0)\mathbf{r}'(0) = 1\,\langle 1, 0, 2\rangle - \mathbf{0} = \langle 1, 0, 2\rangle$$
$$\|v(0)\mathbf{r}''(0) - v'(0)\mathbf{r}'(0)\| = \|\,\langle 1, 0, 2\rangle\,\| = \sqrt{5}$$

Substituting in (1) gives the following unit normal:

$$\mathbf{N}(0) = \frac{v(0)\mathbf{r}''(0) - v'(0)\mathbf{r}'(0)}{\|v(0)\mathbf{r}''(0) - v'(0)\mathbf{r}'(0)\|} = \frac{1}{\sqrt{5}}\langle 1, 0, 2\rangle = \left\langle \frac{1}{\sqrt{5}}, 0, \frac{2}{\sqrt{5}} \right\rangle$$

49. Let $f(x) = x^2$. Show that the center of the osculating circle at (x_0, x_0^2) is given by $\left(-4x_0^3, \frac{1}{2} + 3x_0^2\right)$.

SOLUTION We parametrize the curve by $\mathbf{r}(x) = \langle x, x^2 \rangle$. The center Q of the osculating circle at $x = x_0$ has the position vector

$$\overrightarrow{OQ} = \mathbf{r}(x_0) + \kappa(x_0)^{-1}\mathbf{N}(x_0) \tag{1}$$

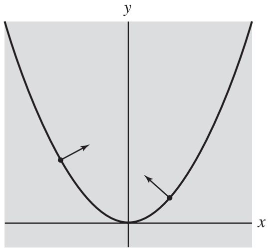
We first find the curvature, using the formula for the curvature of a graph in the plane. We have $f'(x) = 2x$ and $f''(x) = 2$, hence,

$$\kappa(x) = \frac{|f''(x)|}{(1 + f'(x)^2)^{3/2}} = \frac{2}{(1 + 4x^2)^{3/2}} \quad \Rightarrow \quad \kappa(x_0)^{-1} = \frac{1}{2}(1 + 4x_0^2)^{3/2}$$

To find the unit normal vector $\mathbf{N}(x_0)$ we use the following considerations:

- The tangent vector is $\mathbf{r}'(x_0) = \langle 1, 2x_0 \rangle$, hence the vector $\langle -2x_0, 1 \rangle$ is orthogonal to $\mathbf{r}'(x_0)$ (since their dot product is zero). Hence $\mathbf{N}(x_0)$ is one of the two unit vectors $\pm \frac{1}{\sqrt{1+4x_0^2}} \langle -2x_0, 1 \rangle$.
- The graph of $f(x) = x^2$ shows that the unit normal vector points in the positive y-direction, hence, the appropriate choice is:

$$\mathbf{N}(x_0) = \frac{1}{\sqrt{1 + 4x_0^2}}\langle -2x_0, 1 \rangle \tag{2}$$



$f(x) = x^2$

We now substitute (2), (3), and $\mathbf{r}(x_0) = \langle x_0, x_0^2 \rangle$ in (1) to obtain

$$\overrightarrow{OQ} = \langle x_0, x_0^2 \rangle + \frac{1}{2}\left(1 + 4x_0^2\right)^{3/2} \cdot \frac{1}{\sqrt{1 + 4x_0^2}}\langle -2x_0, 1 \rangle = \langle x_0, x_0^2 \rangle + \frac{1}{2}\left(1 + 4x_0^2\right)\langle -2x_0, 1 \rangle$$

$$= \langle x_0, x_0^2 \rangle + \left\langle -x_0 - 4x_0^3, \frac{1}{2}\left(1 + 4x_0^2\right) \right\rangle = \left\langle -4x_0^3, \frac{1}{2} + 3x_0^2 \right\rangle$$

The center of the osculating circle is the terminal point of $\overrightarrow{OQ}$, that is,

$$Q = \left(-4x_0^3, \frac{1}{2} + 3x_0^2\right)$$

50. Use Eq. (8) to find the center of curvature to $\mathbf{r}(t) = \langle t^2, t^3 \rangle$ at $t = 1$.

SOLUTION The center Q of curvature has the position vector:

$$\overrightarrow{OQ} = \mathbf{r}(1) + \kappa(1)^{-1}\mathbf{N}(1) \tag{1}$$

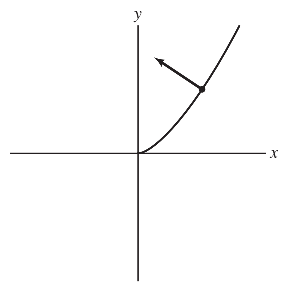
We find the curvature $\kappa(x)$, using the formula for the curvature of a graph in the plane. Since $x = t^2$ and $y = t^3$ we have $y = x^{3/2}$, hence $y'(x) = \frac{3}{2}x^{1/2}$ and $y''(x) = \frac{3}{4}x^{-1/2}$. Thus:

$$\kappa(x) = \frac{|y''(x)|}{\left(1 + y'(x)^2\right)^{3/2}} = \frac{\frac{3}{4}x^{-1/2}}{\left(1 + \frac{9}{4}x\right)^{3/2}}$$

The point $t = 1$ corresponds to $x = 1^2 = 1$, hence the curvature at this point is:

$$\kappa(1) = \frac{\frac{3}{4} \cdot 1^{-1/2}}{\left(1 + \frac{9}{4} \cdot 1\right)^{3/2}} = \frac{\frac{3}{4}}{\left(\frac{13}{4}\right)^{3/2}} = \frac{6}{13^{3/2}} \tag{2}$$

We now must find the unit vector $\mathbf{N}$. The tangent vector is $\mathbf{r}'(t) = \left\langle 2t, 3t^2 \right\rangle$, and we observe that the vector $\langle -3t, 2\rangle$ is orthogonal to $\mathbf{r}'(t)$ (since the dot product is zero). Therefore $\mathbf{N}(t)$ is the unit vector in the direction of $\langle -3t, 2\rangle$ or $-\langle -3t, 2\rangle$. Recall that the vector $\mathbf{N}$ points to the "inside" of the curve, hence as shown in the graph the unit normal points in the positive y-direction.



$y = x^{3/2}$

Therefore we must take the positive sign. That is,

$$\mathbf{N}(t) = \frac{\langle -3t, 2\rangle}{\sqrt{9t^2 + 4}} \quad \Rightarrow \quad \mathbf{N}(1) = \frac{1}{\sqrt{13}} \langle -3, 2\rangle \tag{3}$$

We now substitute (2), (3), and $\mathbf{r}(1) = \left\langle 1^2, 1^3 \right\rangle = \langle 1, 1\rangle$ in (1) to obtain

$$\overrightarrow{OQ} = \langle 1, 1\rangle + \frac{13^{3/2}}{6} \cdot \frac{1}{13^{1/2}} \langle -3, 2\rangle = \langle 1, 1\rangle + \frac{13}{6} \langle -3, 2\rangle$$

The center of the curvature is the endpoint $Q = \left(-\frac{11}{2}, \frac{16}{3}\right)$.

In Exercises 51–58, find a parametrization of the osculating circle at the point indicated.

51. $\mathbf{r}(t) = \left\langle \cos t, \sin t \right\rangle, \quad t = \frac{\pi}{4}$

SOLUTION The curve $\mathbf{r}(t) = \langle \cos t, \sin t\rangle$ is the unit circle. By the definition of the osculating circle, it follows that the osculating circle at each point of the circle is the circle itself. Therefore the osculating circle to the unit circle at $t = \frac{\pi}{4}$ is the unit circle itself.

52. $\mathbf{r}(t) = \left\langle \sin t, \cos t \right\rangle, \quad t = 0$

SOLUTION The parametrization $\mathbf{r}(t) = \langle \sin t, \cos t\rangle$ parametrizes the unit circle. We can see this by using the parametrization $s = \frac{\pi}{2} - t$ to obtain:

$$\mathbf{r}(s) = \mathbf{r}\left(\frac{\pi}{2} - t\right) = \left\langle \sin\left(\frac{\pi}{2} - t\right), \cos\left(\frac{\pi}{2} - t\right)\right\rangle = \langle \cos t, \sin t\rangle = \mathbf{r}_1(t)$$

which is a parametrization of the unit circle. Since the osculating circle at each point of a circle is the circle itself, the osculating circle at $t = 0$ is the unit circle itself.

53. $y = x^2, \quad x = 1$

SOLUTION Let $f(x) = x^2$. We use the parametrization $\mathbf{r}(x) = \langle x, x^2\rangle$ and proceed by the following steps.

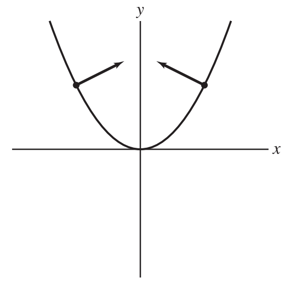
Step 1. Find κ and $\mathbf{N}$. We compute κ using the curvature of a graph in the plane:

$$\kappa(x) = \frac{|f''(x)|}{\left(1 + f'(x)^2\right)^{3/2}}$$

We have $f'(x) = 2x$, $f''(x) = 2$, therefore,

$$\kappa(x) = \frac{2}{(1 + (2x)^2)^{3/2}} = \frac{2}{(1 + 4x^2)^{3/2}} \quad \Rightarrow \quad \kappa(1) = \frac{2}{5^{3/2}} \tag{1}$$

To find $\mathbf{N}(x)$ we notice that the tangent vector is $\mathbf{r}'(x) = \langle 1, 2x\rangle$ hence $\langle -2x, 1\rangle$ is orthogonal to $\mathbf{r}'(x)$ (their dot product is zero). Therefore, $\mathbf{N}(x)$ is the unit vector in the direction of $\langle -2x, 1\rangle$ or $-\langle -2x, 1\rangle$ that points to the "inside" of the curve.



$y = x^2$

As shown in the figure, the unit normal vector points in the positive y-direction, hence:

$$\mathbf{N}(x) = \frac{\langle -2x, 1\rangle}{\sqrt{4x^2+1}} \quad \Rightarrow \quad \mathbf{N}(1) = \frac{1}{\sqrt{5}}\langle -2, 1\rangle \tag{2}$$

Step 2. Find the center of the osculating circle. The center Q at $\mathbf{r}(1)$ has the position vector

$$\overrightarrow{OQ} = \mathbf{r}(1) + \kappa(1)^{-1}\mathbf{N}(1)$$

Substituting (1), (2) and $\mathbf{r}(1) = \langle 1, 1\rangle$ we get:

$$\overrightarrow{OQ} = \langle 1, 1\rangle + \frac{5^{3/2}}{2}\cdot\frac{1}{5^{1/2}}\langle -2, 1\rangle = \langle 1, 1\rangle + \frac{5}{2}\langle -2, 1\rangle = \left\langle -4, \frac{7}{2}\right\rangle$$

Step 3. Parametrize the osculating circle. The osculating circle has radius $R = \frac{1}{\kappa(1)} = \frac{5^{3/2}}{2}$ and it is centered at the point $\left(-4, \frac{7}{2}\right)$, therefore it has the following parametrization:

$$\mathbf{c}(t) = \left\langle -4, \frac{7}{2}\right\rangle + \frac{5^{3/2}}{2}\langle \cos t, \sin t\rangle$$

54. $y = \sin x, \quad x = \frac{\pi}{2}$

SOLUTION We use the parametrization $\mathbf{r}(x) = \langle x, \sin x\rangle$. The radius of the osculating circle is the radius of curvature $R = \frac{1}{\kappa\left(\frac{\pi}{2}\right)}$ and the center is the terminal point of the following vector:

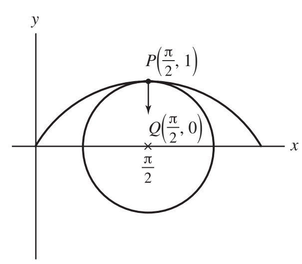
$$\overrightarrow{OQ} = \mathbf{r}\left(\frac{\pi}{2}\right) + R\mathbf{N}\left(\frac{\pi}{2}\right)$$

We first compute the curvature. Since $y'(x) = \cos x$ and $y''(x) = -\sin x$, we have:

$$\kappa(x) = \frac{|y''(x)|}{\left(1+y'(x)^2\right)^{3/2}} = \frac{|-\sin x|}{\left(1+\cos^2 x\right)^{3/2}} \quad \Rightarrow \quad \kappa\left(\frac{\pi}{2}\right) = \frac{\sin\frac{\pi}{2}}{\left(1+\cos^2\frac{\pi}{2}\right)^{3/2}} = \frac{1}{1} = 1$$

We compute the unit normal vector $\mathbf{N}(x)$. $\mathbf{N}(x)$ is a unit vector orthogonal to the tangent vector $\mathbf{r}'(x) = \langle 1, \cos x\rangle$. We observe that $\langle -\cos x, 1\rangle$ is orthogonal to $\mathbf{r}'(x)$, since their dot product is zero. Therefore, $\mathbf{N}(x)$ is the unit vector in the direction of either $\langle -\cos x, 1\rangle$ or $-\langle -\cos x, 1\rangle$, depending on the graph. Considering the accompanying figure, we see that the unit normal vector at $x = \pi/2$ points to the negative y-direction. Thus,

$$\mathbf{N}(x) = \frac{\langle \cos x, -1\rangle}{\|\langle \cos x, -1\rangle\|} = \frac{\langle \cos x, -1\rangle}{\sqrt{\cos^2 x + (-1)^2}} \quad \Rightarrow \quad \mathbf{N}\left(\frac{\pi}{2}\right) = \langle 0, -1\rangle$$



We now find the center of the osculating circle. We substitute $R = \frac{1}{\kappa\left(\frac{\pi}{2}\right)} = 1$, $\mathbf{N}\left(\frac{\pi}{2}\right) = \langle 0, -1\rangle$, and $\mathbf{r}\left(\frac{\pi}{2}\right) = \left\langle \frac{\pi}{2}, \sin\frac{\pi}{2}\right\rangle = \left\langle \frac{\pi}{2}, 1\right\rangle$ into (1) to obtain

$$\overrightarrow{OQ} = \left\langle \frac{\pi}{2}, 1\right\rangle + 1\cdot\langle 0, -1\rangle = \left\langle \frac{\pi}{2}, 0\right\rangle$$

The osculating circle is the circle with center at the point $\left(\frac{\pi}{2}, 0\right)$ and radius 1, so it has the following parametrization:

$$\mathbf{c}(t) = \left\langle \frac{\pi}{2}, 0 \right\rangle + 1 \cdot \langle \cos t, \sin t \rangle = \left\langle \frac{\pi}{2}, 0 \right\rangle + \langle \cos t, \sin t \rangle$$

55. $\langle t - \sin t, 1 - \cos t \rangle, \quad t = \pi$

SOLUTION

Step 1. Find κ and $\mathbf{N}$. In Exercise 44 we found that:

$$\mathbf{N}(\pi) = \langle 0, -1 \rangle \tag{1}$$

To find κ we use the formula for curvature:

$$\kappa(\pi) = \frac{\|\mathbf{r}'(\pi) \times \mathbf{r}''(\pi)\|}{\|\mathbf{r}'(\pi)\|^3} \tag{2}$$

For $\mathbf{r}(t) = \langle t - \sin t, 1 - \cos t \rangle$ we have:

$$\mathbf{r}'(t) = \langle 1 - \cos t, \sin t \rangle \quad \Rightarrow \quad \mathbf{r}'(\pi) = \langle 1 - \cos \pi, \sin \pi \rangle = \langle 2, 0 \rangle$$
$$\mathbf{r}''(t) = \langle \sin t, \cos t \rangle \quad \Rightarrow \quad \mathbf{r}''(\pi) = \langle \sin \pi, \cos \pi \rangle = \langle 0, -1 \rangle$$

Hence,

$$\mathbf{r}'(\pi) \times \mathbf{r}''(\pi) = 2\mathbf{i} \times (-\mathbf{j}) = -2\mathbf{k}$$
$$\|\mathbf{r}'(\pi) \times \mathbf{r}''(\pi)\| = \|-2\mathbf{k}\| = 2 \quad \text{and} \quad \|\mathbf{r}'(\pi)\| = \|\langle 2, 0 \rangle\| = 2$$

Substituting in (2) we get:

$$\kappa(\pi) = \frac{2}{2^3} = \frac{1}{4} \tag{3}$$

Step 2. Find the center of the osculating circle. The center Q of the osculating circle at $\mathbf{r}(\pi) = \langle \pi, 2 \rangle$ has position vector

$$\overrightarrow{OQ} = \mathbf{r}(\pi) + \kappa(\pi)^{-1} N(\pi)$$

Substituting (1), (3) and $\mathbf{r}(\pi) = \langle \pi, 2 \rangle$ we get:

$$\overrightarrow{OQ} = \langle \pi, 2 \rangle + \left(\frac{1}{4}\right)^{-1} \langle 0, -1 \rangle = \langle \pi, 2 \rangle + \langle 0, -4 \rangle = \langle \pi, -2 \rangle$$

Step 3. Parametrize the osculating circle. The osculating circle has radius $R = \frac{1}{\kappa(\pi)}$ and it is centered at $(\pi, -2)$, hence it has the following parametrization:

$$\mathbf{c}(t) = \langle \pi, -2 \rangle + 4 \langle \cos t, \sin t \rangle$$

56. $\mathbf{r}(t) = \langle t^2/2, t^3/3, t \rangle, \quad t = 0$

SOLUTION

Step 1. Find κ and $\mathbf{N}$. The unit normal is:

$$\mathbf{N}(t) = \frac{\mathbf{r}''(t) - v'(t)\mathbf{T}(t)}{\|\mathbf{r}''(t) - v'(t)\mathbf{T}(t)\|}$$

and the curvature is

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3}$$

For $\mathbf{r}(t) = \left\langle t^2/2, t^3/3, t \right\rangle$, we have:

$$\mathbf{r}'(t) = \left\langle t, t^2, 1 \right\rangle$$
$$\mathbf{r}''(t) = \langle 1, 2t, 0 \rangle$$
$$v(t) = \|\mathbf{r}'(t)\| = \sqrt{t^2 + t^4 + 1}$$
$$v'(t) = \frac{1}{2}(t^2 + t^4 + 1)^{-1/2}(4t^3 + 2t) = \frac{4t^3 + 2t}{2\sqrt{t^2 + t^4 + 1}}$$

At the point $t = 0$ we have:

$$\begin{aligned}\mathbf{r}'(0) &= \langle 0, 0, 1\rangle\\ \mathbf{r}''(0) &= \langle 1, 0, 0\rangle\\ \mathbf{r}'(0)\times\mathbf{r}''(0) &= \langle 0, 1, 0\rangle\\ v'(0) &= 0\end{aligned}$$

And calculating norms we get:

$$\begin{aligned}\|\mathbf{r}'(0)\| &= \sqrt{0^2+0^2+1^2} = 1\\ \|\mathbf{r}'(0)\times\mathbf{r}''(0)\| &= \sqrt{0^2+1^2+0^2} = 1\\ \mathbf{T}(0) &= \frac{\mathbf{r}'(0)}{\|\mathbf{r}'(0)\|} = \langle 0, 0, 1\rangle\end{aligned}$$

Also,

$$\mathbf{r}''(0) - v'(0)\mathbf{T}(0) = \langle 1, 0, 0\rangle \quad \Rightarrow \quad \|\mathbf{r}''(0) - v'(0)\mathbf{T}(0)\| = 1$$

Therefore,

$$\mathbf{N}(0) = \frac{\mathbf{r}''(0) - v'(0)\mathbf{T}(0)}{\|\mathbf{r}''(0) - v'(0)\mathbf{T}(0)\|} = \langle 1, 0, 0\rangle$$

and

$$\kappa(0) = \frac{\|\mathbf{r}'(0)\times\mathbf{r}''(0)\|}{\|\mathbf{r}'(0)\|^3} = \frac{1}{1} = 1$$

Step 2. Find the center of the osculating circle. In this case, the center Q of the osculating circle at $\mathbf{r}(0) = \langle 0, 0, 0\rangle$ has position vector:

$$\overrightarrow{OQ} = \mathbf{r}(0) + \kappa^{-1}(0)\mathbf{N}(0) = \langle 0, 0, 0\rangle + 1\,\langle 1, 0, 0\rangle = \langle 1, 0, 0\rangle$$

Step 3. Parametrize the osculating circle. The circle has radius $R = 1/\kappa(0) = 1$ and it is centered at $(1, 0, 0)$. Therefore, it has the following parametrization:

$$\begin{aligned}\mathbf{c}(t) &= \overrightarrow{OQ} + R\mathbf{N}(0)\cos t + R\mathbf{T}(0)\sin t\\ &= \langle 1, 0, 0\rangle + \cos t\,\langle 1, 0, 0\rangle + \sin t\,\langle 0, 0, 1\rangle\\ &= \langle 1+\cos t, 0, \sin t\rangle\end{aligned}$$

57. $\mathbf{r}(t) = \left\langle \cos t, \sin t, t\right\rangle, \quad t = 0$

SOLUTION The curvature is the following quotient:

$$\kappa(t) = \frac{\|\mathbf{r}'(t)\times\mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} \tag{1}$$

We compute the vectors $\mathbf{r}'(t)$ and $\mathbf{r}''(t)$:

$$\begin{aligned}\mathbf{r}'(t) &= \frac{d}{dt}\langle \cos t, \sin t, t\rangle = \langle -\sin t, \cos t, 1\rangle \quad (2)\\ \mathbf{r}''(t) &= \frac{d}{dt}\langle -\sin t, \cos t, 1\rangle = \langle -\cos t, -\sin t, 0\rangle\end{aligned}$$

We now compute the following cross product:

$$\begin{aligned}\mathbf{r}'(t)\times\mathbf{r}''(t) &= \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ -\sin t & \cos t & 1\\ -\cos t & -\sin t & 0\end{vmatrix} = \begin{vmatrix}\cos t & 1\\ -\sin t & 0\end{vmatrix}\mathbf{i} - \begin{vmatrix}-\sin t & 1\\ -\cos t & 0\end{vmatrix}\mathbf{j} + \begin{vmatrix}-\sin t & \cos t\\ -\cos t & -\sin t\end{vmatrix}\mathbf{k}\\ &= (\sin t)\mathbf{i} - (\cos t)\mathbf{j} + 1\cdot\mathbf{k} \quad (3)\end{aligned}$$

We calculate the norms of the vectors in (1). By (2) and (3) we have:

$$\|\mathbf{r}'(t)\times\mathbf{r}''(t)\| = \sqrt{\sin^2 t + (-\cos t)^2 + 1^2} = \sqrt{1+1} = \sqrt{2}$$

$$\|\mathbf{r}'(t)\| = \sqrt{(-\sin t)^2 + \cos^2 t + 1^2} = \sqrt{1+1} = \sqrt{2} \tag{4}$$

Substituting (4) in (1) yields the following curvature:

$$\kappa(t) = \frac{\sqrt{2}}{\left(\sqrt{2}\right)^3} = \frac{1}{2} \quad \Rightarrow \quad \kappa(0) = \frac{1}{2} \tag{5}$$

The unit normal vector is the following vector:

$$\mathbf{N}(t) = \frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|} \tag{6}$$

By (2) and (4) we have:

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \frac{1}{\sqrt{2}}\langle -\sin t, \cos t, 1\rangle \quad \Rightarrow \quad \mathbf{T}'(t) = \frac{1}{\sqrt{2}}\langle -\cos t, -\sin t, 0\rangle \tag{7}$$

$$\|\mathbf{T}'(t)\| = \frac{1}{\sqrt{2}}\sqrt{(-\cos t)^2 + (-\sin t)^2 + 0^2} = \frac{1}{\sqrt{2}} \cdot 1 = \frac{1}{\sqrt{2}}$$

Combining (6) and (7) gives:

$$\mathbf{N}(t) = \langle -\cos t, -\sin t, 0\rangle \quad \Rightarrow \quad \mathbf{N}(0) = \langle -1, 0, 0\rangle \tag{8}$$

The center of curvature at $t = 0$ is:

$$\overrightarrow{OQ} = \mathbf{r}(0) + \kappa(0)^{-1}\mathbf{N}(0)$$

By (5), (8) and $\mathbf{r}(0) = \langle 1, 0, 0\rangle$ we get:

$$\overrightarrow{OQ} = \langle 1, 0, 0\rangle + 2\langle -1, 0, 0\rangle = \langle 1, 0, 0\rangle + \langle -2, 0, 0\rangle = \langle -1, 0, 0\rangle$$

Finally, we find a parametrization of the osculating circle at $t = 0$. The osculating circle has radius $R = \frac{1}{\kappa(0)} = 2$ and center $\langle -1, 0, 0\rangle$, hence it has the following parametrization:

$$\mathbf{c}(t) = \langle -1, 0, 0\rangle + 2\mathbf{N}(0)\cos t + 2\mathbf{T}(0)\sin t = \langle -1, 0, 0\rangle + 2\langle -1, 0, 0\rangle \cos t + \frac{2}{\sqrt{2}}\langle 0, 1, 1\rangle \sin t$$

$$\mathbf{c}(t) = \left\langle -1 - 2\cos t, \frac{2\sin t}{\sqrt{2}}, \frac{2\sin t}{\sqrt{2}}\right\rangle$$

58. $\mathbf{r}(t) = \langle \cosh t, \sinh t, t\rangle, \quad t = 0$

SOLUTION

Step 1. Find κ and $\mathbf{N}$. In Exercise 14 we found that:

$$\kappa(t) = \frac{1}{2\cosh^2 t} \quad \Rightarrow \quad \kappa(0) = \frac{1}{2\cosh^2 0} = \frac{1}{2} \tag{1}$$

We now must find the unit normal $\mathbf{N}$. We have:

$$\mathbf{r}'(t) = \langle \sinh t, \cosh t, 1\rangle$$

$$\|\mathbf{r}'(t)\| = \sqrt{\sinh^2 t + \cosh^2 t + 1} = \sqrt{\cosh^2 t - 1 + \cosh^2 t + 1} = \sqrt{2\cosh^2 t} = \sqrt{2}\cosh t$$

$$\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|} = \frac{1}{\sqrt{2}\cosh t}\langle \sinh t, \cosh t, 1\rangle = \frac{1}{\sqrt{2}}\langle \tanh t, 1, \operatorname{sech} t\rangle$$

$$\mathbf{T}'(t) = \frac{1}{\sqrt{2}}\left\langle \operatorname{sech}^2 t, 0, -\operatorname{sech} t \tanh t\right\rangle$$

We compute the length of $\mathbf{T}'(t)$. Using the identity $\tanh^2 t + \operatorname{sech}^2 t = 1$ we get:

$$\|\mathbf{T}'(t)\| = \frac{1}{\sqrt{2}}\sqrt{\operatorname{sech}^4 t + 0 + \operatorname{sech}^2 t \tanh^2 t} = \frac{1}{\sqrt{2}}\sqrt{\operatorname{sech}^2 t\left(\tanh^2 t + \operatorname{sech}^2 t\right)} = \frac{1}{\sqrt{2}}\sqrt{\operatorname{sech}^2 t \cdot 1} = \frac{\operatorname{sech} t}{\sqrt{2}}$$

Hence,

$$\mathbf{N}(t) = \frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|} = \frac{\sqrt{2}}{\operatorname{sech} t}\frac{1}{\sqrt{2}} \cdot \left\langle \operatorname{sech}^2 t, 0, -\operatorname{sech} t \tanh t\right\rangle = \langle \operatorname{sech} t, 0, -\tanh t\rangle$$

At the point $t = 0$ we have $\operatorname{sech} 0 = 1$, $\tanh 0 = 0$, hence

$$\mathbf{N}(0) = \langle 1, 0, 0\rangle \tag{2}$$

Step 2. Find the center of the osculating circle. The center Q of the osculating circle at $\mathbf{r}(0) = \langle 1, 0, 0\rangle$ has position vector:

$$\overrightarrow{OQ} = \mathbf{r}(0) + \kappa(0)^{-1}\mathbf{N}(0)$$

Substituting (1), (2) and $\mathbf{r}(0) = \langle 1, 0, 0\rangle$ we get:

$$\overrightarrow{OQ} = \langle 1, 0, 0\rangle + 2 \cdot \langle 1, 0, 0\rangle = \langle 3, 0, 0\rangle$$

Step 3. Parametrize the osculating circle. The osculating circle is centered at $Q = (3, 0, 0)$ and has radius $R = \frac{1}{\kappa(0)} = 2$, hence it has the following parametrization:

$$\mathbf{c}(t) = \langle 3, 0, 0\rangle + 2\mathbf{N}\cos t + 2\mathbf{T}\sin t = \langle 3, 0, 0\rangle + 2\langle 1, 0, 0\rangle \cos t + \frac{2}{\sqrt{2}}\langle 0, 1, 1\rangle \sin t$$

59. Figure 18 shows the graph of the half-ellipse $y = \pm\sqrt{2rx - px^2}$, where r and p are positive constants. Show that the radius of curvature at the origin is equal to r. *Hint:* One way of proceeding is to write the ellipse in the form of Exercise 25 and apply Eq. (9).

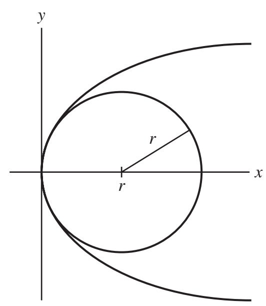


FIGURE 18 The curve $y = \pm\sqrt{2rx - px^2}$ and the osculating circle at the origin.

SOLUTION The radius of curvature is the reciprocal of the curvature. We thus must find the curvature at the origin. We use the following simple variant of the formula for the curvature of a graph in the plane:

$$\kappa(y) = \frac{|x''(y)|}{\left(1 + x'(y)^2\right)^{3/2}} \tag{1}$$

(The traditional formula of $\kappa(x) = \frac{|y''(x)|}{\left(1+y'(x)^2\right)^{3/2}}$ is inappropriate for this problem, as $y'(x)$ is undefined at $x = 0$.) We find x in terms of y:

$$\begin{aligned} y &= \sqrt{2rx - px^2} \\ y^2 &= 2rx - px^2 \\ px^2 - 2rx + y^2 &= 0 \end{aligned}$$

We solve for x and obtain:

$$x = \pm\frac{1}{p}\sqrt{r^2 - py^2} + \frac{r}{p}, \quad y \geq 0.$$

We find x' and x'':

$$x' = \pm\frac{-2py}{2p\sqrt{r^2 - py^2}} = \pm\frac{y}{\sqrt{r^2 - py^2}}$$

$$x'' = \pm\frac{1 \cdot \sqrt{r^2 - py^2} - y \cdot \frac{-py}{\sqrt{r^2 - py^2}}}{r^2 - py^2} = \pm\frac{r^2 - py^2 + py^2}{\left(r^2 - py^2\right)^{3/2}} = \pm\frac{r^2}{\left(r^2 - py^2\right)^{3/2}}$$

At the origin we get:

$$x'(0) = 0, \quad x''(0) = \frac{\pm r^2}{(r^2)^{3/2}} = \frac{\pm 1}{r}$$

Substituting in (1) gives the following curvature at the origin:

$$\kappa(0) = \frac{|x''(0)|}{(1 + x'(0)^2)^{3/2}} = \frac{|\frac{\pm 1}{r}|}{(1+0)^{3/2}} = \frac{1}{|r|} = \frac{1}{r}$$

We conclude that the radius of curvature at the origin is

$$R = \frac{1}{\kappa(0)} = r$$

60. In a recent study of laser eye surgery by Gatinel, Hoang-Xuan, and Azar, a vertical cross section of the cornea is modeled by the half-ellipse of Exercise 59. Show that the half-ellipse can be written in the form $x = f(y)$, where $f(y) = p^{-1}\left(r - \sqrt{r^2 - py^2}\right)$. During surgery, tissue is removed to a depth $t(y)$ at height y for $-S \le y \le S$, where $t(y)$ is given by Munnerlyn's equation (for some $R > r$):

$$t(y) = \sqrt{R^2 - S^2} - \sqrt{R^2 - y^2} - \sqrt{r^2 - S^2} + \sqrt{r^2 - y^2}$$

After surgery, the cross section of the cornea has the shape $x = f(y) + t(y)$ (Figure 19). Show that after surgery, the radius of curvature at the point P (where $y = 0$) is R.

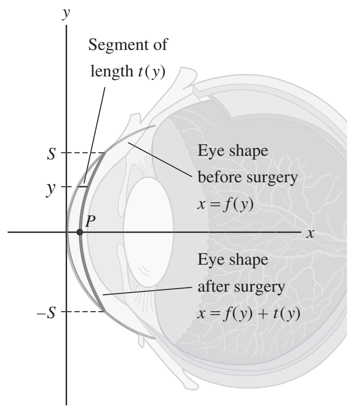

FIGURE 19 Contour of cornea before and after surgery.

SOLUTION We consider the half-ellipse:

$$r > 0, \quad p > 0, \quad y = \sqrt{2rx - px^2}$$

As in Exercise 59, squaring the two sides and solving for x gives:

$$x - \frac{r}{p} = \pm\frac{1}{p}\sqrt{r^2 - py^2} \quad \Rightarrow \quad x = \frac{1}{p}\left(r \pm \sqrt{r^2 - py^2}\right)$$

The negative sign must be taken, since this is the half in which we are interested. That is,

$$f(y) = x = \frac{1}{p}\left(r - \sqrt{r^2 - py^2}\right) \tag{1}$$

We are given the following curve:

$$x = f(y) + t(y)$$

where

$$t(y) = \sqrt{R^2 - S^2} - \sqrt{R^2 - y^2} - \sqrt{r^2 - S^2} + \sqrt{r^2 - y^2} \tag{2}$$

We must show that the radius of curvature at O is R. We use the curvature of a graph in the plane:

$$\kappa(y) = \frac{|x''(y)|}{\left(1 + x'(y)^2\right)^{3/2}} \quad \Rightarrow \quad \kappa(0) = \frac{|x''(0)|}{\left(1 + x'(0)^2\right)^{3/2}} \tag{3}$$

We differentiate $f(y)$ in (1) and $t(y)$ in (2) twice. This gives:

$$f'(y) = -\frac{1}{p} \cdot \frac{-py}{\sqrt{r^2 - py^2}} = \frac{y}{\sqrt{r^2 - py^2}}$$

$$f''(y) = \frac{\sqrt{r^2 - py^2} - y \cdot \frac{-py}{\sqrt{r^2-py^2}}}{r^2 - py^2} = \frac{r^2 - py^2 + py^2}{\left(r^2 - py^2\right)^{3/2}} = \frac{r^2}{\left(r^2 - py^2\right)^{3/2}}$$

$$t'(y) = -\frac{-2y}{2\sqrt{R^2 - y^2}} + \frac{-2y}{2\sqrt{r^2 - y^2}} = \frac{y}{\sqrt{R^2 - y^2}} - \frac{y}{\sqrt{r^2 - y^2}}$$

$$t''(y) = \frac{\sqrt{R^2 - y^2} - y \cdot \frac{-y}{\sqrt{R^2-y^2}}}{R^2 - y^2} - \frac{\sqrt{r^2 - y^2} - y \cdot \frac{-y}{\sqrt{r^2-y^2}}}{r^2 - y^2} = \frac{R^2 - y^2 + y^2}{\left(R^2 - y^2\right)^{3/2}} - \frac{r^2 - y^2 + y^2}{\left(r^2 - y^2\right)^{3/2}}$$

$$= \frac{R^2}{\left(R^2 - y^2\right)^{3/2}} - \frac{r^2}{\left(r^2 - y^2\right)^{3/2}}$$

At $y = 0$ we obtain:

$$f'(0) = 0; \quad t'(0) = 0$$

$$f''(0) = \frac{r^2}{(r^2)^{3/2}} = \frac{1}{r}; \quad t''(0) = \frac{R^2}{(R^2)^{3/2}} - \frac{r^2}{(r^2)^{3/2}} = \frac{1}{R} - \frac{1}{r}$$

Hence,

$$x''(0) = f''(0) + t''(0) = \frac{1}{r} + \frac{1}{R} - \frac{1}{r} = \frac{1}{R}$$

$$x'(0) = f'(0) + t'(0) = 0$$

Substituting in (3) gives the following curvature:

$$\kappa(0) = \frac{\frac{1}{R}}{\left(1 + 0^2\right)^{3/2}} = \frac{1}{R}.$$

The radius of curvature at the origin is therefore,

$$\frac{1}{\kappa(0)} = \frac{1}{\frac{1}{R}} = R.$$

61. The **angle of inclination** at a point P on a plane curve is the angle θ between the unit tangent vector $\mathbf{T}$ and the x-axis (Figure 20). Assume that $\mathbf{r}(s)$ is a arc length parametrization, and let $\theta = \theta(s)$ be the angle of inclination at $\mathbf{r}(s)$. Prove that

$$\kappa(s) = \left|\frac{d\theta}{ds}\right| \qquad \boxed{12}$$

Hint: Observe that $\mathbf{T}(s) = \langle \cos\theta(s), \sin\theta(s)\rangle$.

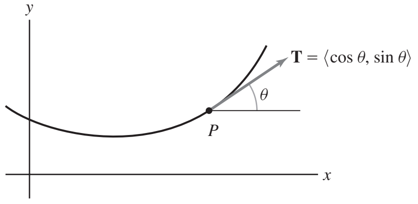

FIGURE 20 The curvature at P is the quantity $|d\theta/ds|$.

SOLUTION Since $\mathbf{T}(t)$ is a unit vector that makes an angle $\theta(t)$ with the positive x-axis, we have

$$\mathbf{T}(t) = \langle \cos\theta(t), \sin\theta(t)\rangle .$$

Differentiating this vector using the Chain Rule gives:

$$\mathbf{T}'(t) = \left\langle -\theta'(t)\sin\theta(t), \theta'(t)\cos\theta(t)\right\rangle = \theta'(t)\left\langle -\sin\theta(t), \cos\theta(t)\right\rangle$$

We compute the norm of the vector $\mathbf{T}'(t)$:

$$\|\mathbf{T}'(t)\| = \|\theta'(t)\left\langle -\sin\theta(t), \cos\theta(t)\right\rangle\| = |\theta'(t)|\sqrt{(-\sin\theta(t))^2 + (\cos\theta(t))^2} = |\theta'(t)| \cdot 1 = |\theta'(t)|$$

When $\mathbf{r}(s)$ is a parametrization by arc length we have:

$$\kappa(s) = \left\| \frac{d\mathbf{T}}{ds} \right\| = \left\| \frac{d\mathbf{T}}{dt} \right\| \left| \frac{dt}{d\theta} \frac{d\theta}{ds} \right| = \left|\theta'(t)\right| \frac{1}{|\theta'(t)|} \left| \frac{d\theta}{ds} \right| = \left| \frac{d\theta}{ds} \right|$$

as desired.

62. A particle moves along the path $y = x^3$ with unit speed. How fast is the tangent turning (i.e., how fast is the angle of inclination changing) when the particle passes through the point (2, 8)?

SOLUTION The particle has unit speed hence the parametrization is in arc length parametrization. Therefore, the change in the angle of inclination is, by Exercise 61:

$$\left| \frac{d\theta}{ds} \right| = \kappa(s)$$

In particular at the point (2, 8) we have:

$$\left| \frac{d\theta}{ds} \right|_{(2,8)} = \kappa(s)\big|_{(2,8)} \tag{1}$$

We, thus, must find the curvature at the given point. We use the formula for the curvature of a graph in the plane:

$$\kappa(x) = \frac{|y''(x)|}{\left(1 + y'(x)^2\right)^{3/2}} \quad \Rightarrow \quad \kappa(2) = \frac{|y''(2)|}{\left(1 + y'(2)^2\right)^{3/2}} \tag{2}$$

For $y = x^3$ we have $y' = 3x^2$ and $y'' = 6x$, hence $y'(2) = 12$ and $y''(2) = 12$. Substituting in (2), we get:

$$\kappa(2) = \frac{12}{\left(1 + 12^2\right)^{3/2}} = \frac{12}{145^{3/2}} \approx 0.0069$$

Combining with (1) we conclude that when the particle passes through the point (2, 8) the tangent is turning at a rate of 0.0069.

63. Let $\theta(x)$ be the angle of inclination at a point on the graph $y = f(x)$ (see Exercise 61).

(a) Use the relation $f'(x) = \tan\theta$ to prove that $\dfrac{d\theta}{dx} = \dfrac{f''(x)}{(1 + f'(x)^2)}$.

(b) Use the arc length integral to show that $\dfrac{ds}{dx} = \sqrt{1 + f'(x)^2}$.

(c) Now give a proof of Eq. (5) using Eq. (12).

SOLUTION

(a) By the relation $f'(x) = \tan\theta$ we have $\theta = \tan^{-1} f'(x)$. Differentiating using the Chain Rule we get:

$$\frac{d\theta}{dx} = \frac{d}{dx}\left(\tan^{-1} f'(x)\right) = \frac{1}{1 + f'(x)^2} \frac{d}{dx}\left(f'(x)\right) = \frac{f''(x)}{1 + f'(x)^2}$$

(b) We use the parametrization $\mathbf{r}(x) = \langle x, f(x)\rangle$. Hence, $\mathbf{r}'(x) = \left\langle 1, f'(x)\right\rangle$ and we obtain the following arc length function:

$$S(x) = \int_0^x \|\mathbf{r}'(u)\|\, du = \int_0^x \left\|\left\langle 1, f'(u)\right\rangle\right\| du = \int_0^x \sqrt{1 + f'(u)^2}\, du$$

Differentiating using the Fundamental Theorem gives:

$$\frac{ds}{dx} = \frac{d}{dx}\left(\int_0^x \sqrt{1 + f'(u)^2}\, du\right) = \sqrt{1 + f'(x)^2}$$

(c) By Eq. (12),

$$\kappa(s) = \left| \frac{d\theta}{ds} \right| \tag{1}$$

Using the Chain Rule and the equalities in part (a) and part (b), we obtain:

$$\frac{d\theta}{ds} = \frac{d\theta}{dx} \cdot \frac{dx}{ds} = \frac{d\theta}{dx} \cdot \frac{1}{\frac{ds}{dx}} = \frac{f''(x)}{1 + f'(x)^2} \cdot \frac{1}{\sqrt{1 + f'(x)^2}} = \frac{f''(x)}{\left(1 + f'(x)^2\right)^{3/2}}$$

Combining with (1) we obtain the curvature as the following function of x:

$$\kappa(x) = \frac{|f''(x)|}{\left(1 + f'(x)^2\right)^{3/2}}$$

which proves Eq. (5).

64. Use the parametrization $\mathbf{r}(\theta) = \langle f(\theta)\cos\theta, f(\theta)\sin\theta\rangle$ to show that a curve $r = f(\theta)$ in polar coordinates has curvature

$$\kappa(\theta) = \frac{|f(\theta)^2 + 2f'(\theta)^2 - 2f(\theta)f''(\theta)|}{\left(f(\theta)^2 + f'(\theta)^2\right)^{3/2}} \qquad \boxed{13}$$

SOLUTION By the formula for curvature we have

$$\kappa(\theta) = \frac{\|\mathbf{r}'(\theta) \times \mathbf{r}''(\theta)\|}{\|\mathbf{r}'(\theta)\|^3} \tag{1}$$

We differentiate $\mathbf{r}(\theta)$ and $\mathbf{r}'(\theta)$:

$$\begin{aligned}
\mathbf{r}'(\theta) &= \left\langle f'(\theta)\cos\theta - f(\theta)\sin\theta,\ f'(\theta)\sin\theta + f(\theta)\cos\theta\right\rangle\\
\mathbf{r}''(\theta) &= \left\langle f''(\theta)\cos\theta - f'(\theta)\sin\theta - f'(\theta)\sin\theta - f(\theta)\cos\theta,\right.\\
&\qquad \left. f''(\theta)\sin\theta + f'(\theta)\cos\theta + f'(\theta)\cos\theta - f(\theta)\sin\theta\right\rangle\\
&= \left\langle \left(f''(\theta) - f(\theta)\right)\cos\theta - 2f'(\theta)\sin\theta,\ \left(f''(\theta) - f(\theta)\right)\sin\theta + 2f'(\theta)\cos\theta\right\rangle
\end{aligned}$$

Hence,

$$\begin{aligned}
\mathbf{r}'(\theta) \times \mathbf{r}''(\theta) &= \left(f'(\theta)\cos\theta - f(\theta)\sin\theta\right)\cdot\left(\left(f''(\theta) - f(\theta)\right)\sin\theta + 2f'(\theta)\cos\theta\right)\mathbf{k}\\
&\quad - \left(f'(\theta)\sin\theta + f(\theta)\cos\theta\right)\cdot\left(\left(f''(\theta) - f(\theta)\right)\cos\theta - 2f'(\theta)\sin\theta\right)\mathbf{k}\\
&= \Big\{ f'(\theta)\left(f''(\theta) - f(\theta)\right)\cos\theta\sin\theta - f(\theta)\left(f''(\theta) - f(\theta)\right)\sin^2\theta + 2f'^2(\theta)\cos^2\theta\\
&\quad - 2f(\theta)f'(\theta)\sin\theta\cos\theta\Big(-f'(\theta)\left(f''(\theta) - f(\theta)\right)\sin\theta\cos\theta - f(\theta)\left(f''(\theta) - f(\theta)\right)\cos^2\theta\\
&\quad + 2f'(\theta)^2\sin^2\theta + 2f(\theta)f'(\theta)\cos\theta\sin\theta\Big)\Big\}\mathbf{k}\\
&= \Big(-f(\theta)\left(f''(\theta) - f(\theta)\right)\left(\sin^2\theta + \cos^2\theta\right) + 2f'^2(\theta)\left(\cos^2\theta + \sin^2\theta\right)\Big)\mathbf{k}\\
&= \Big(-f(\theta)\left(f''(\theta) - f(\theta)\right) + 2f'^2(\theta)\Big)\mathbf{k}\\
&= \Big(-f(\theta)f''(\theta) + f^2(\theta) + 2f'^2(\theta)\Big)\mathbf{k}
\end{aligned}$$

The length of the cross product is:

$$\|\mathbf{r}'(\theta) \times \mathbf{r}''(\theta)\| = |f^2(\theta) + 2f'^2(\theta) - f(\theta)f''(\theta)| \tag{2}$$

We compute the length of $\mathbf{r}'(\theta)$:

$$\begin{aligned}
\|\mathbf{r}'(\theta)\|^2 &= \left(f'(\theta)\cos\theta - f(\theta)\sin\theta\right)^2 + \left(f'(\theta)\sin\theta + f(\theta)\cos\theta\right)^2\\
&= f'^2(\theta)\cos^2\theta - 2f'(\theta)f(\theta)\cos\theta\sin\theta + f^2(\theta)\sin^2\theta + f'^2(\theta)\sin^2\theta\\
&\quad + 2f'(\theta)f(\theta)\sin\theta\cos\theta + f^2(\theta)\cos^2\theta\\
&= f'^2(\theta)\left(\cos^2\theta + \sin^2\theta\right) + f^2(\theta)\left(\sin^2\theta + \cos^2\theta\right) = f'^2(\theta) + f^2(\theta)
\end{aligned}$$

Hence,

$$\|\mathbf{r}'(\theta)\| = \sqrt{f'^2(\theta) + f^2(\theta)} \tag{3}$$

Substituting (2) and (3) in (1) gives:

$$\kappa(\theta) = \frac{|f^2(\theta) + 2f'^2(\theta) - f(\theta)f''(\theta)|}{\left(f'^2(\theta) + f^2(\theta)\right)^{3/2}}$$

In Exercises 65–67, use Eq. (13) to find the curvature of the curve given in polar form.

65. $f(\theta) = 2\cos\theta$

SOLUTION By Eq. (13):,

$$\kappa(\theta) = \frac{|f(\theta)^2 + 2f'(\theta)^2 - f(\theta)f''(\theta)|}{\left(f(\theta)^2 + f'^2(\theta)\right)^{3/2}}$$

We compute the derivatives $f'(\theta)$ and $f''(\theta)$ and evaluate the numerator of $\kappa(\theta)$. This gives:

$$\begin{aligned} f'(\theta) &= -2\sin\theta \\ f''(\theta) &= -2\cos\theta \\ f(\theta)^2 + 2f'(\theta)^2 - f(\theta)f''(\theta) &= 4\cos^2\theta + 2\cdot 4\sin^2\theta - 2\cos\theta(-2\cos\theta) \\ &= 8\cos^2\theta + 8\sin^2\theta = 8 \end{aligned}$$

We compute the denominator of $\kappa(\theta)$:

$$\left(f(\theta)^2 + f'(\theta)^2\right)^{3/2} = \left(4\cos^2\theta + 4\sin^2\theta\right)^{3/2} = 4^{3/2} = 8$$

Hence,

$$\kappa(\theta) = \frac{8}{8} = 1$$

66. $f(\theta) = \theta$

SOLUTION We have $f'(\theta) = 1$, $f''(\theta) = 0$. The numerator and denominator in Eq. (13) are thus:

$$\begin{aligned} f(\theta)^2 + 2f'(\theta) - f(\theta)f''(\theta) &= \theta^2 + 2\cdot 1 - 0 = \theta^2 + 2 \\ \left(f(\theta)^2 + f'(\theta)^2\right)^{3/2} &= \left(\theta^2 + 1\right)^{3/2} \end{aligned}$$

Hence,

$$\kappa(\theta) = \frac{\theta^2 + 2}{\left(\theta^2 + 1\right)^{3/2}}$$

67. $f(\theta) = e^\theta$

SOLUTION By Eq. (13) we have the following curvature:

$$\kappa(\theta) = \frac{|f(\theta)^2 + 2f'(\theta)^2 - f(\theta)f''(\theta)|}{\left(f(\theta)^2 + f'^2(\theta)\right)^{3/2}}$$

Since $f(\theta) = e^\theta$ also $f'(\theta) = f''(\theta) = e^\theta$. We compute the numerator and denominator of $\kappa(\theta)$:

$$\begin{aligned} f(\theta)^2 + 2f'(\theta)^2 - f(\theta)f''(\theta) &= e^{2\theta} + 2e^{2\theta} - e^\theta\cdot e^\theta = 2e^{2\theta} \\ \left(f(\theta)^2 + f'(\theta)^2\right)^{3/2} &= \left(e^{2\theta} + e^{2\theta}\right)^{3/2} = \left(2e^{2\theta}\right)^{3/2} = 2\sqrt{2}e^{3\theta} \end{aligned}$$

Substituting in the formula for $\kappa(\theta)$ we obtain:

$$\kappa(\theta) = \frac{2e^{2\theta}}{2\sqrt{2}e^{3\theta}} = \frac{1}{\sqrt{2}}e^{-\theta}$$

68. Use Eq. (13) to find the curvature of the general Bernoulli spiral $r = ae^{b\theta}$ in polar form (a and b are constants).

SOLUTION By Eq. (13):

$$\kappa(\theta) = \frac{|f(\theta)^2 + 2f'(\theta)^2 - f(\theta)f''(\theta)|}{\left(f(\theta)^2 + f'^2(\theta)\right)^{3/2}}$$

In our case $f(\theta) = ae^{b\theta}$ hence $f'(\theta) = abe^{b\theta}$ and $f''(\theta) = ab^2e^{b\theta}$. We compute the numerator of $\kappa(\theta)$:

$$f(\theta)^2 + 2f'(\theta)^2 - f(\theta)f''(\theta) = a^2e^{2b\theta} + 2a^2b^2e^{2b\theta} - ae^{b\theta}\cdot ab^2e^{b\theta} = a^2e^{2b\theta} + 2a^2b^2e^{2b\theta} - a^2b^2e^{2b\theta}$$

$$= a^2e^{2b\theta} + a^2b^2e^{2b\theta} = a^2(1+b^2)e^{2b\theta}$$

We compute the denominator of $\kappa(\theta)$:

$$\left(f(\theta)^2 + f'(\theta)^2\right)^{3/2} = \left(a^2e^{2b\theta} + a^2b^2e^{2b\theta}\right)^{3/2} = \left(a^2e^{2b\theta}\left(1+b^2\right)\right)^{3/2} = a^3e^{3b\theta}\left(1+b^2\right)^{3/2}$$

Therefore:

$$\kappa(\theta) = \frac{a^2(1+b^2)e^{2b\theta}}{a^3(1+b^2)^{3/2}e^{3b\theta}} = \frac{1}{a\sqrt{1+b^2}}e^{-b\theta}$$

69. Show that both $\mathbf{r}'(t)$ and $\mathbf{r}''(t)$ lie in the osculating plane for a vector function $\mathbf{r}(t)$. *Hint:* Differentiate $\mathbf{r}'(t) = v(t)\mathbf{T}(t)$.

SOLUTION The osculating plane at P is the plane through P determined by the unit tangent $\mathbf{T}$ and the unit normal $\mathbf{N}$ at P. Since $\mathbf{T}(t) = \frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|}$ we have $\mathbf{r}'(t) = v(t)\mathbf{T}(t)$ where $v(t) = \|\mathbf{r}'(t)\|$. That is, $\mathbf{r}'(t)$ is a scalar multiple of $\mathbf{T}(t)$, hence it lies in every plane containing $\mathbf{T}(t)$, in particular in the osculating plane. We now differentiate $\mathbf{r}'(t) = v(t)\mathbf{T}(t)$ using the Product Rule:

$$\mathbf{r}''(t) = v'(t)\mathbf{T}(t) + v(t)\mathbf{T}'(t) \tag{1}$$

By $\mathbf{N}(t) = \frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|}$ we have $\mathbf{T}'(t) = b(t)\mathbf{N}(t)$ for $b(t) = \|\mathbf{T}'(t)\|$. Substituting in (1) gives:

$$\mathbf{r}''(t) = v'(t)\mathbf{T}(t) + v(t)b(t)\mathbf{N}(t)$$

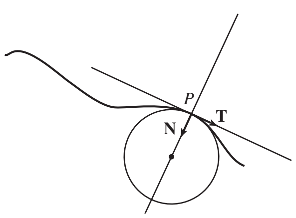
We see that $\mathbf{r}''(t)$ is a linear combination of $\mathbf{T}(t)$ and $\mathbf{N}(t)$, hence $\mathbf{r}''(t)$ lies in the plane determined by these two vectors, that is, $\mathbf{r}''(t)$ lies in the osculating plane.

70. Show that

$$\gamma(s) = \mathbf{r}(t_0) + \frac{1}{\kappa}\mathbf{N} + \frac{1}{\kappa}\left((\sin\kappa s)\mathbf{T} - (\cos\kappa s)\mathbf{N}\right)$$

is an arc length parametrization of the osculating circle at $\mathbf{r}(t_0)$.

SOLUTION Let P be a fixed point on the curve $\mathcal{C}$, $\mathbf{T}$ and $\mathbf{N}$ are the unit tangent and the unit normal to the curve at P. We place the xy-coordinate system so that the origin is at P and the x and y axes are in the directions of $\mathbf{T}$ and $\mathbf{N}$, respectively. We next show that $\gamma(s)$ is an arc length parametrization of the osculating circle at P.



We compute the following expression:

$$\left\|\gamma(s) - \frac{1}{\kappa}\mathbf{N}\right\|^2 = \frac{1}{\kappa^2}\|(\sin\kappa s)\,\mathbf{T} - (\cos\kappa s)\,\mathbf{N}\|^2 = \frac{1}{\kappa^2}\left((\sin\kappa s)\,\mathbf{T} - (\cos\kappa s)\,\mathbf{N}\right)\cdot\left((\sin\kappa s)\,\mathbf{T} - (\cos\kappa s)\,\mathbf{N}\right)$$

$$= \frac{1}{\kappa^2}\left(\sin^2\kappa s\mathbf{T}\cdot\mathbf{T} - (\sin\kappa s\cos\kappa s)\,\mathbf{T}\cdot\mathbf{N} - (\cos\kappa s\sin\kappa s)\,\mathbf{N}\cdot\mathbf{T} + \left(\cos^2\kappa s\right)\mathbf{N}\cdot\mathbf{N}\right)$$

The vectors $\mathbf{T}$ and $\mathbf{N}$ are orthogonal unit vectors, hence $\mathbf{T}\cdot\mathbf{N} = \mathbf{N}\cdot\mathbf{T} = 0$ and $\mathbf{T}\cdot\mathbf{T} = \|\mathbf{T}\|^2 = 1$, $\mathbf{N}\cdot\mathbf{N} = \|\mathbf{N}\|^2 = 1$. We use the identity $\sin^2(\kappa s) + \cos^2(\kappa s) = 1$ to obtain

$$\left\|\gamma(s) - \frac{1}{\kappa}\mathbf{N}\right\|^2 = \frac{1}{\kappa^2}\left(\sin^2\kappa s + \cos^2\kappa s\right) = \frac{1}{\kappa^2}$$

That is,

$$\left\|\gamma(s) - \frac{1}{\kappa}\mathbf{N}\right\| = \frac{1}{\kappa} \tag{1}$$

Notice that κ, $\mathbf{N}$, and $\mathbf{T}$ are fixed and only s is changing in $\gamma(s)$. It follows by (1) that $\gamma(s)$ is a circle of radius $\frac{1}{\kappa}$ centered at $\frac{1}{\kappa}\mathbf{N}$. The curvature of the circle is the reciprocal of the radius, which is κ (the curvature of $\mathcal{C}$ at the point P). We thus showed that the circle $\gamma(s)$ satisfies the second condition in the definition of the osculating circle. We now show that the first condition is satisfied as well.

The center of the circle is the terminal point of the vector $\frac{1}{\kappa}\mathbf{N}$, which is in the direction of $\mathbf{N}$ and orthogonal to $\mathbf{T}$. This shows that $\mathbf{T}$ and $\mathbf{N}$ are the unit tangent and unit normal to the circle at P. Finally, we verify that the given parametrization is the arc length parametrization, by showing that $\|\gamma'(s)\| = 1$. Differentiating $\gamma(s)$ with respect to s gives (notice that κ, $\mathbf{T}$, and $\mathbf{N}$ are fixed):

$$\gamma'(s) = \frac{1}{\kappa}\big((\kappa\cos\kappa s)\,\mathbf{T} + (\kappa\sin\kappa s)\,\mathbf{N}\big) = (\cos\kappa s)\mathbf{T} + (\sin\kappa s)\mathbf{N}$$

Hence, since $\mathbf{T}\cdot\mathbf{T} = \mathbf{N}\cdot\mathbf{N} = 1$ and $\mathbf{T}\cdot\mathbf{N} = \mathbf{N}\cdot\mathbf{T} = 0$ we get:

$$\begin{aligned}\|\gamma'(s)\|^2 &= \big((\cos\kappa s)\mathbf{T} + (\sin\kappa s)\mathbf{N}\big)\cdot\big((\cos\kappa s)\mathbf{T} + (\sin\kappa s)\mathbf{N}\big)\\ &= \big(\cos^2\kappa s\big)\mathbf{T}\cdot\mathbf{T} + (\cos\kappa s)(\sin\kappa s)\mathbf{T}\cdot\mathbf{N} + (\sin\kappa s\cos\kappa s)\mathbf{N}\cdot\mathbf{T} + \big(\sin^2\kappa s\big)\mathbf{N}\cdot\mathbf{N}\\ &= \cos^2\kappa s + \sin^2\kappa s = 1\end{aligned}$$

Hence

$$\|\gamma'(s)\| = 1$$

71. Two vector-valued functions $\mathbf{r}_1(s)$ and $\mathbf{r}_2(s)$ are said to *agree to order 2* at s_0 if

$$\mathbf{r}_1(s_0) = \mathbf{r}_2(s_0), \quad \mathbf{r}_1'(s_0) = \mathbf{r}_2'(s_0), \quad \mathbf{r}_1''(s_0) = \mathbf{r}_2''(s_0)$$

Let $\mathbf{r}(s)$ be an arc length parametrization of a path $\mathcal{C}$, and let P be the terminal point of $\mathbf{r}(0)$. Let $\gamma(s)$ be the arc length parametrization of the osculating circle given in Exercise 70. Show that $\mathbf{r}(s)$ and $\gamma(s)$ agree to order 2 at $s = 0$ (in fact, the osculating circle is the unique circle that approximates $\mathcal{C}$ to order 2 at P).

SOLUTION The arc length parametrization of the osculating circle at P, described in the xy-coordinate system with P at the origin and the x and y axes in the directions of $\mathbf{T}$ and $\mathbf{N}$ respectively, is given in Exercise 70 by:

$$\gamma(s) = \frac{1}{\kappa}\mathbf{N} + \frac{1}{\kappa}\big((\sin\kappa s)\mathbf{T} - (\cos\kappa s)\mathbf{N}\big)$$

Hence

$$\begin{aligned}\gamma(0) &= \frac{1}{\kappa}\mathbf{N} + \frac{1}{\kappa}\big((\sin 0)\mathbf{T} - (\cos 0)\mathbf{N}\big) = \frac{1}{\kappa}\mathbf{N} + \frac{1}{\kappa}(0 - 1\cdot\mathbf{N}) = \frac{1}{\kappa}\mathbf{N} - \frac{1}{\kappa}\mathbf{N} = \mathbf{0}\\ \mathbf{r}(0) &= \overrightarrow{OP} = \mathbf{0}\end{aligned}$$

We get:

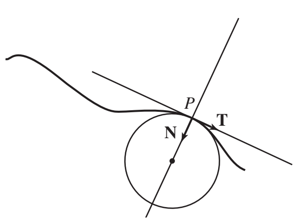
$$\gamma(0) = \mathbf{r}(0) \tag{1}$$

Differentiating $\gamma(s)$ gives (notice that $\mathbf{N}$, $\mathbf{T}$, and κ are fixed):

$$\gamma'(s) = \frac{1}{\kappa}\big((\kappa\cos\kappa s)\mathbf{T} + (\kappa\sin\kappa s)\mathbf{N}\big) = (\cos\kappa s)\mathbf{T} + (\sin\kappa s)\mathbf{N}$$

Hence:

$$\gamma'(0) = (\cos\kappa\cdot 0)\,\mathbf{T} + (\sin\kappa\cdot 0)\,\mathbf{N} = 1\cdot\mathbf{T} + 0\cdot\mathbf{N} = \mathbf{T}$$



Also, since $\mathbf{r}(s)$ is the arc length parametrization, $\|\mathbf{r}'(s)\| = 1$, hence:

$$\mathbf{T} = \mathbf{T}(0) = \frac{\mathbf{r}'(0)}{\|\mathbf{r}'(0)\|} = \mathbf{r}'(0)$$

We conclude that:

$$\gamma'(0) = \mathbf{r}'(0) \tag{2}$$

We differentiate $\gamma'(s)$ to obtain:

$$\gamma''(s) = (-\kappa \sin \kappa s)\,\mathbf{T} + (\kappa \cos \kappa s)\,\mathbf{N}$$

Hence:

$$\gamma''(0) = (-\kappa \sin 0)\,\mathbf{T} + (\kappa \cos 0)\,\mathbf{N} = 0\mathbf{T} + \kappa\mathbf{N} = \kappa\mathbf{N}$$

For the arc length parametrization $\mathbf{r}(s)$ we have:

$$\mathbf{r}''(s) = \mathbf{T}'(s) = \|\mathbf{T}'(s)\|\mathbf{N}(s) = \|\mathbf{r}'(s)\|\kappa(s)\mathbf{N}(s) = 1 \cdot \kappa(s)\mathbf{N}(s)$$

Hence:

$$\mathbf{r}''(0) = \kappa(0)\mathbf{N}(0) = \kappa\mathbf{N}$$

We conclude that:

$$\gamma''(0) = \mathbf{r}''(0) \tag{3}$$

(1), (2), and (3) show that $\mathbf{r}(s)$ and $\gamma(s)$ agree to order two at $s = 0$.

72. Let $\mathbf{r}(t) = \langle x(t), y(t), z(t)\rangle$ be a path with curvature $\kappa(t)$ and define the scaled path $\mathbf{r}_1(t) = \langle \lambda x(t), \lambda y(t), \lambda z(t)\rangle$, where $\lambda \neq 0$ is a constant. Prove that curvature varies inversely with the scale factor. That is, prove that the curvature $\kappa_1(t)$ of $\mathbf{r}_1(t)$ is $\kappa_1(t) = \lambda^{-1}\kappa(t)$. This explains why the curvature of a circle of radius R is proportional to $1/R$ (in fact, it is equal to $1/R$). *Hint:* Use Eq. (3).

SOLUTION The resulting curvature k_1 and the original curvature κ are:

$$\kappa_1(t) = \frac{\|\mathbf{r}_1'(t) \times \mathbf{r}_1''(t)\|}{\|\mathbf{r}_1'(t)\|^3}, \quad \kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3}$$

We have

$$\mathbf{r}_1'(t) = \frac{d}{dt}\left(\lambda\mathbf{r}(t)\right) = \lambda\mathbf{r}'(t)$$

$$\mathbf{r}_1''(t) = \frac{d}{dt}\left(r_1'(t)\right) = \frac{d}{dt}\left(\lambda\mathbf{r}'(t)\right) = \lambda\mathbf{r}''(t)$$

Hence,

$$\|\mathbf{r}_1'(t) \times \mathbf{r}_1''(t)\| = \|\lambda\mathbf{r}'(t) \times \lambda\mathbf{r}''(t)\| = \lambda^2\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|$$

$$\|\mathbf{r}_1'(t)\| = \|\lambda\mathbf{r}'(t)\| = |\lambda|\|\mathbf{r}'(t)\|$$

Substituting in (1) we get:

$$\kappa_1(t) = \frac{\lambda^2\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{|\lambda|^3\|\mathbf{r}'(t)\|^3} = \frac{1}{|\lambda|}\frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} = \frac{1}{|\lambda|}\kappa(t)$$

We conclude that the resulting curvature is:

$$\kappa_1(t) = \frac{1}{|\lambda|}\kappa(t)$$

Multiplying the vector by λ causes the curvature to be divided by $|\lambda|$.

Further Insights and Challenges

73. Show that the curvature of Viviani's curve, given by $\mathbf{r}(t) = \langle 1 + \cos t, \sin t, 2\sin(t/2)\rangle$, is

$$\kappa(t) = \frac{\sqrt{13 + 3\cos t}}{(3 + \cos t)^{3/2}}$$

SOLUTION We use the formula for curvature:

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3} \tag{1}$$

Differentiating $\mathbf{r}(t)$ gives

$$\mathbf{r}'(t) = \left\langle -\sin t, \cos t, 2 \cdot \frac{1}{2}\cos\frac{t}{2}\right\rangle = \left\langle -\sin t, \cos t, \cos\frac{t}{2}\right\rangle$$

$$\mathbf{r}''(t) = \left\langle -\cos t, -\sin t, -\frac{1}{2}\sin\frac{t}{2}\right\rangle$$

We compute the cross product in (1):

$$\mathbf{r}'(t) \times \mathbf{r}''(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin t & \cos t & \cos\frac{t}{2} \\ -\cos t & -\sin t & -\frac{1}{2}\sin\frac{t}{2} \end{vmatrix}$$

$$= \left(-\frac{1}{2}\cos t \sin\frac{t}{2} + \sin t\cos\frac{t}{2}\right)\mathbf{i} - \left(\frac{1}{2}\sin t\sin\frac{t}{2} + \cos t\cos\frac{t}{2}\right)\mathbf{j} + \mathbf{k}$$

We find the length of the cross product:

$$\|\mathbf{r}'(t)\times\mathbf{r}''(t)\|^2 = \left(-\frac{1}{2}\cos t\sin\frac{t}{2} + \sin t\cos\frac{t}{2}\right)^2 + \left(\frac{1}{2}\sin t\sin\frac{t}{2} + \cos t\cos\frac{t}{2}\right)^2 + 1$$

$$= \frac{1}{4}\sin^2\frac{t}{2}\left(\cos^2 t + \sin^2 t\right) + \cos^2\frac{t}{2}\left(\sin^2 t + \cos^2 t\right) + 1$$

$$= \frac{1}{4}\sin^2\frac{t}{2} + \cos^2\frac{t}{2} + 1$$

We use the identities $\sin^2\frac{t}{2} + \cos^2\frac{t}{2} = 1$ and $\cos^2\frac{t}{2} = \frac{1}{2} + \frac{1}{2}\cos t$ to write:

$$\|\mathbf{r}'(t)\times\mathbf{r}''(t)\|^2 = \frac{1}{4}\sin^2\frac{t}{2} + \cos^2\frac{t}{2} + 1 = \frac{1}{4}\left(\sin^2\frac{t}{2} + \cos^2\frac{t}{2}\right) + \frac{3}{4}\cos^2\frac{t}{2} + 1$$

$$= \frac{1}{4} + \frac{3}{4}\left(\frac{1}{2} + \frac{1}{2}\cos t\right) + 1 = \frac{3}{8}\cos t + \frac{13}{8}$$

Hence:

$$\|\mathbf{r}'(t)\times\mathbf{r}''(t)\| = \frac{1}{\sqrt{8}}\sqrt{13 + 3\cos t} \tag{2}$$

We compute the length of $\mathbf{r}'(t)$:

$$\|\mathbf{r}'(t)\|^2 = (-\sin t)^2 + \cos^2 t + \cos^2\frac{t}{2} = 1 + \cos^2\frac{t}{2} = 1 + \left(\frac{1}{2} + \frac{1}{2}\cos t\right) = \frac{3}{2} + \frac{1}{2}\cos t$$

Hence,

$$\|\mathbf{r}'(t)\| = \frac{1}{\sqrt{2}}\sqrt{3 + \cos t} \tag{3}$$

Substituting (2) and (3) in (1) gives:

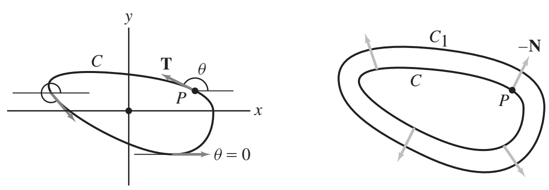
$$\kappa(t) = \frac{\frac{1}{\sqrt{8}}\sqrt{13 + 3\cos t}}{\left(\frac{1}{\sqrt{2}}\sqrt{3 + \cos t}\right)^3} = \frac{\frac{1}{\sqrt{8}}\sqrt{13 + 3\cos t}}{\frac{1}{2}\frac{1}{\sqrt{2}}(3 + \cos t)^{3/2}} = \frac{\sqrt{13 + 3\cos t}}{(3 + \cos t)^{3/2}}$$

74. Let $\mathbf{r}(s)$ be an arc length parametrization of a closed curve $\mathcal{C}$ of length L. We call $\mathcal{C}$ an **oval** if $d\theta/ds > 0$ (see Exercise 61). Observe that $-\mathbf{N}$ points to the *outside* of $\mathcal{C}$. For $k > 0$, the curve $\mathcal{C}_1$ defined by $\mathbf{r}_1(s) = \mathbf{r}(s) - k\mathbf{N}$ is called the expansion of $c(s)$ in the normal direction.

(a) Show that $\|\mathbf{r}_1'(s)\| = \|\mathbf{r}'(s)\| + k\kappa(s)$.

(b) As P moves around the oval counterclockwise, θ increases by 2π [Figure 21(A)]. Use this and a change of variables to prove that $\int_0^L \kappa(s)\,ds = 2\pi$.

(c) Show that $\mathcal{C}_1$ has length $L + 2\pi k$.



(A) An oval

(B) C_1 is the expansion of C in the normal direction.

FIGURE 21 As P moves around the oval, θ increases by 2π.

SOLUTION

(a) Since $\mathbf{r}_1(s) = \mathbf{r}(s) - k\mathbf{N}$ we have

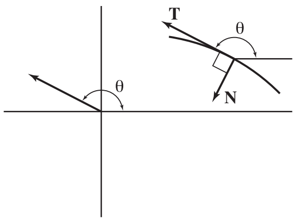
$$\mathbf{r}_1'(s) = \mathbf{r}'(s) - k\frac{d\mathbf{N}}{ds} \tag{1}$$

We compute $\frac{d\mathbf{N}}{ds}$ using the Chain Rule:

$$\frac{d\mathbf{N}}{ds} = \frac{d\mathbf{N}}{d\theta} \cdot \frac{d\theta}{ds} \tag{2}$$

By Exercise 61 and since $\mathcal{C}$ is oval we have:

$$\kappa(s) = \left|\frac{d\theta}{ds}\right| = \frac{d\theta}{ds} \tag{3}$$



Also, as illustrated in the figure, the following holds:

$$\mathbf{N} = \left\langle \cos\left(\frac{\pi}{2} + \theta\right), \sin\left(\frac{\pi}{2} + \theta\right)\right\rangle = \langle -\sin\theta, \cos\theta\rangle$$

Hence:

$$\frac{d\mathbf{N}}{d\theta} = \langle -\cos\theta, -\sin\theta\rangle = -\langle\cos\theta, \sin\theta\rangle = -\mathbf{T} \tag{4}$$

Substituting (3) and (4) in (2) yields:

$$\frac{d\mathbf{N}}{ds} = -\kappa(s)\mathbf{T}(s)$$

Substituting in (1) we obtain:

$$\mathbf{r}_1'(s) = \mathbf{r}'(s) + k\kappa(s)\mathbf{T}(s)$$

In the arc length parametrization, $\mathbf{T}(s) = \mathbf{r}'(s)$, therefore:

$$\mathbf{r}_1'(s) = \mathbf{r}'(s) + k\kappa(s)\mathbf{r}'(s) = \mathbf{r}'(s)\,(1 + k\kappa(s))$$

Computing the length and using $\|\mathbf{r}'(s)\| = 1$ we obtain:

$$\|\mathbf{r}_1'(s)\| = \|\mathbf{r}'(s)\|\,(1 + k\kappa(s)) = \|\mathbf{r}'(s)\| + \|\mathbf{r}'(s)\| \cdot k\kappa(s) = \|\mathbf{r}'(s)\| + k\kappa(s)$$

(b) In Exercise 61 we showed that:

$$\kappa(s) = \left|\frac{d\theta}{ds}\right|$$

Since $\frac{d\theta}{ds} > 0$ we have $\kappa(s) = \frac{d\theta}{ds}$. As P moves around the oval, θ increases by 2π, hence $\theta\,(s = L) - \theta\,(s = 0) = 2\pi$. Using these considerations we get:

$$\int_0^L \kappa(s)\,ds = \int_{\theta(0)}^{\theta(L)} \frac{d\theta}{ds}\,ds = \int_{\theta(0)}^{\theta(L)} d\theta = \theta(L) - \theta(0) = 2\pi.$$

(c) We use the Arc Length Formula and the equality in part (a) to write the length L_1 of C_1 as the following integral:

$$L_1 = \int_0^L \|\mathbf{r}_1'(s)\|\,ds = \int_0^L \|\mathbf{r}'(s)\|\,ds + k\int_0^L \kappa(s)\,ds$$

By the Arc Length Formula, the first integral is the length L of $\mathcal{C}$. The second integral was computed in part (b). Therefore we get:

$$L_1 = L + k \cdot 2\pi = L + 2\pi k.$$

In Exercises 75–82, let **B** *denote the* **binormal vector** *at a point on a space curve $\mathcal{C}$, defined by* $\mathbf{B} = \mathbf{T} \times \mathbf{N}$.

75. Show that **B** is a unit vector.

SOLUTION **T** and **N** are orthogonal unit vectors, therefore the length of their cross product is:

$$\|\mathbf{B}\| = \|\mathbf{T} \times \mathbf{N}\| = \|\mathbf{T}\|\|\mathbf{N}\| \sin \frac{\pi}{2} = 1 \cdot 1 \cdot 1 = 1$$

Therefore **B** is a unit vector.

76. Follow steps (a)–(c) to prove that there is a number τ (lowercase Greek "tau") called the **torsion** such that

$$\frac{d\mathbf{B}}{ds} = -\tau \mathbf{N} \tag{14}$$

(a) Show that $\frac{d\mathbf{B}}{ds} = \mathbf{T} \times \frac{d\mathbf{N}}{ds}$ and conclude that $d\mathbf{B}/ds$ is orthogonal to **T**.
(b) Differentiate $\mathbf{B} \cdot \mathbf{B} = 1$ with respect to s to show that $d\mathbf{B}/ds$ is orthogonal to **B**.
(c) Conclude that $d\mathbf{B}/ds$ is a multiple of **N**.

SOLUTION

(a) Using the Product Rule for cross product we have:

$$\frac{d\mathbf{B}}{ds} = \frac{d}{ds}(\mathbf{T} \times \mathbf{N}) = \frac{d\mathbf{T}}{ds} \times \mathbf{N} + \mathbf{T} \times \frac{d\mathbf{N}}{ds}$$

N is a unit vector in the direction of $\frac{d\mathbf{T}}{ds}$, hence $\frac{d\mathbf{T}}{ds} \times \mathbf{N} = \mathbf{0}$, so we obtain:

$$\frac{d\mathbf{B}}{ds} = \mathbf{T} \times \frac{d\mathbf{N}}{ds}$$

By properties of cross products we conclude that $\frac{d\mathbf{B}}{ds}$ is orthogonal to **T**.

(b) We differentiate $\mathbf{B} \cdot \mathbf{B} = 1$ using the Product Rule for dot products:

$$\mathbf{B} \cdot \frac{d\mathbf{B}}{ds} + \frac{d\mathbf{B}}{ds} \cdot \mathbf{B} = 0$$

$$2\mathbf{B} \cdot \frac{d\mathbf{B}}{ds} = 0 \quad \Rightarrow \quad \mathbf{B} \cdot \frac{d\mathbf{B}}{ds} = 0$$

Since the dot product of **B** and $\frac{d\mathbf{B}}{ds}$ is zero, the two vectors are orthogonal.

(c) In parts (a) and (b) we showed that $\frac{d\mathbf{B}}{ds}$ is orthogonal to **B** and **T**. It follows that $\frac{d\mathbf{B}}{ds}$ is parallel to any other vector that is orthogonal to **B** and **T**. We show that **N** is such a vector.

Since $\mathbf{B} = \mathbf{T} \times \mathbf{N}$, the vectors **N** and **B** are orthogonal. The unit normal **N** is also orthogonal to the unit tangent **T**. We conclude that $\frac{d\mathbf{B}}{ds}$ and **N** are parallel, hence there exists a number $(-\tau)$ such that:

$$\frac{d\mathbf{B}}{ds} = -\tau \mathbf{N}.$$

77. Show that if $\mathcal{C}$ is contained in a plane $\mathcal{P}$, then **B** is a unit vector normal to $\mathcal{P}$. Conclude that $\tau = 0$ for a plane curve.

SOLUTION If $\mathcal{C}$ is contained in a plane $\mathcal{P}$, then the unit normal **N** and the unit tangent **T** are in $\mathcal{P}$. The cross product $\mathbf{B} = \mathbf{T} \times \mathbf{N}$ is orthogonal to **T** and **N** which are in the plane, hence **B** is normal to the plane. Thus, **B** is a unit vector normal to the plane. There are only two different unit normal vectors to a plane, one pointing "up" and the other pointing "down". Thus, we can assume (due to continuity) that **B** is a constant vector, therefore

$$\frac{d\mathbf{B}}{ds} = 0 \quad \text{or} \quad \tau = 0.$$

78. Torsion means "twisting." Is this an appropriate name for τ? Explain by interpreting τ geometrically.

SOLUTION **B** is the unit normal to the osculating plane at a point P on the curve. As P moves along the curve, the unit normal **B** is changing by $\frac{d\mathbf{B}}{ds} = -\tau \mathbf{N}$. Geometrically the osculating plane is "twisted" and τ is a measure for this twisting.

79. Use the identity

$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}$$

to prove

$$\mathbf{N} \times \mathbf{B} = \mathbf{T}, \qquad \mathbf{B} \times \mathbf{T} = \mathbf{N} \tag{15}$$

SOLUTION We use the given equality and the definition $\mathbf{B} = \mathbf{T} \times \mathbf{N}$ to write:

$$\mathbf{N} \times \mathbf{B} = \mathbf{N} \times (\mathbf{T} \times \mathbf{N}) = (\mathbf{N} \cdot \mathbf{N})\,\mathbf{T} - (\mathbf{N} \cdot \mathbf{T})\,\mathbf{N} \tag{1}$$

The unit normal $\mathbf{N}$ and the unit tangent $\mathbf{T}$ are orthogonal unit vectors, hence $\mathbf{N} \cdot \mathbf{N} = \|\mathbf{N}\|^2 = 1$ and $\mathbf{N} \cdot \mathbf{T} = 0$. Therefore, (1) gives:

$$\mathbf{N} \times \mathbf{B} = 1 \cdot \mathbf{T} - 0\mathbf{N} = \mathbf{T}$$

To prove the second equality, we substitute $\mathbf{T} = \mathbf{N} \times \mathbf{B}$ and then use the given equality. We obtain:

$$\mathbf{B} \times \mathbf{T} = \mathbf{B} \times (\mathbf{N} \times \mathbf{B}) = (\mathbf{B} \cdot \mathbf{B})\,\mathbf{N} - (\mathbf{B} \cdot \mathbf{N})\,\mathbf{B} \tag{2}$$

Now, $\mathbf{B}$ is a unit vector, hence $\mathbf{B} \cdot \mathbf{B} = \|\mathbf{B}\|^2 = 1$. Also, since $\mathbf{B} = \mathbf{T} \times \mathbf{N}$, $\mathbf{B}$ is orthogonal to $\mathbf{N}$ which implies that $\mathbf{B} \cdot \mathbf{N} = 0$. Substituting in (2) we get:

$$\mathbf{B} \times \mathbf{T} = 1\mathbf{N} - 0\mathbf{B} = \mathbf{N}.$$

80. Follow steps (a)–(b) to prove

$$\frac{d\mathbf{N}}{ds} = -\kappa \mathbf{T} + \tau \mathbf{B} \tag{16}$$

(a) Show that $d\mathbf{N}/ds$ is orthogonal to $\mathbf{N}$. Conclude that $d\mathbf{N}/ds$ lies in the plane spanned by $\mathbf{T}$ and $\mathbf{B}$, and hence, $d\mathbf{N}/ds = a\mathbf{T} + b\mathbf{B}$ for some scalars a, b.

(b) Use $\mathbf{N} \cdot \mathbf{T} = 0$ to show that $\mathbf{T} \cdot \dfrac{d\mathbf{N}}{ds} = -\mathbf{N} \cdot \dfrac{d\mathbf{T}}{ds}$ and compute a. Compute b similarly. Equations (14) and (16) together with $d\mathbf{T}/dt = \kappa \mathbf{N}$ are called the **Frenet formulas** and were discovered by the French geometer Jean Frenet (1816–1900).

SOLUTION

(a) We first show that $\frac{d\mathbf{N}}{ds}$ is orthogonal to $\mathbf{N}$. Earlier we showed that $\frac{d\mathbf{B}}{ds} = \mathbf{T} \times \frac{d\mathbf{N}}{ds}$ and $\frac{d\mathbf{B}}{ds} = -\tau \mathbf{N}$, hence:

$$-\tau \mathbf{N} = \mathbf{T} \times \frac{d\mathbf{N}}{ds}$$

By properties of the cross product, this equality implies that $\frac{d\mathbf{N}}{ds}$ is orthogonal to $-\tau\mathbf{N}$, hence it is orthogonal to $\mathbf{N}$. Now, $\mathbf{N}$ is orthogonal to $\mathbf{T}$ and $\mathbf{B}$, hence $\mathbf{N}$ is normal to the plane spanned by $\mathbf{T}$ and $\mathbf{B}$. Therefore, since $\mathbf{N}$ is orthogonal to $\frac{d\mathbf{N}}{ds}$, this last vector lies in the plane spanned by $\mathbf{T}$ and $\mathbf{B}$, that is, there exist scalars a and b such that:

$$\frac{d\mathbf{N}}{ds} = a\mathbf{T} + b\mathbf{B}$$

(b) By the orthogonality of $\mathbf{N}$ and $\mathbf{T}$ we have:

$$\mathbf{N} \cdot \mathbf{T} = 0$$

Differentiating this equality, using the product rule for dot product we get:

$$\mathbf{N} \cdot \frac{d\mathbf{T}}{ds} + \frac{d\mathbf{N}}{ds} \cdot \mathbf{T} = 0 \quad \Rightarrow \quad \mathbf{T} \cdot \frac{d\mathbf{N}}{ds} = -\mathbf{N} \cdot \frac{d\mathbf{T}}{ds}$$

To compute a, we substitute $\frac{d\mathbf{N}}{ds} = a\mathbf{T} + b\mathbf{B}$ and use $\mathbf{T} \cdot \mathbf{T} = \|\mathbf{T}\|^2 = 1$ and $\mathbf{T} \cdot \mathbf{B} = 0$. This gives:

$$\begin{aligned} \mathbf{T} \cdot (a\mathbf{T} + b\mathbf{B}) &= -\mathbf{N} \cdot \frac{d\mathbf{T}}{ds} \\ a\mathbf{T} \cdot \mathbf{T} + b\mathbf{T} \cdot \mathbf{B} &= -\mathbf{N} \cdot \frac{d\mathbf{T}}{ds} \\ a \cdot 1 + b \cdot 0 &= -\mathbf{N} \cdot \frac{d\mathbf{T}}{ds} \quad \Rightarrow \quad a = -\mathbf{N} \cdot \frac{d\mathbf{T}}{ds} \end{aligned} \tag{1}$$

To find b we differentiate the equality $\mathbf{N} \cdot \mathbf{B} = 0$ (notice that by $\mathbf{B} = \mathbf{T} \times \mathbf{N}$ follows the orthogonality of $\mathbf{N}$ and $\mathbf{B}$). We get:

$$\mathbf{N} \cdot \frac{d\mathbf{B}}{ds} + \frac{d\mathbf{N}}{ds} \cdot \mathbf{B} = 0 \quad \Rightarrow \quad \frac{d\mathbf{N}}{ds} \cdot \mathbf{B} = -\mathbf{N} \cdot \frac{d\mathbf{B}}{ds}$$

We now substitute $\frac{d\mathbf{N}}{ds} = a\mathbf{T} + b\mathbf{B}$ and we use $\mathbf{B} \cdot \mathbf{B} = \|\mathbf{B}\|^2 = 1$ and $\mathbf{T} \cdot \mathbf{B} = 0$ to obtain:

$$(a\mathbf{T} + b\mathbf{B}) \cdot \mathbf{B} = -\mathbf{N} \cdot \frac{d\mathbf{B}}{ds}$$

$$a\mathbf{T}\cdot\mathbf{B}+b\mathbf{B}\cdot\mathbf{B}=-\mathbf{N}\cdot\frac{d\mathbf{B}}{ds}$$

$$a\cdot 0+b\cdot 1=-\mathbf{N}\cdot\frac{d\mathbf{B}}{ds}\quad\Rightarrow\quad b=-\mathbf{N}\cdot\frac{d\mathbf{B}}{ds}$$

Since $\frac{d\mathbf{B}}{ds}=-\tau\mathbf{N}$ we may write:

$$b=-\mathbf{N}\cdot(-\tau\mathbf{N})=\tau\mathbf{N}\cdot\mathbf{N}=\tau\|\mathbf{N}\|^2=\tau \tag{2}$$

Also for the arc length parametrization $\frac{d\mathbf{T}}{ds}=\kappa(s)\mathbf{N}$, hence by (1):

$$a=-\mathbf{N}\cdot\kappa(s)\mathbf{N}=-\kappa(s)\mathbf{N}\cdot\mathbf{N}=-\kappa(s)\|\mathbf{N}\|^2=-\kappa(s) \tag{3}$$

We combine (2), (3), and part (a) to conclude:

$$\frac{d\mathbf{N}}{ds}=-\kappa\mathbf{T}+\tau\mathbf{B}.$$

81. Show that $\mathbf{r}'\times\mathbf{r}''$ is a multiple of $\mathbf{B}$. Conclude that

$$\mathbf{B}=\frac{\mathbf{r}'\times\mathbf{r}''}{\|\mathbf{r}'\times\mathbf{r}''\|} \qquad \boxed{17}$$

SOLUTION By the definition of the binormal vector, $\mathbf{B}=\mathbf{T}\times\mathbf{N}$. We denote $a(t)=\frac{1}{\|\mathbf{r}'(t)\|}$ and write:

$$\mathbf{T}(t)=\frac{\mathbf{r}'(t)}{\|\mathbf{r}'(t)\|}=a(t)\mathbf{r}'(t) \tag{1}$$

We differentiate $\mathbf{T}(t)$ using the Product Rule:

$$\mathbf{T}'(t)=a(t)\mathbf{r}''(t)+a'(t)\mathbf{r}'(t)$$

We denote $b(t)=\|\mathbf{T}'(t)\|$ and obtain:

$$\mathbf{N}(t)=\frac{\mathbf{T}'(t)}{\|\mathbf{T}'(t)\|}=\frac{a(t)}{b(t)}\mathbf{r}''(t)+\frac{a'(t)}{b(t)}\mathbf{r}'(t)$$

For $c_1=\frac{a(t)}{b(t)}$ and $c_2=\frac{a'(t)}{b(t)}$ we have:

$$\mathbf{N}(t)=c_1(t)\mathbf{r}''(t)+c_2(t)\mathbf{r}'(t) \tag{2}$$

We now find $\mathbf{B}$ as the cross product of $\mathbf{T}(t)$ in (1) and $\mathbf{N}(t)$ in (2). This gives:

$$\begin{aligned}\mathbf{B}(t)&=a(t)\mathbf{r}'(t)\times\big(c_1(t)\mathbf{r}''(t)+c_2(t)\mathbf{r}'(t)\big)=a(t)c_1(t)\mathbf{r}'(t)\times\mathbf{r}''(t)+a(t)c_2(t)\mathbf{r}'(t)\times\mathbf{r}'(t)\\&=a(t)c_1(t)\mathbf{r}'(t)\times\mathbf{r}''(t)+\mathbf{0}=a(t)c_1(t)\mathbf{r}'(t)\times\mathbf{r}''(t)\end{aligned}$$

We see that $\mathbf{B}$ is parallel to $\mathbf{r}'\times\mathbf{r}''$. Since $\mathbf{B}$ is a unit vector we have:

$$\mathbf{B}=\frac{\mathbf{r}'\times\mathbf{r}''}{\|\mathbf{r}'\times\mathbf{r}''\|}.$$

82. The vector $\mathbf{N}$ can be computed using $\mathbf{N}=\mathbf{B}\times\mathbf{T}$ [Eq. (15)] with $\mathbf{B}$, as in Eq. (17). Use this method to find $\mathbf{N}$ in the following cases:

(a) $\mathbf{r}(t)=\left\langle\cos t,t,t^2\right\rangle$ at $t=0$

(b) $\mathbf{r}(t)=\left\langle t^2,t^{-1},t\right\rangle$ at $t=1$

SOLUTION

(a) We first compute the vector $\mathbf{B}$ using Eq. (17):

$$\mathbf{B}=\frac{\mathbf{r}'\times\mathbf{r}''}{\|\mathbf{r}'\times\mathbf{r}''\|} \tag{1}$$

Differentiating $\mathbf{r}(t)=\left\langle\cos t,t,t^2\right\rangle$ gives

$$\begin{matrix}\mathbf{r}'(t)=\langle-\sin t,1,2t\rangle\\ \mathbf{r}''(t)=\langle-\cos t,0,2\rangle\end{matrix}\quad\Rightarrow\quad\begin{matrix}\mathbf{r}'(0)=\langle 0,1,0\rangle\\ \mathbf{r}''(0)=\langle-1,0,2\rangle\end{matrix}$$

We compute the cross product:

$$\mathbf{r}'(0) \times \mathbf{r}''(0) = \mathbf{j} \times (-\mathbf{i} + 2\mathbf{k}) = -\mathbf{j} \times \mathbf{i} + 2\mathbf{j} \times \mathbf{k} = \mathbf{k} + 2\mathbf{i} = \langle 2, 0, 1 \rangle$$
$$\|\mathbf{r}'(0) \times \mathbf{r}''(0)\| = \sqrt{2^2 + 0^2 + 1^2} = \sqrt{5}$$

Substituting in (1) we obtain:

$$\mathbf{B}(0) = \frac{\langle 2, 0, 1 \rangle}{\sqrt{5}} = \frac{1}{\sqrt{5}} \langle 2, 0, 1 \rangle$$

We now compute $\mathbf{T}(0)$:

$$\mathbf{T}(0) = \frac{\mathbf{r}'(0)}{\|\mathbf{r}'(0)\|} = \frac{\langle 0, 1, 0 \rangle}{\| \langle 0, 1, 0 \rangle \|} = \langle 0, 1, 0 \rangle$$

Finally we find $\mathbf{N} = \mathbf{B} \times \mathbf{T}$:

$$\mathbf{N}(0) = \frac{1}{\sqrt{5}} \langle 2, 0, 1 \rangle \times \langle 0, 1, 0 \rangle = \frac{1}{\sqrt{5}} (2\mathbf{i} + \mathbf{k}) \times \mathbf{j} = \frac{1}{\sqrt{5}} (2\mathbf{i} \times \mathbf{j} + \mathbf{k} \times \mathbf{j}) = \frac{1}{\sqrt{5}} (2\mathbf{k} - \mathbf{i}) = \frac{1}{\sqrt{5}} \langle -1, 0, 2 \rangle$$

(b) Differentiating $\mathbf{r}(t) = \langle t^2, t^{-1}, t \rangle$ gives

$$\begin{array}{l} \mathbf{r}'(t) = \langle 2t, -t^{-2}, 1 \rangle \\ \mathbf{r}''(t) = \langle 2, 2t^{-3}, 0 \rangle \end{array} \Rightarrow \begin{array}{l} \mathbf{r}'(1) = \langle 2, -1, 1 \rangle \\ \mathbf{r}''(1) = \langle 2, 2, 0 \rangle \end{array}$$

We compute the cross product:

$$\mathbf{r}'(1) \times \mathbf{r}''(1) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & -1 & 1 \\ 2 & 2 & 0 \end{vmatrix} = \begin{vmatrix} -1 & 1 \\ 2 & 0 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 2 & 1 \\ 2 & 0 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 2 & -1 \\ 2 & 2 \end{vmatrix} \mathbf{k} = -2\mathbf{i} + 2\mathbf{j} + 6\mathbf{k} = \langle -2, 2, 6 \rangle$$

$$\|\mathbf{r}'(1) \times \mathbf{r}''(1)\| = \sqrt{(-2)^2 + 2^2 + 6^2} = \sqrt{44} = 2\sqrt{11}$$

Substituting in (1) gives:

$$\mathbf{B}(1) = \frac{\langle -2, 2, 6 \rangle}{2\sqrt{11}} = \frac{1}{\sqrt{11}} \langle -1, 1, 3 \rangle$$

We now find $\mathbf{T}(1)$:

$$\mathbf{T}(1) = \frac{\mathbf{r}'(1)}{\|\mathbf{r}'(1)\|} = \frac{\langle 2, -1, 1 \rangle}{\sqrt{4 + 1 + 1}} = \frac{1}{\sqrt{6}} \langle 2, -1, 1 \rangle$$

Finally we find $\mathbf{N}(1)$ by computing the following cross product:

$$\mathbf{N}(1) = \mathbf{B}(1) \times \mathbf{T}(1) = \frac{1}{\sqrt{11}} \langle -1, 1, 3 \rangle \times \frac{1}{\sqrt{6}} \langle 2, -1, 1 \rangle = \frac{1}{\sqrt{66}} \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -1 & 1 & 3 \\ 2 & -1 & 1 \end{vmatrix}$$
$$= \frac{1}{\sqrt{66}} \left\{ \begin{vmatrix} 1 & 3 \\ -1 & 1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} -1 & 3 \\ 2 & 1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} -1 & 1 \\ 2 & -1 \end{vmatrix} \mathbf{k} \right\} = \frac{1}{\sqrt{66}} (4\mathbf{i} + 7\mathbf{j} - \mathbf{k}) = \frac{1}{\sqrt{66}} \langle 4, 7, -1 \rangle$$

13.5 Motion in Three-Space (LT Section 14.5)

Preliminary Questions

1. If a particle travels with constant speed, must its acceleration vector be zero? Explain.

SOLUTION If the speed of the particle is constant, the tangential component, $a_T(t) = v'(t)$, of the acceleration is zero. However, the normal component, $a_N(t) = \kappa(t)v(t)^2$ is not necessarily zero, since the particle may change its direction.

2. For a particle in uniform circular motion around a circle, which of the vectors $\mathbf{v}(t)$ or $\mathbf{a}(t)$ always points toward the center of the circle?

SOLUTION For a particle in uniform circular motion around a circle, the acceleration vector $\mathbf{a}(t)$ points towards the center of the circle, whereas $\mathbf{v}(t)$ is tangent to the circle.

3. Two objects travel to the right along the parabola $y = x^2$ with nonzero speed. Which of the following statements must be true?

(a) Their velocity vectors point in the same direction.
(b) Their velocity vectors have the same length.
(c) Their acceleration vectors point in the same direction.

SOLUTION

(a) The velocity vector points in the direction of motion, hence the velocities of the two objects point in the same direction.

(b) The length of the velocity vector is the speed. Since the speeds are not necessarily equal, the velocity vectors may have different lengths.

(c) The acceleration is determined by the tangential component $v'(t)$ and the normal component $\kappa(t)v(t)^2$. Since v and v' may be different for the two objects, the acceleration vectors may have different directions.

4. Use the decomposition of acceleration into tangential and normal components to explain the following statement: If the speed is constant, then the acceleration and velocity vectors are orthogonal.

SOLUTION If the speed is constant, $v'(t) = 0$. Therefore, the acceleration vector has only the normal component:

$$\mathbf{a}(t) = a_N(t)\mathbf{N}(t)$$

The velocity vector always points in the direction of motion. Since the vector $\mathbf{N}(t)$ is orthogonal to the direction of motion, the vectors $\mathbf{a}(t)$ and $\mathbf{v}(t)$ are orthogonal.

5. If a particle travels along a straight line, then the acceleration and velocity vectors are (choose the correct description):

(a) Orthogonal **(b)** Parallel

SOLUTION Since a line has zero curvature, the normal component of the acceleration is zero, hence $\mathbf{a}(t)$ has only the tangential component. The velocity vector is always in the direction of motion, hence the acceleration and the velocity vectors are parallel to the line. We conclude that (b) is the correct statement.

6. What is the length of the acceleration vector of a particle traveling around a circle of radius 2 cm with constant velocity 4 cm/s?

SOLUTION The acceleration vector is given by the following decomposition:

$$\mathbf{a}(t) = v'(t)\mathbf{T}(t) + \kappa(t)v(t)^2\mathbf{N}(t) \tag{1}$$

In our case $v(t) = 4$ is constant hence $v'(t) = 0$. In addition, the curvature of a circle of radius 2 is $\kappa(t) = \frac{1}{2}$. Substituting $v(t) = 4$, $v'(t) = 0$ and $\kappa(t) = \frac{1}{2}$ in (1) gives:

$$\mathbf{a}(t) = \frac{1}{2} \cdot 4^2 N(t) = 8N(t)$$

The length of the acceleration vector is, thus,

$$\|\mathbf{a}(t)\| = 8 \text{ cm/s}^2$$

7. Two cars are racing around a circular track. If, at a certain moment, both of their speedometers read 110 mph. then the two cars have the same (choose one):

(a) $a_{\mathbf{T}}$ **(b)** $a_{\mathbf{N}}$

SOLUTION The tangential acceleration a_T and the normal acceleration a_N are the following values:

$$a_T(t) = v'(t); \quad a_N(t) = \kappa(t)v(t)^2$$

At the moment where both speedometers read 110 mph, the speeds of the two cars are $v = 110$ mph. Since the track is circular, the curvature $\kappa(t)$ is constant, hence the normal accelerations of the two cars are equal at this moment. Statement (b) is correct.

Exercises

1. Use the table below to calculate the difference quotients $\dfrac{\mathbf{r}(1+h) - \mathbf{r}(1)}{h}$ for $h = -0.2, -0.1, 0.1, 0.2$. Then estimate the velocity and speed at $t = 1$.

$\mathbf{r}(0.8)$	$\langle 1.557, 2.459, -1.970 \rangle$
$\mathbf{r}(0.9)$	$\langle 1.559, 2.634, -1.740 \rangle$
$\mathbf{r}(1)$	$\langle 1.540, 2.841, -1.443 \rangle$
$\mathbf{r}(1.1)$	$\langle 1.499, 3.078, -1.035 \rangle$
$\mathbf{r}(1.2)$	$\langle 1.435, 3.342, -0.428 \rangle$

SOLUTION

$$(h = -0.2)$$
$$\frac{\mathbf{r}(1-0.2)-\mathbf{r}(1)}{-0.2} = \frac{\mathbf{r}(0.8)-\mathbf{r}(1)}{-0.2} = \frac{\langle 1.557, 2.459, -1.970\rangle - \langle 1.540, 2.841, -1.443\rangle}{-0.2}$$
$$= \frac{\langle 0.017, -0.382, -0.527\rangle}{-0.2} = \langle -0.085, 1.91, 2.635\rangle$$

$$(h = -0.1)$$
$$\frac{\mathbf{r}(1-0.1)-\mathbf{r}(1)}{-0.1} = \frac{\mathbf{r}(0.9)-\mathbf{r}(1)}{-0.1} = \frac{\langle 1.559, 2.634, -1.740\rangle - \langle 1.540, 2.841, -1.443\rangle}{-0.1}$$
$$= \frac{\langle 0.019, -0.207, -0.297\rangle}{-0.1} = \langle -0.19, 2.07, 2.97\rangle$$

$$(h = 0.1)$$
$$\frac{\mathbf{r}(1+0.1)-\mathbf{r}(1)}{0.1} = \frac{\mathbf{r}(1.1)-\mathbf{r}(1)}{0.1} = \frac{\langle 1.499, 3.078, -1.035\rangle - \langle 1.540, 2.841, -1.443\rangle}{0.1}$$
$$= \frac{\langle -0.041, 0.237, 0.408\rangle}{0.1} = \langle -0.41, 2.37, 4.08\rangle$$

$$(h = 0.2)$$
$$\frac{\mathbf{r}(1+0.2)-\mathbf{r}(1)}{0.2} = \frac{\mathbf{r}(1.2)-\mathbf{r}(1)}{0.2} = \frac{\langle 1.435, 3.342, -0.428\rangle - \langle 1.540, 2.841, -1.443\rangle}{0.2}$$
$$= \frac{\langle -0.105, 0.501, 1.015\rangle}{0.2} = \langle -0.525, 2.505, 5.075\rangle$$

The velocity vector is defined by:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \lim_{h\to 0} \frac{\mathbf{r}(t+h)-\mathbf{r}(t)}{h}$$

We may estimate the velocity at $t = 1$ by:

$$\mathbf{v}(1) \approx \langle -0.3, 2.2, 3.5\rangle$$

and the speed by:

$$v(1) = \|\mathbf{v}(1)\| \approx \sqrt{0.3^2 + 2.2^2 + 3.5^2} \cong 4.1$$

2. Draw the vectors $\mathbf{r}(2+h) - \mathbf{r}(2)$ and $\dfrac{\mathbf{r}(2+h)-\mathbf{r}(2)}{h}$ for $h = 0.5$ for the path in Figure 10. Draw $\mathbf{v}(2)$ (using a rough estimate for its length).

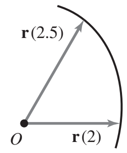


FIGURE 10

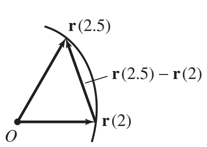
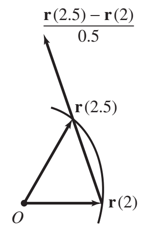
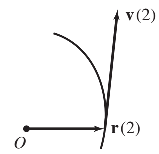
SOLUTION The difference $\mathbf{r}(2+h) - \mathbf{r}(2) = \mathbf{r}(2.5) - \mathbf{r}(2)$ is the following vector:



The vector $\frac{\mathbf{r}(2.5)-\mathbf{r}(2)}{0.5}$ points in the direction of $\mathbf{r}(2.5) - \mathbf{r}(2)$, and its length is twice the length of this vector, as shown in the following figure:



By definition, $\mathbf{v}(2) = \lim_{h\to 0} \dfrac{\mathbf{r}(2+h)-\mathbf{r}(2)}{h}$. This vector is tangent to the path at the endpoint of $\mathbf{r}(2)$. The vector $\mathbf{v}(2)$ is shown in the following figure:



In Exercises 3–6, calculate the velocity and acceleration vectors and the speed at the time indicated.

3. $\mathbf{r}(t) = \left\langle t^3, 1-t, 4t^2\right\rangle, \quad t = 1$

SOLUTION In this case $\mathbf{r}(t) = \left\langle t^3, 1-t, 4t^2\right\rangle$ hence:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \left\langle 3t^2, -1, 8t\right\rangle \quad \Rightarrow \quad \mathbf{v}(1) = \langle 3, -1, 8\rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 6t, 0, 8\rangle \quad \Rightarrow \quad \mathbf{a}(1) = \langle 6, 0, 8\rangle$$

The speed is the magnitude of the velocity vector, that is,

$$v(1) = \|\mathbf{v}(1)\| = \sqrt{3^2 + (-1)^2 + 8^2} = \sqrt{74}$$

4. $\mathbf{r}(t) = e^t\mathbf{j} - \cos(2t)\mathbf{k}, \quad t = 0$

SOLUTION Since $\mathbf{r}(t) = e^t\mathbf{j} - \cos(2t)\mathbf{k}$ we have:

$$\mathbf{v}(t) = \mathbf{r}'(t) = e^t\mathbf{j} + 2\sin(2t)\mathbf{k} \quad \Rightarrow \quad \mathbf{v}(0) = e^0\mathbf{j} + (2\sin 0)\mathbf{k} = \mathbf{j}$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = e^t\mathbf{j} + 4\cos(2t)\mathbf{k} \quad \Rightarrow \quad \mathbf{a}(0) = e^0\mathbf{j} + (4\cos 0)\mathbf{k} = \mathbf{j} + 4\mathbf{k}$$

The speed is the magnitude of the velocity vectors, that is,

$$v(0) = \|\mathbf{v}(0)\| = \|\mathbf{j}\| = 1$$

5. $\mathbf{r}(\theta) = \langle \sin\theta, \cos\theta, \cos 3\theta\rangle, \quad \theta = \frac{\pi}{3}$

SOLUTION Differentiating $\mathbf{r}(\theta) = \langle \sin\theta, \cos\theta, \cos 3\theta\rangle$ gives:

$$\begin{aligned}
\mathbf{v}(\theta) &= \mathbf{r}'(\theta) = \langle \cos\theta, -\sin\theta, -3\sin 3\theta\rangle \\
&\Rightarrow \mathbf{v}\left(\frac{\pi}{3}\right) = \left\langle \cos\frac{\pi}{3}, -\sin\frac{\pi}{3}, -3\sin\pi\right\rangle = \left\langle \frac{1}{2}, -\frac{\sqrt{3}}{2}, 0\right\rangle \\
\mathbf{a}(\theta) &= \mathbf{r}''(\theta) = \langle -\sin\theta, -\cos\theta, -9\cos 3\theta\rangle \\
&\Rightarrow \mathbf{a}\left(\frac{\pi}{3}\right) = \left\langle -\sin\frac{\pi}{3}, -\cos\frac{\pi}{3}, -9\cos\pi\right\rangle = \left\langle -\frac{\sqrt{3}}{2}, -\frac{1}{2}, 9\right\rangle
\end{aligned}$$

The speed is the magnitude of the velocity vector, that is:

$$v\left(\frac{\pi}{3}\right) = \left\|\mathbf{v}\left(\frac{\pi}{3}\right)\right\| = \sqrt{\left(\frac{1}{2}\right)^2 + \left(-\frac{\sqrt{3}}{2}\right)^2 + 0^2} = 1$$

6. $\mathbf{r}(s) = \left\langle \dfrac{1}{1+s^2}, \dfrac{s}{1+s^2} \right\rangle, \quad s = 2$

SOLUTION The velocity and acceleration vectors are the first and second derivatives of $\mathbf{r}(s) = \left\langle \frac{1}{1+s^2}, \frac{s}{1+s^2} \right\rangle$. We compute these vectors:

$$\mathbf{v}(s) = \mathbf{r}'(s) = \left\langle \frac{-2s}{(1+s^2)^2}, \frac{1+s^2-s\cdot 2s}{(1+s^2)^2} \right\rangle = \left\langle -\frac{2s}{(1+s^2)^2}, \frac{1-s^2}{(1+s^2)^2} \right\rangle$$

$$\mathbf{a}(s) = \mathbf{r}''(s) = \left\langle \frac{-2(1+s^2)^2 + 2s\cdot 2(1+s^2)\cdot 2s}{(1+s^2)^4}, \frac{-2s(1+s^2)^2 - (1-s^2)\cdot 2(1+s^2)\cdot 2s}{(1+s^2)^4} \right\rangle$$

$$= \left\langle \frac{6s^2-2}{(1+s^2)^3}, \frac{s(2s^2-6)}{(1+s^2)^3} \right\rangle$$

At the point $s = 2$ we obtain:

$$\mathbf{v}(2) = \left\langle -\frac{4}{(1+2^2)^2}, \frac{1-4}{(1+2^2)^2} \right\rangle = -\frac{1}{25}\langle 4, 3\rangle$$

$$\mathbf{a}(2) = \left\langle \frac{6\cdot 4-2}{(1+2^2)^3}, \frac{2(2\cdot 4-6)}{(1+2^2)^3} \right\rangle = \frac{2}{125}\langle 11, 2\rangle$$

The speed is the magnitude of the velocity vector:

$$v(2) = \frac{1}{25}\sqrt{4^2+3^2} = \frac{1}{5}$$

7. Find $\mathbf{a}(t)$ for a particle moving around a circle of radius 8 cm at a constant speed of $v = 4$ cm/s (see Example 4). Draw the path and acceleration vector at $t = \frac{\pi}{4}$.

SOLUTION The position vector is:

$$\mathbf{r}(t) = 8\langle \cos\omega t, \sin\omega t\rangle$$

Hence,

$$\mathbf{v}(t) = \mathbf{r}'(t) = 8\langle -\omega\sin\omega t, \omega\cos\omega t\rangle = 8\omega\langle -\sin\omega t, \cos\omega t\rangle \tag{1}$$

We are given that the speed of the particle is $v = 4$ cm/s. The speed is the magnitude of the velocity vector, hence:

$$v = 8\omega\sqrt{(-\sin\omega \mathrm{t})^2 + \cos^2\omega \mathrm{t}} = 8\omega = 4 \quad\Rightarrow\quad \omega = \frac{1}{2}\ \text{rad/s}$$

Substituting in (2) we get:

$$\mathbf{v}(t) = 4\left\langle -\sin\frac{t}{2}, \cos\frac{t}{2} \right\rangle$$

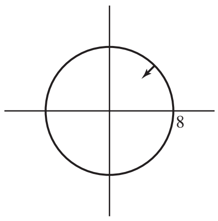
We now find $\mathbf{a}(t)$ by differentiating the velocity vector. This gives

$$\mathbf{a}(t) = \mathbf{v}'(t) = 4\left\langle -\frac{1}{2}\cos\frac{t}{2}, -\frac{1}{2}\sin\frac{t}{2} \right\rangle = -2\left\langle \cos\frac{t}{2}, \sin\frac{t}{2} \right\rangle$$

The path of the particle is $\mathbf{r}(t) = 8\left\langle \cos\frac{t}{2}, \sin\frac{t}{2}\right\rangle$ and the acceleration vector at $t = \frac{\pi}{4}$ is:

$$\mathbf{a}\left(\frac{\pi}{4}\right) = -2\left\langle \cos\frac{\pi}{8}, \sin\frac{\pi}{8} \right\rangle \approx \langle -1.85, -0.77\rangle$$

The path $\mathbf{r}(t)$ and the acceleration vector at $t = \frac{\pi}{4}$ are shown in the following figure:



$\mathbf{r}(t) = 8\left\langle \cos\frac{t}{2}, \sin\frac{t}{2}\right\rangle$

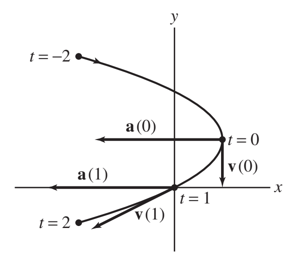
8. Sketch the path $\mathbf{r}(t) = \langle 1 - t^2, 1 - t\rangle$ for $-2 \le t \le 2$, indicating the direction of motion. Draw the velocity and acceleration vectors at $t = 0$ and $t = 1$.

SOLUTION We compute the velocity and acceleration vectors at $t = 0$ and $t = 1$:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \langle -2t, -1\rangle \quad \Rightarrow \quad \begin{array}{l} \mathbf{v}(0) = \langle 0, -1\rangle \\ \mathbf{v}(1) = \langle -2, -1\rangle \end{array}$$

$$\mathbf{a}(t) = \mathbf{v}'(t) = \langle -2, 0\rangle \quad \Rightarrow \quad \mathbf{a}(0) = \mathbf{a}(1) = \langle -2, 0\rangle$$

Below is a sketch of the path and the velocity and acceleration vectors at $t = 0$ and $t = 1$:



$\mathbf{r}(t) = \langle 1 - t^2, 1 - t\rangle, -2 \le t \le 2$

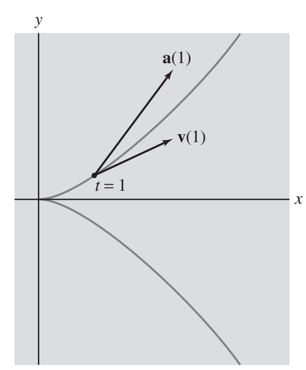
9. Sketch the path $\mathbf{r}(t) = \langle t^2, t^3\rangle$ together with the velocity and acceleration vectors at $t = 1$.

SOLUTION We compute the velocity and acceleration vectors at $t = 1$:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \langle 2t, 3t^2\rangle \quad \Rightarrow \quad \mathbf{v}(1) = \langle 2, 3\rangle$$

$$\mathbf{a}(t) = \mathbf{v}'(t) = \langle 2, 6t\rangle \quad \Rightarrow \quad \mathbf{a}(1) = \langle 2, 6\rangle$$

The following figure shows the path $\mathbf{r}(t) = \langle t^2, t^3\rangle$ and the vectors $\mathbf{v}(1)$ and $\mathbf{a}(1)$:



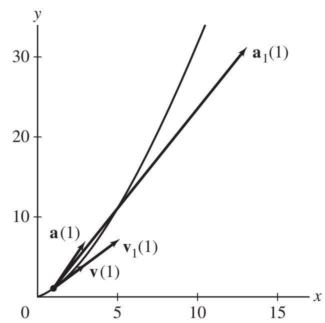
$\mathbf{r}(t) = (t^2, t^3)$

10. The paths $\mathbf{r}(t) = \langle t^2, t^3\rangle$ and $\mathbf{r}_1(t) = \langle t^4, t^6\rangle$ trace the same curve, and $\mathbf{r}_1(1) = \mathbf{r}(1)$. Do you expect either the velocity vectors or the acceleration vectors of these paths at $t = 1$ to point in the same direction? Compute these vectors and draw them on a single plot of the curve.

SOLUTION The paths $\mathbf{r}_1(t) = \langle t^4, t^6\rangle$ and $\mathbf{r}(t) = \langle t^2, t^3\rangle$ trace the same curve and $\mathbf{r}_1(1) = \mathbf{r}(1)$. However, the velocity and acceleration vectors determined by the two parametrizations may differ at the same point $*$. Notice that a parametrization of a curve includes information on the velocity and acceleration of the particle, hence different parametrizations correspond to different velocity and acceleration vectors. We compute these vectors at $t = 1$ for each parametrization:

$$\begin{array}{ll}
\mathbf{r}_1(t) = \langle t^4, t^6\rangle & \mathbf{r}(t) = \langle t^2, t^3\rangle \\
\mathbf{v}_1(t) = \mathbf{r}_1'(t) = \langle 4t^3, 6t^5\rangle & \mathbf{v}(t) = \mathbf{r}'(t) = \langle 2t, 3t^2\rangle \\
\mathbf{a}_1(1) = \mathbf{r}_1''(t) = \langle 12t^2, 30t^4\rangle & \mathbf{a}(1) = \mathbf{r}''(t) = \langle 2, 6t\rangle \\
\text{Hence,} & \text{Hence,} \\
\mathbf{v}_1(1) = \langle 4, 6\rangle, \mathbf{a}_1(1) = \langle 12, 30\rangle & \mathbf{v}(1) = \langle 2, 3\rangle, \mathbf{a}(1) = \langle 2, 6\rangle
\end{array}$$

We see that the vectors in the two parametrizations, are different. We draw the vectors on the following plot:



The velocity vectors should point in the same direction but may be of different size. The acceleration vectors may point to different directions.

In Exercises 11–14, find $\mathbf{v}(t)$ *given* $\mathbf{a}(t)$ *and the initial velocity.*

11. $\mathbf{a}(t) = \langle t, 4\rangle, \quad \mathbf{v}(0) = \left\langle \frac{1}{3}, -2\right\rangle$

SOLUTION We find $\mathbf{v}(t)$ by integrating $\mathbf{a}(t)$:

$$\mathbf{v}(t) = \int_0^t \mathbf{a}(u)du = \int_0^t \langle u, 4\rangle\, du = \left\langle \frac{1}{2}u^2, 4u\right\rangle\Big|_0^t + \mathbf{v}_0 = \left\langle \frac{t^2}{2}, 4t\right\rangle + \mathbf{v}_0$$

The initial condition gives:

$$\mathbf{v}(0) = \langle 0, 0\rangle + \mathbf{v}_0 = \left\langle \frac{1}{3}, -2\right\rangle \quad \Rightarrow \quad \mathbf{v}_0 = \left\langle \frac{1}{3}, -2\right\rangle$$

Hence,

$$\mathbf{v}(t) = \left\langle \frac{t^2}{2}, 4t\right\rangle + \left\langle \frac{1}{3}, -2\right\rangle = \left\langle \frac{3t^2+2}{6}, 4t-2\right\rangle$$

12. $\mathbf{a}(t) = \langle e^t, 0, t+1\rangle, \quad \mathbf{v}(0) = \langle 1, -3, \sqrt{2}\rangle$

SOLUTION Integrating $\mathbf{a}(t)$ gives:

$$\mathbf{v}(t) = \int_0^t \mathbf{a}(u)du = \int_0^t \langle e^u, 0, u+1\rangle du = \left\langle e^u, 0, \frac{u^2}{2} + u\right\rangle\Big|_0^t + \mathbf{v}_0 = \left\langle e^t - 1, 0, \frac{t^2}{2} + t\right\rangle + \mathbf{v}_0 \tag{1}$$

The initial condition gives:

$$\mathbf{v}(0) = \left\langle e^0 - 1, 0, \frac{0^2}{2} + 0\right\rangle + \mathbf{v}_0 = \langle 1, -3, \sqrt{2}\rangle$$

$$\langle 0, 0, 0\rangle + \mathbf{v}_0 = \langle 1, -3, \sqrt{2}\rangle$$

$$\Rightarrow \quad \mathbf{v}_0 = \langle 1, -3, \sqrt{2}\rangle$$

Substituting in (1) we obtain:

$$\mathbf{v}(t) = \left\langle e^t - 1, 0, \frac{t^2}{2} + t\right\rangle + \langle 1, -3, \sqrt{2}\rangle = \left\langle e^t, -3, \frac{t^2}{2} + t + \sqrt{2}\right\rangle$$

13. $\mathbf{a}(t) = \mathbf{k}, \quad \mathbf{v}(0) = \mathbf{i}$

SOLUTION We compute $\mathbf{v}(t)$ by integrating the acceleration vector:

$$\mathbf{v}(t) = \int_0^t \mathbf{a}(u)\, du = \int_0^t \mathbf{k}\, du = \mathbf{k}u\Big|_0^t + \mathbf{v}_0 = t\mathbf{k} + \mathbf{v}_0 \tag{1}$$

Substituting the initial condition gives:

$$\mathbf{v}(0) = 0\mathbf{k} + \mathbf{v}_0 = \mathbf{i} \quad \Rightarrow \quad \mathbf{v}_0 = \mathbf{i}$$

Combining with (1) we obtain:

$$\mathbf{v}(t) = \mathbf{i} + t\mathbf{k}$$

14. $\mathbf{a}(t) = t^2\mathbf{k}, \quad \mathbf{v}(0) = \mathbf{i} - \mathbf{j}$

SOLUTION We integrate the acceleration vector to find the velocity vector $\mathbf{v}(t)$. This gives

$$\mathbf{v}(t) = \int_0^t \mathbf{a}(u)\,du = \int_0^t u^2\mathbf{k}\,du = \frac{u^3}{3}\mathbf{k}\Big|_0^t + \mathbf{v}_0 = \frac{t^3}{3}\mathbf{k} + \mathbf{v}_0 \tag{1}$$

The initial condition gives:

$$\mathbf{v}(0) = \frac{0^3}{3}\mathbf{k} + \mathbf{v}_0 = \mathbf{i} - \mathbf{j} \quad \Rightarrow \quad \mathbf{v}_0 = \mathbf{i} - \mathbf{j}$$

Substituting in (1) we obtain:

$$\mathbf{v}(t) = \frac{t^3}{3}\mathbf{k} + \mathbf{i} - \mathbf{j} = \mathbf{i} - \mathbf{j} + \frac{t^3}{3}\mathbf{k}$$

In Exercises 15–18, find $\mathbf{r}(t)$ and $\mathbf{v}(t)$ given $\mathbf{a}(t)$ and the initial velocity and position.

15. $\mathbf{a}(t) = \langle t, 4\rangle, \quad \mathbf{v}(0) = \langle 3, -2\rangle, \quad \mathbf{r}(0) = \langle 0, 0\rangle$

SOLUTION We first integrate $\mathbf{a}(t)$ to find the velocity vector:

$$\mathbf{v}(t) = \int_0^t \langle u, 4\rangle\; du = \left\langle \frac{u^2}{2}, 4u \right\rangle\Big|_0^t + \mathbf{v}_0 = \left\langle \frac{t^2}{2}, 4t \right\rangle + \mathbf{v}_0 \tag{1}$$

The initial condition $\mathbf{v}(0) = \langle 3, -2\rangle$ gives:

$$\mathbf{v}(0) = \langle 0, 0\rangle + \mathbf{v}_0 = \langle 3, -2\rangle \quad \Rightarrow \quad \mathbf{v}_0 = \langle 3, -2\rangle$$

Substituting in (1) we get:

$$\mathbf{v}(t) = \left\langle \frac{t^2}{2}, 4t \right\rangle + \langle 3, -2\rangle = \left\langle \frac{t^2}{2} + 3, 4t - 2 \right\rangle$$

We now integrate the velocity vector to find $\mathbf{r}(t)$:

$$\mathbf{r}(t) = \int_0^t \left\langle \frac{u^2}{2} + 3, 4u - 2 \right\rangle du = \left\langle \frac{u^3}{6} + 3u, 2u^2 - 2u \right\rangle\Big|_0^t + \mathbf{r}_0 = \left\langle \frac{t^3}{6} + 3t, 2t^2 - 2t \right\rangle + \mathbf{r}_0$$

The initial condition $\mathbf{r}(0) = \langle 0, 0\rangle$ gives:

$$\mathbf{r}(0) = \langle 0, 0\rangle + \mathbf{r}_0 = \langle 0, 0\rangle \quad \Rightarrow \quad \mathbf{r}_0 = \langle 0, 0\rangle$$

Hence,

$$\mathbf{r}(t) = \left\langle \frac{t^3}{6} + 3t, 2t^2 - 2t \right\rangle$$

16. $\mathbf{a}(t) = \langle e^t, 2t, t+1\rangle, \quad \mathbf{v}(0) = \langle 1, 0, 1\rangle, \quad \mathbf{r}(0) = \langle 2, 1, 1\rangle$

SOLUTION We integrate $\mathbf{a}(t)$ to find $\mathbf{v}(t)$:

$$\mathbf{v}(t) = \int_0^t \langle e^u, 2u, u+1\rangle\, du = \left\langle e^t - 1, t^2, \frac{t^2}{2} + t \right\rangle + \mathbf{v}_0$$

The initial condition for the velocity vector gives:

$$\begin{aligned} \mathbf{v}(0) &= \langle e^0 - 1, 0, 0\rangle + \mathbf{v}_0 = \langle 1, 0, 1\rangle \\ &\langle 0, 0, 0\rangle + \mathbf{v}_0 = \langle 1, 0, 1\rangle \quad \Rightarrow \quad \mathbf{v}_0 = \langle 1, 0, 1\rangle \end{aligned}$$

Hence,

$$\mathbf{v}(t) = \left\langle e^t, t^2, \frac{t^2}{2} + t + 1 \right\rangle$$

We now integrate $\mathbf{v}(t)$ to find $\mathbf{r}(t)$:

$$\mathbf{r}(t) = \int_0^t \left\langle e^u, u^2, \frac{u^2}{2} + u + 1 \right\rangle du = \left\langle e^t - 1, \frac{t^3}{3}, \frac{t^3}{6} + \frac{t^2}{2} + t \right\rangle + \mathbf{r}_0 \tag{1}$$

The initial condition for $\mathbf{r}(t)$ gives:

$$\mathbf{r}(0) = \langle 0, 0, 0 \rangle + \mathbf{r}_0 = \langle 2, 1, 1 \rangle$$
$$\langle 0, 0, 0 \rangle + \mathbf{r}_0 = \langle 2, 1, 1 \rangle \quad \Rightarrow \quad \mathbf{r}_0 = \langle 2, 1, 1 \rangle$$

Substituting in (1) we get:

$$\mathbf{r}(t) = \left\langle e^t + 1, \frac{t^3}{3} + 1, \frac{t^3}{6} + \frac{t^2}{2} + t + 1 \right\rangle$$

17. $\mathbf{a}(t) = t\mathbf{k}, \quad \mathbf{v}(0) = \mathbf{i}, \quad \mathbf{r}(0) = \mathbf{j}$

SOLUTION Integrating the acceleration vector gives:

$$\mathbf{v}(t) = \int_0^t u\mathbf{k}\, du = \frac{u^2}{2}\mathbf{k}\Big|_0^t + \mathbf{v}_0 = \frac{t^2}{2}\mathbf{k} + \mathbf{v}_0 \tag{1}$$

The initial condition for $\mathbf{v}(t)$ gives:

$$\mathbf{v}(0) = \frac{0^2}{2}\mathbf{k} + \mathbf{v}_0 = \mathbf{i} \quad \Rightarrow \quad \mathbf{v}_0 = \mathbf{i}$$

We substitute in (1):

$$\mathbf{v}(t) = \frac{t^2}{2}\mathbf{k} + \mathbf{i} = \mathbf{i} + \frac{t^2}{2}\mathbf{k}$$

We now integrate $\mathbf{v}(t)$ to find $\mathbf{r}(t)$:

$$\mathbf{r}(t) = \int_0^t \left(\mathbf{i} + \frac{u^2}{2}\mathbf{k}\right) du = u\mathbf{i} + \frac{u^3}{6}\mathbf{k}\Big|_0^t + \mathbf{r}_0 = t\mathbf{i} + \frac{t^3}{6}\mathbf{k} + \mathbf{r}_0 \tag{2}$$

The initial condition for $\mathbf{r}(t)$ gives:

$$\mathbf{r}(0) = 0\mathbf{i} + 0\mathbf{k} + \mathbf{r}_0 = \mathbf{j} \quad \Rightarrow \quad \mathbf{r}_0 = \mathbf{j}$$

Combining with (2) gives the position vector:

$$\mathbf{r}(t) = t\mathbf{i} + \mathbf{j} + \frac{t^3}{6}\mathbf{k}$$

18. $\mathbf{a}(t) = \cos t\mathbf{k}, \quad \mathbf{v}(0) = \mathbf{i} - \mathbf{j}, \quad \mathbf{r}(0) = \mathbf{i}$

SOLUTION We integrate $\mathbf{a}(t)$ to find the velocity vector $\mathbf{v}(t)$:

$$\mathbf{v}(t) = \int_0^t \cos u\mathbf{k}\, du = \sin t\mathbf{k} + \mathbf{v}_0 \tag{1}$$

The initial condition for $\mathbf{v}(t)$ gives:

$$\mathbf{v}(0) = \sin 0\mathbf{k} + \mathbf{v}_0 = \mathbf{0} + \mathbf{v}_0 = \mathbf{i} - \mathbf{j} \quad \Rightarrow \quad \mathbf{v}_0 = \mathbf{i} - \mathbf{j}$$

Substituting in (1) we obtain:

$$\mathbf{v}(t) = \mathbf{i} - \mathbf{j} + \sin t\mathbf{k}$$

We now integrate $\mathbf{v}(t)$ to find the position vector $\mathbf{r}(t)$:

$$\mathbf{r}(t) = \int_0^t (\mathbf{i} - \mathbf{j} + \sin u\mathbf{k})\, du = t\mathbf{i} - t\mathbf{j} - (\cos t - 1)\mathbf{k} + \mathbf{r}_0$$

The initial condition for $\mathbf{r}(t)$ gives:

$$\mathbf{r}(0) = 0\mathbf{i} - 0\mathbf{j} - 0\mathbf{k} + \mathbf{r}_0 = \mathbf{i}$$

$$\Rightarrow \quad \mathbf{r}_0 = \mathbf{i}$$

Substituting in (2) we obtain:

$$\mathbf{r}(t) = (t+1)\mathbf{i} - t\mathbf{j} + (1 - \cos t)\mathbf{k}$$

In Exercises 19–24, recall that $g = 9.8$ m/s^2 is the acceleration due to gravity on the earth's surface.

19. A bullet is fired from the ground at an angle of 45°. What initial speed must the bullet have in order to hit the top of a 120-m tower located 180 m away?

SOLUTION We place the gun at the origin and let $\mathbf{r}(t)$ be the bullet's position vector.

Step 1. Use Newton's Law. The net force vector acting on the bullet is the force of gravity $\mathbf{F} = \langle 0, -gm \rangle = m\langle 0, -g \rangle$. By Newton's Second Law, $\mathbf{F} = m\mathbf{r}''(t)$, hence:

$$m\langle 0, -g \rangle = m\mathbf{r}''(t) \quad \Rightarrow \quad \mathbf{r}''(t) = \langle 0, -g \rangle$$

We compute the position vector by integrating twice:

$$\mathbf{r}'(t) = \int_0^t \mathbf{r}''(u)\,du = \int_0^t \langle 0, -g \rangle\,du = \langle 0, -gt \rangle + \mathbf{v}_0$$

$$\mathbf{r}(t) = \int_0^t \mathbf{r}'(u)\,du = \int_0^t (\langle 0, -gu \rangle + \mathbf{v}_0)\,du = \left\langle 0, -g\frac{t^2}{2} \right\rangle + \mathbf{v}_0 t + \mathbf{r}_0$$

That is,

$$\mathbf{r}(t) = \left\langle 0, \frac{-g}{2}t^2 \right\rangle + \mathbf{v}_0 t + \mathbf{r}_0 \tag{1}$$

Since the gun is at the origin, $\mathbf{r}_0 = \mathbf{0}$. The bullet is fired at an angle of 45°, hence the initial velocity $\mathbf{v}_0$ points in the direction of the unit vector $\langle \cos 45°, \sin 45° \rangle = \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle$ therefore, $\mathbf{v}_0 = v_0 \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle$. Substituting these initial values in (1) gives:

$$\mathbf{r}(t) = \left\langle 0, \frac{-g}{2}t^2 \right\rangle + t v_0 \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle$$

Step 2. Solve for v_0. The position vector of the top of the tower is $\langle 180, 120 \rangle$, hence at the moment of hitting the tower we have,

$$\mathbf{r}(t) = \left\langle 0, \frac{-g}{2}t^2 \right\rangle + t v_0 \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle = \langle 180, 120 \rangle$$

$$\left\langle t v_0 \frac{\sqrt{2}}{2}, \frac{-g}{2}t^2 + \frac{\sqrt{2}}{2} t v_0 \right\rangle = \langle 180, 120 \rangle$$

Equating components, we get the equations:

$$\begin{cases} t v_0 \dfrac{\sqrt{2}}{2} = 180 \\[2mm] -\dfrac{g}{2}t^2 + \dfrac{\sqrt{2}}{2} t v_0 = 120 \end{cases}$$

The first equation implies that $t = \frac{360}{\sqrt{2}v_0}$. We substitute in the second equation and solve for v_0 (we use $g = 9.8$ m/s^2):

$$-\frac{9.8}{2}\left(\frac{360}{\sqrt{2}v_0}\right)^2 + \frac{\sqrt{2}}{2}\left(\frac{360}{\sqrt{2}v_0}\right)v_0 = 120$$

$$-2.45\left(\frac{360}{v_0}\right)^2 + 180 = 120$$

$$\left(\frac{360}{v_0}\right)^2 = \frac{1200}{49} \quad \Rightarrow \quad \frac{360}{v_0} = \sqrt{\frac{1200}{49}} \quad \Rightarrow \quad v_0 = 42\sqrt{3} \approx 72.746 \text{ m/s}$$

The initial speed of the bullet must be $v_0 = 42\sqrt{3}$ m/s ≈ 72.746 m/s.

20. Find the initial velocity vector $\mathbf{v}_0$ of a projectile released with initial speed 100 m/s that reaches a maximum height of 300 m.

SOLUTION If $\mathbf{v} = \langle a, b\rangle$, then in the text we found that the maximum height is $\frac{b^2}{2g} = 300$ and

$$b = \sqrt{2(9.8)(300)} = \sqrt{5880} = 14\sqrt{30} \approx 76.68$$

and using the Pythagorean Theorem for right triangles, $a = \sqrt{100^2 - (\sqrt{5880})^2} = 2\sqrt{1030} \approx 64.19$. Therefore, the initial velocity vector is

$$\mathbf{v}_0 = \left\langle 2\sqrt{1030}, 14\sqrt{30}\right\rangle \approx \langle 64.19, 76.68\rangle$$

21. Show that a projectile fired at an angle θ with initial speed v_0 travels a total distance $(v_0^2/g)\sin 2\theta$ before hitting the ground. Conclude that the maximum distance (for a given v_0) is attained for $\theta = 45°$.

SOLUTION We place the gun at the origin and let $\mathbf{r}(t)$ be the projectile's position vector. The net force acting on the projectile is $\mathbf{F} = \langle 0, -mg\rangle = m\langle 0, -g\rangle$. By Newton's Second Law, $\mathbf{F} = m\mathbf{r}''(t)$, hence:

$$m\langle 0, -g\rangle = m\mathbf{r}''(t) \quad \Rightarrow \quad \mathbf{r}''(t) = \langle 0, -g\rangle$$

Integrating twice we get:

$$\mathbf{r}'(t) = \int_0^t \mathbf{r}''(u)\,du = \int_0^t \langle 0, -g\rangle\,du = \langle 0, -\text{gt}\rangle + \mathbf{v}_0$$

$$\mathbf{r}(t) = \int_0^t \mathbf{r}'(u)\,du = \int_0^t (\langle 0, -g\cdot u\rangle + \mathbf{v}_0)\,du = \left\langle 0, -\frac{g}{2}t^2\right\rangle + \mathbf{v}_0 t + \mathbf{r}_0 \tag{1}$$

Since the gun is at the origin, $\mathbf{r}_0 = 0$. The firing was at an angle θ, hence the initial velocity points in the direction of the unit vector $\langle\cos\theta, \sin\theta\rangle$. Hence, $\mathbf{v}_0 = v_0\langle\cos\theta, \sin\theta\rangle$. We substitute the initial vectors in (1) to obtain:

$$\mathbf{r}(t) = \left\langle 0, -\frac{g}{2}t^2\right\rangle + v_0 t\langle\cos\theta, \sin\theta\rangle \tag{2}$$

The total distance is obtained when the y-component of $\mathbf{r}(t)$ is zero (besides the original moment, that is,

$$-\frac{g}{2}t^2 + (v_0\sin\theta)\,t = 0$$

$$t\left(-\frac{g}{2}t + v_0\sin\theta\right) = 0 \quad \Rightarrow \quad t = 0 \quad \text{or} \quad t = \frac{2v_0\sin\theta}{g}$$

The appropriate choice is $t = \frac{2v_0\sin\theta}{g}$. We now find the total distance x_T by substituting this value of t in the x-component of $\mathbf{r}(t)$ in (2). We obtain:

$$x(t) = v_0 t\cos\theta$$

$$x_T = v_0\cos\theta\cdot\frac{2v_0\sin\theta}{g} = \frac{2v_0^2\cos\theta\sin\theta}{g} = \frac{v_0^2\sin 2\theta}{g}$$

The maximum distance is attained when $\sin 2\theta = 1$, that is $2\theta = 90°$ or $\theta = 45°$.

22. One player throws a baseball to another player standing 25 m away with initial speed 18 m/s. Use the result of Exercise 21 to find two angles θ at which the ball can be released. Which angle gets the ball there faster?

SOLUTION We suppose that the baseball is thrown from the origin, and that $\mathbf{r}(t)$ is the baseball's position vector. By Exercise 21 the total distance travelled by the ball is $\frac{v_0^2}{g}\sin 2\theta$. Using the given information we obtain the following equation:

$$\frac{18^2}{9.8}\sin 2\theta = 25$$

$$\sin 2\theta = \frac{9.8\cdot 25}{18^2} \approx 0.756$$

The solutions for $0 \le \theta \le 90°$ are:

$$\begin{array}{c} 2\theta \approx 49.13° \\ \theta \approx 24.56° \end{array} \quad \text{or} \quad \begin{array}{c} 2\theta \approx 139.12° \\ \theta \approx 69.56° \end{array}$$

By Newton's Second Law we have:

$$\mathbf{F} = m\langle 0, -g\rangle = m\mathbf{r}''(t) \quad\Rightarrow\quad \mathbf{r}''(t) = \langle 0, -g\rangle = \langle 0, -9.8\rangle$$

Integrating gives:

$$\mathbf{v}(t) = \int_0^t \mathbf{r}''(u)\,du = \int_0^t \langle 0, -9.8\rangle\,du = \langle 0, -9.8t\rangle + \mathbf{v}_0 \tag{1}$$

The initial velocity points in the direction of the unit vector $\langle\cos\theta, \sin\theta\rangle$ and its magnitude is the initial speed $v_0 = 18$. Hence, $\mathbf{v}_0 = 18\langle\cos\theta, \sin\theta\rangle$. Substituting in (1) we get:

$$\mathbf{v}(t) = \langle 0, -9.8t\rangle + 18\langle\cos\theta, \sin\theta\rangle \tag{2}$$

Integrating this vector with respect to t and using $\mathbf{r}_0 = \mathbf{0}$ we obtain:

$$\mathbf{r}(t) = \int_0^t \mathbf{v}(u)\,du = \int_0^t (\langle 0, -9.8u\rangle + 18\langle\cos\theta, \sin\theta\rangle)\,du = \left\langle 0, -4.9t^2\right\rangle + 18t\langle\cos\theta, \sin\theta\rangle$$

At the final time $x(t) = 25$. This gives:

$$x(t) = 18t\cos\theta = 25 \quad\Rightarrow\quad t = \frac{25}{18\cos\theta}$$

Since we want to minimize t we need to maximize $\cos\theta$, hence, to minimize θ. Therefore, $\theta = 24.56^\circ$ will get the ball faster to the other player.

23. A bullet is fired at an angle $\theta = \frac{\pi}{4}$ at a tower located $d = 600$ m away, with initial speed $v_0 = 120$ m/s. Find the height H at which the bullet hits the tower.

SOLUTION We place the gun at the origin and let $\mathbf{r}(t)$ be the bullet's position vector.

Step 1. Use Newton's Law. The net force vector acting on the bullet is the force of gravity $\mathbf{F} = \langle 0, -gm\rangle = m\langle 0, -g\rangle$. By Newton's Second Law, $\mathbf{F} = m\mathbf{r}''(t)$, hence:

$$m\langle 0, -g\rangle = m\mathbf{r}''(t) \quad\Rightarrow\quad \mathbf{r}''(t) = \langle 0, -g\rangle$$

We compute the position vector by integrating twice:

$$\mathbf{r}'(t) = \int_0^t \mathbf{r}''(u)\,du = \int_0^t \langle 0, -g\rangle\,du = \langle 0, -gt\rangle + \mathbf{v}_0$$

$$\mathbf{r}(t) = \int_0^t \mathbf{r}'(u)\,du = \int_0^t (\langle 0, -gu\rangle + \mathbf{v}_0)\,du = \left\langle 0, -g\frac{t^2}{2}\right\rangle + \mathbf{v}_0 t + \mathbf{r}_0$$

That is,

$$\mathbf{r}(t) = \left\langle 0, \frac{-g}{2}t^2\right\rangle + \mathbf{v}_0 t + \mathbf{r}_0 \tag{1}$$

Since the gun is at the origin, $\mathbf{r}_0 = \mathbf{0}$. The bullet is fired at an angle of $\pi/4$ radians, hence the initial velocity $\mathbf{v}_0$ points in the direction of the unit vector $\langle\cos\pi/4, \sin\pi/4\rangle = \left\langle\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right\rangle$ therefore, $\mathbf{v}_0 = v_0\left\langle\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right\rangle$. Substituting these initial values in (1) gives:

$$\mathbf{r}(t) = \left\langle 0, \frac{-g}{2}t^2\right\rangle + tv_0\left\langle\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right\rangle$$

Step 2. Solve for H.

The position vector for the point at which the bullet hits the tower, 600 meters away, is $\langle 600, H\rangle$, hence at the moment of hitting the tower we have,

$$\left\langle 0, \frac{-g}{2}t^2\right\rangle + tv_0\left\langle\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right\rangle = \langle 600, H\rangle$$

Therefore, for $v_0 = 120$:

$$\frac{tv_0}{\sqrt{2}} = 600 \quad\Rightarrow\quad t = \frac{600\sqrt{2}}{120} = 5\sqrt{2}$$

and

$$-\frac{gt^2}{2} + \frac{tv_0}{\sqrt{2}} = \frac{-9.8(50)}{2} + \frac{5(\sqrt{2})(120)}{\sqrt{2}} = H$$

Hence, $H = 355$ meters. The bullet hits the tower at 355 meters high.

24. Show that a bullet fired at an angle θ will hit the top of an h-meter tower located d meters away if its initial speed is

$$v_0 = \frac{\sqrt{g/2}\, d \sec\theta}{\sqrt{d\tan\theta - h}}$$

SOLUTION We place the gun at the origin and let $\mathbf{r}(t)$ be the position vector of the bullet. The net force acting on the bullet is $\mathbf{F} = \langle 0, -mg \rangle = m\langle 0, -g \rangle$. By Newton's Second Law, $\mathbf{F} = m\mathbf{r}''(t)$, hence:

$$m\langle 0, -g \rangle = m\mathbf{r}''(t) \quad \Rightarrow \quad \mathbf{r}''(t) = \langle 0, -g \rangle$$

We integrate twice and use the initial value $\mathbf{r}(0) = \mathbf{0}$, to obtain:

$$\mathbf{v}(t) = \int_0^t \mathbf{r}''(u)\,du = \int_0^t \langle 0, -g \rangle\,du = \langle 0, -gt \rangle + \mathbf{v}_0$$

$$\mathbf{r}(t) = \int_0^t \mathbf{v}(u)\,du = \int_0^t (\langle 0, -gu \rangle + \mathbf{v}_0)\,du = \left\langle 0, -\frac{g}{2}t^2 \right\rangle + \mathbf{v}_0 t \tag{1}$$

To determine $\mathbf{v}_0$ we notice that the initial velocity vector points in the direction of the unit vector $\langle \cos\theta, \sin\theta \rangle$ and its magnitude is the initial speed v_0. Hence $\mathbf{v}_0 = v_0\langle \cos\theta, \sin\theta \rangle$. Substituting in (1), we get:

$$\mathbf{r}(t) = \left\langle 0, -\frac{g}{2}t^2 \right\rangle + v_0 t\langle \cos\theta, \sin\theta \rangle$$

For the bullet to hit the top of the tower, there must be a value of t such that $\mathbf{r}(t) = \langle d, h \rangle$. That is:

$$\left\langle 0, -\frac{g}{2}t^2 \right\rangle + v_0 t\langle \cos\theta, \sin\theta \rangle = \langle d, h \rangle$$

Equating components we get the following equations:

$$v_0 t\cos\theta = d$$
$$-\frac{g}{2}t^2 + v_0 t\sin\theta = h$$

The first equation implies that $t = \frac{d}{v_0\cos\theta}$. We substitute in the second equation and solve for v_0:

$$-\frac{g}{2}\left(\frac{d}{v_0\cos\theta}\right)^2 + v_0\left(\frac{d}{v_0\cos\theta}\right)\sin\theta = h$$

$$-\frac{gd^2}{2v_0^2\cos^2\theta} + d\tan\theta = h$$

$$\frac{gd^2}{2v_0^2\cos^2\theta} = d\tan\theta - h$$

$$v_0{}^2 = \frac{gd^2}{2\cos^2\theta\,(d\tan\theta - h)} = \frac{gd^2\sec^2\theta}{2\,(d\tan\theta - h)}$$

Therefore,

$$v_0 = \frac{\sqrt{g/2}\, d \sec\theta}{\sqrt{d\tan\theta - h}}$$

25. A constant force $\mathbf{F} = \langle 5, 2 \rangle$ (in newtons) acts on a 10-kg mass. Find the position of the mass at $t = 10$ s if it is located at the origin at $t = 0$ and has initial velocity $\mathbf{v}_0 = \langle 2, -3 \rangle$ (in meters per second).

SOLUTION We know that $\mathbf{F} = m\mathbf{a}$ and thus $\langle 5, 2 \rangle = 10\mathbf{a}$ so then $\mathbf{a} = \langle 0.5, 0.2 \rangle$. Using integration we know

$$\mathbf{v}(t) = \int \mathbf{a}(t)\,dt = t\mathbf{a} + \mathbf{c}$$

and we know $\mathbf{v}(0) = \langle 2, -3 \rangle = \mathbf{c}$. Therefore,

$$\mathbf{v}(t) = t\mathbf{a} + \mathbf{v}_0 = t\langle 0.5, 0.2 \rangle + \langle 2, -3 \rangle = \langle 0.5t + 2, 0.2t - 3 \rangle$$

Again, integrating,

$$\mathbf{r}(t) = \int \mathbf{v}(t)\,dt$$

$$= \int t\mathbf{a} + \mathbf{v}_0\, dt$$

$$= \frac{t^2}{2}\mathbf{a} + t\mathbf{v}_0 + \mathbf{c}$$

$$= \frac{t^2}{2}\langle 0.5, 0.2\rangle + t\langle 2, -3\rangle$$

$$= \left\langle 0.25t^2 + 2t, 0.1t^2 - 3t\right\rangle + \mathbf{r}_0$$

Using the initial condition $\mathbf{r}(0) = \langle 0, 0\rangle = \mathbf{c}$, we conclude

$$\mathbf{r}(t) = \left\langle 0.25t^2 + 2t, 0.1t^2 - 3t\right\rangle$$

and hence the position of the mass at $t = 10$ is $\mathbf{r}(10) = \langle 45, -20\rangle$.

26. A force $\mathbf{F} = \langle 24t, 16 - 8t\rangle$ (in newtons) acts on a 4-kg mass. Find the position of the mass at $t = 3$ s if it is located at (10, 12) at $t = 0$ and has zero initial velocity.

SOLUTION We know $\mathbf{F} = m\mathbf{a}$ and thus $\langle 24t, 16 - 8t\rangle = 4\mathbf{a}$, therefore, $\mathbf{a} = \langle 6t, 4 - 2t\rangle$, and

$$\mathbf{v}(t) = \int \mathbf{a}\, dt = \int \langle 6t, 4 - 2t\rangle\, dt = \left\langle 3t^2, 4t - t^2\right\rangle + \mathbf{c}$$

using the initial velocity condition, $\mathbf{v}(0) = \langle 0, 0\rangle$, then $\mathbf{c} = \langle 0, 0\rangle$ and

$$\mathbf{v}(t) = \left\langle 3t^2, 4t - t^2\right\rangle$$

Now integrating again, we get:

$$\mathbf{r}(t) = \int \mathbf{v}(t)\, dt = \int \left\langle 3t^2, 4t - t^2\right\rangle dt = \left\langle t^3, 2t^2 - \frac{t^3}{3}\right\rangle + \mathbf{c}$$

Using the initial position condition $\mathbf{r}(0) = \langle 10, 12\rangle$, we get $\mathbf{r}(0) = \langle 10, 12\rangle = \mathbf{c}$ and therefore,

$$\mathbf{r} = \left\langle t^3 + 10, 2t^2 - \frac{t^3}{3} + 12\right\rangle$$

and at $t = 3$ the position of the mass is $\mathbf{r}(3) = \left\langle 3^3 + 10, 2(9) - 9 + 12\right\rangle = \langle 37, 21\rangle$.

27. A particle follows a path $\mathbf{r}(t)$ for $0 \le t \le T$, beginning at the origin O. The vector $\overline{\mathbf{v}} = \frac{1}{T}\int_0^T \mathbf{r}'(t)\, dt$ is called the **average velocity** vector. Suppose that $\overline{\mathbf{v}} = \mathbf{0}$. Answer and explain the following:

(a) Where is the particle located at time T if $\overline{\mathbf{v}} = \mathbf{0}$?

(b) Is the particle's average speed necessarily equal to zero?

SOLUTION

(a) If the average velocity is 0, then the particle must be back at its original position at time $t = T$. This is perhaps best seen by noting that $\overline{\mathbf{v}} = \frac{1}{T}\int_0^T \mathbf{r}'(t)\, dt = \mathbf{r}(t)\Big|_0^T$.

(b) The average speed need not be zero! Consider a particle moving at constant speed around a circle, with position vector $\mathbf{r}(t) = \langle \cos t, \sin t\rangle$. From 0 to 2π, this has average velocity of 0, but constant average speed of 1.

28. At a certain moment, a moving particle has velocity $\mathbf{v} = \langle 2, 2, -1\rangle$ and $\mathbf{a} = \langle 0, 4, 3\rangle$. Find $\mathbf{T}$, $\mathbf{N}$, and the decomposition of $\mathbf{a}$ into tangential and normal components.

SOLUTION We go through the following steps:

Step 1. Compute $\mathbf{T}$ and $a_{\mathbf{T}}$. The unit tangent is the following vector:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 2, 2, -1\rangle}{\sqrt{2^2 + 2^2 + (-1)^2}} = \frac{1}{3}\langle 2, 2, -1\rangle \tag{1}$$

The tangential component of $\mathbf{a} = \langle 0, 4, 3\rangle$ is:

$$a_{\mathbf{T}} = \mathbf{a}\cdot\mathbf{T} = \langle 0, 4, 3\rangle \cdot \frac{1}{3}\langle 2, 2, -1\rangle = \frac{1}{3}(0 + 8 - 3) = \frac{5}{3}$$

Step 2. Compute $a_{\mathbf{N}}$ and $\mathbf{N}$. Since $a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T}$, we have:

$$a_{\mathbf{N}}\mathbf{N} = \langle 0, 4, 3\rangle - \frac{5}{3}\cdot\frac{1}{3}\langle 2, 2, -1\rangle = \langle 0, 4, 3\rangle - \left\langle \frac{10}{9}, \frac{10}{9}, -\frac{5}{9}\right\rangle = \frac{1}{9}\langle -10, 26, 32\rangle \tag{3}$$

The unit normal $\mathbf{N}$ is a unit vector, therefore:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = \frac{1}{9}\sqrt{(-10)^2 + 26^2 + 32^2} = \frac{1}{9}\cdot 30\sqrt{2} = \frac{10\sqrt{2}}{3} \tag{4}$$

We compute $\mathbf{N}$, using (3) and (4):

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\frac{1}{9}\langle -10, 26, 32\rangle}{\frac{10\sqrt{2}}{3}} = \frac{1}{15\sqrt{2}}\langle -5, 13, 16\rangle$$

Step 3. Write the decomposition. Using (1)–(4) we obtain the following decomposition:

$$\mathbf{a} = a_{\mathbf{T}}\mathbf{T} + a_{\mathbf{N}}\mathbf{N}$$
$$\langle 0, 4, 3\rangle = \frac{5}{3}\mathbf{T} + \frac{10\sqrt{2}}{3}\mathbf{N},$$

where $\mathbf{T} = \left\langle \frac{2}{3}, \frac{2}{3}, -\frac{1}{3}\right\rangle$ and $\mathbf{N} = \frac{1}{15\sqrt{2}}\langle -5, 13, 16\rangle$.

29. At a certain moment, a particle moving along a path has velocity $\mathbf{v} = \langle 12, 20, 20\rangle$ and acceleration $\mathbf{a} = \langle 2, 1, -3\rangle$. Is the particle speeding up or slowing down?

SOLUTION We are asked if the particle is speeding up or slowing down, that is if $\|\mathbf{v}\|$ or $\|\mathbf{v}\|^2$ is increasing or decreasing. We check $\left(\|\mathbf{v}\|^2\right)'$:

$$\left(\|\mathbf{v}\|^2\right)' = (\mathbf{v}\cdot\mathbf{v})' = 2\mathbf{v}'\cdot\mathbf{v} = 2\cdot\mathbf{a}\cdot\mathbf{v} = 2\langle 2, 1, -3\rangle\cdot\langle 12, 20, 20\rangle = 2\cdot(24 + 20 - 60) = -32 < 0$$

So the speed is decreasing.

In Exercises 30–33, use Eq. (3) to find the coefficients $a_{\mathbf{T}}$ and $a_{\mathbf{N}}$ as a function of t (or at the specified value of t).

30. $\mathbf{r}(t) = \langle t^2, t^3\rangle$

SOLUTION We find $\mathbf{v}(t)$ and $\mathbf{a}(t)$ by differentiating $\mathbf{r}(t)$ twice:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \langle 2t, 3t^2\rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 2, 6t\rangle$$

The unit tangent vector $\mathbf{T}$ is:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 2t, 3t^2\rangle}{\sqrt{(2t)^2 + \left(3t^2\right)^2}} = \frac{\langle 2t, 3t^2\rangle}{\sqrt{4t^2 + 9t^4}}$$

We compute $a_{\mathbf{T}}$:

$$a_{\mathbf{T}} = \mathbf{a}\cdot\mathbf{T} = \frac{\langle 2, 6t\rangle\cdot\langle 2t, 3t^2\rangle}{\sqrt{4t^2 + 9t^4}} = \frac{4t + 18t^3}{\sqrt{4t^2 + 9t^4}}$$

To find $a_{\mathbf{N}}$ we first compute the cross product $\mathbf{a}\times\mathbf{v}$:

$$\mathbf{a}\times\mathbf{v} = (2\mathbf{i} + 6t\mathbf{j})\times\left(2t\mathbf{i} + 3t^2\mathbf{j}\right) = 6t^2\mathbf{i}\times\mathbf{j} + 12t^2\mathbf{j}\times\mathbf{i} = 6t^2\mathbf{k} - 12t^2\mathbf{k} = -6t^2\mathbf{k}$$

Hence,

$$a_{\mathbf{N}} = \frac{\|\mathbf{a}\times\mathbf{v}\|}{\|\mathbf{v}\|} = \frac{\|-6t^2\mathbf{k}\|}{\sqrt{4t^2 + 9t^4}} = \frac{6t^2}{\sqrt{4t^2 + 9t^4}}$$

31. $\mathbf{r}(t) = \langle t, \cos t, \sin t\rangle$

SOLUTION We find $a_{\mathbf{T}}$ and $a_{\mathbf{N}}$ using the following equalities:

$$a_{\mathbf{T}} = \mathbf{a}\cdot\mathbf{T},\ a_{\mathbf{N}} = \frac{\|\mathbf{a}\times\mathbf{v}\|}{\|\mathbf{v}\|}.$$

We compute $\mathbf{v}$ and $\mathbf{a}$ by differentiating $\mathbf{r}$ twice:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \langle 1, -\sin t, \cos t\rangle \quad \Rightarrow \quad \|\mathbf{v}(t)\| = \sqrt{1 + (-\sin t)^2 + \cos^2 t} = \sqrt{2}$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 0, -\cos t, -\sin t\rangle$$

The unit tangent vector $\mathbf{T}$ is, thus:

$$\mathbf{T}(t) = \frac{\mathbf{v}(t)}{\|\mathbf{v}(t)\|} = \frac{1}{\sqrt{2}}\langle 1, -\sin t, \cos t\rangle$$

Since the speed is constant ($v = \|\mathbf{v}(t)\| = \sqrt{2}$), the tangential component of the acceleration is zero, that is:

$$a_{\mathbf{T}} = 0$$

To find $a_{\mathbf{N}}$ we first compute the following cross product:

$$\mathbf{a}\times\mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & -\cos t & -\sin t \\ 1 & -\sin t & \cos t \end{vmatrix} = \begin{vmatrix} -\cos t & -\sin t \\ -\sin t & \cos t \end{vmatrix}\mathbf{i} - \begin{vmatrix} 0 & -\sin t \\ 1 & \cos t \end{vmatrix}\mathbf{j} + \begin{vmatrix} 0 & -\cos t \\ 1 & -\sin t \end{vmatrix}\mathbf{k}$$
$$= -\left(\cos^2 t + \sin^2 t\right)\mathbf{i} - \sin t\,\mathbf{j} + \cos t\,\mathbf{k} = -\mathbf{i} - \sin t\,\mathbf{j} + \cos t\,\mathbf{k} = \langle -1, -\sin t, \cos t\rangle$$

Hence,

$$a_{\mathbf{N}} = \frac{\|\mathbf{a}\times\mathbf{v}\|}{\|\mathbf{v}\|} = \frac{\sqrt{(-1)^2 + (-\sin t)^2 + \cos^2 t}}{\sqrt{2}} = \frac{\sqrt{2}}{\sqrt{2}} = 1.$$

32. $\mathbf{r}(t) = \left\langle t^{-1}, \ln t, t^2\right\rangle, \quad t = 1$

SOLUTION We use the following equalities:

$$a_{\mathbf{T}} = \mathbf{a}\cdot\mathbf{T}, \quad a_{\mathbf{N}} = \frac{\|\mathbf{a}\times\mathbf{v}\|}{\|\mathbf{v}\|}.$$

We first find $\mathbf{a}$ and $\mathbf{v}$ by twice differentiating $\mathbf{r}$. We get:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \left\langle -\frac{1}{t^2}, \frac{1}{t}, 2t\right\rangle \quad \Rightarrow \quad \|\mathbf{v}(t)\| = \sqrt{\frac{1}{t^4} + \frac{1}{t^2} + 4t^2} = \frac{1}{t^2}\sqrt{1 + t^2 + 4t^6}$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \left\langle 2t^{-3}, -t^{-2}, 2\right\rangle$$

At the point $t = 1$ we have:

$$\mathbf{v}(1) = \langle -1, 1, 2\rangle, \quad \|\mathbf{v}(1)\| = \sqrt{6}, \quad \mathbf{a}(1) = \langle 2, -1, 2\rangle$$

Hence, $\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{6}}\langle -1, 1, 2\rangle$ and we obtain:

$$a_{\mathbf{T}} = \mathbf{a}\cdot\mathbf{T} = \langle 2, -1, 2\rangle\cdot\frac{1}{\sqrt{6}}\langle -1, 1, 2\rangle = \frac{1}{\sqrt{6}}(-2 - 1 + 4) = \frac{1}{\sqrt{6}}$$

To find $a_{\mathbf{N}}$ we first compute the following cross product:

$$\mathbf{a}\times\mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & -1 & 2 \\ -1 & 1 & 2 \end{vmatrix} = \begin{vmatrix} -1 & 2 \\ 1 & 2 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2 & 2 \\ -1 & 2 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2 & -1 \\ -1 & 1 \end{vmatrix}\mathbf{k} = -4\mathbf{i} - 6\mathbf{j} + \mathbf{k} = \langle -4, -6, 1\rangle$$

Therefore:

$$a_{\mathbf{N}} = \frac{\|\mathbf{a}\times\mathbf{v}\|}{\|\mathbf{v}\|} = \frac{\sqrt{(-4)^2 + (-6)^2 + 1^2}}{\sqrt{6}} = \sqrt{\frac{53}{6}}$$

33. $\mathbf{r}(t) = \left\langle e^{2t}, t, e^{-t}\right\rangle, \quad t = 0$

SOLUTION We will use the following equalities:

$$a_{\mathbf{T}} = \mathbf{a}\cdot\mathbf{T}, \quad a_{\mathbf{N}} = \frac{\|\mathbf{a}\times\mathbf{v}\|}{\|\mathbf{v}\|}.$$

We first find **a** and **v** by twice differentiating **r**. We get:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \left\langle 2e^{2t}, 1, -e^{-t} \right\rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \left\langle 4e^{2t}, 0, e^{-t} \right\rangle$$

Then evaluating at $t = 0$ we get:

$$\mathbf{v}(0) = \langle 2, 1, -1 \rangle, \quad \Rightarrow \|\mathbf{v}(0)\| = \sqrt{2^2 + 1^2 + (-1)^2} = \sqrt{6}$$
$$\mathbf{a}(0) = \langle 4, 0, 1 \rangle$$

Hence, $\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{6}} \langle 2, 1, -1 \rangle$ and we obtain:

$$a_{\mathbf{T}} = \mathbf{a} \cdot \mathbf{T} = \langle 4, 0, 1 \rangle \cdot \frac{1}{\sqrt{6}} \langle 2, 1, -1 \rangle = \frac{1}{\sqrt{6}}(8 + 0 - 1) = \frac{7}{\sqrt{6}}$$

To find $a_{\mathbf{N}}$ we first compute the following cross product:

$$\mathbf{a} \times \mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 4 & 0 & 1 \\ 2 & 1 & -1 \end{vmatrix} = \langle -1, 6, 4 \rangle$$

Therefore,

$$a_{\mathbf{N}} = \frac{\|\mathbf{a} \times \mathbf{v}\|}{\|\mathbf{v}\|} = \frac{\sqrt{(-1)^2 + 6^2 + 4^2}}{\sqrt{6}} = \sqrt{\frac{53}{6}}$$

In Exercise 34–41, find the decomposition of $\mathbf{a}(t)$ *into tangential and normal components at the point indicated, as in Example 6.*

34. $\mathbf{r}(t) = \left\langle e^t, 1 - t \right\rangle, \quad t = 0$

SOLUTION First note here that:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \left\langle e^t, -1 \right\rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \left\langle e^t, 0 \right\rangle$$

At $t = 0$ we have:

$$\mathbf{v} = \mathbf{r}'(0) = \langle 1, -1 \rangle$$
$$\mathbf{a} = \mathbf{r}''(0) = \langle 1, 0 \rangle$$

Thus,

$$\mathbf{a} \cdot \mathbf{v} = \langle 1, 0 \rangle \cdot \langle 1, -1 \rangle = 1$$
$$\|\mathbf{v}\| = \sqrt{1 + 1} = \sqrt{2}$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 1, -1 \rangle}{\sqrt{1 + 1}} = \left\langle \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}} \right\rangle$$
$$a_{\mathbf{T}} = \frac{\mathbf{a} \cdot \mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{2}}$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} = \langle 1, 0 \rangle - \frac{1}{\sqrt{2}} \left\langle \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}} \right\rangle = \langle 1, 0 \rangle - \left\langle \frac{1}{2}, -\frac{1}{2} \right\rangle = \left\langle \frac{1}{2}, \frac{1}{2} \right\rangle$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = \sqrt{\frac{1}{4} + \frac{1}{4}} = \frac{1}{\sqrt{2}}$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\left\langle \frac{1}{2}, \frac{1}{2} \right\rangle}{1/\sqrt{2}} = \left\langle \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}} \right\rangle$$

Finally, we obtain the decomposition,

$$\mathbf{a} = \langle 1, 0 \rangle = \frac{1}{\sqrt{2}}\mathbf{T} + \frac{1}{\sqrt{2}}\mathbf{N}$$

where $\mathbf{T} = \left\langle \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}} \right\rangle$ and $\mathbf{N} = \left\langle \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}} \right\rangle$.

35. $\mathbf{r}(t) = \left\langle \frac{1}{3}t^3, 1 - 3t \right\rangle, \quad t = -2$

SOLUTION First note here that:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \left\langle t^2, -3 \right\rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 2t, 0 \rangle$$

At $t = -2$ we have:

$$\mathbf{v} = \mathbf{r}'(-2) = \langle 4, -3 \rangle$$
$$\mathbf{a} = \mathbf{r}''(-2) = \langle -4, 0 \rangle$$

Thus,

$$\mathbf{a} \cdot \mathbf{v} = \langle -4, 0 \rangle \cdot \langle 4, -3 \rangle = -16$$
$$\|\mathbf{v}\| = \sqrt{16 + 9} = 5$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 4, -3 \rangle}{5} = \left\langle \frac{4}{5}, -\frac{3}{5} \right\rangle$$
$$a_{\mathbf{T}} = \frac{\mathbf{a} \cdot \mathbf{v}}{\|\mathbf{v}\|} = -\frac{16}{5}$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} = \langle -4, 0 \rangle + \frac{16}{5}\left\langle \frac{4}{5}, -\frac{3}{5} \right\rangle = \left\langle -\frac{36}{25}, -\frac{48}{25} \right\rangle$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = \sqrt{\left(-\frac{36}{25}\right)^2 + \left(-\frac{48}{25}\right)^2} = \frac{60}{25} = \frac{12}{5}$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\left\langle -\frac{36}{25}, -\frac{48}{25} \right\rangle}{12/5} = \left\langle -\frac{3}{5}, -\frac{4}{5} \right\rangle$$

Finally we obtain the decomposition,

$$\mathbf{a} = \langle -4, 0 \rangle = -\frac{16}{5}\mathbf{T} + \frac{12}{5}\mathbf{N}$$

where $\mathbf{T} = \left\langle \frac{4}{5}, -\frac{3}{5} \right\rangle$ and $\mathbf{N} = \left\langle -\frac{3}{5}, -\frac{4}{5} \right\rangle$.

36. $\mathbf{r}(t) = \left\langle t, \frac{1}{2}t^2, \frac{1}{6}t^3 \right\rangle, \quad t = 1$

SOLUTION First note here that:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \left\langle 1, t, \frac{1}{2}t^2 \right\rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 0, 1, t \rangle$$

At $t = 1$ we have:

$$\mathbf{v} = \mathbf{r}'(1) = \left\langle 1, 1, \frac{1}{2} \right\rangle$$
$$\mathbf{a} = \mathbf{r}''(1) = \langle 0, 1, 1 \rangle$$

Thus,

$$\mathbf{a} \cdot \mathbf{v} = \langle 0, 1, 1 \rangle \cdot \left\langle 1, 1, \frac{1}{2} \right\rangle = \frac{3}{2}$$
$$\|\mathbf{v}\| = \sqrt{1 + 1 + \frac{1}{4}} = \frac{3}{2}$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\left\langle 1, 1, \frac{1}{2} \right\rangle}{3/2} = \left\langle \frac{2}{3}, \frac{2}{3}, \frac{1}{3} \right\rangle$$
$$a_{\mathbf{T}} = \frac{\mathbf{a} \cdot \mathbf{v}}{\|\mathbf{v}\|} = \frac{3/2}{3/2} = 1$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} = \langle 0, 1, 1 \rangle - 1 \left\langle \frac{2}{3}, \frac{2}{3}, \frac{1}{3} \right\rangle = \left\langle -\frac{2}{3}, \frac{1}{3}, \frac{2}{3} \right\rangle$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = \sqrt{\frac{4}{9} + \frac{1}{9} + \frac{4}{9}} = 1$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\left\langle -\frac{2}{3}, \frac{1}{3}, \frac{2}{3} \right\rangle}{1} = \left\langle -\frac{2}{3}, \frac{1}{3}, \frac{2}{3} \right\rangle$$

Finally we obtain the decomposition,

$$\mathbf{a} = \langle 0, 1, 1 \rangle = (1)\mathbf{T} + (1)\mathbf{N}$$

where $\mathbf{T} = \left\langle \frac{2}{3}, \frac{2}{3}, \frac{1}{3} \right\rangle$ and $\mathbf{N} = \left\langle -\frac{2}{3}, \frac{1}{3}, \frac{2}{3} \right\rangle$.

37. $\mathbf{r}(t) = \left\langle t, \frac{1}{2}t^2, \frac{1}{6}t^3 \right\rangle, \quad t = 4$

SOLUTION First note here that:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \left\langle 1, t, \frac{1}{2}t^2 \right\rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 0, 1, t \rangle$$

At $t = 4$ we have:

$$\mathbf{v} = \mathbf{r}'(4) = \langle 1, 4, 8 \rangle$$
$$\mathbf{a} = \mathbf{r}''(4) = \langle 0, 1, 4 \rangle$$

Thus,

$$\mathbf{a} \cdot \mathbf{v} = \langle 0, 1, 4 \rangle \cdot \langle 1, 4, 8 \rangle = 36$$
$$\|\mathbf{v}\| = \sqrt{1 + 16 + 64} = \sqrt{81} = 9$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 1, 4, 8 \rangle}{9} = \left\langle \frac{1}{9}, \frac{4}{9}, \frac{8}{9} \right\rangle$$
$$a_{\mathbf{T}} = \frac{\mathbf{a} \cdot \mathbf{v}}{\|\mathbf{v}\|} = \frac{36}{9} = 4$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} = \langle 0, 1, 4\rangle - 4\left\langle \frac{1}{9}, \frac{4}{9}, \frac{8}{9}\right\rangle = \left\langle -\frac{4}{9}, -\frac{7}{9}, \frac{4}{9}\right\rangle$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = \sqrt{\frac{16}{81} + \frac{49}{81} + \frac{16}{81}} = 1$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\left\langle -\frac{4}{9}, -\frac{7}{9}, \frac{4}{9}\right\rangle}{1} = \left\langle -\frac{4}{9}, -\frac{7}{9}, \frac{4}{9}\right\rangle$$

Finally we obtain the decomposition,

$$\mathbf{a} = \langle 0, 1, 4\rangle = 4\mathbf{T} + (1)\mathbf{N}$$

where $\mathbf{T} = \left\langle \frac{1}{9}, \frac{4}{9}, \frac{8}{9}\right\rangle$ and $\mathbf{N} = \left\langle -\frac{4}{9}, -\frac{7}{9}, \frac{4}{9}\right\rangle$.

38. $\mathbf{r}(t) = \langle 4 - t, t + 1, t^2\rangle, \quad t = 2$

SOLUTION First note here that:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \langle -1, 1, 2t\rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 0, 0, 2\rangle$$

At $t = 2$ we have:

$$\mathbf{v} = \mathbf{r}'(2) = \langle -1, 1, 4\rangle$$
$$\mathbf{a} = \mathbf{r}''(2) = \langle 0, 0, 2\rangle$$

Thus,

$$\mathbf{a}\cdot\mathbf{v} = \langle 0, 0, 2\rangle \cdot \langle -1, 1, 4\rangle = 8$$
$$\|\mathbf{v}\| = \sqrt{1 + 1 + 16} = 3\sqrt{2}$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle -1, 1, 4\rangle}{3\sqrt{2}} = \left\langle \frac{-1}{3\sqrt{2}}, \frac{1}{3\sqrt{2}}, \frac{4}{3\sqrt{2}}\right\rangle$$
$$a_{\mathbf{T}} = \frac{\mathbf{a}\cdot\mathbf{v}}{\|\mathbf{v}\|} = \frac{8}{3\sqrt{2}}$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} = \langle 0, 0, 2\rangle - \frac{8}{3\sqrt{2}}\left\langle \frac{-1}{3\sqrt{2}}, \frac{1}{3\sqrt{2}}, \frac{4}{3\sqrt{2}}\right\rangle$$
$$= \langle 0, 0, 2\rangle + \left\langle \frac{4}{9}, -\frac{4}{9}, -\frac{16}{9}\right\rangle = \left\langle \frac{4}{9}, -\frac{4}{9}, \frac{2}{9}\right\rangle$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = \left\|\frac{2}{9}\langle 2, -2, 1\rangle\right\| = \frac{2}{9}\sqrt{4 + 4 + 1} = \frac{2}{3}$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\frac{2}{9}\langle 2, -2, 1\rangle}{2/3} = \left\langle \frac{2}{3}, -\frac{2}{3}, \frac{1}{3}\right\rangle$$

Finally we obtain the decomposition,

$$\mathbf{a} = \langle 0, 0, 2\rangle = \frac{8}{3\sqrt{2}}\mathbf{T} + \frac{2}{3}\mathbf{N}$$

where $\mathbf{T} = \left\langle \frac{-1}{3\sqrt{2}}, \frac{1}{3\sqrt{2}}, \frac{4}{3\sqrt{2}}\right\rangle$ and $\mathbf{N} = \left\langle \frac{2}{3}, -\frac{2}{3}, \frac{1}{3}\right\rangle$.

39. $\mathbf{r}(t) = \langle t, e^t, te^t \rangle, \quad t = 0$

SOLUTION First note here that:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \langle 1, e^t, (t+1)e^t \rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 0, e^t, (t+2)e^t \rangle$$

At $t = 0$ we have:

$$\mathbf{v} = \mathbf{r}'(0) = \langle 1, 1, 1 \rangle$$
$$\mathbf{a} = \mathbf{r}''(0) = \langle 0, 1, 2 \rangle$$

Thus,

$$\mathbf{a} \cdot \mathbf{v} = \langle 0, 1, 2 \rangle \cdot \langle 1, 1, 1 \rangle = 3$$
$$\|\mathbf{v}\| = \sqrt{1+1+1} = \sqrt{3}$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{3}} \langle 1, 1, 1 \rangle$$
$$a_{\mathbf{T}} = \frac{\mathbf{a} \cdot \mathbf{v}}{\|\mathbf{v}\|} = \frac{3}{\sqrt{3}} = \sqrt{3}$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} = \langle 0, 1, 2 \rangle - \sqrt{3}\frac{1}{\sqrt{3}} \langle 1, 1, 1 \rangle = \langle -1, 0, 1 \rangle$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = \sqrt{1+1} = \sqrt{2}$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\langle -1, 0, 1 \rangle}{\sqrt{2}} = \left\langle -\frac{1}{\sqrt{2}}, 0, \frac{1}{\sqrt{2}} \right\rangle$$

Finally we obtain the decomposition,

$$\mathbf{a} = \langle 0, 1, 2 \rangle = \sqrt{3}\mathbf{T} + \sqrt{2}\mathbf{N}$$

where $\mathbf{T} = \frac{1}{\sqrt{3}} \langle 1, 1, 1 \rangle$ and $\mathbf{N} = \left\langle -\frac{1}{\sqrt{2}}, 0, \frac{1}{\sqrt{2}} \right\rangle$.

40. $\mathbf{r}(\theta) = \langle \cos\theta, \sin\theta, \theta \rangle, \quad \theta = 0$

SOLUTION First note here that:

$$\mathbf{v}(\theta) = \mathbf{r}'(\theta) = \langle -\sin\theta, \cos\theta, 1 \rangle$$
$$\mathbf{a}(\theta) = \mathbf{r}''(\theta) = \langle -\cos\theta, -\sin\theta, 0 \rangle$$

At $\theta = 0$ we have:

$$\mathbf{v} = \mathbf{r}'(0) = \langle 0, 1, 1 \rangle$$
$$\mathbf{a} = \mathbf{r}''(0) = \langle -1, 0, 0 \rangle$$

Thus,

$$\mathbf{a} \cdot \mathbf{v} = \langle -1, 0, 0 \rangle \cdot \langle 0, 1, 1 \rangle = 0$$
$$\|\mathbf{v}\| = \sqrt{1+1} = \sqrt{2}$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{2}} \langle 0, 1, 1 \rangle$$
$$a_{\mathbf{T}} = \frac{\mathbf{a} \cdot \mathbf{v}}{\|\mathbf{v}\|} = \frac{0}{\sqrt{2}} = 0$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} = \langle -1, 0, 0\rangle - \mathbf{0} = \langle -1, 0, 0\rangle$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = 1$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\langle -1, 0, 0\rangle}{1} = \langle -1, 0, 0\rangle$$

Finally we obtain the decomposition,

$$\mathbf{a} = \langle -1, 0, 0\rangle = 0\mathbf{T} + (1)\mathbf{N}$$

where $\mathbf{T} = \frac{1}{\sqrt{2}}\langle 0, 1, 1\rangle$ and $\mathbf{N} = \langle -1, 0, 0\rangle$.

Notice that the vector $\mathbf{a}(0) = \langle -1, 0, 0\rangle$ is already a unit vector, hence (1) implies that $\mathbf{N}(0) = \mathbf{a}(0)$ and $a_{\mathbf{N}}(0) = 1$. Hence the required decomposition reduces to:

$$\mathbf{a}(0) = 1 \cdot \mathbf{N}(0) = 1 \cdot \mathbf{N} \quad \text{where} \quad \mathbf{N} = \mathbf{a}(0) = \langle -1, 0, 0\rangle$$

41. $\mathbf{r}(t) = \langle t, \cos t, t\sin t\rangle, \quad t = \frac{\pi}{2}$

SOLUTION First note here that:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \langle 1, -\sin t, t\cos t + \sin t, \rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 0, -\cos t, -t\sin t + 2\cos t\rangle$$

At $t = \frac{\pi}{2}$ we have:

$$\mathbf{v} = \mathbf{r}'(\pi/2) = \langle 1, -1, 1\rangle$$
$$\mathbf{a} = \mathbf{r}''(-2) = \left\langle 0, 0, -\frac{\pi}{2}\right\rangle$$

Thus,

$$\mathbf{a}\cdot\mathbf{v} = \left\langle 0, 0, -\frac{\pi}{2}\right\rangle \cdot \langle 1, -1, 1\rangle = -\frac{\pi}{2}$$
$$\|\mathbf{v}\| = \sqrt{1+1+1} = \sqrt{3}$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{3}}\langle 1, -1, 1\rangle$$
$$a_{\mathbf{T}} = \frac{\mathbf{a}\cdot\mathbf{v}}{\|\mathbf{v}\|} = \frac{-\pi/2}{\sqrt{3}} = -\frac{\pi}{2\sqrt{3}}$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$\begin{aligned} a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} &= \left\langle 0, 0, -\frac{\pi}{2}\right\rangle + \frac{\pi}{2\sqrt{3}}\frac{1}{\sqrt{3}}\langle 1, -1, 1\rangle \\ &= \left\langle 0, 0, -\frac{\pi}{2}\right\rangle + \frac{\pi}{6}\langle 1, -1, 1\rangle \\ &= \left\langle \frac{\pi}{6}, -\frac{\pi}{6}, -\frac{\pi}{3}\right\rangle = \frac{\pi}{6}\langle 1, -1, -2\rangle \end{aligned}$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = \left\|\frac{\pi}{6}\langle 1, -1, -2\rangle\right\| = \frac{\pi}{6}\sqrt{1+1+4} = \frac{\pi\sqrt{6}}{6} = \frac{\pi}{\sqrt{6}}$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\frac{\pi}{6}\langle 1, -1, -2\rangle}{\frac{\pi}{\sqrt{6}}} = \frac{1}{\sqrt{6}}\langle 1, -1, -2\rangle$$

Finally we obtain the decomposition,

$$\mathbf{a} = \left\langle 0, 0, -\frac{\pi}{2} \right\rangle = \frac{\pi}{2\sqrt{3}}\mathbf{T} + \frac{\pi}{\sqrt{6}}\mathbf{N}$$

where $\mathbf{T} = \frac{1}{\sqrt{3}}\langle 1, -1, 1\rangle$ and $\mathbf{N} = \frac{1}{\sqrt{6}}\langle 1, -1, -2\rangle$.

42. Let $\mathbf{r}(t) = \left\langle t^2, 4t - 3\right\rangle$. Find $\mathbf{T}(t)$ and $\mathbf{N}(t)$, and show that the decomposition of $\mathbf{a}(t)$ into tangential and normal components is

$$\mathbf{a}(t) = \left(\frac{2t}{\sqrt{t^2+4}}\right)\mathbf{T} + \left(\frac{4}{\sqrt{t^2+4}}\right)\mathbf{N}$$

SOLUTION

(a) We differentiate $\mathbf{r}(t)$ twice to obtain:

$$\mathbf{r}'(t) = \langle 2t, 4\rangle \tag{1}$$
$$\mathbf{r}''(t) = \langle 2, 0\rangle$$

By the formula for the tangential component of $\mathbf{a}(t)$, we have:

$$a_{\mathbf{T}} = \frac{\mathbf{a}\cdot\mathbf{v}}{\|\mathbf{v}\|} = \frac{\mathbf{a}\cdot\mathbf{r}'}{\|\mathbf{r}'\|} \tag{2}$$

By (1) we get:

$$\|\mathbf{r}'\| = \|\langle 2t, 4\rangle\| = \sqrt{(2t)^2 + 4^2} = \sqrt{4t^2+16} = 2\sqrt{t^2+4} \tag{3}$$
$$\mathbf{a} = \mathbf{r}'' = \langle 2, 0\rangle$$

Substituting (3) in (2) yields:

$$a_{\mathbf{T}} = \frac{\langle 2, 0\rangle \cdot \langle 2t, 4\rangle}{2\sqrt{t^2+4}} = \frac{2\cdot 2t + 0\cdot 4}{2\sqrt{t^2+4}} = \frac{2t}{\sqrt{t^2+4}} \tag{4}$$

(b) By the formula for the normal component of $\mathbf{a}(t)$, we have:

$$a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - \left(\frac{\mathbf{a}\cdot\mathbf{v}}{\mathbf{v}\cdot\mathbf{v}}\right)\mathbf{v} = \mathbf{a} - \left(\frac{\mathbf{a}\cdot\mathbf{r}'}{\mathbf{r}'\cdot\mathbf{r}'}\right)\mathbf{r}' \tag{5}$$

We use (1) and (3) to compute the values in (5):

$$\mathbf{a}\cdot\mathbf{r}' = \langle 2, 0\rangle \cdot \langle 2t, 4\rangle = 2\cdot 2t + 0\cdot 4 = 4t$$
$$\mathbf{r}'\cdot\mathbf{r}' = \langle 2t, 4\rangle\cdot\langle 2t, 4\rangle = 2t\cdot 2t + 4\cdot 4 = 4t^2 + 16 = 4(t^2+4) \tag{6}$$

Substituting (1), (3) and (6) into (5) gives:

$$a_{\mathbf{N}}\mathbf{N} = \langle 2, 0\rangle - \frac{4t}{4\left(t^2+4\right)}\langle 2t, 4\rangle = \langle 2, 0\rangle - \frac{t}{t^2+4}\langle 2t, 4\rangle$$
$$= \left\langle 2 - \frac{2t^2}{t^2+4}, \frac{-4t}{t^2+4}\right\rangle = \left\langle \frac{8}{t^2+4}, \frac{-4t}{t^2+4}\right\rangle = \frac{1}{t^2+4}\langle 8, -4t\rangle \tag{7}$$

Since $a_{\mathbf{N}} = \frac{\|\mathbf{a}\times\mathbf{v}\|}{\|\mathbf{v}\|}$, $a_{\mathbf{N}}$ is positive, hence $\mathbf{N}$ is a unit vector in the direction of $a_{\mathbf{N}}\mathbf{N}$. Hence, by (7):

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{\|a_{\mathbf{N}}\mathbf{N}\|} = \frac{\frac{1}{t^2+4}\langle 8, -4t\rangle}{\frac{1}{t^2+4}\sqrt{8^2+(-4t)^2}} = \frac{\langle 8, -4t\rangle}{\sqrt{64+16t^2}} = \frac{4\langle 2, -t\rangle}{4\sqrt{4+t^2}} = \frac{1}{\sqrt{4+t^2}}\langle 2, -t\rangle \tag{8}$$

Combining (7) and (8) yields:

$$a_{\mathbf{N}}\mathbf{N} = \frac{4}{t^2+4}\langle 2, -t\rangle = \frac{4}{\sqrt{t^2+4}}\mathbf{N} \quad \Rightarrow \quad a_{\mathbf{N}} = \frac{4}{\sqrt{t^2+4}} \tag{9}$$

(c) By (4) and (9) we obtain the following decomposition:

$$\mathbf{a}(t) = a_{\mathbf{T}}(t)\mathbf{T} + a_{\mathbf{N}}(t)\mathbf{N} = \left(\frac{2t}{\sqrt{t^2+4}}\right)\mathbf{T} + \left(\frac{4}{\sqrt{t^2+4}}\right)\mathbf{N}$$

43. Find the components $a_{\mathbf{T}}$ and $a_{\mathbf{N}}$ of the acceleration vector of a particle moving along a circular path of radius $R = 100$ cm with constant velocity $v_0 = 5$ cm/s.

SOLUTION Since the particle moves with constant speed, we have $v'(t) = 0$, hence:

$$a_{\mathbf{T}} = v'(t) = 0$$

The normal component of the acceleration is $a_{\mathbf{N}} = \kappa(t)v(t)^2$. The curvature of a circular path of radius $R = 100$ is $\kappa(t) = \frac{1}{R} = \frac{1}{100}$, and the velocity is the constant value $v(t) = v_0 = 5$. Hence,

$$a_{\mathbf{N}} = \frac{1}{R}v_0^2 = \frac{25}{100} = 0.25 \text{ cm/s}^2$$

44. In the notation of Example 5, find the acceleration vector for a person seated in a car at (a) the highest point of the Ferris wheel and (b) the two points level with the center of the wheel.

SOLUTION In Example 6 we are given that the ferris wheel has radius $R = 30$ m. At time $t = t_0$, the wheel rotates counterclockwise with speed of 40 meters per minute and is slowing at a rate of 15 m/min^2. The decomposition of $\mathbf{a}(t)$ into tangential and normal direction at time t_0 is:

$$\mathbf{a}(t_0) = a_{\mathbf{T}}(t_0)\mathbf{T}(t_0) + a_{\mathbf{N}}(t_0)\mathbf{N}(t_0) \tag{1}$$

where

$$a_{\mathbf{T}}(t_0) = v'(t_0) \quad \text{and} \quad a_{\mathbf{N}}(t_0) = \kappa(t_0)v(t_0)^2 \tag{2}$$

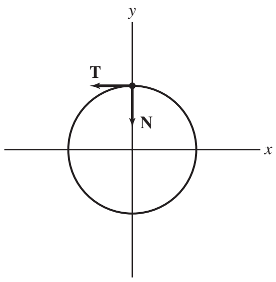
By the given information, $v(t_0) = 40$ and $v'(t_0) = -15$. Also, the curvature of the wheel is $\kappa = \frac{1}{R} = \frac{1}{30}$. Substituting in (2) we have:

$$a_{\mathbf{T}}(t_0) = -15, \quad a_{\mathbf{N}}(t_0) = \frac{40^2}{30} = \frac{160}{3}$$

Combining with (1) we get:

$$\mathbf{a}(t_0) = -15\mathbf{T}(t_0) + \frac{160}{3}\mathbf{N}(t_0) \tag{3}$$

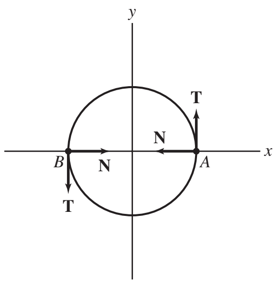
(a)



At the highest point of the wheel, $\mathbf{T} = \langle -1, 0\rangle$ and $\mathbf{N} = \langle 0, -1\rangle$, therefore by (3) the acceleration vector at this point is:

$$\mathbf{a}(t_0) = -15\,\langle -1, 0\rangle + \frac{160}{3}\,\langle 0, -1\rangle \approx \langle 15, -53.3\rangle$$

(b)



At the point A (see figure) we have $\mathbf{T} = \langle 0, 1\rangle$ and $\mathbf{N} = \langle -1, 0\rangle$, and at the point B, $\mathbf{T} = \langle 0, -1\rangle$ and $\mathbf{N} = \langle 1, 0\rangle$. Substituting in (3) we obtain the following accelerations at these points, at $t = t_0$:

At the point A:

$$\mathbf{a}(t_0) = -15\,\langle 0, 1\rangle + \frac{160}{3}\,\langle -1, 0\rangle = \langle -160/3, -15\rangle$$

At the point B:

$$\mathbf{a}(t_0) = -15\,\langle 0, -1\rangle + \frac{160}{3}\,\langle 1, 0\rangle = \langle 160/3, 15\rangle$$

45. Suppose that the Ferris wheel in Example 5 is rotating clockwise and that the point P at angle 45° has acceleration vector $\mathbf{a} = \langle 0, -50\rangle$ m/min^2 pointing down, as in Figure 11. Determine the speed and tangential acceleration of the Ferris wheel.

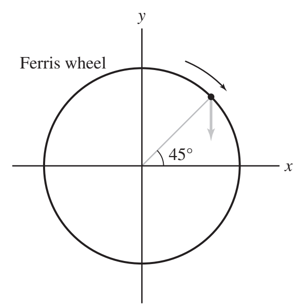


FIGURE 11

SOLUTION The normal and tangential accelerations are both $50/\sqrt{2} \approx 35$ m/min^2. The normal acceleration is $v^2/R = v^2/30 = 35$, so the speed is

$$v = \sqrt{35(28)} \approx 31.3$$

46. At time t_0, a moving particle has velocity vector $\mathbf{v} = 2\mathbf{i}$ and acceleration vector $\mathbf{a} = 3\mathbf{i} + 18\mathbf{k}$. Determine the curvature $\kappa(t_0)$ of the particle's path at time t_0.

SOLUTION The curvature is the following value:

$$\kappa(t_0) = \frac{\|\mathbf{r}'(t_0) \times \mathbf{r}''(t_0)\|}{\|\mathbf{r}'(t_0)\|^3} \tag{1}$$

Since $\mathbf{r}'(t_0) = \mathbf{v}(t) = 2\mathbf{i}$ and $\mathbf{r}''(t_0) = \mathbf{a}(t_0) = 3\mathbf{i} + 18\mathbf{k}$ we have:

$$\mathbf{r}'(t_0) \times \mathbf{r}''(t_0) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 0 & 0 \\ 3 & 0 & 18 \end{vmatrix} = \begin{vmatrix} 0 & 0 \\ 0 & 18 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2 & 0 \\ 3 & 18 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2 & 0 \\ 3 & 0 \end{vmatrix}\mathbf{k} = -36\mathbf{j} \tag{2}$$

$$\|\mathbf{r}'(t_0) \times \mathbf{r}''(t_0)\| = \|-36\mathbf{j}\| = 36 \tag{3}$$

$$\|\mathbf{r}'(t_0)\| = \|2\mathbf{i}\| = 2$$

Substituting (2) into (1) gives the following curvature:

$$\kappa(t_0) = \frac{36}{2^3} = 4.5$$

47. A space shuttle orbits the earth at an altitude 400 km above the earth's surface, with constant speed $v = 28{,}000$ km/h. Find the magnitude of the shuttle's acceleration (in km/h^2), assuming that the radius of the earth is 6378 km (Figure 12).

FIGURE 12 Space shuttle orbit.

SOLUTION The shuttle is in a uniform circular motion, therefore the tangential component of its acceleration is zero, and the acceleration can be written as:

$$\mathbf{a} = \kappa v^2 \mathbf{N} \tag{1}$$

The radius of motion is $6378 + 400 = 6778$ km hence the curvature is $\kappa = \frac{1}{6778}$. Also by the given information the constant speed is $v = 28000$ km/h. Substituting these values in (1) we get:

$$\mathbf{a} = \left(\frac{1}{6778} \cdot 28000^2\right)\mathbf{N} = (11.5668 \cdot 10^4 \text{ km/h}^2)\mathbf{N}$$

The magnitude of the shuttle's acceleration is thus:

$$\|\mathbf{a}\| = 11.5668 \cdot 10^4 \text{ km/h}^2$$

In units of m/s^2 we obtain

$$\|\mathbf{a}\| = \frac{11.5668 \cdot 10^4 \cdot 1000}{3600^2} = 8.925 \text{ m/s}^2$$

48. A car proceeds along a circular path of radius $R = 300$ m centered at the origin. Starting at rest, its speed increases at a rate of t m/s^2. Find the acceleration vector $\mathbf{a}$ at time $t = 3$ s and determine its decomposition into normal and tangential components.

SOLUTION The acceleration vector can be decomposed into tangential and normal directions as follows:

$$\mathbf{a}(t) = a_{\mathbf{T}}(t)\mathbf{T}(t) + a_{\mathbf{N}}(t)\mathbf{N}(t) \tag{1}$$

where

$$a_{\mathbf{T}}(t) = v'(t) \quad \text{and} \quad a_{\mathbf{N}}(t) = \kappa(t)v(t)^2 \tag{2}$$

Since the speed $v(t)$ is increasing at a rate of t m/s^2, we have $v'(t) = t$. The car starts at rest hence the initial speed is $v_0 = 0$. We now integrate to find $v(t)$:

$$v(t) = \int_0^t v'(u)\,du = \int_0^t u\,du = \frac{1}{2}t^2 + v_0 = \frac{1}{2}t^2 + 0 = \frac{1}{2}t^2$$

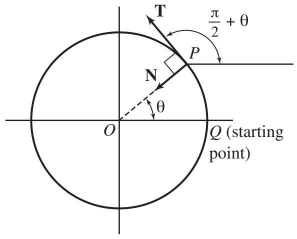
The curvature of the circular path is $\kappa(t) = \frac{1}{R} = \frac{1}{300}$. Substituting $v'(t) = t$, $\kappa = \frac{1}{300}$, and $v(t) = \frac{1}{2}t^2$ in (2) gives:

$$a_{\mathbf{T}}(t) = t, \quad a_{\mathbf{N}}(t) = \frac{1}{300}\left(\frac{1}{2}t^2\right)^2 = \frac{1}{1200}t^4$$

Combining with (1) gives the following decomposition:

$$a(t) = t\mathbf{T}(t) + \frac{1}{1200}t^4\mathbf{N}(t) \tag{3}$$

We now find the unit tangent $\mathbf{T}(t)$ and the unit normal $\mathbf{N}(t)$.



We have (see figure):

$$\mathbf{T} = \left\langle \cos\left(\frac{\pi}{2} + \theta\right), \sin\left(\frac{\pi}{2} + \theta\right) \right\rangle = \langle -\sin\theta, \cos\theta \rangle \tag{4}$$

$$\mathbf{N} = \langle \cos(\pi + \theta), \sin(\pi + \theta) \rangle = \langle -\cos\theta, -\sin\theta \rangle \tag{5}$$

We use the arc length formula to find θ:

$$\widehat{PQ} = \int_0^t \|r'(u)\|\,du = \int_0^t v(u)\,du = \int_0^t \frac{1}{2}u^2\,du = \frac{t^3}{6}$$

In addition, $\widehat{PQ} = R\theta = 300\theta$. Hence,

$$300\theta = \frac{t^3}{6} \quad \Rightarrow \quad \theta = \frac{t^3}{1800}$$

Substituting in (4) and (5) yields:

$$\mathbf{T} = \left\langle -\sin\frac{t^3}{1800}, \cos\frac{t^3}{1800} \right\rangle; \quad \mathbf{N} = \left\langle -\cos\frac{t^3}{1800}, -\sin\frac{t^3}{1800} \right\rangle \tag{6}$$

We now combine (3) and (6) to obtain the following decomposition:

$$\mathbf{a}(t) = t\left\langle -\sin\frac{t^3}{1800}, \cos\frac{t^3}{1800} \right\rangle + \frac{1}{1200}t^4\left\langle -\cos\frac{t^3}{1800}, -\sin\frac{t^3}{1800} \right\rangle$$

At $t = 3$ we get:

$$a_{\mathbf{T}} = 3a_{\mathbf{N}} = \frac{3^4}{1200} \approx 0.0675$$

$$\mathbf{T} = \left\langle -\sin\frac{3^3}{1800}, \cos\frac{3^3}{1800} \right\rangle \approx \langle -0.0150, 0.9999 \rangle$$

$$\mathbf{N} = \left\langle -\cos\frac{3^3}{1800}, -\sin\frac{3^3}{1800} \right\rangle \approx \langle -0.9999, -0.0150 \rangle$$

49. A runner runs along the helix $\mathbf{r}(t) = \langle \cos t, \sin t, t \rangle$. When he is at position $\mathbf{r}\left(\frac{\pi}{2}\right)$, his speed is 3 m/s and he is accelerating at a rate of $\frac{1}{2}$ m/s^2. Find his acceleration vector $\mathbf{a}$ at this moment. *Note:* The runner's acceleration vector does not coincide with the acceleration vector of $\mathbf{r}(t)$.

SOLUTION We have

$$\mathbf{r}'(t) = \langle -\sin t, \cos t, 1 \rangle, \quad \|\mathbf{r}'(t)\| = \sqrt{(-\sin t)^2 + \cos^2 t + 1^2} = \sqrt{2},$$

$$\Rightarrow \quad \mathbf{T} = \frac{1}{\sqrt{2}} \langle -\sin t, \cos t, 1 \rangle$$

By definition, $\mathbf{N}$ is the unit vector in the direction of

$$\frac{d\mathbf{T}}{dt} = \frac{1}{\sqrt{2}} \langle -\cos t, -\sin t, 0 \rangle \qquad \Rightarrow \quad \mathbf{N} = \langle -\cos t, -\sin t, 0 \rangle$$

Therefore $\mathbf{N} = \langle -\cos t, -\sin t, 0 \rangle$. At $t = \pi/2$, we have

$$\mathbf{T} = \frac{1}{\sqrt{2}} \langle -1, 0, 1 \rangle, \qquad \mathbf{N} = \langle 0, -1, 0 \rangle$$

The acceleration vector is

$$\mathbf{a} = v'\mathbf{T} + \kappa v^2 \mathbf{N}$$

We need to find the curvature, which happens to be constant:

$$\kappa = \left\| \frac{d\mathbf{T}}{ds} \right\| = \frac{\|\frac{d\mathbf{T}}{dt}\|}{\|\mathbf{r}'\|} = \frac{\|\frac{1}{\sqrt{2}} \langle -\cos t, -\sin t, 0 \rangle\|}{\sqrt{2}} = \frac{1}{2}$$

Now we have

$$\mathbf{a} = v'\mathbf{T} + \kappa v^2\mathbf{N} = \left(\frac{1}{2}\right)\mathbf{T} + \left(\frac{1}{2}\right)(3^2)\mathbf{N} = \left(\frac{1}{2}\right)\left(\frac{1}{\sqrt{2}}\right)\langle -1, 0, 1 \rangle + \frac{9}{2}\langle 0, -1, 0 \rangle$$

$$= \left\langle -\frac{1}{2\sqrt{2}}, -\frac{9}{2}, \frac{1}{2\sqrt{2}} \right\rangle$$

50. Explain why the vector **w** in Figure 13 cannot be the acceleration vector of a particle moving along the circle. *Hint:* Consider the sign of $\mathbf{w} \cdot \mathbf{N}$.

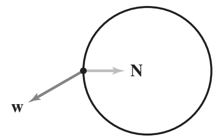


FIGURE 13

SOLUTION If we consider the sign of $\mathbf{w} \cdot \mathbf{N}$, recall that:

$$\mathbf{w} \cdot \mathbf{N} = \|\mathbf{w}\|\|\mathbf{N}\| \cos\theta$$

where θ is the angle between them. Since θ in the figure is larger than $\pi/2$ we know that $\cos\theta < 0$. Therefore, $\mathbf{w} \cdot \mathbf{N} < 0$ as well.

If we assume that the particle follows this circular path, and **w** is the acceleration vector ($\mathbf{w} = \mathbf{a}$), we will compute $\mathbf{a} \cdot \mathbf{N}$ to see:

$$\mathbf{w} \cdot \mathbf{N} = \mathbf{a} \cdot \mathbf{N} = \mathbf{r}'' \cdot \frac{\mathbf{T}'}{\|\mathbf{T}'\|} = \frac{1}{\|\mathbf{T}'\|}(\mathbf{r}'' \cdot \mathbf{T}')$$

Now we know $\mathbf{T} = \frac{\mathbf{r}'}{\|\mathbf{r}'\|}$ so then differentiating we get:

$$\mathbf{T}' = \frac{1}{\|\mathbf{r}'\|}\mathbf{r}''$$

Substituting this fact in we see:

$$\begin{aligned} \mathbf{w} \cdot \mathbf{N} = \mathbf{a} \cdot \mathbf{N} &= \mathbf{r}'' \cdot \frac{\mathbf{T}'}{\|\mathbf{T}'\|} = \frac{1}{\|\mathbf{T}'\|}(\mathbf{r}'' \cdot \mathbf{T}') \\ &= \frac{1}{\|\mathbf{T}'\|}\left(\mathbf{r}'' \cdot \frac{\mathbf{r}''}{\|\mathbf{r}'\|}\right) = \frac{1}{\|\mathbf{T}'\|}\frac{1}{\|\mathbf{r}'\|}(\mathbf{r}'' \cdot \mathbf{r}'') = \frac{\|\mathbf{r}''\|^2}{\|\mathbf{T}'\|\|\mathbf{r}'\|} > 0 \end{aligned}$$

This is a contradiction, **w** cannot be the acceleration vector of the particle moving along this circle.

51. Figure 14 shows acceleration vectors of a particle moving clockwise around a circle. In each case, state whether the particle is speeding up, slowing down, or momentarily at constant speed. Explain.

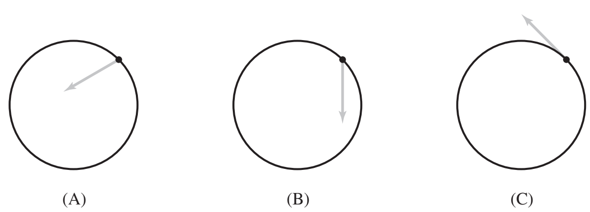

FIGURE 14

SOLUTION In (A) and (B) the acceleration vector has a nonzero tangential and normal components; these are both possible acceleration vectors. In (C) the normal component of the acceleration toward the inside of the curve is zero, that is, **a** is parallel to **T**, so $\kappa \cdot v(t)^2 = 0$, so either $\kappa = 0$ (meaning our curve is not a circle) or $v(t) = 0$ (meaning our particle isn't moving). Either way, (C) is not a possible acceleration vector.

52. Prove that $a_{\mathbf{N}} = \dfrac{\|\mathbf{a} \times \mathbf{v}\|}{\|\mathbf{v}\|}$.

SOLUTION We have $\mathbf{a} = a_T\mathbf{T} + a_N\mathbf{N}$ and $\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|}$ and therefore

$$\mathbf{v} = \|\mathbf{v}\|\mathbf{T}$$

Using this information, consider the following:

$$\begin{aligned} \mathbf{a} \times \mathbf{v} &= (a_{\mathbf{T}}\mathbf{T} + a_{\mathbf{N}}\mathbf{N}) \times (\|v\|)\mathbf{T} \\ &= (a_{\mathbf{T}}\mathbf{T} \times \|\mathbf{v}\|\mathbf{T}) + (a_{\mathbf{N}}\mathbf{N} \times \|\mathbf{v}\|\mathbf{T}) \\ &= a_{\mathbf{T}}\|\mathbf{v}\|(\mathbf{T} \times \mathbf{T}) + a_{\mathbf{N}}\|\mathbf{v}\|(\mathbf{N} \times \mathbf{T}) \\ &= \mathbf{0} + a_{\mathbf{N}}\|\mathbf{v}\|(\mathbf{N} \times \mathbf{T}) \end{aligned}$$

$$= a_{\mathbf{N}}\|\mathbf{v}\|(\mathbf{N}\times\mathbf{T})$$

Both $\mathbf{T}$ and $\mathbf{N}$ are unit vectors and they are orthogonal to each other. It follows that $\mathbf{N}\times\mathbf{T}$ is a unit vector and

$$\|\mathbf{a}\times\mathbf{v}\| = a_{\mathbf{N}}\|\mathbf{v}\|(\mathbf{N}\times\mathbf{T}) = a_{\mathbf{N}}\|\mathbf{v}\|\cdot 1 \quad \Rightarrow \frac{\|\mathbf{a}\times\mathbf{v}\|}{\|\mathbf{v}\|} = a_{\mathbf{N}}$$

53. Suppose that $\mathbf{r} = \mathbf{r}(t)$ lies on a sphere of radius R for all t. Let $\mathbf{J} = \mathbf{r}\times\mathbf{r}'$. Show that $\mathbf{r}' = (\mathbf{J}\times\mathbf{r})/\|\mathbf{r}\|^2$. *Hint:* Observe that $\mathbf{r}$ and $\mathbf{r}'$ are perpendicular.

SOLUTION

(a) Solution 1. Since $\mathbf{r} = \mathbf{r}(t)$ lies on the sphere, the vectors $\mathbf{r} = \mathbf{r}(t)$ and $\mathbf{r}' = \mathbf{r}'(t)$ are orthogonal, therefore:

$$\mathbf{r}\cdot\mathbf{r}' = 0 \tag{1}$$

We use the following well-known equality:

$$\mathbf{a}\times(\mathbf{b}\times\mathbf{c}) = (\mathbf{a}\cdot\mathbf{c})\,\mathbf{b} - (\mathbf{a}\cdot\mathbf{b})\cdot\mathbf{c}$$

Using this equality and (1) we obtain:

$$\begin{aligned}\mathbf{J}\times\mathbf{r} &= \left(\mathbf{r}\times\mathbf{r}'\right)\times\mathbf{r} = -\mathbf{r}\times\left(\mathbf{r}\times\mathbf{r}'\right) = -\left(\left(\mathbf{r}\cdot\mathbf{r}'\right)\mathbf{r} - (\mathbf{r}\cdot\mathbf{r})\,\mathbf{r}'\right)\\ &= -\left(\mathbf{r}\cdot\mathbf{r}'\right)\mathbf{r} + \|\mathbf{r}\|^2\mathbf{r}' = 0\mathbf{r} + \|\mathbf{r}\|^2\mathbf{r}' = \|\mathbf{r}\|^2\mathbf{r}'\end{aligned}$$

Divided by the scalar $\|\mathbf{r}\|^2$ we obtain:

$$\mathbf{r}' = \frac{\mathbf{J}\times\mathbf{r}}{\|\mathbf{r}\|^2}$$

(b) Solution 2. The cross product $\mathbf{J} = \mathbf{r}\times\mathbf{r}'$ is orthogonal to $\mathbf{r}$ and $\mathbf{r}'$. Also, $\mathbf{r}$ and $\mathbf{r}'$ are orthogonal, hence the vectors $\mathbf{r}$, $\mathbf{r}'$ and $\mathbf{J}$ are mutually orthogonal. Now, since $\mathbf{r}'$ is orthogonal to $\mathbf{r}$ and $\mathbf{J}$, the right-hand rule implies that $\mathbf{r}'$ points in the direction of $\mathbf{J}\times\mathbf{r}$. Therefore, for some $\alpha > 0$ we have:

$$\mathbf{r}' = \alpha\mathbf{J}\times\mathbf{r} = \|\mathbf{r}'\|\cdot\frac{\mathbf{J}\times\mathbf{r}}{\|\mathbf{J}\times\mathbf{r}\|} \tag{2}$$

By properties of the cross product and since $\mathbf{J}$, $\mathbf{r}$, and $\mathbf{r}'$ are mutually orthogonal we have:

$$\|\mathbf{J}\times\mathbf{r}\| = \|\mathbf{J}\|\|\mathbf{r}\| = \|\mathbf{r}\times\mathbf{r}'\|\|\mathbf{r}\| = \|\mathbf{r}\|\|\mathbf{r}'\|\|\mathbf{r}\| = \|\mathbf{r}\|^2\|\mathbf{r}'\|$$

Substituting in (2) we get:

$$\mathbf{r}' = \|\mathbf{r}'\|\frac{\mathbf{J}\times\mathbf{r}}{\|\mathbf{r}\|^2\|\mathbf{r}'\|} = \frac{\mathbf{J}\times\mathbf{r}}{\|\mathbf{r}\|^2}$$

Further Insights and Challenges

54. The orbit of a planet is an ellipse with the sun at one focus. The sun's gravitational force acts along the radial line from the planet to the sun (the dashed lines in Figure 15), and by Newton's Second Law, the acceleration vector points in the same direction. Assuming that the orbit has positive eccentricity (the orbit is not a circle), explain why the planet must slow down in the upper half of the orbit (as it moves away from the sun) and speed up in the lower half. Kepler's Second Law, discussed in the next section, is a precise version of this qualitative conclusion. *Hint:* Consider the decomposition of $\mathbf{a}$ into normal and tangential components.

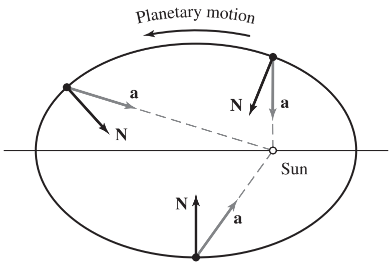

FIGURE 15 Elliptical orbit of a planet around the sun.

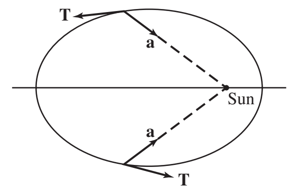
SOLUTION In the upper half of the orbit, as the planet moves away from the sun the acceleration vector has a negative component in the tangential direction $\mathbf{T}$, so the particle's velocity is decreasing (since $a_{\mathbf{T}}(t) = v'(t) < 0$).



However, in the lower half of the orbit, as the planet gets closer to the sun, the acceleration has a positive component in the tangential direction, that is, $a_{\mathbf{T}}(t) = v'(t) > 0$. Therefore the velocity $v(t)$ is increasing.

In Exercises 55–59, we consider an automobile of mass m traveling along a curved but level road. To avoid skidding, the road must supply a frictional force $\mathbf{F} = m\mathbf{a}$*, where* $\mathbf{a}$ *is the car's acceleration vector. The maximum magnitude of the frictional force is* μmg*, where* μ *is the coefficient of friction and* $g = 9.8$ m/s^2*. Let* v *be the car's speed in meters per second.*

55. Show that the car will not skid if the curvature κ of the road is such that (with $R = 1/\kappa$)

$$(v')^2 + \left(\frac{v^2}{R}\right)^2 \le (\mu g)^2 \qquad \boxed{5}$$

Note that braking ($v' < 0$) and speeding up ($v' > 0$) contribute equally to skidding.

SOLUTION To avoid skidding, the frictional force the road must supply is:

$$\mathbf{F} = m\mathbf{a}$$

where **a** is the acceleration of the car. We consider the decomposition of the acceleration **a** into normal and tangential directions:

$$\mathbf{a}(t) = v'(t)\mathbf{T}(t) + \kappa v^2(t)\mathbf{N}(t)$$

Since **N** and **T** are orthogonal unit vectors, $\mathbf{T} \cdot \mathbf{N} = 0$ and $\mathbf{T} \cdot \mathbf{T} = \mathbf{N} \cdot \mathbf{N} = 1$. Thus:

$$\begin{aligned}\|\mathbf{a}\|^2 &= \left(v'\mathbf{T} + \kappa v^2\mathbf{N}\right) \cdot \left(v'\mathbf{T} + \kappa v^2\mathbf{N}\right) = v'^2\mathbf{T} \cdot \mathbf{T} + 2\kappa v^2 v'\mathbf{N} \cdot \mathbf{T} + \kappa^2 v^4 \mathbf{N} \cdot \mathbf{N} \\ &= v'^2 + \kappa^2 v^4 = v'^2 + \frac{v^4}{R^2}\end{aligned}$$

Therefore:

$$\|\mathbf{a}\| = \sqrt{\left(v'\right)^2 + \frac{v^4}{R^2}}$$

Since the maximal fractional force is μmg we obtain that to avoid skidding the curvature must satisfy:

$$m\sqrt{\left(v'\right)^2 + \frac{v^4}{R^2}} \le m\mu g.$$

Hence,

$$\left(v'\right)^2 + \frac{v^4}{R^2} \le (\mu g)^2,$$

which becomes:

$$\left(v'\right)^2 + \left(\frac{v^2}{R}\right)^2 \le (\mu g)^2$$

56. Suppose that the maximum radius of curvature along a curved highway is $R = 180$ m. How fast can an automobile travel (at constant speed) along the highway without skidding if the coefficient of friction is $\mu = 0.5$?

SOLUTION Recall the general result that max speed is

$$v = \sqrt{\mu g R}$$

In Exercise 55 we showed that the car will not skid if the following inequality is satisfied:

$$\left(v'\right)^2 + \frac{v^4}{R^2} < \mu^2 g^2$$

We compute the constant speed v for which the car can travel without skidding. In case of constant speed, $v' = 0$. We substitute $R = 180$, $\mu = 0.5$ and $g = 9.8$ and solve for v. This gives:

$$\frac{v^4}{180^2} < 0.5^2 \cdot 9.8^2$$

$$v^4 < 777924 \quad \Rightarrow \quad v < 29.70 \text{ m/s}$$

The maximum speed (in case of constant speed) is about 29.70 m/s.

57. Beginning at rest, an automobile drives around a circular track of radius $R = 300$ m, accelerating at a rate of 0.3 m/s^2. After how many seconds will the car begin to skid if the coefficient of friction is $\mu = 0.6$?

SOLUTION By Exercise 55 the car will begin to skid when:

$$(v')^2 + \frac{v^4}{R^2} = \mu^2 g^2 \tag{1}$$

We are given that $v' = 0.3$ and $v_0 = 0$. Integrating gives:

$$v = \int_0^t v'\,dt = \int_0^t 0.3\,dt = 0.3t + v_0 = 0.3t$$

We substitute $v = t$, $v' = 0.3$, $R = 300$, $\mu = 0.6$ and $g = 9.8$ in (1) and solve for t. This gives:

$$(0.3)^2 + \frac{0.3^4 t^4}{300^2} = 0.6^2 \cdot 9.8^2$$

$$t^4 = \frac{300^2\left(0.6^2 \cdot 9.8^2 - 0.3^2\right)}{0.3^4} = 383{,}160{,}000$$

$$t = 139.91 \text{ s}$$

After 139.91 s or 2.33 minutes, the car will begin to skid.

58. You want to reverse your direction in the shortest possible time by driving around a semicircular bend (Figure 16). If you travel at the maximum possible *constant speed* v that will not cause skidding, is it faster to hug the inside curve (radius r) or the outside curb (radius R)? *Hint:* Use Eq. (5) to show that at maximum speed, the time required to drive around the semicircle is proportional to the square root of the radius.

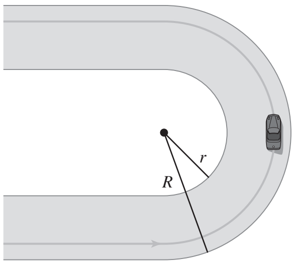


FIGURE 16 Car going around the bend.

SOLUTION In Exercise 55 we showed that the car will not skid if the following inequality is satisfied:

$$\left(v'\right)^2 + \frac{v^4}{R^2} < \mu^2 g^2$$

In case of constant speed, $v' = 0$, so the inequality becomes:

$$\frac{v^4}{R^2} < \mu^2 g^2$$

We solve for v:

$$v^4 < (\mu g R)^2 \quad \Rightarrow \quad v < \sqrt{\mu g R}$$

The maximum speed in which skidding does not occur is, thus,

$$v \approx \sqrt{\mu g R} \tag{1}$$

If T is the time required to drive around the semicircle of radius R at the constant speed v, then the length of the semicircle can be written as:

$$\pi R = \int_0^T \|\mathbf{r}'(t)\|\,dt = \int_0^T v\,dt = vT$$

Hence,

$$T = \frac{\pi R}{v} \tag{2}$$

Combining (1) and (2) gives:

$$T \approx \frac{\pi R}{\sqrt{\mu g R}} \approx \frac{\pi}{\sqrt{\mu g}}\sqrt{R}$$

We conclude that it is faster to hug the inside curve of radius r $(r < R)$, rather than the outside curve of radius R.

59. What is the smallest radius R about which an automobile can turn without skidding at 100 km/h if $\mu = 0.75$ (a typical value)?

SOLUTION In Exercise 55 we showed that the car will not skid if the following inequality holds:

$$\left(v'\right)^2 + \frac{v^4}{R^2} < \mu^2 g^2$$

In case of constant speed, $v' = 0$, so the inequality becomes:

$$\frac{v^4}{R^2} < \mu^2 g^2$$

Solving for R we get:

$$v^4 < \mu^2 g^2 R^2$$

$$\frac{v^4}{\mu^2 g^2} < R^2 \quad \Rightarrow \quad R > \frac{v^2}{\mu g}$$

The smallest radius R in which skidding does not occur is, thus,

$$R \approx \frac{v^2}{\mu g}$$

We substitute $v = 100$ km/h, $\mu = 0.75$, and $g \approx 127{,}008$ km/h^2 to obtain:

$$R \approx \frac{100^2}{0.75 \cdot 127{,}008} = 0.105 \text{ km}.$$

13.6 Planetary Motion According to Kepler and Newton (LT Section 14.6)

Preliminary Questions

1. Describe the relation between the vector $\mathbf{J} = \mathbf{r} \times \mathbf{r}'$ and the rate at which the radial vector sweeps out area.

SOLUTION The rate at which the radial vector sweeps out area equals half the magnitude of the vector $\mathbf{J}$. This relation is expressed in the formula:

$$\frac{dA}{dt} = \frac{1}{2}\|\mathbf{J}\|.$$

2. Equation (1) shows that $\mathbf{r}''$ is proportional to $\mathbf{r}$. Explain how this fact is used to prove Kepler's Second Law.

SOLUTION In the proof of Kepler's Second Law it is shown that the rate at which area is swept out is

$$\frac{dA}{dt} = \frac{1}{2}\|\mathbf{J}\|, \quad \text{where} \quad \mathbf{J} = \mathbf{r}(t) \times \mathbf{r}'(t)$$

To show that $\|\mathbf{J}\|$ is constant, show that $\mathbf{J}$ is constant. This is done using the proportionality of $\mathbf{r}''$ and $\mathbf{r}$ which implies that $\mathbf{r}(t) \times \mathbf{r}''(t) = 0$. Using this we get:

$$\frac{d\mathbf{J}}{dt} = \frac{d}{dt}\left(\mathbf{r} \times \mathbf{r}'\right) = \mathbf{r} \times \mathbf{r}'' + \mathbf{r}' \times \mathbf{r}' = \mathbf{0} + \mathbf{0} = \mathbf{0} \Rightarrow \mathbf{J} = \text{const}$$

3. How is the period T affected if the semimajor axis a is increased four-fold?

SOLUTION Kepler's Third Law states that the period T of the orbit is given by:

$$T^2 = \left(\frac{4\pi^2}{GM}\right) a^3$$

or

$$T = \frac{2\pi}{\sqrt{GM}}a^{3/2}$$

If a is increased four-fold the period becomes:

$$\frac{2\pi}{\sqrt{GM}}(4a)^{3/2} = 8 \cdot \frac{2\pi}{\sqrt{GM}}a^{3/2}$$

That is, the period is increased eight-fold.

Exercises

1. Kepler's Third Law states that T^2/a^3 has the same value for each planetary orbit. Do the data in the following table support this conclusion? Estimate the length of Jupiter's period, assuming that $a = 77.8 \times 10^{10}$ m.

Planet	Mercury	Venus	Earth	Mars
a (10^{10} m)	5.79	10.8	15.0	22.8
T (years)	0.241	0.615	1.00	1.88

SOLUTION Using the given data we obtain the following values of T^2/a^3, where a, as always, is measured not in meters but in 10^{10} m:

Planet	Mercury	Venus	Earth	Mars
T^2/a^3	$2.99 \cdot 10^{-4}$	$3 \cdot 10^{-4}$	$2.96 \cdot 10^{-4}$	$2.98 \cdot 10^{-4}$

The data on the planets supports Kepler's prediction. We estimate Jupiter's period (using the given a) as $T \approx \sqrt{a^3 \cdot 3 \cdot 10^{-4}} \approx 11.9$ years.

2. Finding the Mass of a Star Using Kepler's Third Law, show that if a planet revolves around a star with period T and semimajor axis a, then the mass of the star is $M = \left(\frac{4\pi^2}{G}\right)\left(\frac{a^3}{T^2}\right)$.

SOLUTION By Kepler's Third Law with the star replacing the sun we have:

$$T^2 = \left(\frac{4\pi^2}{GM}\right)a^3$$

Solving for M we obtain:

$$T^2GM = 4\pi^2a^3 \Rightarrow M = \frac{4\pi^2}{G} \cdot \frac{a^3}{T^2}$$

3. Ganymede, one of Jupiter's moons discovered by Galileo, has an orbital period of 7.154 days and a semimajor axis of 1.07×10^9 m. Use Exercise 2 to estimate the mass of Jupiter.

SOLUTION By Exercise 2, the mass of Jupiter can be computed using the following equality:

$$M = \frac{4\pi^2}{G}\frac{a^3}{T^2}$$

We substitute the given data $T = 7.154 \cdot 24 \cdot 60^2 = 618{,}105.6$ $a = 1.07 \times 10^9$ m and $G = 6.67300 \times 10^{-11}\,\mathrm{m}^3\mathrm{kg}^{-1}\mathrm{s}^{-1}$, to obtain:

$$M = \frac{4\pi^2 \cdot \left(1.07 \times 10^9\right)^3}{6.67300 \times 10^{-11} \cdot (618{,}105.6)^2} \approx 1.897 \times 10^{27} \text{ kg.}$$

4. An astronomer observes a planet orbiting a star with a period of 9.5 years and a semimajor axis of 3×10^8 km. Find the mass of the star using Exercise 2.

SOLUTION By Exercise 2 the mass of the star can be computed using the following equality:

$$M = \frac{4\pi^2}{G}\frac{a^3}{T^2} \tag{1}$$

Using units of m, kg, and s we have the following data:

$$T = 9.5 \text{ years} = 9.5 \cdot 365 \cdot 24 \cdot 3600 = 2.99 \cdot 10^8 \text{ s}$$
$$a = 3 \times 10^{11} \text{ m}$$
$$G = 6.673 \times 10^{-11} \text{ m}^3\text{kg}^{-1}\text{s}^{-1}$$

Substituting in (1) we get:

$$M = \frac{4\pi^2 \cdot (3 \times 10^{11})^3}{6.673 \times 10^{-11} \cdot (2.99 \times 10^8)^2} \approx 17.87 \times 10^{28} \text{ kg}.$$

5. Mass of the Milky Way The sun revolves around the center of mass of the Milky Way galaxy in an orbit that is approximately circular, of radius $a \approx 2.8 \times 10^{17}$ km and velocity $v \approx 250$ km/s. Use the result of Exercise 2 to estimate the mass of the portion of the Milky Way inside the sun's orbit (place all of this mass at the center of the orbit).

SOLUTION Write $a = 2.8 \times 10^{20}$ m and $v = 250 \times 10^3$ m/s. The circumference of the sun's orbit (which is assumed circular) is $2\pi a$ m; since the sun's speed is a constant v m/s, its period is $T = \frac{2\pi a}{v}$ s. By Exercise 2, the mass of the portion of the Milky Way inside the sun's orbit is

$$M = \left(\frac{4\pi^2}{G}\right)\left(\frac{a^3}{T^2}\right)$$

Substituting the values of a and T from above, $G = 6.673 \times 10^{-11}$ m^{3}kg^{-1}s^{-2} gives

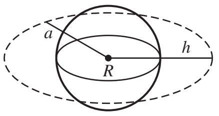
$$M = \frac{4\pi^2 a^3}{G\left(\frac{4\pi^2 a^2}{v^3}\right)} = \frac{av^2}{G} = \frac{2.8 \cdot 10^{20} \cdot (250 \times 10^3)^2}{6.673 \times 10^{-11}} = 2.6225 \times 10^{41} \text{ kg}.$$

The mass of the sun is 1.989×10^{30} kg, hence M is 1.32×10^{11} times the mass of the sun (132 billions times the mass of the sun).

6. A satellite orbiting above the equator of the earth is **geosynchronous** if the period is $T = 24$ hours (in this case, the satellite stays over a fixed point on the equator). Use Kepler's Third Law to show that in a circular geosynchronous orbit, the distance from the center of the earth is $R \approx 42{,}246$ km. Then compute the altitude h of the orbit above the earth's surface. The earth has mass $M \approx 5.974 \times 10^{24}$ kg and radius $R \approx 6371$ km.

SOLUTION By Kepler's Third Law,

$$T^2 = \left(\frac{4\pi^2}{GM}\right)a^3$$



We substitute $T = 24 \cdot 3600 = 86{,}400$ s, $M = 5.974 \times 10^{24}$ kg, and $G = 6.673 \times 10^{-11}$ m^{3}kg^{-1}s^{-1} and solve for a. We obtain:

$$86{,}400^2 = \frac{4\pi^2}{6.673 \cdot 10^{-11} \cdot 5.974 \cdot 10^{24}} a^3$$
$$7.465 \cdot 10^9 = 0.99 \cdot 10^{-13} a^3$$
$$a^3 = 75.4 \cdot 10^{21} \Rightarrow a = 4.2246 \cdot 10^7 \text{ m} = 42{,}246 \text{ km}$$

The altitude h is thus

$$h = a - R_{\text{earth}} = 42{,}246 - 6{,}371 = 35{,}875 \text{ km}.$$

7. Show that a planet in a circular orbit travels at constant speed. *Hint:* Use that $\mathbf{J}$ is constant and that $\mathbf{r}(t)$ is orthogonal to $\mathbf{r}'(t)$ for a circular orbit.

SOLUTION It is shown in the proof of Kepler's Second Law that the vector $\mathbf{J} = \mathbf{r}(t) \times \mathbf{r}'(t)$ is constant, hence its length is constant:

$$\|\mathbf{J}\| = \|\mathbf{r}(t) \times \mathbf{r}'(t)\| = \text{const} \tag{1}$$

We consider the orbit as a circle of radius R, therefore, $\mathbf{r}(t)$ and $\mathbf{r}'(t)$ are orthogonal and $\|\mathbf{r}(t)\| = R$. By (1) and using properties of the cross product we obtain:

$$\|\mathbf{r}(t) \times \mathbf{r}'(t)\| = \|\mathbf{r}(t)\|\|\mathbf{r}'(t)\| \sin \frac{\pi}{2} = R \cdot \|\mathbf{r}'(t)\| = \text{const}$$

We conclude that $\|\mathbf{r}'(t)\|$ is constant, that is the speed $v = \|\mathbf{r}'(t)\|$ of the planet is constant.

8. Verify that the circular orbit

$$\mathbf{r}(t) = \langle R \cos \omega t,\, R \sin \omega t \rangle$$

satisfies the differential equation, Eq. (1), provided that $\omega^2 = kR^{-3}$. Then deduce Kepler's Third Law $T^2 = \left(\frac{4\pi^2}{k}\right) R^3$ for this orbit.

SOLUTION Note that $\|\mathbf{r}\| = R$, and note that

$$\mathbf{r}' = \langle -R\omega \sin \omega t,\, R\omega \cos \omega t \rangle \quad \text{and} \quad \mathbf{r}'' = \left\langle -R\omega^2 \cos \omega t,\, -R\omega^2 \sin \omega t \right\rangle$$

We rewrite this as:

$$\mathbf{r}'' = -\omega^2 \langle R \cos \omega t,\, R \sin \omega t \rangle = -\omega^2 \mathbf{r}$$

Since $\omega^2 = k/R^3$ and $R = \|\mathbf{r}\|$, we get $\mathbf{r}'' = \frac{-k}{\|\mathbf{r}\|^3}\mathbf{r}$, as desired. Since $T = \frac{2\pi}{\omega}$ then $T^2 = \frac{4\pi^2}{\omega^2} = \frac{4\pi^2 R^3}{k}$, as desired.

9. Prove that if a planetary orbit is circular of radius R, then $vT = 2\pi R$, where v is the planet's speed (constant by Exercise 7) and T is the period. Then use Kepler's Third Law to prove that $v = \sqrt{\frac{k}{R}}$.

SOLUTION By the Arc Length Formula and since the speed $v = \|\mathbf{r}'(t)\|$ is constant, the length L of the circular orbit can be computed by the following integral:

$$L = \int_0^T \|\mathbf{r}'(t)\|\, dt = \int_0^T v\, dt = vt\Big|_0^T = vT$$

On the other hand, the length of a circular orbit of radius R is $2\pi R$, so we obtain:

$$vT = 2\pi R \Rightarrow T = \frac{2\pi R}{v} \tag{1}$$

In a circular orbit of radius R, $a = R$, hence by Kepler's Third Law we have:

$$T^2 = \frac{4\pi^2}{GM} R^3 \tag{2}$$

We now substitute (1) in (2) and solve for v. This gives:

$$\left(\frac{2\pi R}{v}\right)^2 = \frac{4\pi^2 R^3}{GM}$$
$$\frac{4\pi^2 R^2}{v^2} = \frac{4\pi^2 R^3}{GM}$$
$$\frac{1}{v^2} = \frac{R}{GM} \Rightarrow v = \sqrt{\frac{GM}{R}}$$

10. Find the velocity of a satellite in geosynchronous orbit about the earth. *Hint:* Use Exercises 6 and 9.

SOLUTION In Exercise 9 we showed that the velocity of a planet in a circular orbit of radius a is:

$$v = \frac{2\pi a}{T} \tag{1}$$

A geosynchronous orbit has period $T = 24$ hours and in Exercise 6 we found that $a = 42{,}246$ km. Substituting in (1) we get:

$$v = \frac{2\pi \cdot 42{,}246}{24} = 11{,}060 \text{ km/h}$$

11. A communications satellite orbiting the earth has initial position $\mathbf{r} = \langle 29{,}000, 20{,}000, 0\rangle$ (in km) and initial velocity $\mathbf{r}' = \langle 1, 1, 1\rangle$ (in km/s), where the origin is the earth's center. Find the equation of the plane containing the satellite's orbit. *Hint:* This plane is orthogonal to $\mathbf{J}$.

SOLUTION The vectors $\mathbf{r}(t)$ and $\mathbf{r}'(t)$ lie in the plane containing the satellite's orbit, in particular the initial position $\mathbf{r} = \langle 29{,}000, 20{,}000, 0\rangle$ and the initial velocity $\mathbf{r}' = \langle 1, 1, 1\rangle$. Therefore, the cross product $\mathbf{J} = \mathbf{r} \times \mathbf{r}'$ is perpendicular to the plane. We compute $\mathbf{J}$:

$$\mathbf{J} = \mathbf{r} \times \mathbf{r}' = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 29{,}000 & 20{,}000 & 0 \\ 1 & 1 & 1 \end{vmatrix} = \begin{vmatrix} 20{,}000 & 0 \\ 1 & 1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 29{,}000 & 0 \\ 1 & 1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 29{,}000 & 20{,}000 \\ 1 & 1 \end{vmatrix}\mathbf{k}$$

$$= 20{,}000\mathbf{i} - 29{,}000\mathbf{j} + 9000\mathbf{k} = \langle 20{,}000, -29{,}000, 9000\rangle$$

We now use the vector form of the equation of the plane with $\mathbf{n} = \mathbf{J} = \langle 20{,}000, -29{,}000, 9000\rangle$ and $\langle x_0, y_0, z_0\rangle = \mathbf{r} = \langle 29{,}000, 20{,}000, 0\rangle$, to obtain the following equation:

$$\langle 29{,}000, -20{,}000, 9000\rangle \cdot \langle x, y, z\rangle = \langle 29{,}000, -20{,}000, 9000\rangle \cdot \langle 29{,}000, 20{,}000, 9000\rangle$$

$$1000\,\langle 29, -20, 9\rangle \cdot \langle x, y, z\rangle = 1000\,\langle 29, -20, 9\rangle \cdot \langle 29{,}000, 20{,}000, 9000\rangle$$

$$29x - 20y + 9z = 841{,}000 - 400{,}000 + 81{,}000 = 0$$

$$29x - 20y + 9z - 522{,}000 = 0$$

The plane containing the satellite's orbit is, thus:

$$\mathcal{P} = \{(x, y, z) : 29x - 20y + 9z - 522{,}000 = 0\}$$

12. Assume that the earth's orbit is circular of radius $R = 150 \times 10^6$ km (it is nearly circular with eccentricity $e = 0.017$). Find the rate at which the earth's radial vector sweeps out area in units of km^2/s. What is the magnitude of the vector $\mathbf{J} = \mathbf{r} \times \mathbf{r}'$ for the earth (in units of km^2 per second)?

SOLUTION The rate at which the earth's radial vector sweeps out area is

$$\frac{dA}{dt} = \frac{1}{2}\|\mathbf{J}\|; \quad \mathbf{J} = \mathbf{r}(t) \times \mathbf{r}'(t) \tag{1}$$

Since $\mathbf{J}$ is a constant vector, its length is constant. Moreover, if we assume that the orbit is circular then $\mathbf{r}(t)$ lies on a circle, and therefore $\mathbf{r}(t)$ and $\mathbf{r}'(t)$ are orthogonal. Using properties of the cross product we get:

$$\|\mathbf{J}\| = \|\mathbf{r}(t) \times \mathbf{r}'(t)\| = \|\mathbf{r}(t)\|\|\mathbf{r}'(t)\| = R\|\mathbf{r}'(t)\| = \text{const}$$

We conclude that the speed $v = \|\mathbf{r}'(t)\|$ is constant. We find the speed using the following equality:

$$2\pi R = vT \Rightarrow v = \frac{2\pi R}{T}.$$

Therefore,

$$\|\mathbf{J}\| = R \cdot \frac{2\pi R}{T} = \frac{2\pi R^2}{T}.$$

Substituting in (1) we get:

$$\frac{dA}{dt} = \frac{1}{2} \cdot \frac{2\pi R^2}{T} = \frac{\pi R^2}{T}.$$

For $R = 150 \times 10^6$ km and $T = 365 \times 24 \times 3600 = 31{,}536{,}000$ s we obtain:

$$\|\mathbf{J}\| = \frac{2\pi \cdot (150 \cdot 10^6)^2}{31{,}536{,}000} = 4.483 \times 10^9 \text{ km}^2/\text{s}$$

$$\frac{dA}{dt} = 2.241 \times 10^9 \text{ km}^2/\text{s}$$

Exercises 13–19: The perihelion and aphelion are the points on the orbit closest to and farthest from the sun, respectively (Figure 8). The distance from the sun at the perihelion is denoted r_{per} and the speed at this point is denoted v_{per}. Similarly, we write r_{ap} and v_{ap} for the distance and speed at the aphelion. The semimajor axis is denoted a.

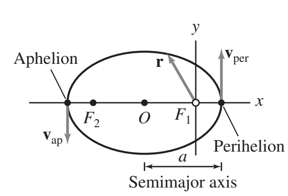


FIGURE 8 $\mathbf{r}$ and $\mathbf{v} = \mathbf{r}'$ are perpendicular at the perihelion and aphelion.

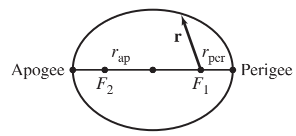
13. Use the polar equation of an ellipse

$$r = \frac{p}{1 + e\cos\theta}$$

to show that $r_{\text{per}} = a(1-e)$ and $r_{\text{ap}} = a(1+e)$. *Hint:* Use the fact that $r_{\text{per}} + r_{\text{ap}} = 2a$.

SOLUTION We use the polar equation of the elliptic orbit:

$$r = \frac{p}{1 + e\cos\theta} \tag{1}$$



At the perigee, $\theta = 0$ and at the apogee $\theta = \pi$. Substituting these values in (1) gives the distances r_{per} and r_{ap} respectively. That is,

$$r_{\text{per}} = \frac{p}{1 + e\cos\theta} = \frac{p}{1+e} \tag{2}$$

$$r_{\text{ap}} = \frac{p}{1 + e\cos\pi} = \frac{p}{1-e} \tag{3}$$

To obtain the solutions in terms of a rather than p, we notice that:

$$r_{\text{per}} + r_{\text{ap}} = 2a$$

Hence:

$$2a = \frac{p}{1+e} + \frac{p}{1-e} = \frac{p(1-e) + p(1+e)}{(1+e)(1-e)} = \frac{2p}{(1+e)(1-e)}$$

yielding

$$p = a(1+e)(1-e)$$

Substituting in (2) and (3) we obtain:

$$r_{\text{per}} = \frac{a(1+e)(1-e)}{1+e} = a(1-e)$$

$$r_{\text{ap}} = \frac{a(1+e)(1-e)}{1-e} = a(1+e)$$

14. Use the result of Exercise 13 to prove the formulas

$$e = \frac{r_{\text{ap}} - r_{\text{per}}}{r_{\text{ap}} + r_{\text{per}}}, \qquad p = \frac{2r_{\text{ap}}r_{\text{per}}}{r_{\text{ap}} + r_{\text{per}}}$$

SOLUTION In Exercise 13 we showed that:

$$r_{\text{per}} = a(1-e)\ ,\ r_{\text{ap}} = a(1+e)$$

Solving for a we get:

$$a = \frac{r_{\text{per}}}{1-e}\ ,\ a = \frac{r_{\text{ap}}}{1+e}$$

We equate the two expressions and solve for e to obtain:

$$\frac{r_{\text{per}}}{1-e} = \frac{r_{\text{ap}}}{1+e}$$

$$(1+e)r_{\text{per}} = (1-e)r_{\text{ap}}$$

$$r_{\text{per}} + er_{\text{per}} = r_{\text{ap}} - er_{\text{ap}}$$

$$e(r_{\text{per}} + r_{\text{ap}}) = r_{\text{ap}} - r_{\text{per}} \quad \Rightarrow \quad e = \frac{r_{\text{ap}} - r_{\text{per}}}{r_{\text{ap}} + r_{\text{per}}}$$

To show the equality for p we use the polar equation $r = \frac{p}{1+e\cos\theta}$. At the perigee $\theta = 0$ and at the apogee $\theta = \pi$, hence,

$$r_{\text{per}} = \frac{p}{1 + e\cos\theta} = \frac{p}{1+e}\ ,\ r_{\text{ap}} = \frac{p}{1 + e\cos\pi} = \frac{p}{1-e}$$

By these equalities we get:

$$r_{\text{per}} = \frac{p}{1+e} \quad \Rightarrow \quad 1+e = \frac{p}{r_{\text{per}}} \quad \Rightarrow \quad e = \frac{p}{r_{\text{per}}} - 1$$
$$r_{\text{ap}} = \frac{p}{1-e} \quad \Rightarrow \quad 1-e = \frac{p}{r_{\text{ap}}} \quad \Rightarrow \quad e = 1 - \frac{p}{r_{\text{ap}}}$$

We equate the two expressions for e and solve for p. This gives:

$$\frac{p}{r_{\text{per}}} - 1 = 1 - \frac{p}{r_{\text{ap}}}$$
$$p\left(\frac{1}{r_{\text{per}}} + \frac{1}{r_{\text{ap}}}\right) = 2$$
$$p\frac{r_{\text{ap}} + r_{\text{per}}}{r_{\text{per}} \cdot r_{\text{ap}}} = 2 \quad \Rightarrow \quad p = \frac{2r_{\text{ap}}r_{\text{per}}}{r_{\text{ap}} + r_{\text{per}}}$$

15. Use the fact that $\mathbf{J} = \mathbf{r} \times \mathbf{r}'$ is constant to prove

$$v_{\text{per}}(1-e) = v_{\text{ap}}(1+e)$$

Hint: $\mathbf{r}$ is perpendicular to $\mathbf{r}'$ at the perihelion and aphelion.

SOLUTION Since the vector $\mathbf{J}(t) = \mathbf{r}(t) \times \mathbf{r}'(t)$ is constant, it is the same vector at the perigee and at the apogee, hence we may equate the length of $\mathbf{J}(t)$ at these two points. Since at the perigee and at the apogee $\mathbf{r}(t)$ and $\mathbf{r}'(t)$ are orthogonal we have by properties of the cross product:

$$\|\mathbf{r}_{\text{ap}} \times \mathbf{r}'_{\text{ap}}\| = \|\mathbf{r}_{\text{ap}}\|\|\mathbf{r}'_{\text{ap}}\| = r_{\text{ap}}v_{\text{ap}}$$
$$\|\mathbf{r}_{\text{per}} \times \mathbf{r}'_{\text{per}}\| = \|\mathbf{r}_{\text{per}}\|\|\mathbf{r}'_{\text{per}}\| = r_{\text{per}}v_{\text{per}}$$

Equating the two values gives:

$$r_{\text{ap}}v_{\text{ap}} = r_{\text{per}}v_{\text{per}} \tag{1}$$

In Exercise 13 we showed that $r_{\text{per}} = a(1-e)$ and $r_{\text{ap}} = a(1+e)$. Substituting in (1) we obtain:

$$a(1+e)v_{\text{ap}} = a(1-e)v_{\text{per}}$$
$$(1+e)v_{\text{ap}} = (1-e)v_{\text{per}}$$

16. Compute r_{per} and r_{ap} for the orbit of Mercury, which has eccentricity $e = 0.244$ (see the table in Exercise 1 for the semimajor axis).

SOLUTION The length of the semi-major axis of the orbit of mercury is $a = 5.79 \cdot 10^7$ km. We substitute a and $e = 0.244$ in the formulas for r_{per} and r_{ap} obtained in Exercise 13, to obtain the shortest and longest distances respectively. This gives:

$$r_{\text{per}} = a(1-e) = 5.79 \cdot 10^7(1 - 0.244) = 4.377 \cdot 10^7 \text{ km}$$
$$r_{\text{ap}} = a(1+e) = 5.79 \cdot 10^7(1 + 0.244) = 7.203 \cdot 10^7 \text{ km}.$$

17. Conservation of Energy The total mechanical energy (kinetic energy plus potential energy) of a planet of mass m orbiting a sun of mass M with position $\mathbf{r}$ and speed $v = \|\mathbf{r}'\|$ is

$$E = \frac{1}{2}mv^2 - \frac{GMm}{\|\mathbf{r}\|} \tag*{$\boxed{8}$}$$

(a) Prove the equations

$$\frac{d}{dt}\frac{1}{2}mv^2 = \mathbf{v} \cdot (m\mathbf{a}), \qquad \frac{d}{dt}\frac{GMm}{\|\mathbf{r}\|} = \mathbf{v} \cdot \left(-\frac{GMm}{\|\mathbf{r}\|^3}\mathbf{r}\right)$$

(b) Then use Newton's Law to show that E is conserved—that is, $\frac{dE}{dt} = 0$.

SOLUTION We start by observing that since $\|\mathbf{r}\|^2 = \mathbf{r} \cdot \mathbf{r}$, we have (using Eq. (4) in Theorem 3, Section 13.2)

$$\frac{d}{dt}\|\mathbf{r}\|^2 = 2\|\mathbf{r}\|\frac{d}{dt}\|\mathbf{r}\|, \quad \text{and} \quad \frac{d}{dt}\|\mathbf{r}\|^2 = \frac{d}{dt}\mathbf{r} \cdot \mathbf{r} = 2\mathbf{r} \cdot \mathbf{r}'$$

Equating these two expressions gives

$$\frac{d}{dt}\|\mathbf{r}\| = \frac{\mathbf{r}\cdot\mathbf{r}'}{\|\mathbf{r}\|} \tag{1}$$

(a) Applying (1) to $\mathbf{r}'$, we have

$$\frac{d}{dt}\frac{1}{2}mv^2 = \frac{d}{dt}\frac{1}{2}m\|\mathbf{r}'\|^2 = m\|\mathbf{r}'\|\frac{d}{dt}\|\mathbf{r}'\| = m\|\mathbf{r}'\|\frac{\mathbf{r}'\cdot\mathbf{r}''}{\|\mathbf{r}'\|} = \mathbf{r}'\cdot(m\mathbf{r}'') = \mathbf{v}\cdot(m\mathbf{a})$$

proving half of formula 2. For the other half, note that again by (1),

$$\begin{aligned}\frac{d}{dt}\frac{GMm}{\|\mathbf{r}\|} &= GMm\frac{d}{dt}\|\mathbf{r}\|^{-1} = -GMm\|\mathbf{r}\|^{-2}\frac{d}{dt}\|\mathbf{r}\| = -GMm\|\mathbf{r}\|^{-2}\cdot\frac{\mathbf{r}\cdot\mathbf{r}'}{\|r\|}\\ &= \mathbf{r}'\cdot\left(-\frac{GMm}{\|\mathbf{r}\|^3}\right)\mathbf{r} = \mathbf{v}\cdot\left(-\frac{GMm}{\|\mathbf{r}\|^3}\mathbf{r}\right)\end{aligned}$$

(b) We have by part (a)

$$\frac{dE}{dt} = \frac{d}{dt}\left(\frac{1}{2}mv^2\right) - \frac{d}{dt}\left(\frac{GMm}{\|\mathbf{r}\|}\right) = \mathbf{v}\cdot(m\mathbf{a}) + \mathbf{v}\cdot\left(\frac{GMm}{\|\mathbf{r}\|^3}\mathbf{r}\right) = \mathbf{v}\cdot\left(m\mathbf{a} + \frac{GMm}{\|\mathbf{r}\|^3}\mathbf{r}\right) \tag{2}$$

By Newton's Law, formula (1) in the text,

$$\mathbf{r}'' = -\frac{GM}{\|\mathbf{r}\|^2}\mathbf{e}_r = -\frac{GM}{\|\mathbf{r}\|^3}\mathbf{r} \tag{3}$$

Substituting (3) into (2), and noting that $\mathbf{v} = \mathbf{r}'$ and $\mathbf{a} = \mathbf{r}''$ gives

$$\frac{dE}{dt} = \mathbf{r}'\cdot\left(m\mathbf{r}'' + \frac{GMm}{\|\mathbf{r}\|^3}\mathbf{r}\right) = \mathbf{r}'\cdot\left(-\frac{GMm}{\|\mathbf{r}\|^3}\mathbf{r} + \frac{GMm}{\|\mathbf{r}\|^3}\mathbf{r}\right) = 0$$

18. Show that the total energy [Eq. (8)] of a planet in a circular orbit of radius R is $E = -\frac{GMm}{2R}$. *Hint:* Use Exercise 9.

SOLUTION The total energy of a planet in a circular orbit of radius R is

$$E = \frac{1}{2}mv^2 - \frac{GMm}{\|\mathbf{r}\|} = \frac{1}{2}mv^2 - \frac{GMm}{R} \tag{1}$$

In Exercise 9 we showed that

$$v^2 = \frac{GM}{R} \tag{2}$$

Substituting (2) in (1) we obtain:

$$E = \frac{1}{2}m\frac{GM}{R} - \frac{GMm}{R} = -\frac{1}{2}\frac{GMm}{R} = -\frac{GMm}{2R}.$$

19. Prove that $v_{\text{per}} = \sqrt{\left(\frac{GM}{a}\right)\frac{1+e}{1-e}}$ as follows:

(a) Use Conservation of Energy (Exercise 17) to show that

$$v_{\text{per}}^2 - v_{\text{ap}}^2 = 2GM\left(r_{\text{per}}^{-1} - r_{\text{ap}}^{-1}\right)$$

(b) Show that $r_{\text{per}}^{-1} - r_{\text{ap}}^{-1} = \frac{2e}{a(1-e^2)}$ using Exercise 13.

(c) Show that $v_{\text{per}}^2 - v_{\text{ap}}^2 = 4\frac{e}{(1+e)^2}v_{\text{per}}^2$ using Exercise 15. Then solve for v_{per} using (a) and (b).

SOLUTION

(a) The total mechanical energy of a planet is constant. That is,

$$E = \frac{1}{2}mv^2 - \frac{GMm}{\|\mathbf{r}\|} = \text{const.}$$

Therefore, E has equal values at the perigee and apogee. Hence,

$$\begin{aligned}\frac{1}{2}mv_{\text{per}}^2 - \frac{GMm}{r_{\text{per}}} &= \frac{1}{2}mv_{\text{ap}}^2 - \frac{GMm}{r_{\text{ap}}}\\ \frac{1}{2}m\left(v_{\text{per}}^2 - v_{\text{ap}}^2\right) &= GMm\left(\frac{1}{r_{\text{per}}} - \frac{1}{r_{\text{ap}}}\right)\\ v_{\text{per}}^2 - v_{\text{ap}}^2 &= 2GM\left(r_{\text{per}}^{-1} - r_{\text{ap}}^{-1}\right)\end{aligned}$$

(b) In Exercise 13 we showed that $r_{\text{per}} = a(1-e)$ and $r_{\text{ap}} = a(1+e)$. Therefore,

$$r_{\text{per}}^{-1} - r_{\text{ap}}^{-1} = \frac{1}{a(1-e)} - \frac{1}{a(1+e)} = \frac{1+e-(1-e)}{a(1-e)(1+e)} = \frac{2e}{a(1-e^2)}$$

(c) In Exercise 15 we showed that

$$v_{\text{per}}(1-e) = v_{\text{ap}}(1+e)$$

Hence,

$$v_{\text{ap}} = \frac{1-e}{1+e} v_{\text{per}}$$

We compute the following difference,

$$v_{\text{per}}^2 - v_{\text{ap}}^2 = v_{\text{per}}^2 - \left(\frac{1-e}{1+e} v_{\text{per}}\right)^2 = v_{\text{per}}^2 \left(1 - \left(\frac{1-e}{1+e}\right)^2\right)$$

$$= v_{\text{per}}^2 \frac{(1+e)^2 - (1-e)^2}{(1+e)^2} = v_{\text{per}}^2 \frac{1+2e+e^2-(1-2e+e^2)}{(1+e)^2} = 4\frac{e}{(1+e)^2} v_{\text{per}}^2$$

We combine this equality with the equality in part (a) to write

$$\frac{4e}{(1+e)^2} v_{\text{per}}^2 = 2GM\left(r_{\text{per}}^{-1} - r_{\text{ap}}^{-1}\right)$$

Replacing the difference in the right-hand side by $\frac{2e}{a(1-e^2)}$ (from part (b)) and solving for v_{per} we obtain:

$$\frac{4e}{(1+e)^2} v_{\text{per}}^2 = 2GM \cdot \frac{2e}{a(1-e^2)}$$

$$v_{\text{per}}^2 = \frac{4GMe}{a(1-e)(1+e)} \cdot \frac{(1+e)^2}{4e} = \frac{GM(1+e)}{a(1-e)}$$

or,

$$v_{\text{per}} = \sqrt{\frac{GM}{a} \frac{1+e}{1-e}}$$

20. Show that a planet in an elliptical orbit has total mechanical energy $E = -\dfrac{GMm}{2a}$, where a is the semimajor axis. *Hint:* Use Exercise 19 to compute the total energy at the perihelion.

SOLUTION The total energy of a planet of mass m orbiting a sun of mass M with position $\mathbf{r}$ and speed $v = \|\mathbf{r}'\|$ is (given in Exercise 17):

$$E = \frac{1}{2}mv^2 - \frac{GMm}{\|\mathbf{r}\|} \tag{1}$$

The energy E is conserved, so we can compute it using any point on the elliptical orbit, for instance the perihelion. By Exercise 13 and Exercise 19 we have:

$$r_{\text{per}} = a(1-e)$$

$$v_{\text{per}} = \sqrt{\frac{GM}{a} \frac{1+e}{1-e}} \tag{2}$$

Substituting (2) into (1) gives:

$$E = \frac{1}{2}m \cdot \frac{GM}{a} \frac{1+e}{1-e} - \frac{GMm}{a(1-e)} = \frac{GMm}{a(1-e)}\left(\frac{1+e}{2} - 1\right) = \frac{GMm}{a(1-e)} \frac{1+e-2}{2}$$

$$= \frac{GMm}{a(1-e)} \frac{e-1}{2} = -\frac{GMm}{2a}$$

21. Prove that $v^2 = GM\left(\dfrac{2}{r} - \dfrac{1}{a}\right)$ at any point on an elliptical orbit, where $r = \|\mathbf{r}\|$, v is the velocity, and a is the semimajor axis of the orbit.

SOLUTION The total energy $E = \frac{1}{2}mv^2 - \frac{GMm}{\|\mathbf{r}\|}$ is conserved, and in Exercise 20 we showed that its constant value is $-\frac{GMm}{2a}$. We obtain the following equality:

$$\frac{1}{2}mv^2 - \frac{GMm}{r} = -\frac{GMm}{2a}$$

Algebraic manipulations yield:

$$v^2 = \frac{2GM}{r} - \frac{GM}{a} = GM\left(\frac{2}{r} - \frac{1}{a}\right)$$

22. Two space shuttles A and B orbit the earth along the solid trajectory in Figure 9. Hoping to catch up to B, the pilot of A applies a forward thrust to increase her shuttle's kinetic energy. Use Exercise 20 to show that shuttle A will move off into a larger orbit as shown in the figure. Then use Kepler's Third Law to show that A's orbital period T will increase (and she will fall farther and farther behind B)!

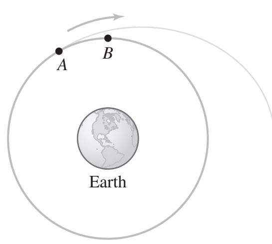


FIGURE 9

SOLUTION In Exercise 20 we showed that the total mechanical energy E of a planet in an elliptical orbit with semimajor axis a is

$$E = \frac{-GMm}{2a} \tag{1}$$

Since E is increased, a is increased, resulting in moving to an elliptic orbit as the dashed orbit in the figure. Now, by Kepler's Third Law,

$$T^2 = \left(\frac{4\pi^2}{GM}\right)a^3$$

We conclude that the orbital period T of shuttle A is also increasing, which means that A will get further and further behind B.

Further Insights and Challenges

Exercises 23 and 24 prove Kepler's Third Law. Figure 10 shows an elliptical orbit with polar equation

$$r = \frac{p}{1 + e\cos\theta}$$

where $p = J^2/k$. The origin of the polar coordinates is at F_1. Let a and b be the semimajor and semiminor axes, respectively.

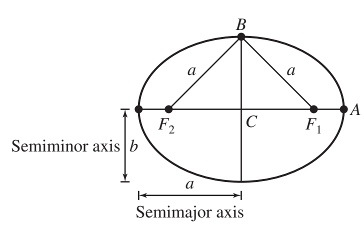

FIGURE 10

23. This exercise shows that $b = \sqrt{pa}$.

(a) Show that $CF_1 = ae$. *Hint:* $r_{\text{per}} = a(1 - e)$ by Exercise 13.

(b) Show that $a = \dfrac{p}{1 - e^2}$.

(c) Show that $F_1A + F_2A = 2a$. Conclude that $F_1B + F_2B = 2a$ and hence $F_1B = F_2B = a$.

(d) Use the Pythagorean Theorem to prove that $b = \sqrt{pa}$.

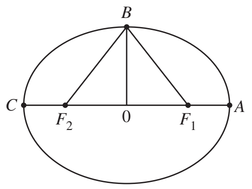
SOLUTION

(a) Since $CF_2 = AF_1$, we have:

$$F_2A = CA - CF_2 = 2a - F_1A$$

Therefore,

$$F_1A + F_2A = 2a \tag{1}$$



The ellipse is the set of all points such that the sum of the distances to the two foci F_1 and F_2 is constant. Therefore,

$$F_1A + F_2A = F_1B + F_2B \tag{2}$$

Combining (1) and (2), we obtain:

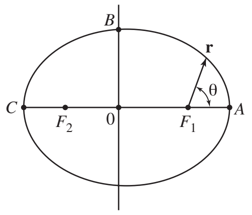
$$F_1B + F_2B = 2a \tag{3}$$

The triangle F_2BF_1 is isosceles, hence $F_2B = F_1B$ and so we conclude that

$$F_1B = F_2B = a$$

(b) The polar equation of the ellipse, where the focus F_1 is at the origin is

$$r = \frac{p}{1 + e\cos\theta}$$



The point A corresponds to $\theta = 0$, hence,

$$F_1A = \frac{p}{1 + e\cos 0} = \frac{p}{1 + e} \tag{4}$$

The point C corresponds to $\theta = \pi$ hence,

$$F_1C = \frac{p}{1 + e\cos\pi} = \frac{p}{1 - e}$$

We now find F_2A. Using the equality $CF_2 = AF_1$ we get:

$$F_2A = F_2F_1 + F_1A = F_2F_1 + F_2C = F_1C = \frac{p}{1 - e}$$

That is,

$$F_2A = \frac{p}{1 - e} \tag{5}$$

Combining (1), (4), and (5) we obtain:

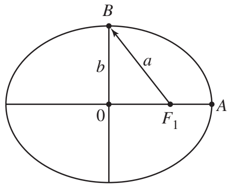
$$\frac{p}{1 + e} + \frac{p}{1 - e} = 2a$$

Hence,

$$a = \frac{1}{2}\left(\frac{p}{1 + e} + \frac{p}{1 - e}\right) = \frac{p(1 - e) + p(1 + e)}{2(1 + e)(1 - e)} = \frac{2p}{2\left(1 - e^2\right)} = \frac{p}{1 - e^2}$$

(c) We use Pythagoras' Theorem for the triangle OBF_1:

$$OB^2 + OF_1^2 = BF_1^2 \tag{6}$$



Using (4) we have

$$OF_1 = a - F_1A = a - \frac{p}{1+e}$$

Also $OB = b$ and $BF_1 = a$, hence (6) gives:

$$b^2 + \left(a - \frac{p}{1+e}\right)^2 = a^2$$

We solve for b:

$$b^2 + a^2 - \frac{2ap}{1+e} + \frac{p^2}{(1+e)^2} = a^2$$

$$b^2 - \frac{2ap}{1+e} + \frac{p^2}{(1+e)^2} = 0$$

In part (b) we showed that $a = \frac{p}{1-e^2}$. We substitute to obtain:

$$b^2 - \frac{2p}{1+e} \cdot \frac{p}{1-e^2} + \frac{p^2}{(1+e)^2} = 0$$

$$b^2 = \frac{2p^2}{(1+e)^2(1-e)} - \frac{p^2}{(1+e)^2} = \frac{2p^2 - p^2(1-e)}{(1+e)^2(1-e)}$$

$$= \frac{p^2(1+e)}{(1+e)^2(1-e)} = \frac{p^2}{1-e^2}$$

Hence,

$$b = \frac{p}{\sqrt{1-e^2}}$$

Since $1 - e^2 = \frac{p}{a}$ we also have

$$b = \frac{p}{\sqrt{\frac{p}{a}}} = \sqrt{ap}$$

24. The area A of the ellipse is $A = \pi ab$.
(a) Prove, using Kepler's First Law, that $A = \frac{1}{2}JT$, where T is the period of the orbit.
(b) Use Exercise 23 to show that $A = (\pi\sqrt{p})a^{3/2}$.
(c) Deduce Kepler's Third Law: $T^2 = \dfrac{4\pi^2}{GM}a^3$.

SOLUTION
(a) The area of an ellipse with semimajor and semiminor axes a , b respectively is,

$$A = \pi ab \tag{1}$$

In Exercise 23 we showed that $b = \sqrt{pa}$. Substituting in (1) gives:

$$A = \pi a\sqrt{pa} = \left(\pi\sqrt{p}\right)a^{3/2}$$

(b) The magnitude $\frac{1}{2}\|\mathbf{J}\|$ is the rate at which the position vector $\mathbf{r}(t)$ sweeps out areas. Since this rate is constant, the total area is obtained by multiplying the rate by the period T. That is,

$$A = \frac{1}{2}\|\mathbf{J}\|T$$

(c) Equating the expressions for A obtained in parts (a) and (b), (recall that $p = \frac{\|\mathbf{J}\|^2}{GM}$) we obtain:

$$\left(\pi\sqrt{p}\right)a^{3/2} = \frac{1}{2}\|\mathbf{J}\|T$$

$$\frac{\pi\|\mathbf{J}\|}{\sqrt{GM}}a^{3/2} = \frac{1}{2}\|\mathbf{J}\|T$$

$$T = \frac{2\pi a^{3/2}}{\sqrt{GM}} \quad \Rightarrow \quad T^2 = \frac{4\pi^2}{GM}a^3$$

25. According to Eq. (7) the velocity vector of a planet as a function of the angle θ is

$$\mathbf{v}(\theta) = \frac{k}{J}\mathbf{e}_\theta + \mathbf{c}$$

Use this to explain the following statement: As a planet revolves around the sun, its velocity vector traces out a circle of radius k/J with center $\mathbf{c}$ (Figure 11). This beautiful but hidden property of orbits was discovered by William Rowan Hamilton in 1847.

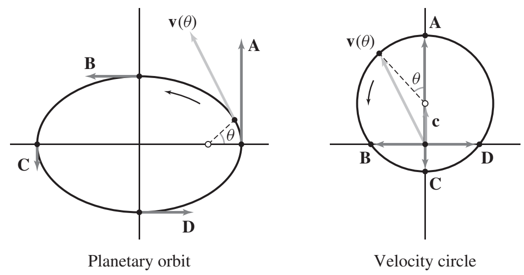


FIGURE 11 The velocity vector traces out a circle as the planet travels along its orbit.

SOLUTION Recall that $\mathbf{e}_\theta = \langle -\sin\theta, \cos\theta\rangle$, so that

$$\mathbf{v}(\theta) = \frac{k}{J}\langle -\sin\theta, \cos\theta\rangle + \mathbf{c} = \frac{k}{J}\langle \sin(-\theta), \cos(-\theta)\rangle + \mathbf{c}$$

The first term is obviously a clockwise (due to having $-\theta$ instead of θ) parametrization of a circle of radius k/J centered at the origin. It follows that $\mathbf{v}(\theta)$ is a clockwise parametrization of a circle of radius k/J and center $\mathbf{c}$.

CHAPTER REVIEW EXERCISES

1. Determine the domains of the vector-valued functions.

(a) $\mathbf{r}_1(t) = \left\langle t^{-1}, (t+1)^{-1}, \sin^{-1} t\right\rangle$ **(b)** $\mathbf{r}_2(t) = \left\langle \sqrt{8-t^3}, \ln t, e^{\sqrt{t}}\right\rangle$

SOLUTION

(a) We find the domain of $\mathbf{r}_1(t) = \left\langle t^{-1}, (t+1)^{-1}, \sin^{-1} t\right\rangle$. The function t^{-1} is defined for $t \neq 0$. $(t+1)^{-1}$ is defined for $t \neq -1$ and $\sin^{-1} t$ is defined for $-1 \le t \le 1$. Hence, the domain of $\mathbf{r}_1(t)$ is defined by the following inequalities:

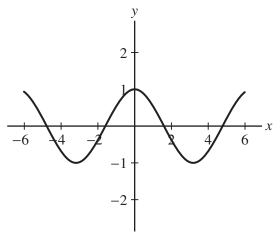
$$\begin{aligned} t &\neq 0 \\ t &\neq -1 \quad \Rightarrow \quad -1 < t < 0 \quad \text{or} \quad 0 < t \le 1 \\ -1 \le t &\le 1 \end{aligned}$$

(b) We find the domain of $\mathbf{r}_2(t) = \left\langle \sqrt{8-t^3}, \ln t, e^{\sqrt{t}}\right\rangle$. The domain of $\sqrt{8-t^3}$ is $8 - t^3 \ge 0$. The domain of $\ln t$ is $t > 0$ and $e^{\sqrt{t}}$ is defined for $t \ge 0$. Hence, the domain of $\mathbf{r}_2(t)$ is defined by the following inequalities:

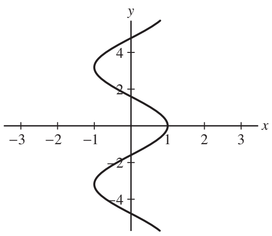
$$\begin{aligned} 8 - t^3 &\ge 0 \\ t &> 0 \\ t &\ge 0 \end{aligned} \quad \Rightarrow \quad \begin{aligned} t^3 &\le 8 \\ t &> 0 \end{aligned} \quad \Rightarrow \quad 0 < t \le 2$$

2. Sketch the paths $\mathbf{r}_1(\theta) = \langle \theta, \cos\theta\rangle$ and $\mathbf{r}_2(\theta) = \langle \cos\theta, \theta\rangle$ in the xy-plane.

SOLUTION The parametric equations of $\mathbf{r}_1(\theta) = (\theta, \cos\theta)$ are $x = \theta$, $y = \cos\theta$. Therefore, $y = \cos x$. The parametric equations of $\mathbf{r}_2(\theta) = (\cos\theta, \theta)$ are $x = \cos\theta$, $y = \theta$. Therefore, $x = \cos y$. We can sketch the graphs of $\mathbf{r}_1(\theta)$ and $\mathbf{r}_2(\theta)$ in the xy-plane, using the explicit relations between y and x for the two parametric representations. We obtain:



$\mathbf{r}_1(\theta) = (\theta, \cos\theta),\ y = \cos x$



$\mathbf{r}_2(\theta) = (\cos\theta, \theta),\ x = \cos y$

As seen in the graph, although $\mathbf{r}_2(\theta) = (\cos\theta, \theta)$ is a function of θ, y is not a function of x.

3. Find a vector parametrization of the intersection of the surfaces $x^2 + y^4 + 2z^3 = 6$ and $x = y^2$ in $\mathbf{R}^3$.

SOLUTION We need to find a vector parametrization $\mathbf{r}(t) = \langle x(t), y(t), z(t)\rangle$ for the intersection curve. Using $t = y$ as a parameter, we have $x = t^2$ and $y = t$. We substitute in the equation of the surface $x^2 + y^4 + 2z^3 = 6$ and solve for z in terms of t. This gives:

$$\begin{aligned} t^4 + t^4 + 2z^3 &= 6 \\ 2t^4 + 2z^3 &= 6 \\ z^3 &= 3 - t^4 \quad \Rightarrow \quad z = \sqrt[3]{3 - t^4} \end{aligned}$$

We obtain the following parametrization of the intersection curve:

$$\mathbf{r}(t) = \left\langle t^2, t, \sqrt[3]{3 - t^4}\right\rangle.$$

4. Find a vector parametrization using trigonometric functions of the intersection of the plane $x + y + z = 1$ and the elliptical cylinder $\left(\frac{y}{3}\right)^2 + \left(\frac{z}{8}\right)^2 = 1$ in $\mathbf{R}^3$.

SOLUTION We need to find a vector parametrization $\mathbf{r}(t) = \langle x(t), y(t), z(t)\rangle$ for the intersection curve. We parametrize the elliptical cylinder by:

$$x = x, \quad y = 3\sin t, \quad z = 8\cos t$$

We substitute in the equation of the plane $x + y + z = 1$ and solve for x in terms of t. This gives:

$$x + 3\sin t + 8\cos t = 1 \quad \Rightarrow \quad x = 1 - 3\sin t - 8\cos t$$

We obtain the following parametrization of the intersection curve:

$$\mathbf{r}(t) = \langle 1 - 3\sin t - 8\cos t, 3\sin t, 8\cos t\rangle$$

In Exercises 5–10, calculate the derivative indicated.

5. $\mathbf{r}'(t), \quad \mathbf{r}(t) = \left\langle 1 - t, t^{-2}, \ln t\right\rangle$

SOLUTION We use the Theorem on Componentwise Differentiation to compute the derivative $\mathbf{r}'(t)$. We get

$$\mathbf{r}'(t) = \left\langle (1-t)', (t^{-2})', (\ln t)'\right\rangle = \left\langle -1, -2t^{-3}, \frac{1}{t}\right\rangle$$

6. $\mathbf{r}'''(t), \quad \mathbf{r}(t) = \left\langle t^3, 4t^2, 7t\right\rangle$

SOLUTION We use the Theorem on Componentwise Differentiation to find $\mathbf{r}'(t)$:

$$\mathbf{r}'(t) = \left\langle (t^3)', (4t^2)', (7t)'\right\rangle = \left\langle 3t^2, 8t, 7\right\rangle$$

We differentiate $\mathbf{r}'(t)$ componentwise to find $\mathbf{r}''(t)$:

$$\mathbf{r}''(t) = \langle 6t, 8, 0\rangle$$

Differentiating $\mathbf{r}''(t)$ componentwise gives $\mathbf{r}'''(t)$:

$$\mathbf{r}'''(t) = \langle 6, 0, 0\rangle$$

7. $\mathbf{r}'(0)$, $\quad \mathbf{r}(t) = \left\langle e^{2t}, e^{-4t^2}, e^{6t} \right\rangle$

SOLUTION We differentiate $\mathbf{r}(t)$ componentwise to find $\mathbf{r}'(t)$:

$$\mathbf{r}'(t) = \left\langle (e^{2t})', \left(e^{-4t^2}\right)', (e^{6t})' \right\rangle = \left\langle 2e^{2t}, -8te^{-4t^2}, 6e^{6t} \right\rangle$$

The derivative $\mathbf{r}'(0)$ is obtained by setting $t = 0$ in $\mathbf{r}'(t)$. This gives

$$\mathbf{r}'(0) = \left\langle 2e^{2\cdot 0}, -8 \cdot 0e^{-4\cdot 0^2}, 6e^{6\cdot 0} \right\rangle = \langle 2, 0, 6 \rangle$$

8. $\mathbf{r}''(-3)$, $\quad \mathbf{r}(t) = \left\langle t^{-2}, (t+1)^{-1}, t^3 - t \right\rangle$

SOLUTION We differentiate componentwise to find $\mathbf{r}'(t)$:

$$\mathbf{r}'(t) = \left\langle -2t^{-3}, -(t+1)^{-2}, 3t^2 - 1 \right\rangle$$

We differentiate componentwise to find $\mathbf{r}''(t)$ and evaluate at $t = -3$:

$$\mathbf{r}''(t) = \left\langle 6t^{-4}, 2(t+1)^{-3}, 6t \right\rangle, \quad \Rightarrow \mathbf{r}''(-3) = \left\langle \frac{2}{27}, -\frac{1}{4}, -18 \right\rangle$$

9. $\dfrac{d}{dt} e^t \left\langle 1, t, t^2 \right\rangle$

SOLUTION Using the Product Rule for differentiation gives

$$\begin{aligned}\frac{d}{dt} e^t \left\langle 1, t, t^2 \right\rangle &= e^t \frac{d}{dt} \left\langle 1, t, t^2 \right\rangle + \left(e^t\right)' \left\langle 1, t, t^2 \right\rangle = e^t \langle 0, 1, 2t \rangle + e^t \left\langle 1, t, t^2 \right\rangle \\ &= e^t \left(\langle 0, 1, 2t \rangle + \left\langle 1, t, t^2 \right\rangle \right) = e^t \left\langle 1, 1+t, 2t + t^2 \right\rangle\end{aligned}$$

10. $\dfrac{d}{d\theta} \mathbf{r}(\cos\theta)$, $\quad \mathbf{r}(s) = \left\langle s, 2s, s^2 \right\rangle$

SOLUTION We use the Chain Rule to compute the derivative. That is,

$$\begin{aligned}\frac{d}{d\theta} \mathbf{r}(\cos\theta) &= \left(\left.\frac{d\mathbf{r}}{ds}\right|_{s=\cos\theta} \right) \cdot \frac{d}{d\theta}(\cos\theta) = -\sin\theta \cdot \langle 1, 2, 2s \rangle \Big|_{s=\cos\theta} \\ &= -\sin\theta \cdot \langle 1, 2, 2\cos\theta \rangle = \langle -\sin\theta, -2\sin\theta, -2\sin\theta\cos\theta \rangle \\ &= -\langle \sin\theta, 2\sin\theta, \sin 2\theta \rangle\end{aligned}$$

In Exercises 11–14, calculate the derivative at $t = 3$, assuming that

$$\begin{aligned}\mathbf{r}_1(3) &= \langle 1, 1, 0 \rangle, \qquad \mathbf{r}_2(3) = \langle 1, 1, 0 \rangle \\ \mathbf{r}_1'(3) &= \langle 0, 0, 1 \rangle, \qquad \mathbf{r}_2'(3) = \langle 0, 2, 4 \rangle\end{aligned}$$

11. $\dfrac{d}{dt}(6\mathbf{r}_1(t) - 4 \cdot \mathbf{r}_2(t))$

SOLUTION Using Differentiation Rules we obtain:

$$\begin{aligned}\left.\frac{d}{dt}(6\mathbf{r}_1(t) - 4\mathbf{r}_2(t))\right|_{t=3} &= 6\mathbf{r}_1'(3) - 4\mathbf{r}_2'(3) = 6 \cdot \langle 0, 0, 1 \rangle - 4 \cdot \langle 0, 2, 4 \rangle \\ &= \langle 0, 0, 6 \rangle - \langle 0, 8, 16 \rangle = \langle 0, -8, -10 \rangle\end{aligned}$$

12. $\dfrac{d}{dt}\left(e^t \mathbf{r}_2(t)\right)$

SOLUTION Using the Product Rule gives:

$$\frac{d}{dt}\left(e^t \mathbf{r}_2(t)\right) = e^t \mathbf{r}_2'(t) + \left(e^t\right)' \mathbf{r}_2(t) = e^t \left(\mathbf{r}_2'(t) + \mathbf{r}_2(t)\right)$$

Setting $t = 3$ we get:

$$\left.\frac{d}{dt}\left(e^t \mathbf{r}_2(t)\right)\right|_{t=3} = e^3 \left(\mathbf{r}_2'(3) + \mathbf{r}_2(3)\right) = e^3 (\langle 0, 2, 4 \rangle + \langle 1, 1, 0 \rangle) = e^3 \langle 1, 3, 4 \rangle$$

13. $\frac{d}{dt}\left(\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)\right)$

SOLUTION Using Product Rule for Dot Products we obtain:

$$\frac{d}{dt}\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)=\mathbf{r}_1(t)\cdot\mathbf{r}_2'(t)+\mathbf{r}_1'(t)\cdot\mathbf{r}_2(t)$$

Setting $t=3$ gives:

$$\left.\frac{d}{dt}\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)\right|_{t=3}=\mathbf{r}_1(3)\cdot\mathbf{r}_2'(3)+\mathbf{r}_1'(3)\cdot\mathbf{r}_2(3)=\langle 1,1,0\rangle\cdot\langle 0,2,4\rangle+\langle 0,0,1\rangle\cdot\langle 1,1,0\rangle=2+0=2$$

14. $\frac{d}{dt}\left(\mathbf{r}_1(t)\times\mathbf{r}_2(t)\right)$

SOLUTION We use the Product Rule for Cross Product to write:

$$\frac{d}{dt}\mathbf{r}_1(t)\times\mathbf{r}_2(t)=\mathbf{r}_1(t)\times\mathbf{r}_2'(t)+\mathbf{r}_1'(t)\times\mathbf{r}_2(t)$$

Setting $t=3$ we obtain:

$$\begin{aligned}\left.\frac{d}{dt}\mathbf{r}_1(t)\times\mathbf{r}_2(t)\right|_{t=3}&=\mathbf{r}_1(3)\times\mathbf{r}_2'(3)+\mathbf{r}_1'(3)\times\mathbf{r}_2(3)=\langle 1,1,0\rangle\times\langle 0,2,4\rangle+\langle 0,0,1\rangle\times\langle 1,1,0\rangle\\&=\begin{vmatrix}\mathbf{i}&\mathbf{j}&\mathbf{k}\\1&1&0\\0&2&4\end{vmatrix}+\begin{vmatrix}\mathbf{i}&\mathbf{j}&\mathbf{k}\\0&0&1\\1&1&0\end{vmatrix}=(4\mathbf{i}-4\mathbf{j}+2\mathbf{k})+(-\mathbf{i}+\mathbf{j})\\&=3\mathbf{i}-3\mathbf{j}+2\mathbf{k}=\langle 3,-3,2\rangle\end{aligned}$$

15. Calculate $\int_0^3\left\langle 4t+3,t^2,-4t^3\right\rangle dt$.

SOLUTION By the definition of vector-valued integration, we have

$$\int_0^3\left\langle 4t+3,t^2,-4t^3\right\rangle dt=\left\langle\int_0^3(4t+3)\,dt,\int_0^3 t^2\,dt,\int_0^3-4t^3\,dt\right\rangle \tag{1}$$

We compute the integrals on the right-hand side:

$$\int_0^3(4t+3)\,dt=2t^2+3t\Big|_0^3=2\cdot 9+3\cdot 3-0=27$$

$$\int_0^3 t^2\,dt=\frac{t^3}{3}\Big|_0^3=\frac{3^3}{3}=9$$

$$\int_0^3-4t^3\,dt=-t^4\Big|_0^3=-3^4=-81$$

Substituting in (1) gives the following integral:

$$\int_0^3\left\langle 4t+3,t^2,-4t^3\right\rangle dt=\langle 27,9,-81\rangle$$

16. Calculate $\int_0^\pi\left\langle\sin\theta,\theta,\cos 2\theta\right\rangle d\theta$.

SOLUTION By the definition of vector-valued integration, we have

$$\int_0^\pi\langle\sin\theta,\theta,\cos 2\theta\rangle\,d\theta=\left\langle\int_0^\pi\sin\theta\,d\theta,\int_0^\pi\theta\,d\theta,\int_0^\pi\cos 2\theta\,d\theta\right\rangle \tag{1}$$

We compute the integrals on the right hand-side:

$$\int_0^\pi\sin\theta\,d\theta=-\cos\theta\Big|_0^\pi=-(\cos\pi-\cos 0)=-(-1-1)=2$$

$$\int_0^\pi\theta\,d\theta=\frac{1}{2}\theta^2\Big|_0^\pi=\frac{\pi^2}{2}$$

$$\int_0^{\pi} \cos 2\theta \, d\theta = \frac{1}{2}\sin 2\theta \Big|_0^{\pi} = \frac{1}{2}(\sin 2\pi - \sin 0) = 0$$

Substituting in (1) gives the following integral:

$$\int_0^{\pi} \langle \sin\theta, \theta, \cos 2\theta \rangle \, d\theta = \left\langle 2, \frac{\pi^2}{2}, 0 \right\rangle$$

17. A particle located at $(1, 1, 0)$ at time $t = 0$ follows a path whose velocity vector is $\mathbf{v}(t) = \langle 1, t, 2t^2 \rangle$. Find the particle's location at $t = 2$.

SOLUTION We first find the path $\mathbf{r}(t)$ by integrating the velocity vector $\mathbf{v}(t)$:

$$\mathbf{r}(t) = \int \left\langle 1, t, 2t^2 \right\rangle dt = \left\langle \int 1\, dt, \int t\, dt, \int 2t^2\, dt \right\rangle = \left\langle t + c_1, \frac{1}{2}t^2 + c_2, \frac{2}{3}t^3 + c_3 \right\rangle$$

Denoting by $\mathbf{c} = \langle c_1, c_2, c_3 \rangle$ the constant vector, we obtain:

$$\mathbf{r}(t) = \left\langle t, \frac{1}{2}t^2, \frac{2}{3}t^3 \right\rangle + \mathbf{c} \tag{1}$$

To find the constant vector $\mathbf{c}$, we use the given information on the initial position of the particle. At time $t = 0$ it is at the point $(1, 1, 0)$. That is, by (1):

$$\mathbf{r}(0) = \langle 0, 0, 0 \rangle + \mathbf{c} = \langle 1, 1, 0 \rangle$$

or,

$$\mathbf{c} = \langle 1, 1, 0 \rangle$$

We substitute in (1) to obtain:

$$\mathbf{r}(t) = \left\langle t, \frac{1}{2}t^2, \frac{2}{3}t^3 \right\rangle + \langle 1, 1, 0 \rangle = \left\langle t + 1, \frac{1}{2}t^2 + 1, \frac{2}{3}t^3 \right\rangle$$

Finally, we substitute $t = 2$ to obtain the particle's location at $t = 2$:

$$\mathbf{r}(2) = \left\langle 2 + 1, \frac{1}{2} \cdot 2^2 + 1, \frac{2}{3} \cdot 2^3 \right\rangle = \left\langle 3, 3, \frac{16}{3} \right\rangle$$

At time $t = 2$ the particle is located at the point

$$\left(3, 3, \frac{16}{3}\right)$$

18. Find the vector-valued function $\mathbf{r}(t) = \langle x(t), y(t) \rangle$ in $\mathbf{R}^2$ satisfying $\mathbf{r}'(t) = -\mathbf{r}(t)$ with initial conditions $\mathbf{r}(0) = \langle 1, 2 \rangle$.

SOLUTION We rewrite the differential equation by components as:

$$\langle x'(t), y'(t) \rangle = -\langle x(t), y(t) \rangle \quad \text{or} \quad \langle x'(t), y'(t) \rangle = \langle -x(t), -y(t) \rangle$$

Equating corresponding components, we obtain:

$$\begin{aligned} x'(t) &= -x(t) \\ y'(t) &= -y(t) \end{aligned} \quad \Rightarrow \quad \frac{x'(t)}{x(t)} = -1, \quad \frac{y'(t)}{y(t)} = -1$$

By integration we get $\ln(x(t)) = -t + A$, $\ln(y(t)) = -t + B$ or:

$$\begin{aligned} x(t) &= ae^{-t} \\ y(t) &= be^{-t} \end{aligned} \quad \text{where} \quad a = e^A, \quad b = e^B$$

By the given information $\mathbf{r}(0) = \langle 1, 2 \rangle$. Therefore,

$$\begin{aligned} x(0) &= ae^{-0} = a = 1 \\ y(0) &= be^{-0} = b = 2 \end{aligned} \quad \Rightarrow \quad a = 1, \quad b = 2$$

We obtain the following vector:

$$\mathbf{r}(t) = \langle x(t), y(t) \rangle = \left\langle ae^{-t}, be^{-t} \right\rangle = \left\langle e^{-t}, 2e^{-t} \right\rangle.$$

19. Calculate $\mathbf{r}(t)$ assuming that

$$\mathbf{r}''(t) = \left\langle 4 - 16t, 12t^2 - t \right\rangle, \qquad \mathbf{r}'(0) = \langle 1, 0 \rangle, \qquad \mathbf{r}(0) = \langle 0, 1 \rangle$$

SOLUTION Using componentwise integration we get:

$$\begin{aligned} \mathbf{r}'(t) &= \int \left\langle 4 - 16t, 12t^2 - t \right\rangle dt \\ &= \left\langle \int 4 - 16t\, dt, \int 12t^2 - t\, dt \right\rangle \\ &= \left\langle 4t - 8t^2, 4t^3 - \frac{t^2}{2} \right\rangle + \mathbf{c}_1 \end{aligned}$$

Then using the initial condition $\mathbf{r}'(0) = \langle 1, 0 \rangle$ we get:

$$\mathbf{r}'(0) = \langle 1, 0 \rangle = \mathbf{c}_1$$

so then

$$\mathbf{r}'(t) = \left\langle 4t - 8t^2, 4t^3 - \frac{t^2}{2} \right\rangle + \langle 1, 0 \rangle = \left\langle 4t - 8t^2 + 1, 4t^3 - \frac{t^2}{2} \right\rangle$$

Then integrating componentwise once more we get:

$$\begin{aligned} \mathbf{r}(t) &= \int \left\langle 4t - 8t^2 + 1, 4t^3 - \frac{t^2}{2} \right\rangle dt \\ &= \left\langle \int 4t - 8t^2 + 1\, dt, \int 4t^3 - \frac{t^2}{2}\, dt \right\rangle \\ &= \left\langle 2t^2 - \frac{8}{3}t^3 + t, t^4 - \frac{t^3}{6} \right\rangle + \mathbf{c}_2 \end{aligned}$$

Using the initial condition $\mathbf{r}(0) = \langle 0, 1 \rangle$ we have:

$$\mathbf{r}(0) = \langle 0, 1 \rangle = \mathbf{c}_2$$

Therefore,

$$\mathbf{r}(t) = \left\langle 2t^2 - \frac{8}{3}t^3 + t, t^4 - \frac{t^3}{6} \right\rangle + \langle 0, 1 \rangle = \left\langle 2t^2 - \frac{8}{3}t^3 + t, t^4 - \frac{t^3}{6} + 1 \right\rangle$$

20. Solve $\mathbf{r}''(t) = \left\langle t^2 - 1, t + 1, t^3 \right\rangle$ subject to the initial conditions $\mathbf{r}(0) = \langle 1, 0, 0 \rangle$ and $\mathbf{r}'(0) = \langle -1, 1, 0 \rangle$

SOLUTION Using integration componentwise we get:

$$\begin{aligned} \mathbf{r}'(t) &= \int \left\langle t^2 - 1, t + 1, t^3 \right\rangle dt \\ &= \left\langle \int t^2 - 1\, dt, \int t + 1\, dt, \int t^3\, dt \right\rangle \\ &= \left\langle \frac{t^3}{3} - t, \frac{t^2}{2} + t, \frac{t^4}{4} \right\rangle + \mathbf{c}_1 \end{aligned}$$

Using the initial condition $\mathbf{r}'(1) = \langle -1, 1, 0 \rangle$ we get:

$$\mathbf{r}'(1) = \langle -1, 1, 0 \rangle = \left\langle -\frac{2}{3}, \frac{3}{2}, \frac{1}{4} \right\rangle + \mathbf{c}_1$$

so then, $\mathbf{c_1} = \left\langle -\frac{1}{3}, -\frac{1}{2}, -\frac{1}{4} \right\rangle$ and

$$\mathbf{r}'(t) = \left\langle \frac{t^3}{3} - t, \frac{t^2}{2} + t, \frac{t^4}{4} \right\rangle + \left\langle -\frac{1}{3}, -\frac{1}{2}, -\frac{1}{4} \right\rangle = \left\langle \frac{t^3}{3} - t - \frac{1}{3}, \frac{t^2}{2} + t - \frac{1}{2}, \frac{t^4}{4} - \frac{1}{4} \right\rangle$$

Using integration componentwise once more we get:

$$\begin{aligned}\mathbf{r}(t) &= \int \left\langle \frac{t^3}{3} - t - \frac{1}{3}, \frac{t^2}{2} + t - \frac{1}{2}, \frac{t^4}{4} - \frac{1}{4} \right\rangle dt \\ &= \left\langle \int \frac{t^3}{3} - t - \frac{1}{3}\, dt, \int \frac{t^2}{2} + t - \frac{1}{2}\, dt, \int \frac{t^4}{4} - \frac{1}{4}\, dt \right\rangle \\ &= \left\langle \frac{t^4}{12} - \frac{t^2}{2} - \frac{t}{3}, \frac{t^3}{6} + \frac{t^2}{2} - \frac{t}{2}, \frac{t^5}{20} - \frac{t}{4} \right\rangle + \mathbf{c}_2\end{aligned}$$

Using the initial condition, $\mathbf{r}(1) = \langle 1, 0, 0 \rangle$ we get:

$$\mathbf{r}(1) = \langle 1, 0, 0 \rangle = \left\langle -\frac{3}{4}, \frac{1}{6}, -\frac{1}{5} \right\rangle + \mathbf{c}_2$$

and

$$\mathbf{c}_2 = \left\langle \frac{7}{4}, -\frac{1}{6}, \frac{1}{5} \right\rangle$$

Therefore,

$$\begin{aligned}\mathbf{r}(t) &= \left\langle \frac{t^4}{12} - \frac{t^2}{2} - \frac{t}{3}, \frac{t^3}{6} + \frac{t^2}{2} - \frac{t}{2}, \frac{t^5}{20} - \frac{t}{4} \right\rangle + \left\langle \frac{7}{4}, -\frac{1}{6}, \frac{1}{5} \right\rangle \\ &= \left\langle \frac{t^4}{12} - \frac{t^2}{2} - \frac{t}{3} + \frac{7}{4}, \frac{t^3}{6} + \frac{t^2}{2} - \frac{t}{2} - \frac{1}{6}, \frac{t^5}{20} - \frac{t}{4} + \frac{1}{5} \right\rangle\end{aligned}$$

21. Compute the length of the path

$$\mathbf{r}(t) = \left\langle \sin 2t, \cos 2t, 3t - 1 \right\rangle \quad \text{for } 1 \le t \le 3$$

SOLUTION We use the formula for the arc length:

$$s = \int_1^3 \|\mathbf{r}'(t)\|\, dt \tag{1}$$

We compute the derivative vector $\mathbf{r}'(t)$ and its length:

$$\begin{aligned}\mathbf{r}'(t) &= \langle 2\cos 2t, -2\sin 2t, 3 \rangle \\ \|\mathbf{r}'(t)\| &= \sqrt{(2\cos 2t)^2 + (-2\sin 2t)^2 + 3^2} = \sqrt{4\cos^2 2t + 4\sin^2 2t + 9} \\ &= \sqrt{4\left(\cos^2 2t + \sin^2 2t\right) + 9} = \sqrt{4 \cdot 1 + 9} = \sqrt{13}\end{aligned}$$

We substitute in (1) and compute the integral to obtain the following length:

$$s = \int_1^3 \sqrt{13}\, dt = \sqrt{13}t \Big|_1^3 = 2\sqrt{13}.$$

22. CAS Express the length of the path $\mathbf{r}(t) = \left\langle \ln t, t, e^t \right\rangle$ for $1 \le t \le 2$ as a definite integral, and use a computer algebra system to find its value to two decimal places.

SOLUTION By the arc length formula we have

$$s = \int_1^2 \|\mathbf{r}'(t)\|\, dt \tag{1}$$

We compute the vector $\mathbf{r}'(t)$ and its length:

$$\begin{aligned}\mathbf{r}'(t) &= \left\langle \frac{1}{t}, 1, e^t \right\rangle \\ \|\mathbf{r}'(t)\| &= \sqrt{\left(\frac{1}{t}\right)^2 + 1^2 + \left(e^t\right)^2} = \sqrt{t^{-2} + 1 + e^{2t}}\end{aligned}$$

Combining with (1) we get:

$$s = \int_1^2 \sqrt{t^{-2} + 1 + e^{2t}}\, dt$$

Using a CAS we obtain the following approximation:

$$s \approx 4.84677$$

23. Find an arc length parametrization of a helix of height 20 cm that makes four full rotations over a circle of radius 5 cm.

SOLUTION Since the radius is 5 cm and the height is 20 cm, the helix is traced by a parametrization of the form:

$$\mathbf{r}(t) = \langle 5\cos at, 5\sin at, t\rangle, \quad 0 \le t \le 20$$

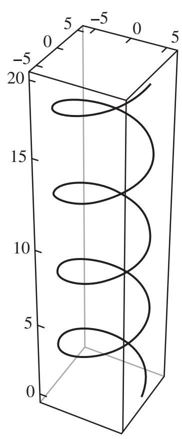
Since the helix makes exactly 4 full rotations, we have:

$$a \cdot 20 = 4 \cdot 2\pi \quad \Rightarrow \quad a = \frac{2\pi}{5}$$

The parametrization of the helix is, thus:

$$\mathbf{r}(t) = \left\langle 5\cos\frac{2\pi t}{5}, 5\sin\frac{2\pi t}{5}, t\right\rangle, \quad 0 \le t \le 20$$

The helix is shown in the following figure:



To find the arc length parametrization for the helix, we use:

$$s(t) = \int_0^t \|\mathbf{r}'(u)\|\, du \tag{1}$$

We find $\mathbf{r}'(t)$ and its length:

$$\mathbf{r}'(t) = \left\langle -5 \cdot \frac{2\pi}{5}\sin\frac{2\pi t}{5}, 5 \cdot \frac{2\pi}{5}\cos\frac{2\pi t}{5}, 1\right\rangle = \left\langle -2\pi\sin\frac{2\pi t}{5}, 2\pi\cos\frac{2\pi t}{5}, 1\right\rangle$$

$$\|\mathbf{r}'(t)\| = \sqrt{4\pi^2\sin^2\frac{2\pi t}{5} + 4\pi^2\cos^2\frac{2\pi t}{5} + 1} = \sqrt{4\pi^2\left(\sin^2\frac{2\pi t}{5} + \cos^2\frac{2\pi t}{5}\right) + 1} = \sqrt{1 + 4\pi^2}$$

Substituting in (1) we get:

$$s(t) = \int_0^t \sqrt{1 + 4\pi^2}\, du = t\sqrt{1 + 4\pi^2}$$

Therefore, we let $s = t\sqrt{1 + 4\pi^2}$ and thus,

$$t = \frac{s}{\sqrt{1 + 4\pi^2}} = g(s)$$

Thus, we can write

$$\mathbf{r}(s) = \left\langle 5\cos\frac{sa}{\sqrt{1 + 4\pi^2}}, 5\sin\frac{sa}{\sqrt{1 + 4\pi^2}}, \frac{s}{\sqrt{1 + 4\pi^2}}\right\rangle, \quad 0 \le s \le 20\sqrt{1 + 4\pi^2} \approx 127.245$$

24. Find the minimum speed of a particle with trajectory $\mathbf{r}(t) = \langle t, e^{t-3}, e^{4-t} \rangle$.

SOLUTION The speed of the particle is the following function:

$$v(t) = \|\mathbf{r}'(t)\|$$

We compute the derivative vector $\mathbf{r}'(t)$ and its length:

$$\mathbf{r}'(t) = \frac{d}{dt}\langle t, e^{t-3}, e^{4-t} \rangle = \langle 1, e^{t-3}, -e^{4-t} \rangle$$
$$\|\mathbf{r}'(t)\| = \sqrt{1^2 + (e^{t-3})^2 + (-e^{4-t})^2} = \sqrt{1 + e^{2t-6} + e^{8-2t}}$$

Therefore:

$$v(t) = \sqrt{1 + e^{2t-6} + e^{8-2t}}$$

Since the function $f(x) = x^2$ is increasing for $x \geq 0$, $v(t)$ and $v^2(t)$ assume their minimum values at the same value of t. Thus, we minimize the function:

$$F(t) = v^2(t) = 1 + e^{2t-6} + e^{8-2t}$$

We compute the critical point by solving $F'(t) = 0$. This gives:

$$F'(t) = 2e^{2t-6} - 2e^{8-2t} = 0$$
$$e^{2t-6} = e^{8-2t}$$

Therefore:

$$2t - 6 = 8 - 2t$$
$$4t = 14 \quad \Rightarrow \quad t = \frac{7}{2}$$

We compute the second derivative and substitute $t = \frac{7}{2}$:

$$F''(t) = 4e^{2t-6} + 4e^{8-2t}$$
$$F''\left(\frac{7}{2}\right) = 4e^{2\cdot(7/2)-6} + 4e^{8-2\cdot(7/2)} = 4e + 4e = 8e > 0$$

The Second Derivative Test implies that $F(t)$, hence $v(t)$ as well, have a minimum at $t = \frac{7}{2}$. The minimum speed is:

$$v\left(\frac{7}{2}\right) = \sqrt{1 + e^{2\cdot(7/2)-6} + e^{8-2\cdot(7/2)}} = \sqrt{1 + 2e}$$

25. A projectile fired at an angle of 60° lands 400 m away. What was its initial speed?

SOLUTION Place the projectile at the origin, and let $\mathbf{r}(t)$ be the position vector of the projectile.

Step 1. Use Newton's Law

Gravity exerts a downward force of magnitude mg, where m is the mass of the bullet and $g = 9.8$ m/s^2. In vector form,

$$\mathbf{F} = \langle 0, -mg \rangle = m \langle 0, -g \rangle$$

Newton's Second Law $\mathbf{F} = m\mathbf{r}'(t)$ yields $m \langle 0, -g \rangle = m\mathbf{r}''(t)$ or $\mathbf{r}''(t) = \langle 0, -g \rangle$. We determine $\mathbf{r}(t)$ by integrating twice:

$$\mathbf{r}'(t) = \int_0^t \mathbf{r}''(u)\, du = \int_0^t \langle 0, -g \rangle \, du = \langle 0, -gt \rangle + \mathbf{v}_0$$
$$\mathbf{r}(t) = \int_0^t \mathbf{r}'(u)\, du = \int_0^t (\langle 0, -gu \rangle + \mathbf{v}_0)\, du = \left\langle 0, -\frac{1}{2}gt^2 \right\rangle + t\mathbf{v}_0 + \mathbf{r}_0$$

Step 2. Use the initial conditions

By our choice of coordinates, $\mathbf{r}_0 = \mathbf{0}$. The initial velocity $\mathbf{v}_0$ has unknown magnitude v_0, but we know that it points in the direction of the unit vector $\langle \cos 60°, \sin 60° \rangle$. Therefore,

$$\mathbf{v}_0 = v_0 \langle \cos 60°, \sin 60° \rangle = v_0 \left\langle \frac{1}{2}, \frac{\sqrt{3}}{2} \right\rangle$$
$$\mathbf{r}(t) = \left\langle 0, -\frac{1}{2}gt^2 \right\rangle + t v_0 \left\langle \frac{1}{2}, \frac{\sqrt{3}}{2} \right\rangle$$

Step 3. Solve for v_0.

The projectile hits the point $\langle 400, 0\rangle$ on the ground if there exists a time t such that $\mathbf{r}(t) = \langle 400, 0\rangle$; that is,

$$\left\langle 0, -\frac{1}{2}gt^2\right\rangle + tv_0\left\langle \frac{1}{2}, \frac{\sqrt{3}}{2}\right\rangle = \langle 400, 0\rangle$$

Equating components, we obtain

$$\frac{1}{2}tv_0 = 400, \quad -\frac{1}{2}gt^2 + \frac{\sqrt{3}}{2}tv_0 = 0$$

The first equation yields $t = \frac{800}{v_0}$. Now substitute in the second equation and solve, using $g = 9.8\text{m/s}^2$:

$$-4.9\left(\frac{800}{v_0}\right)^2 + \frac{\sqrt{3}}{2}\left(\frac{800}{v_0}\right)v_0 = 0$$

$$\left(\frac{800}{v_0}\right)^2 = \frac{400\sqrt{3}}{4.9}$$

$$\left(\frac{v_0}{800}\right)^2 = \frac{4.9}{400\sqrt{3}} \approx 0.00707$$

$$v_0^2 = 4526.42611, \quad v_0 \approx 67.279 \text{ m/s}$$

We obtain $v_0 \approx 67.279$ m/s.

26. A specially trained mouse runs counterclockwise in a circle of radius 0.6 m on the floor of an elevator with speed 0.3 m/s while the elevator ascends from ground level (along the z-axis) at a speed of 12 m/s. Find the mouse's acceleration vector as a function of time. Assume that the circle is centered at the origin of the xy-plane and the mouse is at $(2, 0, 0)$ at $t = 0$.

SOLUTION The x and y coordinates must trace out a circle of radius 0.6 at speed 0.3, starting at $x = 2$ and $y = 0$, so it seems reasonable to choose $x(t) = 0.6\cos\frac{t}{\sqrt{1.2}}$ and $y(t) = 0.6\sin\frac{t}{\sqrt{1.2}}$. Notice that $\left[x'(t)\right]^2 + \left[y'(t)\right]^2 = 0.3$, so this choice of $x(t)$ and $y(t)$ really does trace out a circle with speed 0.3. The z coordinate must give a (vertical) speed of 12, so $z(t) = 12t$. Thus, we have

$$\mathbf{r}(t) = \left\langle 0.6\cos\frac{t}{\sqrt{1.2}}, 0.6\sin\frac{t}{\sqrt{1.2}}, 12t\right\rangle$$

so

$$\mathbf{r}'(t) = \left\langle -\frac{0.6}{\sqrt{1.2}}\sin\frac{t}{\sqrt{1.2}}, \frac{0.6}{\sqrt{1.2}}\cos\frac{t}{\sqrt{1.2}}, 12\right\rangle$$

and

$$\mathbf{r}''(t) = \left\langle -\frac{1}{2}\cos\frac{t}{\sqrt{1.2}}, -\frac{1}{2}\sin\frac{t}{\sqrt{1.2}}, 0\right\rangle,$$

which is the acceleration vector.

27. During a short time interval $[0.5, 1.5]$, the path of an unmanned spy plane is described by

$$\mathbf{r}(t) = \left\langle -\frac{100}{t^2}, 7 - t, 40 - t^2\right\rangle$$

A laser is fired (in the tangential direction) toward the yz-plane at time $t = 1$. Which point in the yz-plane does the laser beam hit?

SOLUTION Notice first that by differentiating we get the tangent vector:

$$\mathbf{r}'(t) = \left\langle \frac{200}{t^3}, -1, -2t\right\rangle, \quad \Rightarrow \quad \mathbf{r}'(1) = \langle 200, -1, -2\rangle$$

and the tangent line to the path would be:

$$\ell(s) = \mathbf{r}(1) + s\mathbf{r}'(1) = \langle -100, 6, 39\rangle + s\langle 200, -1, -2\rangle = \langle -100 + 200s, 6 - s, 39 - 2s\rangle$$

If the laser is fired in the tangential direction toward the yz-plane means that the x-coordinate will be zero - this is when $s = 1/2$. Therefore,

$$\ell(1/2) = \langle 0, 11/2, 38\rangle$$

Hence, the laser beam will hit the point $(0, 11/2, 38)$.

28. A force $\mathbf{F} = \langle 12t + 4, 8 - 24t \rangle$ (in newtons) acts on a 2-kg mass. Find the position of the mass at $t = 2$ s if it is located at $(4, 6)$ at $t = 0$ and has initial velocity $\langle 2, 3 \rangle$ in m/s.

SOLUTION Recall the formula $\mathbf{F} = m\mathbf{a}$ then using $\mathbf{F} = \langle 12t + 4, 8 - 24t \rangle$ and $m = 2$ we get:

$$\langle 12t + 4, 8 - 24t \rangle = 2\mathbf{a}, \quad \Rightarrow \quad \mathbf{a}(t) = \mathbf{r}''(t) = \langle 6t + 2, 4 - 12t \rangle$$

Then using componentwise integration,

$$\mathbf{v}(t) = \int \mathbf{a}(t)\,dt = \int \langle 6t + 2, 4 - 12t \rangle\,dt = \left\langle 3t^2 + 2t, 4t - 6t^2 \right\rangle + \mathbf{c}_1$$

Using the initial condition $\mathbf{v}_0 = \mathbf{v}(0) = \langle 2, 3 \rangle$, we get:

$$\mathbf{v}(0) = \langle 2, 3 \rangle = \mathbf{c}_1$$

and therefore,

$$\mathbf{v}(t) = \left\langle 3t^2 + 2t + 2, 4t - 6t^2 + 3 \right\rangle$$

Using componentwise integration once more,

$$\mathbf{r}(t) = \int \mathbf{v}(t)\,dt = \int \left\langle 3t^2 + 2t + 2, 4t - 6t^2 + 3 \right\rangle dt = \left\langle t^3 + t^2 + 2t, 2t^2 - 2t^3 + 3t \right\rangle + \mathbf{c}_2$$

Using the initial condition $\mathbf{r}(0) = \langle 4, 6 \rangle$ we get:

$$\mathbf{r}(0) = \langle 4, 6 \rangle = \mathbf{c}_2$$

Therefore,

$$\mathbf{r}(t) = \left\langle t^3 + t^2 + 2t + 4, 2t^2 - 2t^3 + 3t + 6 \right\rangle$$

and the position of the mass at $t = 2$ is $\mathbf{r}(2) = \langle 20, 4 \rangle$.

29. Find the unit tangent vector to $\mathbf{r}(t) = \langle \sin t, t, \cos t \rangle$ at $t = \pi$.

SOLUTION The unit tangent vector at $t = \pi$ is

$$\mathbf{T}(\pi) = \frac{\mathbf{r}'(\pi)}{\|\mathbf{r}'(\pi)\|} \tag{1}$$

We differentiate $\mathbf{r}(t)$ componentwise to obtain:

$$\mathbf{r}'(t) = \langle \cos t, 1, -\sin t \rangle$$

Therefore,

$$\mathbf{r}'(\pi) = \langle \cos \pi, 1, -\sin \pi \rangle = \langle -1, 1, 0 \rangle$$

We compute the length of $\mathbf{r}'(\pi)$:

$$\|\mathbf{r}'(\pi)\| = \sqrt{(-1)^2 + 1^2 + 0^2} = \sqrt{2}$$

Substituting in (1) gives:

$$\mathbf{T}(\pi) = \left\langle \frac{-1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 0 \right\rangle$$

30. Find the unit tangent vector to $\mathbf{r}(t) = \langle t^2, \tan^{-1} t, t \rangle$ at $t = 1$.

SOLUTION The unit tangent vector at $t = 1$ is the following vector:

$$\mathbf{T}(1) = \frac{\mathbf{r}'(1)}{\|\mathbf{r}'(1)\|} \tag{1}$$

We differentiate $\mathbf{r}(t) = \langle t^2, \tan^{-1} t, t \rangle$ componentwise:

$$\mathbf{r}'(t) = \left\langle 2t, \frac{1}{1 + t^2}, 1 \right\rangle$$

Setting $t = 1$, we get:

$$\mathbf{r}'(1) = \left\langle 2 \cdot 1, \frac{1}{1+1^2}, 1 \right\rangle = \left\langle 2, \frac{1}{2}, 1 \right\rangle$$

$$\|\mathbf{r}'(1)\| = \sqrt{2^2 + \left(\frac{1}{2}\right)^2 + 1^2} = \frac{\sqrt{21}}{2}$$

Substituting in (1) we obtain the following unit tangent vector:

$$\mathbf{T}(1) = \frac{2}{\sqrt{21}} \left\langle 2, \frac{1}{2}, 1 \right\rangle = \left\langle \frac{4}{\sqrt{21}}, \frac{1}{\sqrt{21}}, \frac{2}{\sqrt{21}} \right\rangle$$

31. Calculate $\kappa(1)$ for $\mathbf{r}(t) = \langle \ln t, t \rangle$.

SOLUTION Recall,

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3}$$

Computing derivatives we get:

$$\mathbf{r}'(t) = \left\langle \frac{1}{t}, 1 \right\rangle, \quad \Rightarrow \quad \mathbf{r}'(1) = \langle 1, 1 \rangle, \quad \Rightarrow \quad \|\mathbf{r}'(1)\| = \sqrt{2}$$

$$\mathbf{r}''(t) = \left\langle -\frac{1}{t^2}, 0 \right\rangle, \quad \Rightarrow \quad \mathbf{r}''(1) = \langle -1, 0 \rangle$$

Computing the cross product we get:

$$\mathbf{r}'(1) \times \mathbf{r}''(1) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & 0 \\ -1 & 0 & 0 \end{vmatrix} = \langle 0, 0, 1 \rangle$$

and $\|\mathbf{r}'(1) \times \mathbf{r}''(1)\| = 1$. Therefore,

$$\kappa(1) = \frac{\|\mathbf{r}'(1) \times \mathbf{r}''(1)\|}{\|\mathbf{r}'(1)\|^3} = \frac{1}{(\sqrt{2})^3} = \frac{1}{2^{3/2}}$$

32. Calculate $\kappa\left(\frac{\pi}{4}\right)$ for $\mathbf{r}(t) = \langle \tan t, \sec t, \cos t \rangle$.

SOLUTION Recall,

$$\kappa(t) = \frac{\|\mathbf{r}'(t) \times \mathbf{r}''(t)\|}{\|\mathbf{r}'(t)\|^3}$$

Computing derivatives we get:

$$\mathbf{r}'(t) = \left\langle \sec^2 t, \sec t \tan t, -\sin t \right\rangle, \quad \Rightarrow \quad \mathbf{r}'\left(\frac{\pi}{4}\right) = \left\langle 2, \sqrt{2}, -\frac{1}{\sqrt{2}} \right\rangle$$

$$\mathbf{r}''(t) = \left\langle 2\sec^2 t \tan t, \sec^3 t + \tan^2 t \sec t, -\cos t \right\rangle, \quad \Rightarrow \quad \mathbf{r}''\left(\frac{\pi}{4}\right) = \left\langle 4, 3\sqrt{2}, -\frac{1}{\sqrt{2}} \right\rangle$$

Note here that $\|\mathbf{r}'(\pi/4)\| = \sqrt{4+2+1/2} = \sqrt{\frac{13}{2}}$. Computing cross products we get:

$$\mathbf{r}'(t) \times \mathbf{r}''(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & \sqrt{2} & -\frac{1}{\sqrt{2}} \\ 4 & 3\sqrt{2} & -\frac{1}{\sqrt{2}} \end{vmatrix} = \left\langle 2, -\sqrt{2}, 2\sqrt{2} \right\rangle$$

where $\|\mathbf{r}'(t) \times \mathbf{r}''(t)\| = \sqrt{4+2+8} = \sqrt{14}$. Therefore,

$$\kappa(\pi/4) = \frac{\|\mathbf{r}'(\pi/4) \times \mathbf{r}''(\pi/4)\|}{\|\mathbf{r}'(\pi/4)\|^3} = \frac{\sqrt{14}}{(\sqrt{13/2})^3} = \frac{2\sqrt{28}}{13^{3/2}}$$

In Exercises 33 and 34, write the acceleration vector **a** *at the point indicated as a sum of tangential and normal components.*

33. $\mathbf{r}(\theta) = \langle \cos\theta, \sin 2\theta \rangle, \quad \theta = \frac{\pi}{4}$

SOLUTION First note here that:

$$\mathbf{v}(\theta) = \mathbf{r}'(\theta) = \langle -\sin\theta, 2\cos 2\theta \rangle$$
$$\mathbf{a}(\theta) = \mathbf{r}''(\theta) = \langle -\cos\theta, -4\sin 2\theta \rangle$$

At $t = \pi/4$ we have:

$$\mathbf{v} = \mathbf{r}'(\pi/4) = \left\langle -\frac{1}{\sqrt{2}}, 0 \right\rangle$$
$$\mathbf{a} = \mathbf{r}''(\pi/4) = \left\langle -\frac{1}{\sqrt{2}}, -4 \right\rangle$$

Thus,

$$\mathbf{a}\cdot\mathbf{v} = \left\langle -\frac{1}{\sqrt{2}}, -4 \right\rangle \cdot \left\langle -\frac{1}{\sqrt{2}}, 0 \right\rangle = \frac{1}{2}$$
$$\|\mathbf{v}\| = \sqrt{\frac{1}{2} + 0} = \frac{1}{\sqrt{2}}$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\left\langle -\frac{1}{\sqrt{2}}, 0 \right\rangle}{1/\sqrt{2}} = \langle -1, 0 \rangle$$
$$a_{\mathbf{T}} = \frac{\mathbf{a}\cdot\mathbf{v}}{\|\mathbf{v}\|} = \frac{1/2}{1/\sqrt{2}} = \frac{1}{\sqrt{2}}$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} = \left\langle -\frac{1}{\sqrt{2}}, -4 \right\rangle - \frac{1}{\sqrt{2}}\langle -1, 0 \rangle = \langle 0, -4 \rangle$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = 4$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\langle 0, -4 \rangle}{4} = \langle 0, -1 \rangle$$

Finally, we obtain the decomposition,

$$\mathbf{a} = \left\langle -\frac{1}{\sqrt{2}}, -4 \right\rangle = \frac{1}{\sqrt{2}}\mathbf{T} + 4\mathbf{N}$$

where $\mathbf{T} = \langle -1, 0 \rangle$ and $\mathbf{N} = \langle 0, -1 \rangle$.

34. $\mathbf{r}(t) = \langle t^2, 2t - t^2, t \rangle, \quad t = 2$

SOLUTION First note here that:

$$\mathbf{v}(t) = \mathbf{r}'(t) = \langle 2t, 2 - 2t, 1 \rangle$$
$$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 2, -2, 0 \rangle$$

At $t = 2$ we have:

$$\mathbf{v} = \mathbf{r}'(2) = \langle 4, -2, 1 \rangle$$
$$\mathbf{a} = \mathbf{r}''(2) = \langle 2, -2, 0 \rangle$$

Thus,

$$\mathbf{a}\cdot\mathbf{v} = \langle 4, -2, 1 \rangle \cdot \langle 2, -2, 0 \rangle = 12$$
$$\|\mathbf{v}\| = \sqrt{16 + 4 + 1} = \sqrt{21}$$

Recall that we have:

$$\mathbf{T} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 4, -2, 1\rangle}{\sqrt{21}} = \frac{1}{\sqrt{21}}\langle 4, -2, 1\rangle$$

$$a_{\mathbf{T}} = \frac{\mathbf{a}\cdot\mathbf{v}}{\|\mathbf{v}\|} = \frac{12}{\sqrt{21}} = \frac{4\sqrt{21}}{7}$$

Next, we compute $a_{\mathbf{N}}$ and $\mathbf{N}$:

$$\begin{aligned} a_{\mathbf{N}}\mathbf{N} = \mathbf{a} - a_{\mathbf{T}}\mathbf{T} &= \langle 2, -2, 0\rangle - \frac{12}{\sqrt{21}}\frac{1}{\sqrt{21}}\langle 4, -2, 1\rangle \\ &= \langle 2, -2, 0\rangle - \frac{4}{7}\langle 4, -2, 1\rangle = \left\langle -\frac{2}{7}, -\frac{6}{7}, -\frac{4}{7}\right\rangle \\ &= \frac{2}{7}\langle -1, -3, -2\rangle \end{aligned}$$

This vector has length:

$$a_{\mathbf{N}} = \|a_{\mathbf{N}}\mathbf{N}\| = \frac{2}{7}\sqrt{1+9+4} = \frac{2\sqrt{14}}{7}$$

and thus,

$$\mathbf{N} = \frac{a_{\mathbf{N}}\mathbf{N}}{a_{\mathbf{N}}} = \frac{\frac{2}{7}\langle -1, -3, -2\rangle}{\frac{2\sqrt{14}}{7}} = \frac{1}{\sqrt{14}}\langle -1, -3, -2\rangle$$

Finally, we obtain the decomposition,

$$\mathbf{a} = \langle 2, -2, 0\rangle = \frac{4\sqrt{21}}{7}\mathbf{T} + \frac{2\sqrt{14}}{7}\mathbf{N}$$

where $\mathbf{T} = \frac{1}{\sqrt{21}}\langle 4, -2, 1\rangle$ and $\mathbf{N} = \frac{1}{\sqrt{14}}\langle -1, -3, -2\rangle$.

35. At a certain time t_0, the path of a moving particle is tangent to the y-axis in the positive direction. The particle's speed at time t_0 is 4 m/s, and its acceleration vector is $\mathbf{a} = \langle 5, 4, 12\rangle$. Determine the curvature of the path at t_0.

SOLUTION We are given that the particle is moving tangent to the y-axis with speed 4 m/s, so then:

$$\mathbf{r}' = \langle 0, 4, 0\rangle$$

and $\mathbf{a} = \mathbf{r}'' = \langle 5, 4, 12\rangle$. Recall the formula for curvature:

$$\kappa = \frac{\|\mathbf{r}' \times \mathbf{r}''\|}{\|\mathbf{r}'\|^3}$$

First calculate the cross product:

$$\mathbf{r}' \times \mathbf{r}'' = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 4 & 0 \\ 5 & 4 & 12 \end{vmatrix} = \langle 48, 0, -20\rangle$$

Then the length of $\mathbf{r}'$ and $\mathbf{r}' \times \mathbf{r}''$:

$$\|\mathbf{r}'\| = 4, \quad \|\mathbf{r}' \times \mathbf{r}''\| = \sqrt{48^2 + 20^2} = \sqrt{2704} = 52$$

so then for curvature we get:

$$\kappa = \frac{\|\mathbf{r}' \times \mathbf{r}''\|}{\|\mathbf{r}'\|^3} = \frac{52}{4^3} = \frac{13}{16}$$

36. Parametrize the osculating circle to $y = x^2 - x^3$ at $x = 1$.

SOLUTION First differentiate twice:

$$f'(x) = 2x - 3x^2, \quad f''(x) = 2 - 6x$$

and at the point $x = 1$ we get:

$$f'(1) = -1, \quad f''(1) = -4$$

Step 1. Find the radius Recall the formula for curvature:

$$\kappa(x) = \frac{|f''(x)|}{[1 + (f'(x))^2]^{3/2}}$$

and evaluating at $x = 1$ we have:

$$\kappa(1) = \frac{4}{[1 + (-1)^2]^{3/2}} = \frac{4}{2^{3/2}} = \sqrt{2}$$

Therefore, the radius of the osculating circle is $R = \frac{1}{\sqrt{2}}$.

Step 2. Find N at $x = 1$.

First we will parametrize the curve $f(x) = x^2 - x^3$ as:

$$\mathbf{r}(x) = \left\langle x, x^2 - x^3 \right\rangle, \quad \mathbf{r}(1) = \langle 1, 0 \rangle$$

and differentiate:

$$\mathbf{r}'(x) = \left\langle 1, 2x - 3x^2 \right\rangle$$

Note here that the vector $\left\langle 2x - 3x^2, -1 \right\rangle$ is orthogonal to $\mathbf{r}'(x)$ for all values of x and points in the direction of the bending of the curve $y = x^2 - x^3$.

Computing the unit normal to the curve, using the vector orthogonal to $\mathbf{r}'(x)$, we get:

$$\mathbf{N}(x) = \frac{\left\langle 2x - 3x^2, -1 \right\rangle}{\sqrt{(2x - 3x^2)^2 + 1}}, \quad \mathbf{N}(1) = \frac{1}{\sqrt{2}} \langle -1, -1 \rangle$$

Step 3. Find the center Q

Now to find the center Q of the osculating circle:

$$\begin{aligned} \overrightarrow{OQ} &= \mathbf{r}(1) + \kappa^{-1}\mathbf{N}(1) \\ &= \langle 1, 0 \rangle + \frac{1}{\sqrt{2}} \frac{1}{\sqrt{2}} \langle -1, -1 \rangle \\ &= \left\langle \frac{1}{2}, -\frac{1}{2} \right\rangle \end{aligned}$$

The center of the osculating circle is $Q = (1/2, -1/2)$.

Step 4. Parametrize the osculating circle.

Then parametrizing the osculating circle we get:

$$\mathbf{c}(t) = \left\langle \frac{1}{2}, -\frac{1}{2} \right\rangle + \frac{1}{\sqrt{2}} \langle \cos t, \sin t \rangle$$

37. Parametrize the osculating circle to $y = \sqrt{x}$ at $x = 4$.

SOLUTION First differentiate twice:

$$f'(x) = \frac{1}{2\sqrt{x}}, \quad f''(x) = -\frac{1}{4x^{3/2}}$$

and at the point $x = 4$ we get:

$$f'(4) = \frac{1}{4}, \quad f''(4) = -\frac{1}{32}$$

Step 1. Find the radius

Then recall the formula for curvature:

$$\kappa(x) = \frac{|f''(x)|}{[1 + (f'(x))^2]^{3/2}}$$

and evaluating at $x = 4$ we have:

$$\kappa(4) = \frac{\frac{1}{32}}{\left[1 + \frac{1}{16}\right]^{3/2}} = \frac{1}{32} \cdot \frac{1}{\left(\frac{17}{16}\right)^{3/2}} = \frac{1}{32} \frac{16^{3/2}}{17^{3/2}} = \frac{2}{17^{3/2}}$$

Therefore the radius of the osculating circle is $R = \frac{17^{3/2}}{2}$.

Step 2. Find N at $x = 4$

First we will parametrize the curve $f(x) = \sqrt{x}$ as:

$$\mathbf{r}(x) = \left\langle x, \sqrt{x} \right\rangle, \quad \mathbf{r}(4) = \langle 4, 2 \rangle$$

and differentiate:

$$\mathbf{r}'(x) = \left\langle 1, \frac{1}{2}x^{-1/2} \right\rangle$$

Note here that the vector $\left\langle \frac{1}{2}x^{-1/2}, -1 \right\rangle$ is orthogonal to $\mathbf{r}'(x)$ for all values of x and points in the direction of the bending of the curve $y = \sqrt{x}$.

Computing the unit normal to the curve, using the vector orthogonal to $\mathbf{r}'(x)$ we get:

$$\mathbf{N}(x) = \frac{\left\langle \frac{1}{2}x^{-1/2}, -1 \right\rangle}{\sqrt{\frac{1}{4x} + 1}}, \quad \mathbf{N}(4) = \frac{\left\langle \frac{1}{4}, -1 \right\rangle}{\sqrt{\frac{1}{16} + 1}} = \frac{4}{\sqrt{17}} \left\langle \frac{1}{4}, -1 \right\rangle$$

Step 3. Find the center Q

Now to find the center Q of the osculating circle:

$$\begin{aligned}
\overrightarrow{OQ} &= \mathbf{r}(4) + \kappa^{-1}\mathbf{N}(4) \\
&= \langle 4, 2 \rangle + \frac{17^{3/2}}{2} \frac{4}{\sqrt{17}} \left\langle \frac{1}{4}, -1 \right\rangle \\
&= \langle 4, 2 \rangle + 34 \left\langle \frac{1}{4}, -1 \right\rangle \\
&= \langle 4, 2 \rangle + \left\langle \frac{17}{2}, -34 \right\rangle \\
&= \left\langle \frac{25}{2}, -32 \right\rangle
\end{aligned}$$

The center of the osculating circle is $Q = (\frac{25}{2}, -32)$.

Step 4. Parametrize the osculating circle

Then parametrizing the osculating circle we get:

$$\mathbf{c}(t) = \left\langle \frac{25}{2}, -32 \right\rangle + \frac{17^{3/2}}{2} \langle \cos t, \sin t \rangle$$

38. If a planet has zero mass ($m = 0$), then Newton's laws of motion reduce to $\mathbf{r}''(t) = \mathbf{0}$ and the orbit is a straight line $\mathbf{r}(t) = \mathbf{r}_0 + t\mathbf{v}_0$, where $\mathbf{r}_0 = \mathbf{r}(0)$ and $\mathbf{v}_0 = \mathbf{r}'(0)$ (Figure 1). Show that the area swept out by the radial vector at time t is $A(t) = \frac{1}{2}\|\mathbf{r}_0 \times \mathbf{v}_0\| t$ and thus Kepler's Second Law continues to hold (the rate is constant).

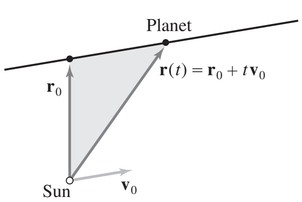


FIGURE 1

SOLUTION Integrating $\mathbf{r}''(t) = \mathbf{0}$ gives:

$$\mathbf{r}'(t) = \mathbf{c}$$

The constant $\mathbf{c}$ is $\mathbf{r}'(0) = \mathbf{v}(0)$. That is,

$$\mathbf{r}'(t) = \mathbf{v}$$

We integrate again:

$$\mathbf{r}(t) = \mathbf{v}t + \mathbf{d}$$

The constant $\mathbf{d}$ is $\mathbf{r} = \mathbf{r}(0)$. Hence, $\mathbf{r}(t) = \mathbf{r} + t\mathbf{v}$, where $\mathbf{r} = \mathbf{r}(0)$ and $\mathbf{v} = \mathbf{r}'(0)$.

39. Suppose the orbit of a planet is an ellipse of eccentricity $e = c/a$ and period T (Figure 2). Use Kepler's Second Law to show that the time required to travel from A' to B' is equal to

$$\left(\frac{1}{4} + \frac{e}{2\pi}\right)T$$

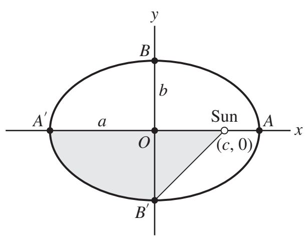

FIGURE 2

SOLUTION By the Law of Equal Areas, the position vector pointing from the sun to the planet sweeps out equal areas in equal times. We denote by S_1 the area swept by the position vector when the planet moves from A' to B', and t is the desired time. Since the position vector sweeps out the whole area of the ellipse (πab) in time T, the Law of Equal Areas implies that:

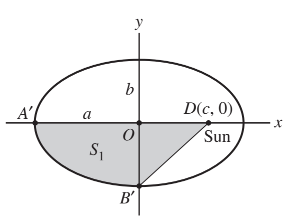
$$\frac{S_1}{\pi ab} = \frac{t}{T} \quad \Rightarrow \quad t = \frac{TS_1}{\pi ab} \tag{1}$$

We now find the area S_1 as the sum of the area of a quarter of the ellipse and the area of the triangle ODB. That is,

$$S_1 = \frac{\pi ab}{4} + \frac{\overline{OD} \cdot \overline{OB}'}{2} = \frac{\pi ab}{4} + \frac{cb}{2} = \frac{b}{4}(\pi a + 2c)$$

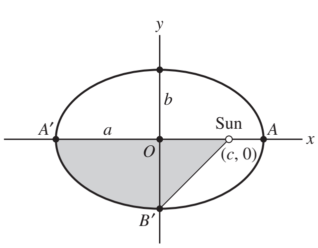
Substituting in (1) we get:

$$t = \frac{Tb(\pi a + 2c)}{4\pi ab} = \frac{T(\pi a + 2c)}{4\pi a} = T\left(\frac{1}{4} + \frac{1}{2\pi}\frac{c}{a}\right) = T\left(\frac{1}{4} + \frac{e}{2\pi}\right)$$



40. The period of Mercury is approximately 88 days, and its orbit has eccentricity 0.205. How much longer does it take Mercury to travel from A' to B' than from B' to A (Figure 2)?

SOLUTION



Let T denote the period of the orbit. By the previous exercise, the time T_1 takes the planet to travel from A' to B' is,

$$T_1 = \left(\frac{1}{4} + \frac{e}{2\pi}\right)T$$

The period of Mercury is $T = 88$ days and the eccentricity of the orbit is $e = 0.205$, hence,

$$T_1 = \left(\frac{1}{4} + \frac{0.205}{2\pi}\right) \cdot 88 \approx 24.871 \text{ days}$$

Using Kepler's Second Law, the time that takes Mercury to travel from A' to A is half a period. Therefore, the time T_2 that it takes for Mercury to travel from B' to A is the difference:

$$T_2 = \frac{1}{2}T - T_1 \approx 44 - 24.871 = 19.129 \text{ days}$$

The required time is the difference:

$$T_1 - T_2 = 24.871 - 19.129 = 5.742 \text{ days}$$

14 DIFFERENTIATION IN SEVERAL VARIABLES

14.1 Functions of Two or More Variables (LT Section 15.1)

Preliminary Questions

1. What is the difference between a horizontal trace and a level curve? How are they related?

SOLUTION A horizontal trace at height c consists of all points (x, y, c) such that $f(x, y) = c$. A level curve is the curve $f(x, y) = c$ in the xy-plane. The horizontal trace is in the $z = c$ plane. The two curves are related in the sense that the level curve is the projection of the horizontal trace on the xy-plane. The two curves have the same shape but they are located in parallel planes.

2. Describe the trace of $f(x, y) = x^2 - \sin(x^3 y)$ in the xz-plane.

SOLUTION The intersection of the graph of $f(x, y) = x^2 - \sin(x^3 y)$ with the xz-plane is obtained by setting $y = 0$ in the equation $z = x^2 - \sin(x^3 y)$. We get the equation $z = x^2 - \sin 0 = x^2$. This is the parabola $z = x^2$ in the xz-plane.

3. Is it possible for two different level curves of a function to intersect? Explain.

SOLUTION Two different level curves of $f(x, y)$ are the curves in the xy-plane defined by equations $f(x, y) = c_1$ and $f(x, y) = c_2$ for $c_1 \neq c_2$. If the curves intersect at a point (x_0, y_0), then $f(x_0, y_0) = c_1$ and $f(x_0, y_0) = c_2$, which implies that $c_1 = c_2$. Therefore, two different level curves of a function do not intersect.

4. Describe the contour map of $f(x, y) = x$ with contour interval 1.

SOLUTION The level curves of the function $f(x, y) = x$ are the vertical lines $x = c$. Therefore, the contour map of f with contour interval 1 consists of vertical lines so that every two adjacent lines are distanced one unit from another.

5. How will the contour maps of

$$f(x, y) = x \quad \text{and} \quad g(x, y) = 2x$$

with contour interval 1 look different?

SOLUTION The level curves of $f(x, y) = x$ are the vertical lines $x = c$, and the level curves of $g(x, y) = 2x$ are the vertical lines $2x = c$ or $x = \frac{c}{2}$. Therefore, the contour map of $f(x, y) = x$ with contour interval 1 consists of vertical lines with distance one unit between adjacent lines, whereas in the contour map of $g(x, y) = 2x$ (with contour interval 1) the distance between two adjacent vertical lines is $\frac{1}{2}$.

Exercises

In Exercises 1–4, evaluate the function at the specified points.

1. $f(x, y) = x + yx^3$, $(2, 2), (-1, 4)$

SOLUTION We substitute the values for x and y in $f(x, y)$ and compute the values of f at the given points. This gives

$$f(2, 2) = 2 + 2 \cdot 2^3 = 18$$
$$f(-1, 4) = -1 + 4 \cdot (-1)^3 = -5$$

2. $g(x, y) = \dfrac{y}{x^2 + y^2}$, $(1, 3), (3, -2)$

SOLUTION We substitute $(x, y) = (1, 3)$ and $(x, y) = (3, -2)$ in the function to obtain

$$g(1, 3) = \frac{3}{1^2 + 3^2} = \frac{3}{10}; \quad g(3, -2) = \frac{-2}{3^2 + (-2)^2} = -\frac{2}{13}$$

3. $h(x, y, z) = xyz^{-2}, \quad (3, 8, 2), (3, -2, -6)$

SOLUTION Substituting $(x, y, z) = (3, 8, 2)$ and $(x, y, z) = (3, -2, -6)$ in the function, we obtain

$$h(3, 8, 2) = 3 \cdot 8 \cdot 2^{-2} = 3 \cdot 8 \cdot \frac{1}{4} = 6$$

$$h(3, -2, -6) = 3 \cdot (-2) \cdot (-6)^{-2} = -6 \cdot \frac{1}{36} = -\frac{1}{6}$$

4. $Q(y, z) = y^2 + y \sin z, \quad (y, z) = \left(2, \frac{\pi}{2}\right), \left(-2, \frac{\pi}{6}\right)$

SOLUTION We have

$$Q\left(2, \frac{\pi}{2}\right) = 2^2 + 2 \sin \frac{\pi}{2} = 4 + 2 \cdot 1 = 6$$

$$Q\left(-2, \frac{\pi}{6}\right) = (-2)^2 - 2 \sin \frac{\pi}{6} = 4 - 2 \cdot \frac{1}{2} = 3$$

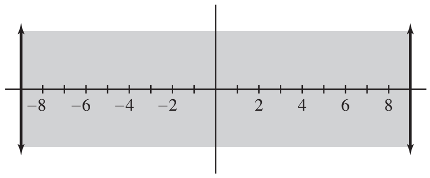
In Exercises 5–12, sketch the domain of the function.

5. $f(x, y) = 12x - 5y$

SOLUTION The function is defined for all x and y, hence the domain is the entire xy-plane.

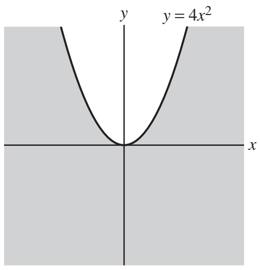
6. $f(x, y) = \sqrt{81 - x^2}$

SOLUTION The function $f(x, y) = \sqrt{81 - x^2}$ is defined if $81 - x^2 \geq 0$, that is, if $x^2 \leq 81$. In other words, $-9 \leq x \leq 9$. This region is the region enclosed by the two vertical lines $x = -9$ and $x = 9$ (including the two lines themselves).



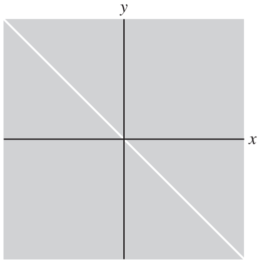
7. $f(x, y) = \ln(4x^2 - y)$

SOLUTION The function is defined if $4x^2 - y > 0$, that is, $y < 4x^2$. The domain is the region in the xy-plane that is below the parabola $y = 4x^2$.



8. $h(x, t) = \dfrac{1}{x + t}$

SOLUTION The function is defined if $x + t \neq 0$, that is, $x \neq -t$. The domain is the xt-plane with the line $x = -t$ excluded.

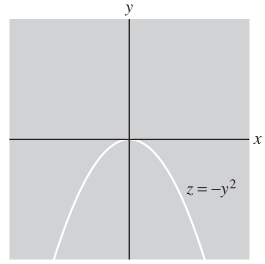


$x \neq -t$

9. $g(y, z) = \dfrac{1}{z + y^2}$

SOLUTION The function is defined if $z + y^2 \neq 0$, that is, $z \neq -y^2$. The domain is the (y, z) plane with the parabola $z = -y^2$ excluded.

$$D = \left\{(y, z) : z \neq -y^2\right\}$$

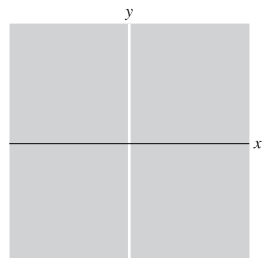


$$z + y^2 \neq 0$$

10. $f(x, y) = \sin \dfrac{y}{x}$

SOLUTION The function is defined for all $x \neq 0$. The domain is the xy-plane with the y-axis excluded.

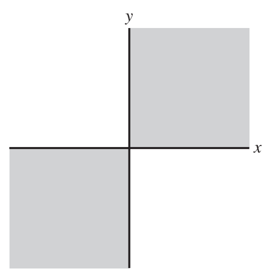
$$D = \{(x, y) : x \neq 0\}$$



$$x \neq 0$$

11. $F(I, R) = \sqrt{IR}$

SOLUTION The function is defined if $IR \geq 0$. Therefore the domain is the first and the third quadrants of the IR-plane including both axes.

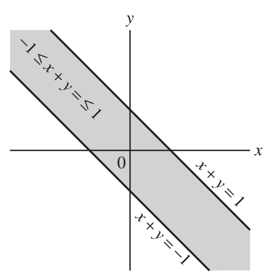


$$IR \geq 0$$

12. $f(x, y) = \cos^{-1}(x + y)$

SOLUTION Since the cosine function assume only values between -1 and 1, $x + y$ must satisfy $-1 \leq x + y \leq 1$. The domain is the region between the lines $x + y = 1$ and $x + y = -1$, including both lines.

$$D = \{(x, y) : -1 \leq x + y \leq 1\}$$



In Exercises 13–16, describe the domain and range of the function.

13. $f(x, y, z) = xz + e^y$

SOLUTION The domain of f is the entire (x, y, z)-space. Since f takes all the real values, the range is the entire real line.

14. $f(x, y, z) = x\sqrt{y + z}e^{z/x}$

SOLUTION The domain of f depends upon the term $\sqrt{y+z}$. We know that $y + z \geq 0$ so then $y \geq -z$. The domain is the region below and including the plane $y = -z$ in $\mathbb{R}^3$.

$$D = \{(x, y, z) \; : \; y \geq -z\} = \{(x, y, z) \; : \; y + z \geq 0\}$$

Since f takes all the real values, the range is the entire real line.

15. $P(r, s, t) = \sqrt{16 - r^2s^2t^2}$

SOLUTION The domain is subset of $\mathbf{R}^3$ where $rst \leq 4$ and the range is $\{w : 0 \leq w \leq 4\}$ because the minimum is 0 and the maximum of P is $\sqrt{16} = 4$.

16. $g(r, s) = \cos^{-1}(rs)$

SOLUTION Recall that the domain of the inverse cosine function is $[-1, 1]$ and the range of the inverse cosine function is $[0, \pi]$. This means that we need $|rs| \leq 1$:

$$D = \{(r, s) \; : \; |rs| \leq 1\}.$$

The range of this new function g will remain $[0, \pi]$.

17. Match graphs (A) and (B) in Figure 21 with the functions

(i) $f(x, y) = -x + y^2$ (ii) $g(x, y) = x + y^2$

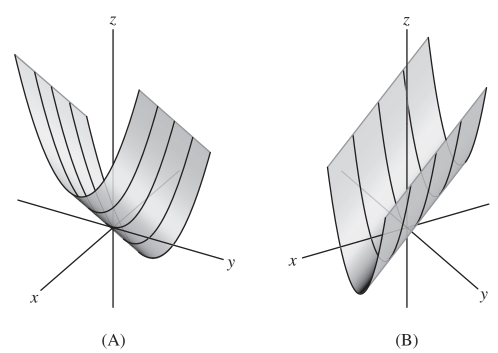


FIGURE 21

SOLUTION

(i) The vertical trace for $f(x, y) = -x + y^2$ in the xz-plane ($y = 0$) is $z = -x$. This matches the graph shown in (B).

(ii) The vertical trace for $f(x, y) = x + y^2$ in the xz-plane ($y = 0$) is $z = x$. This matches the graph show in (A).

18. Match each of graphs (A) and (B) in Figure 22 with one of the following functions:

(i) $f(x, y) = (\cos x)(\cos y)$

(ii) $g(x, y) = \cos(x^2 + y^2)$

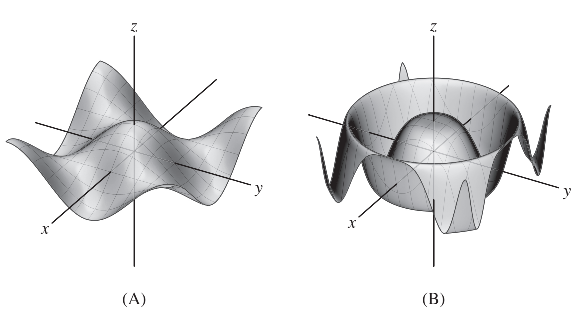

FIGURE 22

SOLUTION The level curves at $z = c$, a constant, for $g(x, y) = \cos(x^2 + y^2)$ will give

$$\cos(x^2 + y^2) = c \quad \Rightarrow \quad x^2 + y^2 = \cos^{-1}(c) \text{ which is a constant}$$

This means that the level curves are an infinite number of concentric circles centered around the z-axis whose radii differ by 2π. This means the graph in (B) is the given function in (ii).

If we consider the function $f(x, y) = (\cos x)(\cos y)$, the vertical trace if $y = 0$ will give us a graph of $\cos x$ in the xz-plane, while the vertical trace if $x = 0$ will give us a graph of $\cos y$ in the yz-plane. This means that the graph in (A) is the given function in (i).

19. Match the functions (a)–(f) with their graphs (A)–(F) in Figure 23.

(a) $f(x, y) = |x| + |y|$

(b) $f(x, y) = \cos(x - y)$

(c) $f(x, y) = \dfrac{-1}{1 + 9x^2 + y^2}$

(d) $f(x, y) = \cos(y^2)e^{-0.1(x^2+y^2)}$

(e) $f(x, y) = \dfrac{-1}{1 + 9x^2 + 9y^2}$

(f) $f(x, y) = \cos(x^2 + y^2)e^{-0.1(x^2+y^2)}$

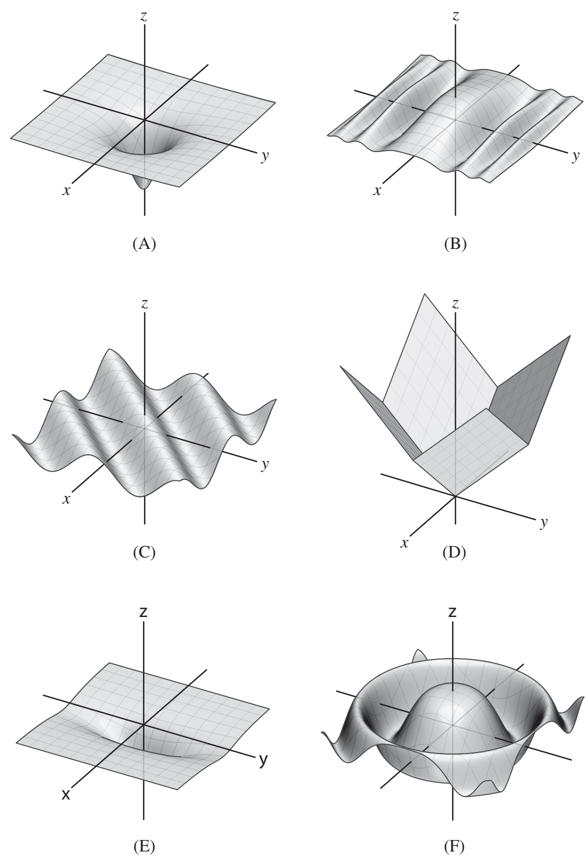

FIGURE 23

SOLUTION

(a) $|x| + |y|$. The level curves are $|x| + |y| = c$, $y = c - |x|$, or $y = -c + |x|$. The graph (D) corresponds to the function with these level curves.

(b) $\cos(x - y)$. The vertical trace in the plane $x = c$ is the curve $z = \cos(c - y)$ in the plane $x = c$. These traces correspond to the graph (C).

(c) $\dfrac{-1}{1 + 9x^2 + y^2}$ **(e)** $\dfrac{-1}{1 + 9x^2 + 9y^2}$.

The level curves of the two functions are:

$$\frac{-1}{1 + 9x^2 + y^2} = c \qquad\qquad \frac{-1}{1 + 9x^2 + 9y^2} = c$$

$$1 + 9x^2 + y^2 = -\frac{1}{c} \qquad\qquad 1 + 9x^2 + 9y^2 = -\frac{1}{c}$$

$$9x^2 + y^2 = -1 - \frac{1}{c} \qquad\qquad 9x^2 + 9y^2 = -1 - \frac{1}{c}$$

$$x^2 + y^2 = -\frac{1 + c}{9c}$$

For suitable values of c, the level curves of the function in (c) are ellipses as in (E), and the level curves of the function (e) are circles as in (A).

(d) $\cos(x^2)e^{-1/(x^2+y^2)}$ **(f)** $\cos(x^2+y^2)e^{-1/(x^2+y^2)}$.

The value of $|z|$ is decreasing to zero as x or y are decreasing, hence the possible graphs are (B) and (F).

In (f), z is constant whenever x^2+y^2 is constant, that is, z is constant whenever (x, y) varies on a circle. Hence (f) corresponds to the graph (F) and (d) corresponds to (B).

To summarize, we have the following matching:

$$\text{(a)} \leftrightarrow \text{(D)} \qquad \text{(b)} \leftrightarrow \text{(C)} \qquad \text{(c)} \leftrightarrow \text{(E)}$$
$$\text{(d)} \leftrightarrow \text{(B)} \qquad \text{(e)} \leftrightarrow \text{(A)} \qquad \text{(f)} \leftrightarrow \text{(F)}$$

20. Match the functions (a)–(d) with their contour maps (A)–(D) in Figure 24.

(a) $f(x, y) = 3x + 4y$

(b) $g(x, y) = x^3 - y$

(c) $h(x, y) = 4x - 3y$

(d) $k(x, y) = x^2 - y$

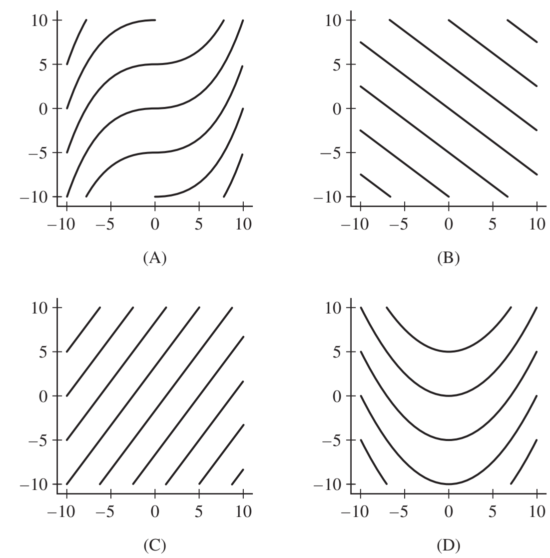

FIGURE 24

SOLUTION

(a) Computing the level curves for $f(x, y) = 3x + 4y$ we set $z = f(x, y) = c$, a constant, to see

$$3x + 4y = c \quad \Rightarrow \quad 4y = c - 3x \quad \Rightarrow \quad y = \frac{c}{4} - \frac{3}{4}x$$

This means the contour maps would be lines having slopes $-3/4$, this corresponds to the contour map shown in (B).

(b) Computing the level curves for $g(x, y) = x^3 - y$ we set $z = g(x, y) = c$, a constant, to see

$$x^3 - y = c \quad \Rightarrow \quad y = x^3 - c$$

This means the contour maps would be contours having the shape of cubic equations, this corresponds to the contour map shown in (A).

(c) Computing the level curves for $h(x, y) = 4x - 3y$ we set $z = h(x, y) = c$, a constant, to see

$$4x - 3y = c \quad \Rightarrow \quad -3y = c - 4x \quad \Rightarrow \quad y = \frac{c}{4} + \frac{4}{3}x$$

This means the contour maps would be contours that are lines having slopes $4/3$, this corresponds to the contour map shown in (C).

(d) Computing the level curves for $k(x, y) = x^2 - y$ we set $z = k(x, y) = c$, a constant, to see

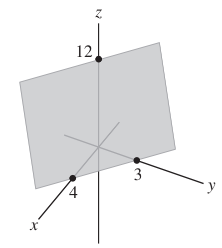
$$x^2 - y = c \quad \Rightarrow \quad y = x^2 - c$$

This means the contour maps would be contours having the shape of parabolas, this corresponds to the contour map shown in (D).

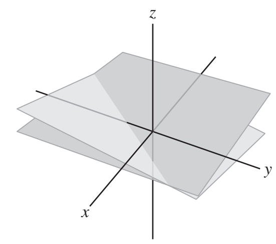
In Exercises 21–26, sketch the graph and describe the vertical and horizontal traces.

21. $f(x, y) = 12 - 3x - 4y$

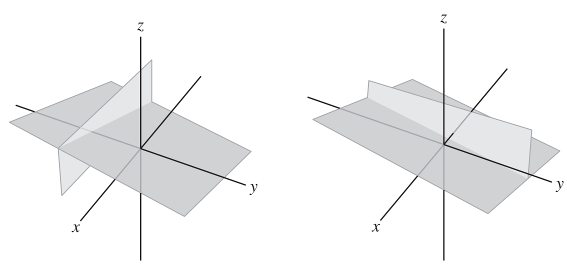
SOLUTION The graph of $f(x, y) = 12 - 3x - 4y$ is shown in the figure:



The horizontal trace at height c is the line $12 - 3x - 4y = c$ or $3x + 4y = 12 - c$ in the plane $z = c$.

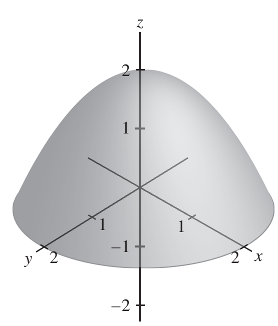


The vertical traces obtained by setting $x = a$ or $y = a$ are the lines $z = (12 - 3a) - 4y$ and $z = -3x + (12 - 4a)$ in the planes $x = a$ and $y = a$, respectively.



22. $f(x, y) = \sqrt{4 - x^2 - y^2}$

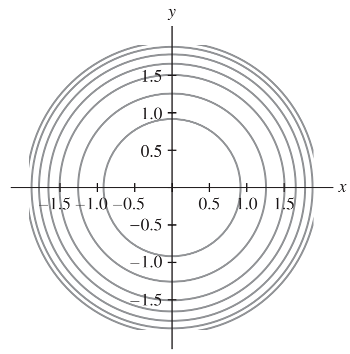
SOLUTION The graph of $f(x, y) = \sqrt{4 - x^2 - y^2}$ is shown in the figure:



The horizontal trace at height c is

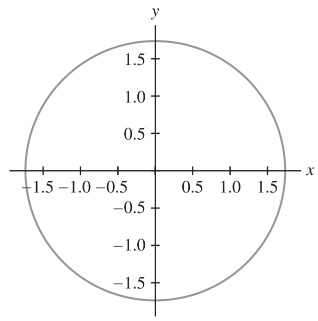
$$\sqrt{4 - x^2 - y^2} = c \quad \Rightarrow \quad 4 - x^2 - y^2 = c^2 \quad \Rightarrow \quad x^2 + y^2 = 4 - c^2$$

in the plane $z = c$ as long as $-2 \le c \le 2$. These are circles centered at the origin with radius $\sqrt{4 - c^2}$ in the plane $z = c$.

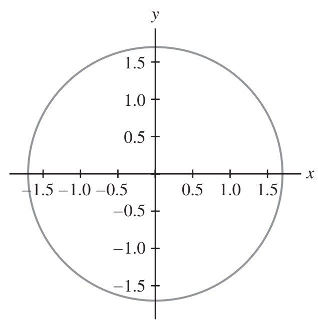


The vertical traces obtained by setting $x = a$ or $y = a$

$$\sqrt{4 - a^2 - y^2} = z \quad \Rightarrow \quad 4 - a^2 - y^2 = z^2 \quad \Rightarrow \quad y^2 + z^2 = 4 - a^2$$



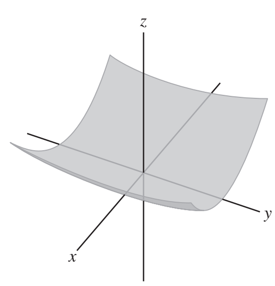
$$\sqrt{4 - x^2 - a^2} = z \quad \Rightarrow \quad 4 - x^2 - a^2 = z^2 \quad \Rightarrow \quad x^2 + z^2 = 4 - a^2$$



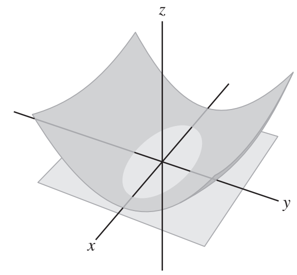
Both are the upper half circles centered at the origin with radius $\sqrt{4 - a^2}$ (in the planes $x = a$ and $y = a$) as long as $-2 \le a \le 2$. The graph is only the upper half of the sphere having radius 2, since it includes only the positive square root of z, so the vertical traces are only upper half circles.

23. $f(x, y) = x^2 + 4y^2$

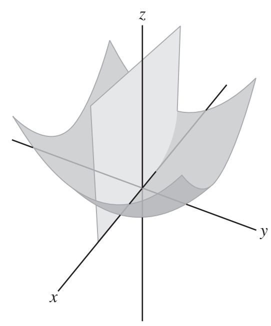
SOLUTION The graph of the function is shown in the figure:

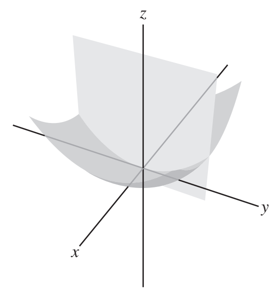


The horizontal trace at height c is the curve $x^2 + 4y^2 = c$, where $c \geq 0$ (if $c = 0$, it is the origin). The horizontal traces are ellipses for $c > 0$.



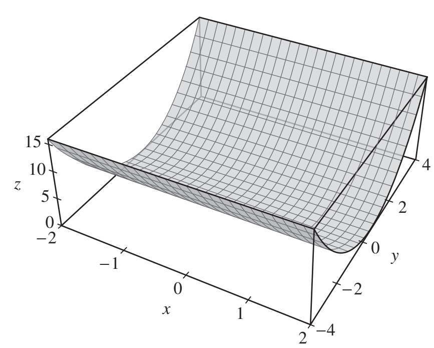
The vertical trace in the plane $x = a$ is the parabola $z = a^2 + 4y^2$, and the vertical trace in the plane $y = a$ is the parabola $z = x^2 + 4a^2$.



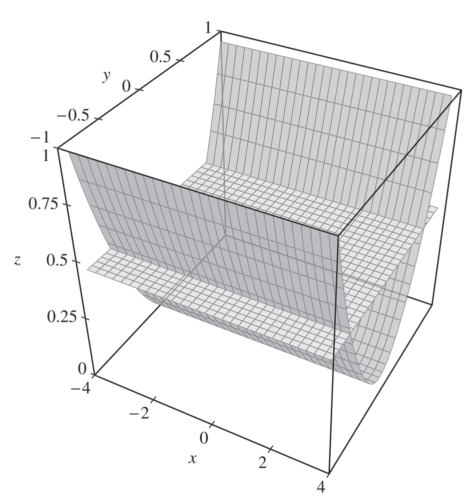


24. $f(x, y) = y^2$

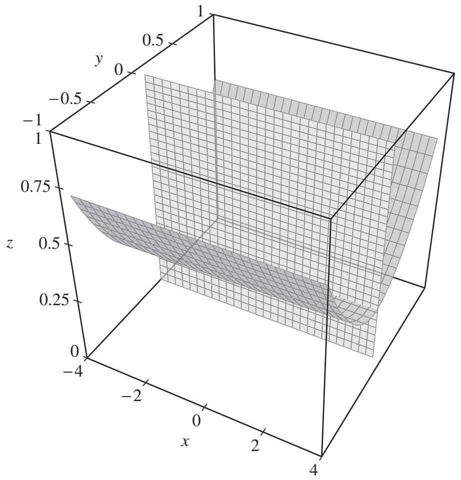
SOLUTION The graph of the function is shown in the figure:



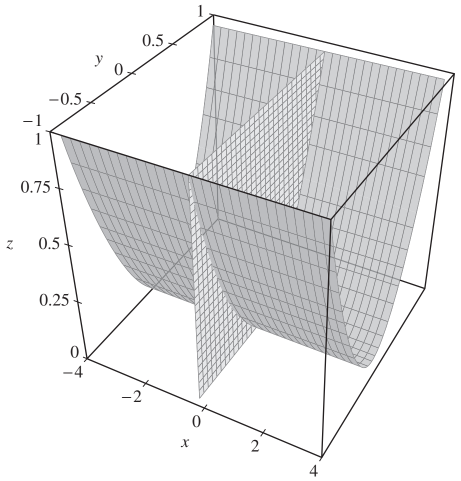
The horizontal trace at height c is $y^2 = c$. For $c > 0$ the trace consists of the two lines $y = \sqrt{c}$ and $y = -\sqrt{c}$ in the plane $z = c$, and for $c = 0$ it is the line $y = 0$.



The vertical trace in the plane $y = a$ is the line $z = a^2$.

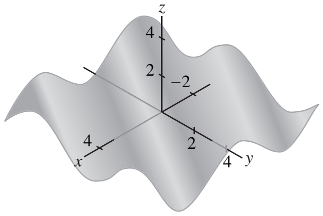


The vertical trace in the plane $x = a$ is the parabola $z = y^2$ on this plane.

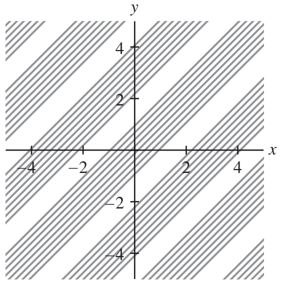


25. $f(x, y) = \sin(x - y)$

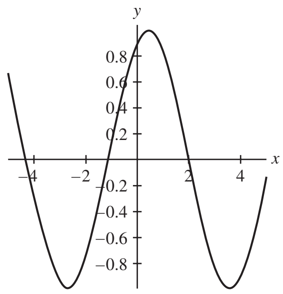
SOLUTION The graph of $f(x, y) = \sin(x - y)$ is shown in the figure:



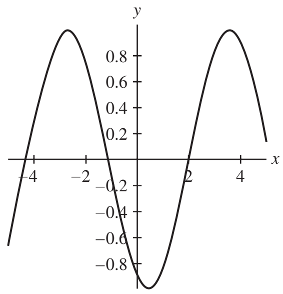
The horizontal trace at the height $z = c$ is $\sin(x - y) = c$ (we could also write $x - y = \sin^{-1}(c)$ or $y = x - \sin^{-1}(c)$). The trace consists of multiple lines all having slope 1, with y-intercepts separated by multiples of 2π.



The vertical trace in the plane $x = a$ is $\sin(a - y) = -\sin(y - a) = z$. This curve is a shifted sine curve reflected through the z-axis.

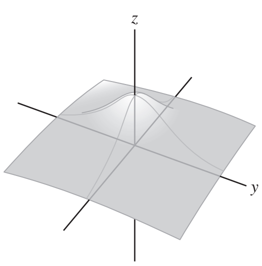


The vertical trace in the plane $y = a$ is $\sin(x - a) = z$. This curve is a shifted sine curve as well.



26. $f(x, y) = \dfrac{1}{x^2 + y^2 + 1}$

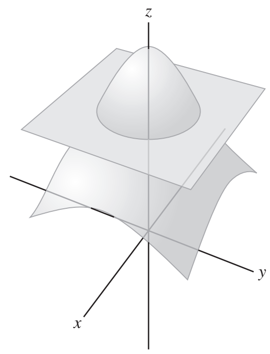
SOLUTION The graph of the function is shown in the figure:



The horizontal trace at height c is the following curve in the plane $z = c$:

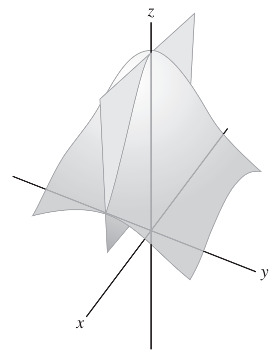
$$\frac{1}{x^2 + y^2 + 1} = c \quad \Rightarrow \quad x^2 + y^2 + 1 = \frac{1}{c} \quad \Rightarrow \quad x^2 + y^2 = \frac{1}{c} - 1$$

For $0 < c < 1$ it is a circle of radius $\sqrt{\frac{1}{c} - 1}$ centered at $(0, 0)$, and for $c = 1$ it is the origin.

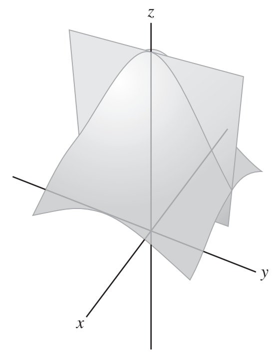


The vertical trace in the plane $x = a$ is the following curve in the plane $x = a$:

$$z = \frac{1}{a^2 + y^2 + 1} \quad \Rightarrow \quad z = \frac{1}{(1 + a^2) + y^2}$$

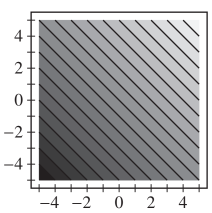


The vertical trace in the plane $y = a$ is the curve $z = \dfrac{1}{x^2 + a^2 + 1}$ in this plane.

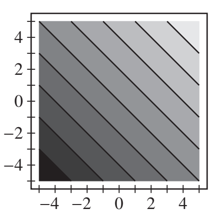


27. Sketch contour maps of $f(x, y) = x + y$ with contour intervals $m = 1$ and 2.

SOLUTION The level curves are $x + y = c$ or $y = c - x$. Using contour interval $m = 1$, we plot $y = c - x$ for various values of c.

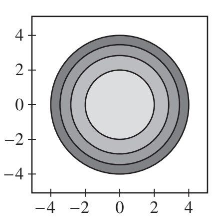


Using contour interval $m = 2$, we plot $y = c - x$ for various values of c.



28. Sketch the contour map of $f(x, y) = x^2 + y^2$ with level curves $c = 0, 4, 8, 12, 16$.

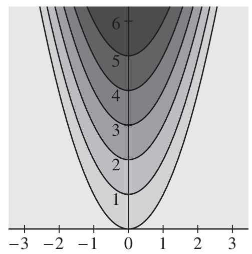
SOLUTION The level curves are $x^2 + y^2 = c$ for $c \ge 0$. We sketch the level curves $c = 0, 4, 8, 12, 16$:



In Exercises 29–36, draw a contour map of $f(x, y)$ with an appropriate contour interval, showing at least six level curves.

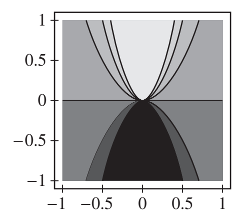
29. $f(x, y) = x^2 - y$

SOLUTION The level curves are the parabolas $y = x^2 + c$. We draw a contour plot with contour interval $m = 1$, for $c = 0, 1, 2, 3, 4, 5$:



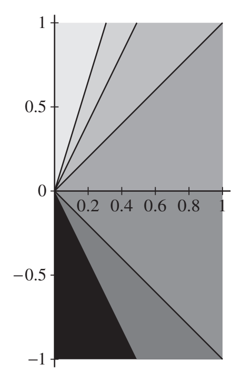
30. $f(x, y) = \dfrac{y}{x^2}$

SOLUTION The level curves are $\frac{y}{x^2} = c$ or $y = cx^2$. We use the contour interval $m = 2$ and plot $y = cx^2$ for $c = -4, -2, 0, 2, 4, 6$. For $c \neq 0$ these are parabolas.



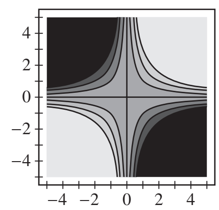
31. $f(x, y) = \dfrac{y}{x}$

SOLUTION The level curves are $\frac{y}{x} = c$ or $y = cx$. We plot $y = cx$ for $c = -2, -1, 0, 1, 2, 3$ using contour interval $m = 1$:



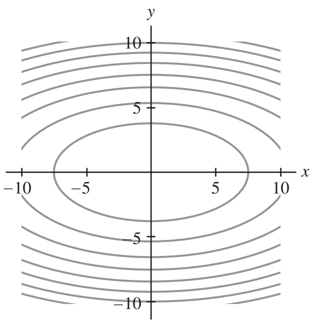
32. $f(x, y) = xy$

SOLUTION The level curves are $xy = c$ or $y = \frac{c}{x}$. These are hyperbolas in the xy-plane. We draw a contour map of the function using contour interval $m = 1$ and $c = 0, \pm 1, \pm 2, \pm 3$:



33. $f(x, y) = x^2 + 4y^2$

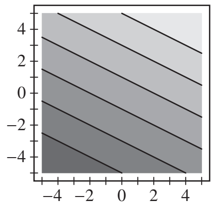
SOLUTION The level curves are $x^2 + 4y^2 = c$. These are ellipses centered at the origin in the xy-plane.



34. $f(x, y) = x + 2y - 1$

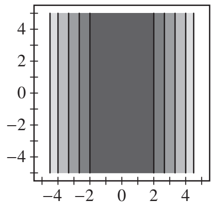
SOLUTION The level curves are the lines $x + 2y - 1 = c$ or $y = -\frac{x}{2} + \frac{c+1}{2}$. We draw a contour map using the contour interval $m = 4$ and $c = -9, -5, -1, 3, 7, 11$. The corresponding level curves are:

$$\underbrace{y = -\frac{x}{2} - 4}_{c=-9}, \quad \underbrace{y = -\frac{x}{2} - 2}_{c=-5}, \quad \underbrace{y = -\frac{x}{2}}_{c=-1}, \quad \underbrace{y = -\frac{x}{2} + 2}_{c=3},$$
$$\underbrace{y = -\frac{x}{2} + 4}_{c=7}, \quad \underbrace{y = -\frac{x}{2} + 6}_{c=11}$$



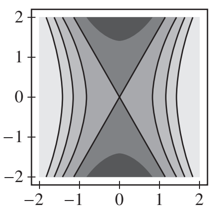
35. $f(x, y) = x^2$

SOLUTION The level curves are $x^2 = c$. For $c > 0$ these are the two vertical lines $x = \sqrt{c}$ and $x = -\sqrt{c}$ and for $c = 0$ it is the y-axis. We draw a contour map using contour interval $m = 4$ and $c = 0, 4, 8, 12, 16, 20$:



36. $f(x, y) = 3x^2 - y^2$

SOLUTION The level curves are the hyperbolas $3x^2 - y^2 = c$, $c \neq 0$, and for $c = 0$ it is the two lines $y = \pm\sqrt{3}x$. We plot a contour map with contour interval $m = 2$ using $c = -4, -2, 0, 2, 4, 6$:



37. Find the linear function whose contour map (with contour interval $m = 6$) is shown in Figure 25. What is the linear function if $m = 3$ (and the curve labeled $c = 6$ is relabeled $c = 3$)?

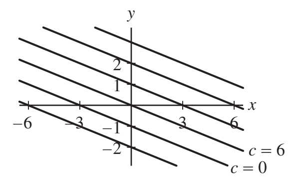


FIGURE 25 Contour map with contour interval $m = 6$

SOLUTION A linear function has the form $f(x, y) = Ax + By + C$.

Case 1: According to the contour map, the level curve through the origin (0, 0) has equation $f(x, y) = 6$. Therefore

$$f(0,0) = A(0) + B(0) + C = 6 \quad \Rightarrow \quad C = 6$$

Next, we see from the contour map that the points $(-3, 0) = 0$ and $f(0, -1)$ lie on the level curve $f(x, y) = 0$. Hence

$$f(-3,0) = A(-3) + B(0) + 6 = 0 \quad \Rightarrow \quad A = 2$$
$$f(0,-1) = A(0) + B(-1) + 6 = 0 \quad \Rightarrow \quad B = 6$$

Therefore $f(x, y) = 2x + 6y + 6$.

Case 1: If $m = 3$, then (0, 0) lies on the level curve $f(x, y) = 3$, and we proceed as before

$$f(0,0) = A(0) + B(0) + C = 3 \quad \Rightarrow \quad C = 3 f(-3,0) = A(-3) + B(0) + 3 = 0 \quad \Rightarrow \quad A = 1$$
$$f(0,-1) = A(0) + B(-1) + 3 = 0 \quad \Rightarrow \quad B = 2$$

Therefore $f(x, y) = x + 3y + 3$.

38. Use the contour map in Figure 26 to calculate the average rate of change:

(a) From A to B. **(b)** From A to C.

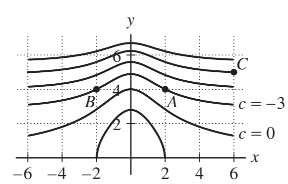

FIGURE 26

SOLUTION

(a) Using the figure to compute, we have the average rate of change from A to B:

$$\frac{\Delta \text{ altitude}}{\Delta \text{ horizontal}} = 0$$

(b) Using the figure to compute, assuming that C is on the level curve $c = -9$, then we have the average rate of change from A to C

$$\frac{\Delta \text{ altitude}}{\Delta \text{ horizontal}} = \frac{-9-(-3)}{\sqrt{2^2+1^2}} = -\frac{6}{\sqrt{5}}$$

39. Referring to Figure 27, answer the following questions:

(a) At which of (A)–(C) is pressure increasing in the northern direction?

(b) At which of (A)–(C) is pressure increasing in the easterly direction?

(c) In which direction at (B) is pressure increasing most rapidly?

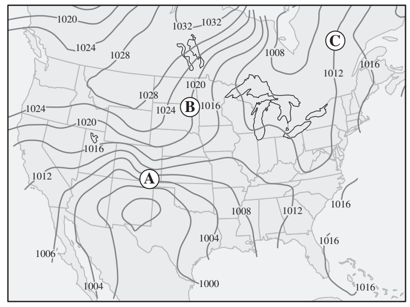

FIGURE 27 Atmospheric Pressure (in millibars) over the continental U.S. on March 26, 2009

SOLUTION

a. (A) and (B)

b. (C)

c. west

In Exercises 40–43, $\rho(S, T)$ is seawater density (kg/m^3) *as a function of salinity S* (ppt) *and temperature T* (°C). *Refer to the contour map in Figure 28.*

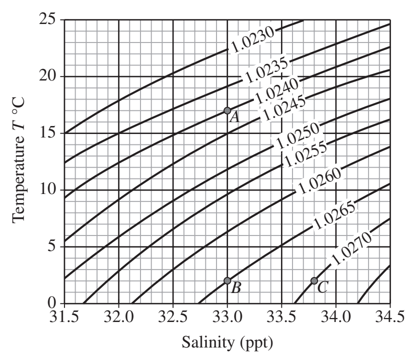

FIGURE 28 Contour map of seawater density $\rho(S, T)$ (kg/m^3).

40. Calculate the average rate of change of ρ with respect to T from B to A.

SOLUTION The segment $\overline{BA}$ spans 5 level curves and the contour interval is 0.0005. Since the density is decreasing in the direction from B to A, the change in density is $\Delta\rho = -0.0005 \cdot 5 = -0.0025$ kg/m^3. The temperature at A is 17°C and at C is 2°C, so the difference in temperature from C to A is $\Delta T = 17 - 2 = 15$°C. Hence,

$$\text{Average ROC from } B \text{ to } A = \frac{\Delta\rho}{\Delta T} = \frac{-0.0025}{15} = -0.000167 \text{ kg/m}^3\ {}^\circ\text{C}.$$

41. Calculate the average rate of change of ρ with respect to S from B to C.

SOLUTION For fixed temperature, the segment $\overline{BC}$ spans one level curve and the level curve of C is to the right of the level curve of B. Therefore, the change in density from B to C is $\Delta\rho = 0.0005$ kg/m^3. The salinity at C is greater than the salinity at B and $\Delta S = 0.8$ ppt. Therefore,

$$\text{Average ROC from } B \text{ to } C = \frac{\Delta\rho}{\Delta S} = \frac{0.0005}{0.8} = 0.000625 \text{ kg/m}^3 \cdot \text{ppt}.$$

42. At a fixed level of salinity, is seawater density an increasing or a decreasing function of temperature?

SOLUTION The level of salinity is fixed on each vertical line. The vertical lines intersect level curves with decreasing values in the direction of increasing temperature (which is the upward direction). Therefore, at a fixed level of salinity, seawater density is a decreasing function of temperature.

43. Does water density appear to be more sensitive to a change in temperature at point A or point B?

SOLUTION The two adjacent level curves are closer to the level curve of A than the corresponding two adjacent level curves are to the level curve of B. This suggests that water density is more sensitive to a change in temperature at A than at B.

In Exercises 44–47, refer to Figure 29.

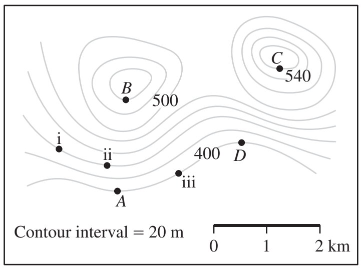

FIGURE 29

44. Find the change in elevation from A and B.

SOLUTION The segment $\overline{AB}$ spans 7 level curves and the contour interval is 20 meters. Therefore, the change in elevation from A to B is $20 \cdot 7 = 140$ m.

45. Estimate the average rate of change from A and B and from A to C.

SOLUTION The change in elevation from A to B is 140 m. The scale shows that $\overline{AB}$ is approximately 2000 m. Therefore,

$$\text{Average ROC from } A \text{ to } B = \frac{140}{2000} \approx 0.07.$$

The change in elevation from A to C is obtained by multiplying the number of level curves between A and C, which is 8, by the contour interval 20 meters, giving $8 \cdot 20 = 160$ m. Using the scale, we approximate the distance $\overline{AC}$ by 3000 m. Therefore,

$$\text{Average ROC from } A \text{ to } C = \frac{160}{3000} \approx 0.0533.$$

46. Estimate the average rate of change from A to points i, ii, and iii.

SOLUTION The points i, and ii are on a level curve two adjacent to the level curve of A, hence the change in elevation is $2 \cdot 20 = 40$ meters. The point iii is on the same level curve as A, hence the change in elevation is 0 meters. Using the scale we approximate the distances from A to the points i, ii, and iii:

From A to i: 1000 m
From A to ii: 500 m
From A to iii: 750 m

Therefore,

$$\text{Average ROC from } A \text{ to i} \approx \frac{40}{1000} = 0.04$$
$$\text{Average ROC from } P \text{ to ii} \approx \frac{40}{500} = 0.08$$
$$\text{Average ROC from } P \text{ to iii} \approx \frac{0}{750} = 0$$

47. Sketch the path of steepest ascent beginning at D.

SOLUTION Starting at D, we draw a path that everywhere along the way points on the steepest direction, that is, moves as straight as possible from one level curve to the next to end at the point C.

Further Insights and Challenges

48. The function $f(x, t) = t^{-1/2}e^{-x^2/t}$, whose graph is shown in Figure 30, models the temperature along a metal bar after an intense burst of heat is applied at its center point.

(a) Sketch the vertical traces at times $t = 1, 2, 3$. What do these traces tell us about the way heat diffuses through the bar?

(b) Sketch the vertical traces $x = c$ for $c = \pm 0.2, \pm 0.4$. Describe how temperature varies in time at points near the center.

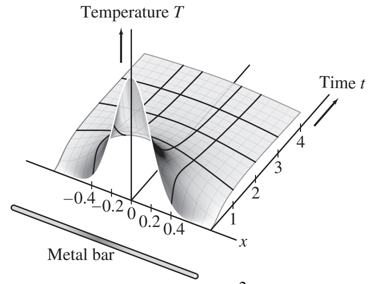

FIGURE 30 Graph of $f(x,t) = t^{-1/2}e^{-x^2/t}$ beginning shortly after $t = 0$.

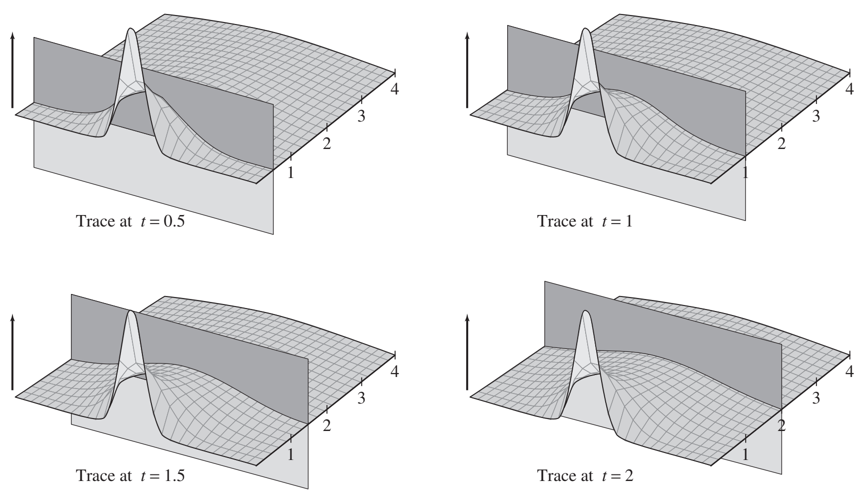
SOLUTION

(a) The vertical traces at times $t = 0.5, 1, 1.5, 2$ are

$$z = \sqrt{2}e^{-2x^2} \text{ in the plane } t = 0.5$$
$$z = e^{-x^2} \text{ in the plane } t = 1$$
$$z = \frac{1}{\sqrt{3/2}}e^{-2x^2/3} \text{ in the plane } t = 1.5$$
$$z = \frac{1}{\sqrt{2}}e^{-x^2/2} \text{ in the plane } t = 2$$

These vertical traces are shown in the following figure:

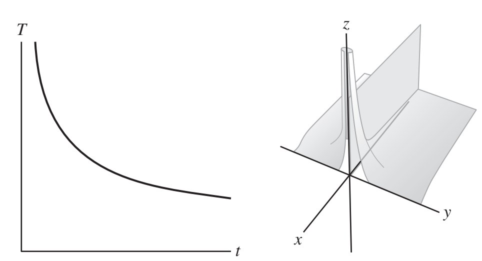


At each time the temperature decreases as we move away from the center point. Also, as t increases, the temperature at each point in the bar (except at the middle) increases and then decreases (as can be seen in Figure 30). It also shows that the temperature tends to equalize throughout the bar (because the traces become closer and closer to flat as time goes on).

(b) The vertical traces $x = c$ for the given values of c are:

$$z = \frac{1}{\sqrt{t}}e^{-\frac{0.04}{t}} \text{ in the planes } x = 0.2 \text{ and } x = -0.2$$
$$z = \frac{1}{\sqrt{t}}e^{-\frac{0.16}{t}} \text{ in the planes } x = 0.4 \text{ and } x = -0.4.$$

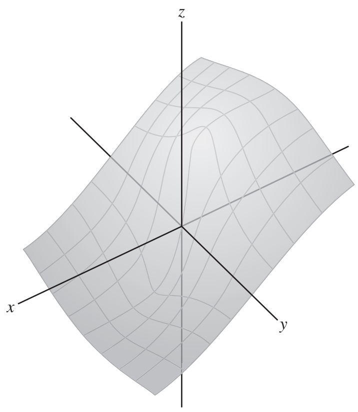
We see that for small values of t the temperature increases quickly and then slowly decreases as t increases.



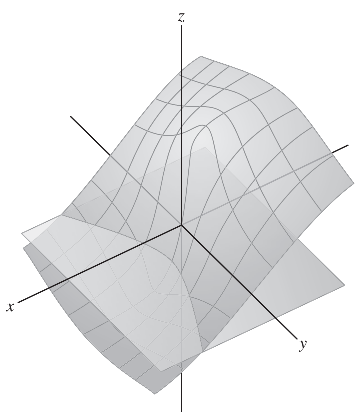
49. Let $f(x,y) = \dfrac{x}{\sqrt{x^2+y^2}}$ for $(x,y) \neq 0$. Write f as a function $f(r,\theta)$ in polar coordinates, and use this to find the level curves of f.

SOLUTION In polar coordinates $x = r\cos\theta$ and $r = \sqrt{x^2+y^2}$. Hence,

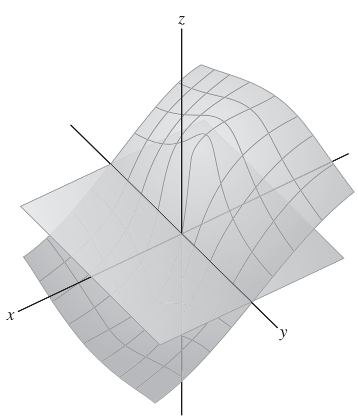
$$f(r,\theta) = \frac{r\cos\theta}{r} = \cos\theta.$$



The level curves are the curves $\cos\theta = c$ in the $r\theta$-plane, for $|c| \leq 1$. For $-1 < c < 1$, $c \neq 0$, the level curves $\cos\theta = c$ are the two rays $\theta = \cos^{-1} c$ and $\theta = -\cos^{-1} c$.



For $c = 0$, the level curve $\cos\theta = 0$ is the y-axis; for $c = 1$ the level curve $\cos\theta = 1$ is the nonnegative x-axis.



For $c = -1$, the level curve $\cos\theta = -1$ is the negative x-axis.

14.2 Limits and Continuity in Several Variables (LT Section 15.2)

Preliminary Questions

1. What is the difference between $D(P, r)$ and $D^*(P, r)$?

SOLUTION $D(P, r)$ is the open disk of radius r and center (a, b). It consists of all points distanced less than r from P, hence $D(P, r)$ includes the point P. $D^*(P, r)$ consists of all points in $D(P, r)$ other than P itself.

2. Suppose that $f(x, y)$ is continuous at $(2, 3)$ and that $f(2, y) = y^3$ for $y \neq 3$. What is the value $f(2, 3)$?

SOLUTION $f(x, y)$ is continuous at $(2, 3)$, hence the following holds:

$$f(2, 3) = \lim_{(x,y)\to(2,3)} f(x, y)$$

Since the limit exists, we may compute it by approaching $(2, 3)$ along the vertical line $x = 2$. This gives

$$f(2,3) = \lim_{(x,y)\to(2,3)} f(x,y) = \lim_{y\to 3} f(2,y) = \lim_{y\to 3} y^3 = 3^3 = 27$$

We conclude that $f(2, 3) = 27$.

3. Suppose that $Q(x, y)$ is a function such that $1/Q(x, y)$ is continuous for all (x, y). Which of the following statements are true?

(a) $Q(x, y)$ is continuous for all (x, y).
(b) $Q(x, y)$ is continuous for $(x, y) \neq (0, 0)$.
(c) $Q(x, y) \neq 0$ for all (x, y).

SOLUTION All three statements are true. Let $f(x, y) = \frac{1}{Q(x,y)}$. Hence $Q(x, y) = \frac{1}{f(x,y)}$.

(a) Since f is continuous, Q is continuous whenever $f(x, y) \neq 0$. But by the definition of f it is never zero, therefore Q is continuous at all (x, y).
(b) Q is continuous everywhere including at $(0, 0)$.
(c) Since $f(x, y) = \frac{1}{Q(x,y)}$ is continuous, the denominator is never zero, that is, $Q(x, y) \neq 0$ for all (x, y).

Moreover, there are no points where $Q(x, y) = 0$. (The equality $Q(x, y) = (0, 0)$ is meaningless since the range of Q consists of real numbers.)

4. Suppose that $f(x, 0) = 3$ for all $x \neq 0$ and $f(0, y) = 5$ for all $y \neq 0$. What can you conclude about $\lim_{(x,y)\to(0,0)} f(x, y)$?

SOLUTION We show that the limit $\lim_{(x,y)\to(0,0)} f(x, y)$ does not exist. Indeed, if the limit exists, it may be computed by approaching $(0, 0)$ along the x-axis or along the y-axis. We compute these two limits:

$$\lim_{\substack{(x,y)\to(0,0)\\ \text{along } y=0}} f(x,y) = \lim_{x\to 0} f(x,0) = \lim_{x\to 0} 3 = 3$$

$$\lim_{\substack{(x,y)\to(0,0)\\ \text{along } x=0}} f(x,y) = \lim_{y\to 0} f(0,y) = \lim_{y\to 0} 5 = 5$$

Since the limits are different, $f(x, y)$ does not approach one limit as $(x, y) \to (0, 0)$, hence the limit $\lim_{(x,y)\to(0,0)} f(x, y)$ does not exist.

Exercises

In Exercises 1–8, evaluate the limit using continuity

1. $\displaystyle\lim_{(x,y)\to(1,2)} (x^2 + y)$

SOLUTION Since the function $x^2 + y$ is continuous, we evaluate the limit by substitution:

$$\lim_{(x,y)\to(1,2)} (x^2 + y) = 1^2 + 2 = 3$$

2. $\displaystyle\lim_{(x,y)\to(\frac{4}{9},\frac{2}{9})} \frac{x}{y}$

SOLUTION The function $\frac{x}{y}$ is continuous at the point $\left(\frac{4}{9}, \frac{2}{9}\right)$, hence we compute the limit by substitution:

$$\lim_{(x,y)\to\left(\frac{4}{9},\frac{2}{9}\right)} \frac{x}{y} = \frac{\frac{4}{9}}{\frac{2}{9}} = 2$$

3. $\displaystyle\lim_{(x,y)\to(2,-1)} (xy - 3x^2y^3)$

SOLUTION The function $xy - 3x^2y^3$ is continuous everywhere because it is a polynomial, hence we compute the limit by substitution:

$$\lim_{(x,y)\to(2,-1)} (xy - 3x^2y^3) = 2(-1) - 3(4)(-1)^3 = -2 + 12 = 10$$

4. $\displaystyle\lim_{(x,y)\to(-2,1)} \frac{2x^2}{4x + y}$

SOLUTION We use the continuity of the function $\frac{2x^2}{4x+y}$ at the point $(-2, 1)$, hence we evaluate the limit by substitution:

$$\lim_{(x,y)\to(-2,1)} \frac{2x^2}{4x + y} = \frac{2(4)}{4(-2) + 1} = -\frac{8}{7}$$

5. $\lim_{(x,y)\to(\frac{\pi}{4},0)} \tan x \cos y$

SOLUTION We use the continuity of $\tan x \cos y$ at the point $\left(\frac{\pi}{4}, 0\right)$ to evaluate the limit by substitution:

$$\lim_{(x,y)\to\left(\frac{\pi}{4},0\right)} \tan x \cos y = \tan \frac{\pi}{4} \cos 0 = 1 \cdot 1 = 1$$

6. $\lim_{(x,y)\to(2,3)} \tan^{-1}(x^2 - y)$

SOLUTION We use the continuity of the function $\tan^{-1}(x^2 - y)$ at the point $(2, 3)$ to evaluate the limit by substitution:

$$\lim_{(x,y)\to(2,3)} \tan^{-1}(x^2 - y) = \tan^{-1}(1) = \frac{\pi}{4}$$

7. $\lim_{(x,y)\to(1,1)} \dfrac{e^{x^2} - e^{-y^2}}{x + y}$

SOLUTION The function is the quotient of two continuous functions, and the denominator is not zero at the point $(1, 1)$. Therefore, the function is continuous at this point, and we may compute the limit by substitution:

$$\lim_{(x,y)\to(1,1)} \frac{e^{x^2} - e^{-y^2}}{x + y} = \frac{e^{1^2} - e^{-1^2}}{1 + 1} = \frac{e - \frac{1}{e}}{2} = \frac{1}{2}(e - e^{-1})$$

8. $\lim_{(x,y)\to(1,0)} \ln(x - y)$

SOLUTION We use the continuity of $\ln(x - y)$ at the point $(1, 0)$ to evaluate the limit by substitution:

$$\lim_{(x,y)\to(1,0)} \ln(x - y) = \ln(1 - 0) = \ln 1 = 0$$

In Exercises 9–12, assume that

$$\lim_{(x,y)\to(2,5)} f(x, y) = 3, \qquad \lim_{(x,y)\to(2,5)} g(x, y) = 7$$

9. $\lim_{(x,y)\to(2,5)} \big(g(x, y) - 2f(x, y)\big)$

SOLUTION

$$\lim_{(x,y)\to(2,5)} \big(g(x, y) - 2f(x, y)\big) = 7 - 2(3) = 1$$

10. $\lim_{(x,y)\to(2,5)} f(x, y)^2 g(x, y)$

SOLUTION

$$\lim_{(x,y)\to(2,5)} f(x, y)^2 g(x, y) = 3^2(7) = 63$$

11. $\lim_{(x,y)\to(2,5)} e^{f(x,y)^2 - g(x,y)}$

SOLUTION

$$\lim_{(x,y)\to(2,5)} e^{f(x,y)^2 - g(x,y)} = e^{3^2 - 7} = e^2$$

12. $\lim_{(x,y)\to(2,5)} \dfrac{f(x, y)}{f(x, y) + g(x, y)}$

SOLUTION

$$\lim_{(x,y)\to(2,5)} \frac{f(x, y)}{f(x, y) + g(x, y)} = \frac{3}{3 + 7} = \frac{3}{10}$$

13. Does $\displaystyle\lim_{(x,y)\to(0,0)} \frac{y^2}{x^2+y^2}$ exist? Explain.

SOLUTION This limit does not exist. Consider the following approaches to the point $(x, y) = (0, 0)$ - first along the line $x = 0$ and second, along the line $y = x$.

First along the line $x = 0$ we calculate:

$$\lim_{(x,y)\to(0,0)} \frac{y^2}{x^2+y^2} = \lim_{y\to 0} \frac{y^2}{0^2+y^2} = \lim_{y\to 0} 1 = 1$$

Second, along the line $y = x$ we calculate:

$$\lim_{(x,y)\to(0,0)} \frac{y^2}{x^2+y^2} = \lim_{x\to 0} \frac{x^2}{x^2+x^2} = \lim_{x\to 0} \frac{1}{2} = \frac{1}{2}$$

Since these two limits are not equal, the limit in question, $\lim_{(x,y)\to(0,0)} \frac{y^2}{x^2+y^2}$ does not exist.

14. Let $f(x, y) = xy/(x^2 + y^2)$. Show that $f(x, y)$ approaches zero as (x, y) approaches the origin along the x- and y-axes. Then prove that $\displaystyle\lim_{(x,y)\to(0,0)} f(x, y)$ does not exist by showing that the limit along the line $y = x$ is nonzero.

SOLUTION

Case 1. Consider the limit along the x-axis ($y = 0$):

$$\lim_{(x,y)\to(0,0)} \frac{xy}{x^2+y^2} = \lim_{x\to 0} \frac{0}{x^2+0^2} = \lim_{x\to 0} 0 = 0$$

Case 2. Consider the limit along the y-axis ($x = 0$):

$$\lim_{(x,y)\to(0,0)} \frac{xy}{x^2+y^2} = \lim_{y\to 0} \frac{0}{0^2+y^2} = \lim_{y\to 0} 0 = 0$$

Case 3. Consider the limit along the line $y = x$:

$$\lim_{(x,y)\to(0,0)} \frac{xy}{x^2+y^2} = \lim_{x\to 0} \frac{x(x)}{x^2+x^2} = \lim_{x\to 0} \frac{x^2}{2x^2} = \lim_{x\to 0} \frac{1}{2} = \frac{1}{2}$$

Therefore, since the last limit we computed is not equal to zero, the limit in question, $\lim_{(x,y)\to(0,0)} xy/(x^2 + y^2)$ does not exist.

15. Prove that

$$\lim_{(x,y)\to(0,0)} \frac{x}{x^2+y^2}$$

does not exist by considering the limit along the x-axis.

SOLUTION Compute this limit approaching $(x, y) = (0, 0)$ along the x-axis ($y = 0$):

$$\lim_{(x,y)\to(0,0)} \frac{x}{x^2+y^2} = \lim_{x\to 0} \frac{x}{x^2+0^2} = \lim_{x\to 0} \frac{1}{x}$$

This limit is known not to exist (it gets arbitrarily large from the right and arbitrarily small from the left), therefore the limit in question, $\lim_{(x,y)\to(0,0)} \frac{x}{x^2+y^2}$, also does not exist.

16. Let $f(x, y) = x^3/(x^2 + y^2)$ and $g(x, y) = x^2/(x^2 + y^2)$. Using polar coordinates, prove that

$$\lim_{(x,y)\to(0,0)} f(x, y) = 0$$

and that $\displaystyle\lim_{(x,y)\to(0,0)} g(x, y)$ does not exist. *Hint:* Show that $g(x, y) = \cos^2\theta$ and observe that $\cos\theta$ can take on any value between -1 and 1 as $(x, y) \to (0, 0)$.

SOLUTION First we will compute $\lim_{(x,y)\to(0,0)} f(x, y)$:

$$\lim_{(x,y)\to(0,0)} \frac{x^3}{x^2+y^2} = \lim_{(r,\theta)\to(0,0)} \frac{r^3\cos^3\theta}{r^2\cos^2\theta + r^2\sin^2\theta} = \lim_{(r,\theta)\to(0,0)} r\cos^3\theta = 0$$

Now, we will compute $\lim_{(x,y)\to(0,0)} g(x, y)$:

$$\lim_{(x,y)\to(0,0)} \frac{x^2}{x^2+y^2} = \lim_{(r,\theta)\to(0,0} \frac{r^2\cos^2\theta}{r^2\cos^2\theta + r^2\sin^2\theta} = \lim_{(r,\theta)\to(0,0)} \cos^2\theta$$

Now $\cos\theta$ can take on any value between -1 and 1 - it depends on the angle at which (x, y) approaches the origin. (If it approaches the origin along the line with $\sin\theta$, then the limit will be $\cos\theta$.) Thus, as a result, $\cos^2\theta$ can be any value between 0 and 1. This limit does not exist, there is not just one finite value.

17. Use the Squeeze Theorem to evaluate

$$\lim_{(x,y)\to(4,0)} (x^2-16)\cos\left(\frac{1}{(x-4)^2+y^2}\right)$$

SOLUTION Consider the following inequalities:

$$-1 \le \cos\left(\frac{1}{(x-4)^2+y^2}\right) \le 1$$

Then for x such that $x \ge 4$ then $x^2 - 16 \ge 0$ and we have:

$$(-1)(x^2-16) \le (x^2-16)\cos\left(\frac{1}{(x-4)^2+y^2}\right) \le (x^2-16)$$

$$\lim_{(x,y)\to(4,0)} (-1)(x^2-16) \le \lim_{(x,y)\to(4,0)} (x^2-16)\cos\left(\frac{1}{(x-4)^2+y^2}\right) \le \lim_{(x,y)\to(4,0)} (x^2-16)$$

Then the two limits at the ends of the inequality are clearly equal to 0, by the Squeeze Theorem.

Now, if $x < 4$, then $x^2 - 16 < 0$ and we have:

$$(x^2-16) \le (x^2-16)\cos\left(\frac{1}{(x-4)^2+y^2}\right) \le (-1)(x^2-16)$$

$$\lim_{(x,y)\to(4,0)} (x^2-16) \le \lim_{(x,y)\to(4,0)} (x^2-16)\cos\left(\frac{1}{(x-4)^2+y^2}\right) \le \lim_{(x,y)\to(4,0)} (-1)(x^2-16)$$

Then the two limits at the ends of the inequality are clearly equal to 0, by the Squeeze Theorem.

Thus we can conclude

$$\lim_{(x,y)\to(4,0)} (x^2-16)\cos\left(\frac{1}{(x-4)^2+y^2}\right) = 0$$

18. Evaluate $\lim_{(x,y)\to(0,0)} \tan x \sin\left(\frac{1}{|x|+|y|}\right)$.

SOLUTION We will try to use the Squeeze Theorem for this problem. Consider the following inequalities:

$$-1 \le \sin\left(\frac{1}{|x|+|y|}\right) \le 1$$

Then we have, if $\tan x \ge 0$:

$$(-1)\tan x \le \tan x \cdot \sin\left(\frac{1}{|x|+|y|}\right) \le \tan x$$

$$\lim_{(x,y)\to(0,0)} -\tan x \le \lim_{(x,y)\to(0,0)} \tan x \cdot \sin\left(\frac{1}{|x|+|y|}\right) \le \lim_{(x,y)\to(0,0)} \tan x$$

If we have $\tan x < 0$ then:

$$\tan x \le \tan x \cdot \sin\left(\frac{1}{|x|+|y|}\right) \le -\tan x$$

$$\lim_{(x,y)\to(0,0)} \tan x \le \lim_{(x,y)\to(0,0)} \tan x \cdot \sin\left(\frac{1}{|x|+|y|}\right) \le \lim_{(x,y)\to(0,0)} -\tan x$$

Then the two limits of the endpoints in both cases are clearly equal to 0, by the Squeeze Theorem we can conclude

$$\lim_{(x,y)\to(0,0)} \tan x \cdot \sin\left(\frac{1}{|x|+|y|}\right) = 0$$

In Exercises 19–32, evaluate the limit or determine that it does not exist.

19. $\displaystyle\lim_{(z,w)\to(-2,1)} \frac{z^4\cos(\pi w)}{e^{z+w}}$

SOLUTION This function is continuous everywhere since the denominator is never equal to 0, therefore, we will evaluate the limit by substitution:

$$\lim_{(z,w)\to(-2,1)} \frac{z^4\cos(\pi w)}{e^{z+w}} = \frac{(-2)^4\cos(\pi)}{e^{-2+1}} = \frac{16(-1)}{e^{-1}} = -16e$$

20. $\displaystyle\lim_{(z,w)\to(-1,2)} (z^2w - 9z)$

SOLUTION The function is continuous everywhere since it is a polynomial. Therefore we use substitution to evaluate the limit:

$$\lim_{(z,\omega)\to(-1,2)} (z^2\omega - 9z) = (-1)^2\cdot 2 - 9\cdot(-1) = 11.$$

21. $\displaystyle\lim_{(x,y)\to(4,2)} \frac{y-2}{\sqrt{x^2-4}}$

SOLUTION The function is continuous at the point $(4, 2)$, since it is the quotient of two continuous functions and the denominator is not zero at $(4, 2)$. We compute the limit by substitution:

$$\lim_{(x,y)\to(4,2)} \frac{y-2}{\sqrt{x^2-4}} = \frac{2-2}{\sqrt{4^2-4}} = \frac{0}{\sqrt{12}} = 0$$

22. $\displaystyle\lim_{(x,y)\to(0,0)} \frac{x^2+y^2}{1+y^2}$

SOLUTION The function $\frac{x^2+y^2}{1+y^2}$ is continuous everywhere since it is a rational function whose denominator is never zero. We evaluate the limit using substitution:

$$\lim_{(x,y)\to(0,0)} \frac{x^2+y^2}{1+y^2} = \frac{0^2+0^2}{1+0^2} = 0$$

23. $\displaystyle\lim_{(x,y)\to(3,4)} \frac{1}{\sqrt{x^2+y^2}}$

SOLUTION The function $\dfrac{1}{\sqrt{x^2+y^2}}$ is continuous at the point $(3, 4)$ since it is the quotient of two continuous functions and the denominator is not zero at $(3, 4)$. We compute the limit by substitution:

$$\lim_{(x,y)\to(3,4)} \frac{1}{\sqrt{x^2+y^2}} = \frac{1}{\sqrt{9+16}} = \frac{1}{5}$$

24. $\displaystyle\lim_{(x,y)\to(0,0)} \frac{xy}{\sqrt{x^2+y^2}}$

SOLUTION We can see that the limit along any line through $(0, 0)$ is 0, as well as along other paths through $(0, 0)$ such as $x = y^2$ and $y = x^2$. So we suspect that the limit exists and equals 0; we use the Squeeze Theorem to prove our assertion. Consider the following inequalities:

$$0 \le \left|\frac{xy}{\sqrt{x^2+y^2}}\right| \le |x|$$

since $|y| \le \sqrt{x^2+y^2}$, and $|x| \to 0$ as $(x, y) \to (0, 0)$. So then by the Squeeze Theorem, we know:

$$\lim_{(x,y)\to(0,0)} \frac{xy}{\sqrt{x^2+y^2}} = 0$$

25. $\displaystyle\lim_{(x,y)\to(1,-3)} e^{x-y}\ln(x-y)$

SOLUTION This function $e^{x-y}\ln(x-y)$ is continuous at the point $(1, -3)$ since it is the product of two continuous functions. We can compute the limit by substitution:

$$\lim_{(x,y)\to(1,-3)} e^{x-y}\ln(x-y) = e^{1+3}\ln(1+3) = e^4\ln 4$$

26. $\lim_{(x,y)\to(0,0)} \frac{|x|}{|x|+|y|}$

SOLUTION We compute the limit as (x, y) approaches the origin along the line $y = mx$, for a fixed positive value of m. Substituting $y = mx$ in the function $f(x, y) = \frac{|x|}{|x|+|y|}$, we get for $x \neq 0$:

$$f(x, mx) = \frac{|x|}{|x| + m|x|} = \frac{|x|}{|x|(1+m)} = \frac{1}{1+m}$$

As (x, y) approaches $(0, 0)$, $(x, y) \neq (0, 0)$. Therefore $x \neq 0$ on the line $y = mx$. Thus,

$$\lim_{\substack{(x,y)\to(0,0)\\ \text{along } y=mx}} f(x, y) = \lim_{x\to 0} \frac{1}{1+m} = \frac{1}{1+m}$$

We see that the limits along the lines $y = mx$ are different, hence $f(x, y)$ does not approach one limit as $(x, y) \to (0, 0)$. We conclude that the given limit does not exist.

27. $\lim_{(x,y)\to(-3,-2)} (x^2y^3 + 4xy)$

SOLUTION The function $x^2y^3 + 4xy$ is continuous everywhere because it is a polynomial. We can compute this limit by substitution:

$$\lim_{(x,y)\to(-3,-2)} (x^2y^3 + 4xy) = 9(-8) + 4(-3)(-2) = -72 + 24 = -48$$

28. $\lim_{(x,y)\to(2,1)} e^{x^2-y^2}$

SOLUTION Since $e^{x^2-y^2} = e^{x^2} \cdot e^{-y^2}$, we evaluate the limit as a product of limits:

$$\lim_{(x,y)\to(2,1)} e^{x^2-y^2} = \left(\lim_{x\to 2} e^{x^2}\right)\left(\lim_{y\to 1} e^{-y^2}\right) = e^{2^2} \cdot e^{-1^2} = e^4 \cdot e^{-1} = e^3$$

Notice that since $e^{x^2-y^2}$ is continuous everywhere, we may evaluate the limit by substitution:

$$\lim_{(x,y)\to(2,1)} e^{x^2-y^2} = e^{2^2-1^2} = e^3.$$

29. $\lim_{(x,y)\to(0,0)} \tan(x^2+y^2)\tan^{-1}\left(\frac{1}{x^2+y^2}\right)$

SOLUTION Consider the following inequalities:

$$-\frac{\pi}{2} \le \tan^{-1}\left(\frac{1}{x^2+y^2}\right) \le \frac{\pi}{2}$$

$$-\frac{\pi}{2} \cdot \tan(x^2+y^2) \le \tan(x^2+y^2) \cdot \left(\frac{1}{x^2+y^2}\right) \le \frac{\pi}{2} \tan(x^2+y^2)$$

and then taking limits:

$$\lim_{(x,y)\to(0,0)} -\frac{\pi}{2} \cdot \tan(x^2+y^2) \le \lim_{(x,y)\to(0,0)} \tan(x^2+y^2) \cdot \left(\frac{1}{x^2+y^2}\right) \le \lim_{(x,y)\to(0,0)} \frac{\pi}{2} \tan(x^2+y^2)$$

Each of the limits on the endpoints of this inequality is equal to 0, thus we can conclude:

$$\lim_{(x,y)\to(0,0)} \tan(x^2+y^2) \cdot \left(\frac{1}{x^2+y^2}\right) = 0$$

30. $\lim_{(x,y)\to(0,0)} (x+y+2)e^{-1/(x^2+y^2)}$

SOLUTION First let us recall that $\lim_{t\to 0} e^{-1/t} = 0$ since $-1/t$ gets infinitely small. Therefore we can conclude,

$$\lim_{(x,y)\to(0,0)} (x+y+2)e^{-1/(x^2+y^2)} = (0+0+2) \cdot 0 = 0$$

31. $\displaystyle\lim_{(x,y)\to(0,0)} \frac{x^2+y^2}{\sqrt{x^2+y^2+1}-1}$

SOLUTION We rewrite the function by dividing and multiplying it by the conjugate of $\sqrt{x^2+y^2+1}-1$ and using the identity $(a-b)(a+b)=a^2-b^2$. This gives

$$\frac{x^2+y^2}{\sqrt{x^2+y^2+1}-1} = \frac{(x^2+y^2)\left(\sqrt{x^2+y^2+1}+1\right)}{\left(\sqrt{x^2+y^2+1}-1\right)\left(\sqrt{x^2+y^2+1}+1\right)} = \frac{(x^2+y^2)\left(\sqrt{x^2+y^2+1}+1\right)}{\left(x^2+y^2+1\right)-1}$$

$$= \frac{(x^2+y^2)\left(\sqrt{x^2+y^2+1}+1\right)}{x^2+y^2} = \sqrt{x^2+y^2+1}+1$$

The resulting function is continuous, hence we may compute the limit by substitution. This gives

$$\lim_{(x,y)\to(0,0)} \frac{x^2+y^2}{\sqrt{x^2+y^2+1}-1} = \lim_{(x,y)\to(0,0)} \left(\sqrt{x^2+y^2+1}+1\right) = \sqrt{0^2+0^2+1}+1 = 2$$

32. $\displaystyle\lim_{(x,y)\to(1,1)} \frac{x^2+y^2-2}{|x-1|+|y-1|}$

Hint: Rewrite the limit in terms of $u=x-1$ and $v=y-1$.

SOLUTION Taking the hint given, let us rewrite the problem, instead of $(x,y)\to(1,1)$, then if $u=x-1$ and $v=y-1$, then $(u,v)\to(0,0)$. Transforming the limit we have:

$$\lim_{(x,y)\to(1,1)} \frac{x^2+y^2-2}{|x-1|+|y-1|} = \lim_{(u,v)\to(0,0)} \frac{(u+1)^2+(v+1)^2-2}{|u|+|v|} = \lim_{(u,v)\to(0,0)} \frac{u^2+2u+v^2+2v}{|u|+|v|}$$

Now consider this limit along two different paths, one is let $v=u=|u|$ and the other $v=-u=|u|$. Examining the limit along $v=u=|u|$ we have

$$\lim_{(u,v)\to(0,0)} \frac{u^2+2u+v^2+2v}{|u|+|v|} = \lim_{u\to0} \frac{u^2+2u+u^2+2u}{u+u} = \lim_{u\to0} \frac{2u^2+4u}{2u} = \lim_{u\to0} u+2 = 2$$

whereas if $v=-u=|u|$ we get:

$$\lim_{(u,v)\to(0,0)} \frac{u^2+2u+v^2+2v}{|u|+|v|} = \lim_{u\to0} \frac{u^2+2u+u^2-2u}{-u-u} = \lim_{u\to0} \frac{2u^2}{-2u} = \lim_{u\to0} -u = 0$$

Since the limits along these two distinct paths are not equal, we conclude that the limit in question does not exist.

33. Let $f(x,y) = \dfrac{x^3+y^3}{x^2+y^2}$.

(a) Show that

$$|x^3| \le |x|(x^2+y^2), \quad |y^3| \le |y|(x^2+y^2)$$

(b) Show that $|f(x,y)| \le |x|+|y|$.

(c) Use the Squeeze Theorem to prove that $\displaystyle\lim_{(x,y)\to(0,0)} f(x,y) = 0$.

SOLUTION

(a) Since $|x|y^2 \ge 0$, we have

$$|x^3| \le |x^3| + |x|y^2 = |x|^3 + |x|y^2 = |x|(x^2+y^2)$$

Similarly, since $|y|x^2 \ge 0$, we have

$$|y^3| \le |y^3| + |y|x^2 = |y|^3 + |y|x^2 = |y|(x^2+y^2)$$

(b) We use the triangle inequality to write

$$|f(x,y)| = \frac{|x^3+y^3|}{x^2+y^2} \le \frac{|x^3|+|y^3|}{x^2+y^2}$$

We continue using the inequality in part (a):

$$|f(x,y)| \le \frac{|x|(x^2+y^2)+|y|(x^2+y^2)}{x^2+y^2} = \frac{(|x|+|y|)(x^2+y^2)}{x^2+y^2} = |x|+|y|$$

That is,

$$|f(x, y)| \le |x| + |y|$$

(c) In part (b) we showed that

$$|f(x, y)| \le |x| + |y| \tag{1}$$

Let $\epsilon > 0$. Then if $|x| < \frac{\epsilon}{2}$ and $|y| < \frac{\epsilon}{2}$, we have by (1)

$$|f(x, y) - 0| \le |x| + |y| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \tag{2}$$

Notice that if $x^2 + y^2 < \frac{\epsilon^2}{4}$, then $x^2 < \frac{\epsilon^2}{4}$ and $y^2 < \frac{\epsilon^2}{4}$. Hence $|x| < \frac{\epsilon}{2}$ and $|y| < \frac{\epsilon}{2}$, so (1) holds. In other words, using $D^\star\left(\frac{\epsilon}{2}\right)$ to represent the punctured disc of radius $\epsilon/2$ centered at the origin, we have

$$(x, y) \in D^\star\left(\frac{\epsilon}{2}\right) \quad \Rightarrow \quad |x| < \frac{\epsilon}{2}$$

and

$$|y| < \frac{\epsilon}{2} \quad \Rightarrow \quad |f(x, y) - 0| < \epsilon$$

We conclude by the limit definition that

$$\lim_{(x,y)\to(0,0)} f(x, y) = 0$$

34. Let $a, b \ge 0$. Show that $\displaystyle\lim_{(x,y)\to(0,0)} \frac{x^a y^b}{x^2 + y^2} = 0$ if $a + b > 2$ and that the limit does not exist if $a + b \le 2$.

SOLUTION We first show that the limit is zero if $a + b > 2$. We compute the limit using the polar coordinates $x = r\cos\theta$, $y = r\sin\theta$. Then $(x, y) \to (0, 0)$ if and only if $x^2 + y^2 \to 0$, that is, if and only if $r \to 0+$. Therefore,

$$\begin{aligned}\lim_{(x,y)\to(0,0)} \frac{x^a y^b}{x^2 + y^2} &= \lim_{r\to 0+} \frac{(r\cos\theta)^a (r\sin\theta)^b}{r^2} = \lim_{r\to 0+} \frac{r^{a+b}\cos^a\theta \sin^b\theta}{r^2} \\ &= \lim_{r\to 0+} (r^{a+b-2}\cos^a\theta\sin^b\theta) \end{aligned} \tag{1}$$

The following inequality holds:

$$0 \le |r^{a+b-2}\cos^a\theta\sin^b\theta| \le r^{a+b-2} \tag{2}$$

Since $a + b > 2$, $\displaystyle\lim_{r\to 0+} r^{a+b-2} = 0$, therefore (2) and the Squeeze Theorem imply that

$$\lim_{r\to 0} (r^{a+b-2}\cos^a\theta\sin^b\theta) = 0 \tag{3}$$

We combine (1) and (3) to conclude that if $a + b > 2$, then

$$\lim_{(x,y)\to(0,0)} \frac{x^a y^b}{x^2 + y^2} = 0$$

We now consider the case $a + b < 2$. We examine the limit as (x, y) approaches the origin along the line $y = x$. Along this line, $\theta = \frac{\pi}{4}$, therefore (1) gives

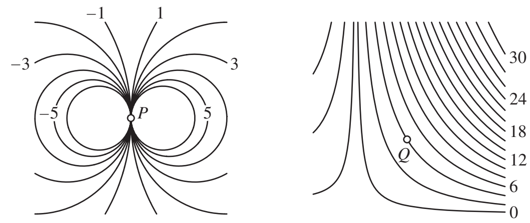
$$\lim_{(x,y)\to(0,0)} \frac{x^a y^b}{x^2 + y^2} = \lim_{r\to 0+} \left(r^{a+b-2}\cos^a\frac{\pi}{4}\sin^b\frac{\pi}{4}\right) = \lim_{r\to 0+} \left(r^{a+b-2} \cdot \left(\frac{1}{\sqrt{2}}\right)^a \cdot \left(\frac{1}{\sqrt{2}}\right)^b\right) = \lim_{r\to 0+} \frac{r^{a+b-2}}{(\sqrt{2})^{a+b}}$$

Since $a + b < 2$, we have $a + b - 2 < 0$ therefore $\displaystyle\lim_{r\to 0+} r^{a+b-2}$ does not exist. It follows that if $a + b < 2$, the given limit does not exist. Finally we examine the case $a + b = 2$. By (1) we get

$$\lim_{(x,y)\to(0,0)} \frac{x^a y^b}{x^2 + y^2} = \lim_{r\to 0+} (r^0\cos^a\theta\sin^b\theta) = \lim_{r\to 0+} \cos^a\theta\sin^b\theta = \cos^a\theta\sin^b\theta$$

We see that the function does not approach one limit. For example, approaching the origin along the lines $y = x$ (i.e., $\theta = \frac{\pi}{4}$) and $y = 0$ (i.e., $\theta = 0$) gives two different limits $\cos^a\frac{\pi}{4}\sin^b\frac{\pi}{4} = \left(\frac{\sqrt{2}}{2}\right)^{a+b}$ and $\cos^a 0 \sin^b 0 = 0$. We conclude that if $a + b = 2$, the limit does not exist.

35. Figure 7 shows the contour maps of two functions. Explain why the limit $\lim_{(x,y)\to P} f(x, y)$ does not exist. Does $\lim_{(x,y)\to Q} g(x, y)$ appear to exist in (B)? If so, what is its limit?



(A) Contour map of $f(x, y)$ (B) Contour map of $g(x, y)$

FIGURE 7

SOLUTION As (x, y) approaches arbitrarily close to P, the function $f(x, y)$ takes the values ±1, ±3, and ±5. Therefore $f(x, y)$ does not approach one limit as $(x, y) \to P$. Rather, the limit depends on the contour along which (x, y) is approaching P. This implies that the limit $\lim_{(x,y)\to P} f(x, y)$ does not exist. In (B) the limit $\lim_{(x,y)\to Q} g(x, y)$ appears to exist. If it exists, it must be 4, which is the level curve of Q.

Further Insights and Challenges

36. Evaluate $\lim_{(x,y)\to(0,2)} (1 + x)^{y/x}$.

SOLUTION We denote $f(x, y) = (1 + x)^{y/x}$. Hence,

$$\ln f(x, y) = \ln(1 + x)^{y/x} = \frac{y}{x}\ln(1 + x) = y\frac{\ln(1 + x)}{x} \tag{1}$$

Using L'Hôpital's Rule we have

$$\lim_{x\to0} \frac{\ln(1 + x)}{x} = \lim_{x\to0} \frac{\frac{1}{1+x}}{1} = \lim_{x\to0} \frac{1}{1 + x} = \frac{1}{1 + 0} = 1$$

Since this limit exists, we may use the Product Rule to compute the limit of (1):

$$\lim_{(x,y)\to(0,2)} \ln f(x, y) = \left(\lim_{y\to2} y\right)\left(\lim_{x\to0} \frac{\ln(1 + x)}{x}\right) = 2 \cdot 1 = 2 \tag{2}$$

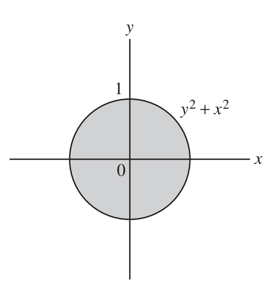
$\ln u$ approaches 2 if and only if u is approaching e^2. Therefore, the limit in (2) implies that

$$\lim_{(x,y)\to(0,2)} f(x, y) = e^2.$$

37. Is the following function continuous?

$$f(x, y) = \begin{cases} x^2 + y^2 & \text{if } x^2 + y^2 < 1 \\ 1 & \text{if } x^2 + y^2 \ge 1 \end{cases}$$

SOLUTION $f(x, y)$ is defined by a polynomial in the domain $x^2 + y^2 < 1$, hence f is continuous in this domain. In the domain $x^2 + y^2 > 1$, f is a constant function, hence f is continuous in this domain also. Thus, we must examine continuity at the points on the circle $x^2 + y^2 = 1$.



We express $f(x, y)$ using polar coordinates:

$$f(r,\theta) = \begin{cases} r^2 & 0 \le r < 1 \\ 1 & r \ge 1 \end{cases}$$

Since $\lim_{r\to 1-} f(r,\theta) = \lim_{r\to 1-} r^2 = 1$ and $\lim_{r\to 1+} f(r,\theta) = \lim_{r\to 1+} 1 = 1$, we have $\lim_{r\to 1} f(r,\theta) = 1$. Therefore $f(r,\theta)$ is continuous at $r = 1$, or $f(x, y)$ is continuous on $x^2 + y^2 = 1$. We conclude that f is continuous everywhere on R^2.

38. CAS The function $f(x, y) = \sin(xy)/xy$ is defined for $xy \neq 0$.

(a) Is it possible to extend the domain of $f(x, y)$ to all of $\mathbf{R}^2$ so that the result is a continuous function?

(b) Use a computer algebra system to plot $f(x, y)$. Does the result support your conclusion in (a)?

SOLUTION

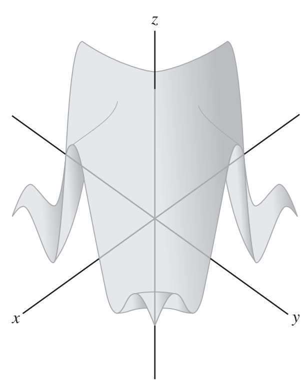
(a) We define $f(x, y)$ on the x- and y-axes by $f(x, y) = 1$ if $xy = 0$. We now show that f is continuous. f is continuous at the points where $xy \neq 0$. We next show continuity at $(x_0, 0)$ (including $x_0 = 0$). For the points $(0, y_0)$, the proof is similar and hence will be omitted. To prove continuity at $P = (x_0, 0)$ we have to show that

$$\lim_{(x,y)\to P} f(x, y) = \lim_{(x,y)\to P} \frac{\sin xy}{xy} = 1 \tag{1}$$

Let us denote $u = xy$. As $(x, y) \to (x_0, 0)$, $u = x \cdot y \to x_0 \cdot 0 = 0$. Thus,

$$\lim_{(x,y)\to P} f(x, y) = \lim_{(x,y)\to(x_0,0)} \frac{\sin xy}{xy} = \lim_{u\to 0} \frac{\sin u}{u} = 1 = f(x_0, 0).$$

(b) The following figure shows the graph of $f(x, y) = \frac{\sin xy}{xy}$:



The graph shows that, near the axes, the values of $f(x, y)$ are approaching 1, as shown in part (a).

39. Prove that the function

$$f(x, y) = \begin{cases} \dfrac{(2^x - 1)(\sin y)}{xy} & \text{if } xy \neq 0 \\ \ln 2 & \text{if } xy = 0 \end{cases}$$

is continuous at $(0, 0)$.

SOLUTION To solve this problem it is necessary to show that $\lim_{(x,y)\to(0,0)} f(x, y) = f(0, 0) = \ln 2$. Consider the following:

$$\begin{aligned} \lim_{(x,y)\to(0,0)} \frac{(2^x - 1)\sin y}{xy} &= \lim_{(x,y)\to(0,0)} \frac{2^x - 1}{x} \cdot \frac{\sin y}{y} \\ &= \left(\lim_{x\to 0} \frac{2^x - 1}{x}\right)\left(\lim_{y\to 0} \frac{\sin y}{y}\right) \\ &= \lim_{x\to 0} \frac{(\ln 2)2^x}{1} \cdot (1) = \ln 2 \end{aligned}$$

(Using L'Hopital's Rule on the limit in terms of x.) Thus since $\lim_{(x,y)\to(0,0)} f(x, y) = f(0, 0)$, we see that $f(x, y)$ is continuous at $(0, 0)$.

40. Prove that if $f(x)$ is continuous at $x = a$ and $g(y)$ is continuous at $y = b$, then $F(x, y) = f(x)g(y)$ is continuous at (a, b).

SOLUTION Given that $f(x)$ is continuous at $x = a$, we know that

$$\lim_{x\to a} f(x) = f(a)$$

and given that $g(x)$ is continuous at $x = b$, we know that

$$\lim_{x\to b} g(x) = g(b).$$

Consider the limit $\lim_{(x,y)\to(a,b)} F(x, y)$. Then using the above information we have

$$\lim_{(x,y)\to(a,b)} F(x, y) = \lim_{(x,y)\to(a,b)} f(x)g(y) = \left(\lim_{x\to a} f(x)\right)\left(\lim_{y\to b} g(y)\right) = f(a)g(b) = F(a, b)$$

Therefore, $F(x, y)$ is continuous at the point (a, b).

41. The function $f(x, y) = x^2y/(x^4 + y^2)$ provides an interesting example where the limit as $(x, y) \to (0, 0)$ does not exist, even though the limit along every line $y = mx$ exists and is zero (Figure 8).

(a) Show that the limit along any line $y = mx$ exists and is equal to 0.

(b) Calculate $f(x, y)$ at the points $(10^{-1}, 10^{-2})$, $(10^{-5}, 10^{-10})$, $(10^{-20}, 10^{-40})$. Do not use a calculator.

(c) Show that $\lim_{(x,y)\to(0,0)} f(x, y)$ does not exist. *Hint:* Compute the limit along the parabola $y = x^2$.

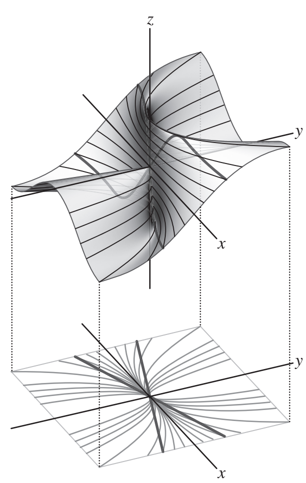


FIGURE 8 Graph of $f(x, y) = \dfrac{x^2y}{x^4 + y^2}$.

SOLUTION

(a) Substituting $y = mx$ in $f(x, y) = \frac{x^2y}{x^4+y^2}$, we get

$$f(x, mx) = \frac{x^2 \cdot mx}{x^4 + (mx)^2} = \frac{mx^3}{x^2(x^2 + m^2)} = \frac{mx}{x^2 + m^2}$$

We compute the limit as $x \to 0$ by substitution:

$$\lim_{x\to 0} f(x, mx) = \lim_{x\to 0} \frac{mx}{x^2 + m^2} = \frac{m \cdot 0}{0^2 + m^2} = 0$$

(b) We compute $f(x, y)$ at the given points:

$$f(10^{-1}, 10^{-2}) = \frac{10^{-2} \cdot 10^{-2}}{10^{-4} + 10^{-4}} = \frac{10^{-4}}{2 \cdot 10^{-4}} = \frac{1}{2}$$

$$f(10^{-5}, 10^{-10}) = \frac{10^{-10} \cdot 10^{-10}}{10^{-20} + 10^{-20}} = \frac{10^{-20}}{2 \cdot 10^{-20}} = \frac{1}{2}$$

$$f(10^{-20}, 10^{-40}) = \frac{10^{-40} \cdot 10^{-40}}{10^{-80} + 10^{-80}} = \frac{10^{-80}}{2 \cdot 10^{-80}} = \frac{1}{2}$$

(c) We compute the limit as (x, y) approaches the origin along the parabola $y = x^2$ (by part (b), the limit appears to be $\frac{1}{2}$). We substitute $y = x^2$ in the function and compute the limit as $x \to 0$. This gives

$$\lim_{\substack{(x,y)\to 0 \\ \text{along } y=x^2}} f(x, y) = \lim_{x\to 0} f(x, x^2) = \lim_{x\to 0} \frac{x^2 \cdot x^2}{x^4 + (x^2)^2} = \lim_{x\to 0} \frac{x^4}{2x^4} = \lim_{x\to 0} \frac{1}{2} = \frac{1}{2}$$

However, in part (a), we showed that the limit along the lines $y = mx$ is zero. Therefore $f(x, y)$ does not approach one limit as $(x, y) \to (0, 0)$, so the limit $\lim_{(x,y)\to(0,0)} f(x, y)$ does not exist.

14.3 Partial Derivatives (LT Section 15.3)

Preliminary Questions

1. Patricia derived the following *incorrect* formula by misapplying the Product Rule:

$$\frac{\partial}{\partial x}(x^2 y^2) = x^2(2y) + y^2(2x)$$

What was her mistake and what is the correct calculation?

SOLUTION To compute the partial derivative with respect to x, we treat y as a constant. Therefore the Constant Multiple Rule must be used rather than the Product Rule. The correct calculation is:

$$\frac{\partial}{\partial x}(x^2 y^2) = y^2 \frac{\partial}{\partial x}(x^2) = y^2 \cdot 2x = 2xy^2.$$

2. Explain why it is not necessary to use the Quotient Rule to compute $\frac{\partial}{\partial x}\left(\frac{x+y}{y+1}\right)$. Should the Quotient Rule be used to compute $\frac{\partial}{\partial y}\left(\frac{x+y}{y+1}\right)$?

SOLUTION In differentiating with respect to x, y is considered a constant. Therefore in this case the Constant Multiple Rule can be used to obtain

$$\frac{\partial}{\partial x}\left(\frac{x+y}{y+1}\right) = \frac{1}{y+1}\frac{\partial}{\partial x}(x+y) = \frac{1}{y+1} \cdot 1 = \frac{1}{y+1}.$$

As for the second part, since y appears in both the numerator and the denominator, the Quotient Rule is indeed needed.

3. Which of the following partial derivatives should be evaluated without using the Quotient Rule?

(a) $\frac{\partial}{\partial x}\frac{xy}{y^2+1}$ **(b)** $\frac{\partial}{\partial y}\frac{xy}{y^2+1}$ **(c)** $\frac{\partial}{\partial x}\frac{y^2}{y^2+1}$

SOLUTION

(a) This partial derivative does not require use of the Quotient Rule, since the Constant Multiple Rule gives

$$\frac{\partial}{\partial x}\left(\frac{xy}{y^2+1}\right) = \frac{y}{y^2+1}\frac{\partial}{\partial x}(x) = \frac{y}{y^2+1} \cdot 1 = \frac{y}{y^2+1}.$$

(b) This partial derivative requires use of the Quotient Rule.

(c) Since y is considered a constant in differentiating with respect to x, we do not need the Quotient Rule to state that $\frac{\partial}{\partial x}\left(\frac{y^2}{y^2+1}\right) = 0.$

4. What is f_x, where $f(x, y, z) = (\sin yz)e^{z^3 - z^{-1}\sqrt{y}}$?

SOLUTION In differentiating with respect to x, we treat y and z as constants. Therefore, the whole expression for $f(x, y, z)$ is treated as constant, so the derivative is zero:

$$\frac{\partial}{\partial x}\left(\sin yz e^{z^3 - z^{-1}\sqrt{y}}\right) = 0.$$

5. Assuming the hypotheses of Clairaut's Theorem are satisfied, which of the following partial derivatives are equal to f_{xxy}?

(a) f_{xyx} **(b)** f_{yyx} **(c)** f_{xyy} **(d)** f_{yxx}

SOLUTION f_{xxy} involves two differentiations with respect to x and one differentiation with respect to y. Therefore, if f satisfies the assumptions of Clairaut's Theorem, then

$$f_{xxy} = f_{xyx} = f_{yxx}$$

Exercises

1. Use the limit definition of the partial derivative to verify the formulas

$$\frac{\partial}{\partial x} xy^2 = y^2, \qquad \frac{\partial}{\partial y} xy^2 = 2xy$$

SOLUTION Using the limit definition of the partial derivative, we have

$$\frac{\partial}{\partial x} xy^2 = \lim_{h\to 0} \frac{(x+h)y^2 - xy^2}{h} = \lim_{h\to 0} \frac{xy^2 + hy^2 - xy^2}{h} = \lim_{h\to 0} \frac{hy^2}{h} = \lim_{h\to 0} y^2 = y^2$$

$$\frac{\partial}{\partial y} xy^2 = \lim_{k\to 0} \frac{x(y+k)^2 - xy^2}{k} = \lim_{k\to 0} \frac{x(y^2+2yk+k^2) - xy^2}{k} = \lim_{k\to 0} \frac{xy^2 + 2xyk + xk^2 - xy^2}{k}$$

$$= \lim_{k\to 0} \frac{k(2xy+xk)}{k} = \lim_{k\to 0} (2xy+k) = 2xy + 0 = 2xy$$

2. Use the Product Rule to compute $\frac{\partial}{\partial y}(x^2+y)(x+y^4)$.

SOLUTION Using the Product Rule we obtain

$$\frac{\partial}{\partial y}(x^2+y)(x+y^4) = (x^2+y)\frac{\partial}{\partial y}(x+y^4) + (x+y^4)\frac{\partial}{\partial y}(x^2+y)$$

$$= (x^2+y)\cdot 4y^3 + (x+y^4)\cdot 1 = 4x^2y^3 + 5y^4 + x$$

3. Use the Quotient Rule to compute $\frac{\partial}{\partial y}\frac{y}{x+y}$.

SOLUTION Using the Quotient Rule we obtain

$$\frac{\partial}{\partial y}\frac{y}{x+y} = \frac{(x+y)\frac{\partial}{\partial y}(y) - y\frac{\partial}{\partial y}(x+y)}{(x+y)^2} = \frac{(x+y)\cdot 1 - y\cdot 1}{(x+y)^2} = \frac{x}{(x+y)^2}$$

4. Use the Chain Rule to compute $\frac{\partial}{\partial u}\ln(u^2+uv)$.

SOLUTION By the Chain Rule $\frac{d}{du}\ln\omega = \frac{1}{\omega}\frac{d\omega}{du}$. Applying this with $\omega = u^2 + uv$ gives

$$\frac{\partial}{\partial u}\ln(u^2+uv) = \frac{1}{u^2+uv}\frac{\partial}{\partial u}(u^2+uv) = \frac{2u+v}{u^2+uv}$$

5. Calculate $f_z(2,3,1)$, where $f(x,y,z) = xyz$.

SOLUTION We first find the partial derivative $f_z(x,y,z)$:

$$f_z(x,y,z) = \frac{\partial}{\partial z}(xyz) = xy$$

Substituting the given point we get

$$f_z(2,3,1) = 2\cdot 3 = 6$$

6. Explain the relation between the following two formulas (c is a constant).

$$\frac{d}{dx}\sin(cx) = c\cos(cx), \qquad \frac{\partial}{\partial x}\sin(xy) = y\cos(xy)$$

SOLUTION $\frac{d}{dx}\sin(cx)$ is the derivative of the single-variable function $\sin(cx)$, where c is a constant. $\frac{\partial}{\partial x}\sin(xy)$ is the partial derivative of the two-variable function $\sin(xy)$ with respect to x. While differentiating, the variable y is considered constant, hence it resembles the first differentiation, and the results are the same where c is replaced by y.

7. The plane $y = 1$ intersects the surface $z = x^4 + 6xy - y^4$ in a certain curve. Find the slope of the tangent line to this curve at the point $P = (1, 1, 6)$.

SOLUTION The slope of the tangent line to the curve $z = z(x, 1) = x^4 + 6x - 1$, obtained by intersecting the surface $z = x^4 + 6xy - y^4$ with the plane $y = 1$, is the partial derivative $\frac{\partial z}{\partial x}(1, 1)$.

$$\frac{\partial z}{\partial x} = \frac{\partial}{\partial x}(x^4 + 6xy - y^4) = 4x^3 + 6y$$

$$m = \frac{\partial z}{\partial x}(1, 1) = 4 \cdot 1^3 + 6 \cdot 1 = 10$$

8. Determine whether the partial derivatives $\partial f/\partial x$ and $\partial f/\partial y$ are positive or negative at the point P on the graph in Figure 7.

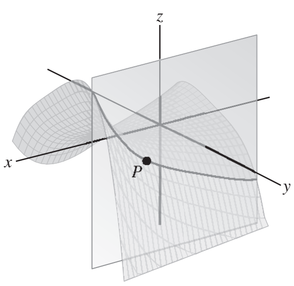

FIGURE 7

SOLUTION The graph shows that f is increasing in the direction of growing x and f is decreasing in the direction of growing y. Therefore, $\frac{\partial f}{\partial x}\big|_P > 0$ and $\frac{\partial f}{\partial y}\big|_P < 0$.

In Exercises 9–12, refer to Figure 8.

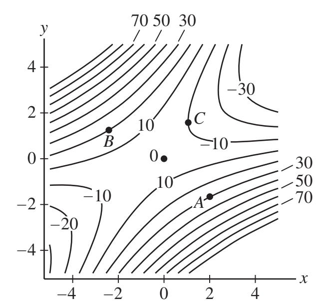

FIGURE 8 Contour map of $f(x, y)$.

9. Estimate f_x and f_y at point A.

SOLUTION To estimate f_x we move horizontally to the next level curve in the direction of growing x, to a point A'. The change in f from A to A' is the contour interval, $\Delta f = 40 - 30 = 10$. The distance between A and A' is approximately $\Delta x \approx 1.0$. Hence,

$$f_x(A) \approx \frac{\Delta f}{\Delta x} = \frac{10}{1.0} = 10$$

To estimate f_y we move vertically from A to a point A'' on the next level curve in the direction of growing y. The change in f from A to A'' is $\Delta f = 20 - 30 = -10$. The distance between A and A'' is $\Delta y \approx 0.5$. Hence,

$$f_y(A) \approx \frac{\Delta f}{\Delta y} = \frac{-10}{0.5} \approx -20.$$

10. Is f_x positive or negative at B?

SOLUTION To estimate f_x at B, we move horizontally to the next level curve in the direction of growing x, to a point B'. The change in f from B to B' is the contour interval $\Delta f = 10 - 20 = -10$ while the distance between B and B' is approximately $\Delta x \approx 1$. Hence

$$f_x(B) \approx \frac{\Delta f}{\Delta x} = \frac{-10}{1} = -10 < 0$$

Therefore $f_x(B)$ is negative.

11. Starting at point B, in which compass direction (N, NE, SW, etc.) does f increase most rapidly?

SOLUTION The distances between adjacent level curves starting at B are the smallest along the line with slope -1, upward. Therefore, f is increasing most rapidly in the direction of $\theta = 135^\circ$ or in the NW direction.

12. At which of A, B, or C is f_y smallest?

SOLUTION We consider vertical lines through A, B, and C. The distance between each point A, B, C and the intersection of the vertical line with the adjacent level curves is the largest at C. It means that f_y is smallest at C.

In Exercises 13–40, compute the first-order partial derivatives.

13. $z = x^2 + y^2$

SOLUTION We compute $z_x(x, y)$ by treating y as a constant, and we compute $z_y(x, y)$ by treating x as a constant:

$$\frac{\partial}{\partial x}(x^2 + y^2) = 2x; \quad \frac{\partial}{\partial y}(x^2 + y^2) = 2y$$

14. $z = x^4 y^3$

SOLUTION Treating y as a constant (to find z_x) and x as a constant (to find z_y) and using Rules for Differentiation, we get,

$$\frac{\partial}{\partial x}(x^4 y^3) = y^3 \frac{\partial}{\partial x}(x^4) = y^3 \cdot 4x^3 = 4x^3 y^3$$
$$\frac{\partial}{\partial y}(x^4 y^3) = x^4 \frac{\partial}{\partial y}(y^3) = x^4 \cdot 3y^2 = 3x^4 y^2$$

15. $z = x^4 y + x y^{-2}$

SOLUTION We obtain the following partial derivatives:

$$\frac{\partial}{\partial x}(x^4 y + x y^{-2}) = 4x^3 y + y^{-2}$$
$$\frac{\partial}{\partial y}(x^4 y + x y^{-2}) = x^4 + x \cdot (-2y^{-3}) = x^4 - 2xy^{-3}$$

16. $V = \pi r^2 h$

SOLUTION We find $\frac{\partial V}{\partial r}$ and $\frac{\partial V}{\partial h}$:

$$\frac{\partial V}{\partial r} = \frac{\partial}{\partial r}(\pi r^2 h) = \pi h \frac{\partial}{\partial r}(r^2) = \pi h \cdot 2r = 2\pi h r$$
$$\frac{\partial V}{\partial h} = \frac{\partial}{\partial h}(\pi r^2 h) = \pi r^2$$

17. $z = \dfrac{x}{y}$

SOLUTION Treating y as a constant we have

$$\frac{\partial}{\partial x}\left(\frac{x}{y}\right) = \frac{1}{y}\frac{\partial}{\partial x}(x) = \frac{1}{y} \cdot 1 = \frac{1}{y}$$

We now find the derivative $z_y(x, y)$, treating x as a constant:

$$\frac{\partial}{\partial y}\left(\frac{x}{y}\right) = x \cdot \frac{\partial}{\partial y}\left(\frac{1}{y}\right) = x \cdot \frac{-1}{y^2} = \frac{-x}{y^2}.$$

18. $z = \dfrac{x}{x - y}$

SOLUTION We differentiate with respect to x, using the Quotient Rule. We get

$$\frac{\partial}{\partial x}\left(\frac{x}{x-y}\right) = \frac{(x-y)\frac{\partial}{\partial x}(x) - x\frac{\partial}{\partial x}(x-y)}{(x-y)^2} = \frac{(x-y)\cdot 1 - x \cdot 1}{(x-y)^2} = \frac{-y}{(x-y)^2}$$

We now differentiate with respect to y, using the Chain Rule:

$$\frac{\partial}{\partial y}\left(\frac{x}{x-y}\right) = x\frac{\partial}{\partial y}\left(\frac{1}{x-y}\right) = x \cdot \frac{-1}{(x-y)^2}\frac{\partial}{\partial y}(x-y) = x \cdot \frac{-1}{(x-y)^2} \cdot (-1) = \frac{x}{(x-y)^2}$$

19. $z = \sqrt{9 - x^2 - y^2}$

SOLUTION Differentiating with respect to x, treating y as a constant, and using the Chain Rule, we obtain

$$\frac{\partial}{\partial x}\left(\sqrt{9 - x^2 - y^2}\right) = \frac{1}{2\sqrt{9 - x^2 - y^2}} \frac{\partial}{\partial x}(9 - x^2 - y^2) = \frac{-2x}{2\sqrt{9 - x^2 - y^2}} = \frac{-x}{\sqrt{9 - x^2 - y^2}}$$

We now differentiate with respect to y, treating x as a constant:

$$\frac{\partial}{\partial y}\left(\sqrt{9 - x^2 - y^2}\right) = \frac{1}{2\sqrt{9 - x^2 - y^2}} \frac{\partial}{\partial y}(9 - x^2 - y^2) = \frac{-2y}{2\sqrt{9 - x^2 - y^2}} = \frac{-y}{\sqrt{9 - x^2 - y^2}}$$

20. $z = \dfrac{x}{\sqrt{x^2 + y^2}}$

SOLUTION We compute $\frac{\partial z}{\partial x}$ using the Quotient Rule and the Chain Rule:

$$\frac{\partial z}{\partial x} = \frac{1 \cdot \sqrt{x^2 + y^2} - x \frac{\partial}{\partial x}\sqrt{x^2 + y^2}}{\left(\sqrt{x^2 + y^2}\right)^2} = \frac{\sqrt{x^2 + y^2} - x \cdot \frac{2x}{2\sqrt{x^2+y^2}}}{x^2 + y^2} = \frac{x^2 + y^2 - x^2}{(x^2 + y^2)^{3/2}} = \frac{y^2}{(x^2 + y^2)^{3/2}}$$

We compute $\frac{\partial z}{\partial y}$ using the Chain Rule:

$$\frac{\partial z}{\partial y} = x \frac{\partial}{\partial y}(x^2 + y^2)^{-1/2} = x \cdot \left(-\frac{1}{2}\right)(x^2 + y^2)^{-3/2} \cdot 2y = \frac{-xy}{(x^2 + y^2)^{3/2}}$$

21. $z = (\sin x)(\sin y)$

SOLUTION We obtain the following partial derivatives:

$$\frac{\partial}{\partial x}(\sin x \sin y) = \sin y \frac{\partial}{\partial x} \sin x = \sin y \cos x$$
$$\frac{\partial}{\partial y}(\sin x \sin y) = \sin x \frac{\partial}{\partial y} \sin y = \sin x \cos y$$

22. $z = \sin(u^2 v)$

SOLUTION By the Chain Rule,

$$\frac{d}{du} \sin \omega = \cos \omega \frac{d\omega}{du} \quad \text{and} \quad \frac{d}{dv} \sin \omega = \cos \omega \frac{d\omega}{dv}.$$

Applying this with $\omega = u^2 v$ gives

$$\frac{\partial}{\partial u} \sin(u^2 v) = \cos(u^2 v) \frac{\partial}{\partial u}(u^2 v) = \cos(u^2 v) \cdot 2uv = 2uv \cos(u^2 v)$$
$$\frac{\partial}{\partial v} \sin(u^2 v) = \cos(u^2 v) \frac{\partial}{\partial v}(u^2 v) = \cos(u^2 v) \cdot u^2 = u^2 \cos(u^2 v)$$

23. $z = \tan \dfrac{x}{y}$

SOLUTION By the Chain Rule,

$$\frac{d}{dx} \tan u = \frac{1}{\cos^2 u} \frac{du}{dx} \quad \text{and} \quad \frac{d}{dy} \tan u = \frac{1}{\cos^2 u} \frac{du}{dy}.$$

(We could also say that the derivative of $\tan u$ is $\sec^2 u$, but of course $\sec^2 u = 1/\cos^2 u$, so it really is the same thing.) We apply this with $u = \frac{x}{y}$ to obtain

$$\frac{\partial}{\partial x} \tan\left(\frac{x}{y}\right) = \frac{1}{\cos^2\left(\frac{x}{y}\right)} \frac{\partial}{\partial x}\left(\frac{x}{y}\right) = \frac{1}{\cos^2\left(\frac{x}{y}\right)} \cdot \frac{1}{y} = \frac{1}{y\cos^2\left(\frac{x}{y}\right)}$$
$$\frac{\partial}{\partial y} \tan\left(\frac{x}{y}\right) = \frac{1}{\cos^2\left(\frac{x}{y}\right)} \frac{\partial}{\partial y}\left(\frac{x}{y}\right) = \frac{1}{\cos^2\left(\frac{x}{y}\right)} \cdot \frac{-x}{y^2} = \frac{-x}{y^2\cos^2\left(\frac{x}{y}\right)}$$

24. $S = \tan^{-1}(wz)$

SOLUTION By the Chain Rule,

$$\frac{d}{dw}\tan^{-1}u = \frac{1}{1+u^2}\frac{du}{dw} \quad \text{and} \quad \frac{d}{dz}\tan^{-1}u = \frac{1}{1+u^2}\frac{du}{dz}$$

Using this rule with $u = wz$ gives

$$\frac{dS}{dw} = \frac{\partial}{\partial w}\tan^{-1}(wz) = \frac{1}{1+(wz)^2}\frac{\partial}{\partial w}(wz) = \frac{z}{1+w^2z^2}$$
$$\frac{dS}{dz} = \frac{\partial}{\partial z}\tan^{-1}(wz) = \frac{1}{1+(wz)^2}\frac{\partial}{\partial z}(wz) = \frac{w}{1+w^2z^2}$$

25. $z = \ln(x^2 + y^2)$

SOLUTION Using the Chain Rule we have

$$\frac{\partial z}{\partial x} = \frac{1}{x^2+y^2}\frac{\partial}{\partial x}(x^2+y^2) = \frac{1}{x^2+y^2}\cdot 2x = \frac{2x}{x^2+y^2}$$
$$\frac{\partial z}{\partial y} = \frac{1}{x^2+y^2}\frac{\partial}{\partial y}(x^2+y^2) = \frac{1}{x^2+y^2}\cdot 2y = \frac{2y}{x^2+y^2}$$

26. $A = \sin(4\theta - 9t)$

SOLUTION We use the Chain Rule to compute $\frac{\partial A}{\partial \theta}$ and $\frac{\partial A}{\partial t}$:

$$\frac{\partial A}{\partial \theta} = \cos(4\theta - 9t)\frac{\partial}{\partial \theta}(4\theta - 9t) = 4\cos(4\theta - 9t)$$
$$\frac{\partial A}{\partial t} = \cos(4\theta - 9t)\frac{\partial}{\partial t}(4\theta - 9t) = -9\cos(4\theta - 9t)$$

27. $W = e^{r+s}$

SOLUTION We use the Chain Rule to compute $\frac{\partial W}{\partial r}$ and $\frac{\partial W}{\partial s}$:

$$\frac{\partial W}{\partial r} = e^{r+s}\cdot\frac{\partial}{\partial r}(r+s) = e^{r+s}\cdot 1 = e^{r+s}$$
$$\frac{\partial W}{\partial s} = e^{r+s}\cdot\frac{\partial}{\partial s}(r+s) = e^{r+s}\cdot 1 = e^{r+s}$$

28. $Q = re^{\theta}$

SOLUTION The partial derivatives are

$$\frac{\partial Q}{\partial r} = \frac{\partial}{\partial r}(re^{\theta}) = e^{\theta}\frac{\partial}{\partial r}(r) = e^{\theta}$$
$$\frac{\partial Q}{\partial \theta} = \frac{\partial}{\partial \theta}(re^{\theta}) = r\frac{\partial}{\partial \theta}(e^{\theta}) = re^{\theta}$$

29. $z = e^{xy}$

SOLUTION We use the Chain Rule, $\frac{d}{dx}e^u = e^u\frac{du}{dx}$; $\frac{d}{dy}e^u = e^u\frac{du}{dy}$ with $u = xy$ to obtain

$$\frac{\partial}{\partial x}e^{xy} = e^{xy}\frac{\partial}{\partial x}(xy) = e^{xy}y = ye^{xy}$$
$$\frac{\partial}{\partial y}e^{xy} = e^{xy}\frac{\partial}{\partial y}(xy) = e^{xy}x = xe^{xy}$$

30. $R = e^{-v^2/k}$

SOLUTION Using the Chain Rule gives

$$\frac{\partial R}{\partial v} = e^{-v^2/k}\frac{\partial}{\partial v}\left(-\frac{v^2}{k}\right) = e^{-v^2/k}\cdot\left(-\frac{2v}{k}\right) = -\frac{2v}{k}e^{-v^2/k}$$
$$\frac{\partial R}{\partial k} = e^{-v^2/k}\frac{\partial}{\partial k}\left(-\frac{v^2}{k}\right) = e^{-v^2/k}\cdot\left(-v^2\right)\frac{\partial}{\partial k}\left(\frac{1}{k}\right) = e^{-v^2/k}(-v^2)\cdot\frac{-1}{k^2} = \left(\frac{v}{k}\right)^2 e^{-v^2/k}$$

31. $z = e^{-x^2-y^2}$

SOLUTION We use the Chain Rule to find $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$:

$$\frac{\partial z}{\partial x} = e^{-x^2-y^2}\frac{\partial}{\partial x}(-x^2-y^2) = e^{-x^2-y^2}\cdot(-2x) = -2xe^{-x^2-y^2}$$
$$\frac{\partial z}{\partial y} = e^{-x^2-y^2}\frac{\partial}{\partial y}(-x^2-y^2) = e^{-x^2-y^2}\cdot(-2y) = -2ye^{-x^2-y^2}$$

32. $P = e^{\sqrt{y^2+z^2}}$

SOLUTION We use the Chain Rule to compute $\frac{\partial P}{\partial y}$ and $\frac{\partial P}{\partial z}$:

$$\frac{\partial P}{\partial y} = e^{\sqrt{y^2+z^2}}\frac{\partial}{\partial y}\sqrt{y^2+z^2} = e^{\sqrt{y^2+z^2}}\cdot\frac{2y}{2\sqrt{y^2+z^2}} = e^{\sqrt{y^2+z^2}}\cdot\frac{y}{\sqrt{y^2+z^2}}$$
$$\frac{\partial P}{\partial z} = e^{\sqrt{y^2+z^2}}\frac{\partial}{\partial z}\sqrt{y^2+z^2} = e^{\sqrt{y^2+z^2}}\cdot\frac{2z}{2\sqrt{y^2+z^2}} = e^{\sqrt{y^2+z^2}}\cdot\frac{z}{\sqrt{y^2+z^2}}$$

33. $U = \dfrac{e^{-rt}}{r}$

SOLUTION We have

$$\frac{\partial U}{\partial r} = \frac{-te^{-rt}\cdot r - e^{-rt}\cdot 1}{r^2} = \frac{-(1+rt)e^{-rt}}{r^2}$$

and also

$$\frac{\partial U}{\partial t} = \frac{-re^{-rt}}{r} = -e^{-rt}$$

34. $z = y^x$

SOLUTION To find $\frac{\partial z}{\partial y}$, we use the Power Rule for differentiation:

$$\frac{\partial z}{\partial y} = xy^{x-1}$$

To find $\frac{\partial z}{\partial x}$, we use the derivative of the exponent function:

$$\frac{\partial z}{\partial x} = y^x \ln y$$

35. $z = \sinh(x^2y)$

SOLUTION By the Chain Rule, $\frac{d}{dx}\sinh u = \cosh u\frac{du}{dx}$ and $\frac{d}{dy}\sinh u = \cosh u\frac{du}{dy}$. We use the Chain Rule with $u = x^2y$ to obtain

$$\frac{\partial}{\partial x}\sinh(x^2y) = \cosh(x^2y)\frac{\partial}{\partial x}(x^2y) = 2xy\cosh(x^2y)$$
$$\frac{\partial}{\partial y}\sinh(x^2y) = \cosh(x^2y)\frac{\partial}{\partial y}(x^2y) = x^2\cosh(x^2y)$$

36. $z = \cosh(t - \cos x)$

SOLUTION The partial derivatives of z are

$$\frac{\partial z}{\partial t} = \sinh(t-\cos x)$$
$$\frac{\partial z}{\partial x} = \sinh(t-\cos x)\frac{\partial}{\partial x}(t-\cos x) = \sinh(t-\cos x)\cdot\sin x$$

37. $w = xy^2z^3$

SOLUTION The partial derivatives of w are

$$\frac{\partial w}{\partial x} = y^2z^3$$
$$\frac{\partial w}{\partial y} = xz^3\frac{\partial}{\partial y}(y^2) = xz^3 \cdot 2y = 2xz^3y$$
$$\frac{\partial w}{\partial z} = xy^2\frac{\partial}{\partial z}(z^3) = xy^2 \cdot 3z^2 = 3xy^2z^2$$

38. $w = \dfrac{x}{y+z}$

SOLUTION We have

$$\frac{\partial w}{\partial x} = \frac{\partial}{\partial x}\left(\frac{x}{y+z}\right) = \frac{1}{y+z}\frac{\partial}{\partial x}(x) = \frac{1}{y+z}$$

To find $\frac{\partial w}{\partial y}$ and $\frac{\partial w}{\partial z}$, we use the Chain Rule:

$$\frac{\partial w}{\partial y} = x\frac{\partial}{\partial y}\left(\frac{1}{y+z}\right) = x \cdot \frac{-1}{(y+z)^2}\frac{\partial}{\partial y}(y+z) = x \cdot \frac{-1}{(y+z)^2} \cdot 1 = \frac{-x}{(y+z)^2}$$
$$\frac{\partial w}{\partial z} = x\frac{\partial}{\partial z}\left(\frac{1}{y+z}\right) = x \cdot \frac{-1}{(y+z)^2}\frac{\partial}{\partial z}(y+z) = x \cdot \frac{-1}{(y+z)^2} \cdot 1 = \frac{-x}{(y+z)^2}$$

39. $Q = \dfrac{L}{M}e^{-Lt/M}$

SOLUTION

$$\begin{aligned}
\frac{\partial Q}{\partial L} &= \frac{\partial}{\partial L}\left(\frac{L}{M}e^{-Lt/M}\right) \\
&= \frac{L}{M} \cdot e^{-Lt/M} \cdot (-t/M) + e^{-Lt/M} \cdot \frac{1}{M} \\
&= -\frac{Lt}{M^2}e^{-Lt/M} + \frac{e^{-Lt/M}}{M} \\
\frac{\partial Q}{\partial M} &= \frac{\partial}{\partial M}\left(\frac{L}{M}e^{-Lt/M}\right) \\
&= \frac{L}{M} \cdot e^{-Lt/M} \cdot \frac{Lt}{M^2} + e^{-Lt/M} \cdot \frac{-L}{M^2} \\
&= \frac{L^2t}{M^3}e^{-Lt/M} - \frac{L}{M^2}e^{-Lt/M} \\
\frac{\partial Q}{\partial t} &= \frac{\partial}{\partial t}\left(\frac{L}{M}e^{-Lt/M}\right) \\
&= -\frac{L^2}{M^2}e^{-Lt/M}
\end{aligned}$$

40. $w = \dfrac{x}{(x^2+y^2+z^2)^{3/2}}$

SOLUTION To find $\frac{\partial w}{\partial x}$, we use the Quotient Rule and the Chain Rule:

$$\begin{aligned}
\frac{\partial w}{\partial x} &= \frac{1 \cdot (x^2+y^2+z^2)^{3/2} - x \cdot \frac{3}{2}(x^2+y^2+z^2)^{1/2} \cdot 2x}{(x^2+y^2+z^2)^3} = (x^2+y^2+z^2)^{1/2}\frac{(x^2+y^2+z^2) - x \cdot 3x}{(x^2+y^2+z^2)^3} \\
&= \frac{x^2+y^2+z^2-3x^2}{(x^2+y^2+z^2)^{5/2}} = \frac{y^2+z^2-2x^2}{(x^2+y^2+z^2)^{5/2}}
\end{aligned}$$

We now use the Chain Rule to compute $\frac{\partial w}{\partial y}$ and $\frac{\partial w}{\partial z}$:

$$\frac{\partial w}{\partial y} = x\frac{\partial}{\partial y}\frac{1}{(x^2+y^2+z^2)^{3/2}} = x\frac{\partial}{\partial y}(x^2+y^2+z^2)^{-3/2}$$

$$= x \cdot \left(-\frac{3}{2}\right)(x^2+y^2+z^2)^{-5/2} \cdot 2y = -\frac{3xy}{\left(x^2+y^2+z^2\right)^{5/2}}$$

$$\frac{\partial w}{\partial z} = x\frac{\partial}{\partial z}\frac{1}{\left(x^2+y^2+z^2\right)^{3/2}} = x\frac{\partial}{\partial z}(x^2+y^2+z^2)^{-3/2}$$

$$= x \cdot \left(-\frac{3}{2}\right)(x^2+y^2+z^2)^{-5/2} \cdot 2z = -\frac{3xz}{(x^2+y^2+z^2)^{5/2}}$$

In Exercises 41–44, compute the given partial derivatives.

41. $f(x, y) = 3x^2y + 4x^3y^2 - 7xy^5, \quad f_x(1, 2)$

SOLUTION Differentiating with respect to x gives

$$f_x(x, y) = 6xy + 12x^2y^2 - 7y^5$$

Evaluating at $(1, 2)$ gives

$$f_x(1, 2) = 6 \cdot 1 \cdot 2 + 12 \cdot 1^2 \cdot 2^2 - 7 \cdot 2^5 = -164.$$

42. $f(x, y) = \sin(x^2 - y), \quad f_y(0, \pi)$

SOLUTION We differentiate with respect to y, using the Chain Rule. This gives

$$f_y(x, y) = \cos(x^2 - y)\frac{\partial}{\partial y}(x^2 - y) = \cos(x^2 - y) \cdot (-1) = -\cos(x^2 - y)$$

Evaluating at $(0, \pi)$ we obtain

$$f_y(0, \pi) = -\cos(0^2 - \pi) = -\cos(-\pi) = -\cos\pi = 1.$$

43. $g(u, v) = u\ln(u + v), \quad g_u(1, 2)$

SOLUTION Using the Product Rule and the Chain Rule we get

$$g_u(u, v) = \frac{\partial}{\partial u}(u\ln(u + v)) = 1 \cdot \ln(u + v) + u \cdot \frac{1}{u + v} = \ln(u + v) + \frac{u}{u + v}$$

At the point $(1, 2)$ we have

$$g_u(1, 2) = \ln(1 + 2) + \frac{1}{1 + 2} = \ln 3 + \frac{1}{3}.$$

44. $h(x, z) = e^{xz - x^2z^3}, \quad h_z(3, 0)$

SOLUTION We obtain the following partial:

$$h_z(x, z) = (x - 3x^2z^2)e^{xz - x^2z^3}$$

Substituting $x = 3$, $z = 0$ we obtain the partial derivative at the point $(3, 0)$:

$$h_z(3, 0) = (3 - 0)e^{0-0} = 3.$$

Exercises 45 and 46 refer to Example 5.

45. Calculate N for $L = 0.4$, $R = 0.12$, and $d = 10$, and use the linear approximation to estimate ΔN if d is increased from 10 to 10.4.

SOLUTION From the example in the text we have

$$N = \left(\frac{2200R}{Ld}\right)^{1.9}$$

Calculating N for $L = 0.4$, $R = 0.12$, and $d = 10$ we have

$$N = \left(\frac{2200 \cdot 0.12}{0.4 \cdot 10}\right)^{1.9} \approx 2865.058$$

then we will use the derivation

$$\Delta N \approx \frac{\partial N}{\partial d}\Delta d$$

since d is increasing from 10 to 10.4. We need to compute $\partial N/\partial d$, with L and R constant:

$$\begin{aligned}\frac{\partial N}{\partial d} &= \frac{\partial}{\partial d}\left(\frac{2200R}{Ld}\right)^{1.9}\\ &= \left(\frac{2200R}{L}\right)^{1.9}\frac{\partial}{\partial d}(d^{-1.9})\\ &= -1.9\left(\frac{2200R}{L}\right)^{1.9} d^{-2.9}\end{aligned}$$

we have first

$$\left.\frac{\partial N}{\partial d}\right|_{(L,R,d)=(0.4,0.12,10)} = -1.9\left(\frac{2200\cdot 0.12}{0.4}\right)^{1.9}(10)^{-2.9} \approx -544.361$$

Therefore we can conclude:

$$\Delta N \approx \frac{\partial N}{\partial d}\Delta d \approx (-544.361)(10.4-10) = -217.744$$

46. Estimate ΔN if $(L, R, d) = (0.5, 0.15, 8)$ and R is increased from 0.15 to 0.17.

SOLUTION From the example in the text we have

$$N = \left(\frac{2200R}{Ld}\right)^{1.9}$$

then we will use the derivation,

$$\Delta N \approx \frac{\partial N}{\partial R}\Delta R$$

since R is increasing from 0.15 to 0.17. We need to compute $\partial N/\partial R$, with L and d constant:

$$\begin{aligned}\frac{\partial N}{\partial R} &= \frac{\partial}{\partial R}\left(\frac{2200R}{Ld}\right)^{1.9}\\ &= \left(\frac{2200}{Ld}\right)^{1.9}\frac{\partial}{\partial R}(R^{1.9})\\ &= 1.9\left(\frac{2200}{Ld}\right)^{1.9} R^{0.9}\end{aligned}$$

We have first

$$\left.\frac{\partial N}{\partial R}\right|_{(L,R,d)=(0.5,0.15,8)} = 1.9\left(\frac{2200}{0.5\cdot 8}\right)^{1.9}(0.15)^{0.9} \approx 55452.974$$

Therefore we can conclude:

$$\Delta N \approx \frac{\partial N}{\partial R}\Delta R \approx (55452.974)(0.17-0.15) \approx 1109.059$$

47. The **heat index** I is a measure of how hot it feels when the relative humidity is H (as a percentage) and the actual air temperature is T (in degrees Fahrenheit). An approximate formula for the heat index that is valid for (T, H) near (90, 40) is

$$\begin{aligned}I(T, H) = 45.33 + 0.6845T + 5.758H - 0.00365T^2\\ - 0.1565HT + 0.001HT^2\end{aligned}$$

(a) Calculate I at $(T, H) = (95, 50)$.

(b) Which partial derivative tells us the increase in I per degree increase in T when $(T, H) = (95, 50)$. Calculate this partial derivative.

SOLUTION

(a) Let us compute I when $T = 95$ and $H = 50$:

$$\begin{aligned} I(95, 50) &= 45.33 + 0.6845(95) + 5.758(50) - 0.00365(95)^2 - 0.1565(50)(95) + 0.001(50)(95)^2 \\ &= 73.19125 \end{aligned}$$

(b) The partial derivative we are looking for here is $\partial I/\partial T$:

$$\frac{\partial I}{\partial T} = 0.6845 - 0.00730T - 0.1565H + 0.002HT$$

and evaluating we have:

$$\frac{\partial I}{\partial T}(95, 50) = 0.6845 - 0.00730(95) - 0.1565(50) + 0.002(50)(95) = 1.666$$

48. The **wind-chill temperature** W measures how cold people feel (based on the rate of heat loss from exposed skin) when the outside temperature is T°C (with $T \le 10$) and wind velocity is v m/s (with $v \ge 2$):

$$W = 13.1267 + 0.6215T - 13.947v^{0.16} + 0.486Tv^{0.16}$$

Calculate $\partial W/\partial v$ at $(T, v) = (-10, 15)$ and use this value to estimate ΔW if $\Delta v = 2$.

SOLUTION Computing the partial derivative we get:

$$\begin{aligned} \frac{\partial W}{\partial v} &= \frac{\partial}{\partial v}\left(13.1267 + 0.6215T - 13.947v^{0.16} + 0.486Tv^{0.16}\right) \\ &= -13.947(0.16)v^{-0.84} + 0.486(0.16)Tv^{-0.84} \end{aligned}$$

$$\frac{\partial W}{\partial v}(-10, 15) = -13.947(0.16)(15)^{-0.84} + 0.486(0.16)(-10)(15)^{-0.84} \approx -0.30940$$

Now using this information we would like to estimate ΔW if $\Delta v = 2$:

$$\Delta W = \frac{\partial W}{\partial v}\Delta v \approx -0.30940 \cdot 2 \approx -0.6188$$

49. The volume of a right-circular cone of radius r and height h is $V = \frac{\pi}{3}r^2h$. Suppose that $r = h = 12$ cm. What leads to a greater increase in V, a 1-cm increase in r or a 1-cm increase in h? Argue using partial derivatives.

SOLUTION We obtain the following derivatives:

$$\begin{aligned} \frac{\partial V}{\partial r} &= \frac{\partial}{\partial r}\left(\frac{\pi}{3}r^2h\right) = \frac{\pi h}{3}\frac{\partial}{\partial r}r^2 = \frac{\pi h}{3} \cdot 2r = \frac{2\pi hr}{3} \\ \frac{\partial V}{\partial h} &= \frac{\partial}{\partial h}\left(\frac{\pi}{3}r^2h\right) = \frac{\pi}{3}r^2 \end{aligned}$$

An increase $\Delta r = 1$ cm in r leads to an increase of $\frac{\partial V}{\partial r}(12, 12) \cdot 1$ in the volume, and an increase $\Delta h = 1$ cm in h leads to an increase of $\frac{\partial V}{\partial h}(12, 12) \cdot 1$ in V. We compute these values, using the partials computed. This gives

$$\begin{aligned} \frac{\partial V}{\partial r}(12, 12) &= \left.\frac{2\pi hr}{3}\right|_{(12,12)} = \frac{2\pi \cdot 12 \cdot 12}{3} = 301.6 \\ \frac{\partial V}{\partial h}(12, 12) &= \frac{\pi}{3} \cdot 12^2 = 150.8 \end{aligned}$$

We conclude that an increase of 1 cm in r leads to a greater increase in V than an increase of 1 cm in h.

50. Use the linear approximation to estimate the percentage change in volume of a right-circular cone of radius $r = 40$ cm if the height is increased from 40 to 41 cm.

SOLUTION First, the volume of a right-circular cone is $V = \frac{1}{3}\pi r^2h$. We obtain the following partial derivative:

$$\frac{\partial V}{\partial h} = \frac{1}{3}\pi r^2$$

Then an increase $\Delta h = 1$ cm in h leads to an increase of $\partial V/\partial h \cdot 1$ in V.

To compute the percent change in volume of the right-circular cone we consider:

$$\frac{\Delta V}{V} \approx \frac{\partial V/\partial h \cdot \Delta h}{V} = \frac{\frac{1}{3}\pi r^2 \Delta h}{\frac{1}{3}\pi r^2 h} = \frac{\Delta h}{h} = \frac{1}{40} = 0.025$$

Therefore, the percent change is about 2.5%.

51. Calculate $\partial W/\partial E$ and $\partial W/\partial T$, where $W = e^{-E/kT}$, where k is a constant.

SOLUTION We use the Chain Rule

$$\frac{d}{dE}e^u = e^u\frac{du}{dE} \quad \text{and} \quad \frac{d}{dT}e^u = e^u\frac{du}{dT}$$

with $u = -\frac{E}{kT}$, to obtain

$$\frac{\partial W}{\partial E} = e^{-E/kT}\frac{\partial}{\partial E}\left(-\frac{E}{kT}\right) = e^{-E/kT}\left(-\frac{1}{kT}\right) = -\frac{1}{kT}e^{-E/kT}$$
$$\frac{\partial W}{\partial T} = e^{-E/kT}\frac{\partial}{\partial T}\left(-\frac{E}{kT}\right) = e^{-E/kT}\cdot\left(-\frac{E}{k}\right)\frac{\partial}{\partial T}\left(\frac{1}{T}\right) = e^{-E/kT}\left(-\frac{E}{k}\right)\left(-\frac{1}{T^2}\right) = \frac{E}{kT^2}e^{-E/kT}$$

52. Calculate $\partial P/\partial T$ and $\partial P/\partial V$, where pressure P, volume V, and temperature T are related by the ideal gas law, $PV = nRT$ (R and n are constants).

SOLUTION We differentiate the two sides of the equation $PV = nRT$ with respect to V (treating T as a constant). Using the Product Rule we obtain

$$\frac{\partial}{\partial V}PV = V\frac{\partial P}{\partial V} + P\frac{\partial V}{\partial V} = V\frac{\partial P}{\partial V} + P; \quad \frac{\partial}{\partial V}nRT = 0$$

Hence,

$$V\frac{\partial P}{\partial V} + P = 0$$

We substitute $P = \frac{nRT}{V}$ and solve for $\frac{\partial P}{\partial V}$. This gives

$$V\frac{\partial P}{\partial V} + \frac{nRT}{V} = 0 \quad \Rightarrow \quad \frac{\partial P}{\partial V} = -\frac{nRT}{V^2}$$

We now differentiate $PV = nRT$ with respect to T, treating V as a constant:

$$\frac{\partial}{\partial T}PV = V\frac{\partial P}{\partial T}; \quad \frac{\partial}{\partial T}nRT = nR$$

Hence,

$$V\frac{\partial P}{\partial T} = nR \quad \Rightarrow \quad \frac{\partial P}{\partial T} = \frac{nR}{V}.$$

53. Use the contour map of $f(x, y)$ in Figure 9 to explain the following statements.

(a) f_y is larger at P than at Q, and f_x is smaller (more negative) at P than at Q.

(b) $f_x(x, y)$ is decreasing as a function of y; that is, for any fixed value $x = a$, $f_x(a, y)$ is decreasing in y.

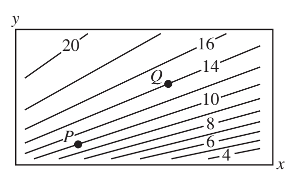

FIGURE 9 Contour interval 2.

SOLUTION

(a) A vertical segment through P meet more level curves than a vertical segment of the same size through Q, so f is increasing more rapidly in the y at P than at Q. Therefore, f_y are both larger at P than at Q.

Similarly, a horizontal segment through P meet more level curves at P than at Q, but f is *decreasing* in the positive x-direction, so f is decreasing more rapidly in the x-direction at P than at Q. Therefore, f_x is more negative at P than at Q.

(b) For any fixed value $x = a$, a horizontal segment meets fewer level curves as we move it vertically upward. This indicates that $f_x(a, y)$ in a decreasing function of y.

54. Estimate the partial derivatives at P of the function whose contour map is shown in Figure 10.

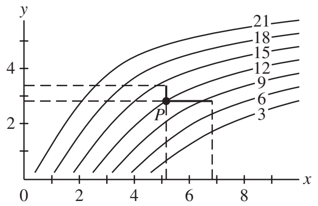

FIGURE 10

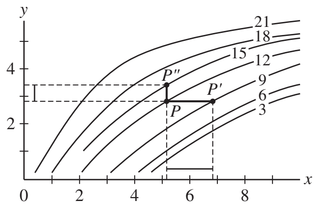
SOLUTION The contour interval is $m = 3$. To estimate the partial derivative $\frac{\partial f}{\partial x}$ at P, we estimate the change Δx between P and the point P' on the next level curve to the right, which is the length of the segment $\overline{PP'}$:

$$\Delta x \approx 2$$



The change in f between P and P' is the contour interval $\Delta f = -3$. Hence,

$$\left.\frac{\partial f}{\partial x}\right|_P \approx \frac{\Delta f}{\Delta x} = \frac{-3}{2} = -1.5$$

To estimate the partial derivative $\frac{\partial f}{\partial y}$ at P, we estimate the change Δy between P and the point P'' on the next level curve vertically above P:

$$\Delta y \approx 0.5$$

The change in f is $\Delta f = 3$ (since the level curve of P'' is to the left of the level curve of P). Hence,

$$\left.\frac{\partial f}{\partial y}\right|_P \approx \frac{\Delta f}{\Delta y} \approx \frac{3}{0.5} = 6.$$

55. Over most of the earth, a magnetic compass does not point to true (geographic) north; instead, it points at some angle east or west of true north. The angle D between magnetic north and true north is called the **magnetic declination**. Use Figure 11 to determine which of the following statements is true.

(a) $\left.\frac{\partial D}{\partial y}\right|_A > \left.\frac{\partial D}{\partial y}\right|_B$ **(b)** $\left.\frac{\partial D}{\partial x}\right|_C > 0$ **(c)** $\left.\frac{\partial D}{\partial y}\right|_C > 0$

Note that the horizontal axis increases from right to left because of the way longitude is measured.

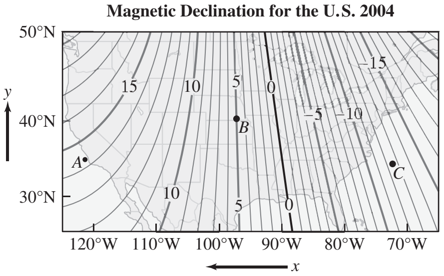


FIGURE 11 Contour interval 1°.

SOLUTION

(a) To estimate $\left.\frac{\partial D}{\partial y}\right|_A$ and $\left.\frac{\partial D}{\partial y}\right|_B$, we move vertically from A and B to the points on the next level curve in the direction of increasing y (upward). From A, we quickly come to a level curve corresponding to higher value of D; but from B, moving vertically, there is hardly any change as we move along the curve. The statement is thus true.

(b) The derivative $\frac{\partial D}{\partial x}\big|_C$ is estimated by $\frac{\Delta D}{\Delta x}$. Since x varies in the horizontal direction, we move horizontally from C to a point on the next level curve in the direction of increasing x (leftwards). Since the value of D on this level curve is greater than on the level curve of C, $\Delta D = 1$. Also $\Delta x > 0$, hence

$$\frac{\partial D}{\partial x}\bigg|_C \approx \frac{\Delta D}{\Delta x} = \frac{1}{\Delta x} > 0.$$

The statement is correct.

(c) Moving from C vertically upward (in the direction of increasing y), we come to a point on a level curve with a smaller value of D. Therefore, $\Delta D = -1$ and $\Delta y > 0$, so we obtain

$$\frac{\partial D}{\partial y}\bigg|_C \approx \frac{\Delta D}{\Delta y} = \frac{-1}{\Delta y} < 0$$

Hence, the statement is false.

56. Refer to Table 1.

(a) Estimate $\partial\rho/\partial T$ and $\partial\rho/\partial S$ at the points $(S, T) = (34, 2)$ and $(35, 10)$ by computing the average of left-hand and right-hand difference quotients.

(b) For fixed salinity $S = 33$, is ρ concave up or concave down as a function of T? *Hint:* Determine whether the quotients $\Delta\rho/\Delta T$ are increasing or decreasing. What can you conclude about the sign of $\partial^2\rho/\partial T^2$?

TABLE 1 **Seawater Density ρ as a Function of Temperature T and Salinity S**

T \ S	30	31	32	33	34	35	36
12	22.75	23.51	24.27	25.07	25.82	26.6	27.36
10	23.07	23.85	24.62	25.42	26.17	26.99	27.73
8	23.36	24.15	24.93	25.73	26.5	27.28	29.09
6	23.62	24.44	25.22	26	26.77	27.55	28.35
4	23.85	24.62	25.42	26.23	27	27.8	28.61
2	24	24.78	25.61	26.38	27.18	28.01	28.78
0	24.11	24.92	25.72	26.5	27.34	28.12	28.91

SOLUTION

(a) We estimate $\frac{\partial\rho}{\partial T}$ at the given points using the values in Table 1 and the following approximation:

$$\frac{\partial\rho}{\partial T}(34, 2) \approx \frac{\rho(34, 2+2) - \rho(34, 2)}{2} = \frac{\rho(34, 4) - \rho(34, 2)}{2} = \frac{27 - 27.18}{2} = -0.09$$

$$\frac{\partial\rho}{\partial T}(35, 10) \approx \frac{\rho(35, 10+2) - \rho(35, 10)}{2} = \frac{\rho(35, 12) - \rho(35, 10)}{2} = \frac{26.6 - 26.99}{2} = -0.195$$

Therefore, the average of the left-hand and right-hand difference quotients is:

$$\frac{1}{2}\left(\frac{\partial\rho}{\partial T}(34, 2) + \frac{\partial\rho}{\partial T}(35, 10)\right) \approx \frac{1}{2}(-0.09 - 0.195) = -0.1425$$

We estimate the partial derivative $\frac{\partial\rho}{\partial S}$ at the given points:

$$\frac{\partial\rho}{\partial S}(34, 2) \approx \frac{\rho(34+1, 2) - \rho(34, 2)}{1} = \frac{\rho(35, 2) - \rho(34, 2)}{1} = 28.01 - 27.18 = 0.83$$

$$\frac{\partial\rho}{\partial S}(35, 10) \approx \frac{\rho(35+1, 10) - \rho(35, 10)}{1} = \frac{\rho(36, 10) - \rho(35, 10)}{1} = 27.73 - 26.99 = 0.74$$

Therefore, the average of the left-hand and right-hand difference quotients is:

$$\frac{1}{2}\left(\frac{\partial\rho}{\partial S}(34, 2) + \frac{\partial\rho}{\partial S}(35, 10)\right) \approx \frac{1}{2}(0.85 + 0.74) = 0.795$$

(b) The function $\rho(33, T)$ is concave up (concave down) if $\frac{\partial\rho}{\partial T}(33, T)$ is an increasing (decreasing) function of T. We use Table 1 to estimate whether the function $\frac{\partial\rho}{\partial T}(33, T)$ is increasing or decreasing. We compute the following values:

$$\frac{\partial\rho}{\partial T}(33, 2) \approx \frac{\rho(33, 4) - \rho(33, 2)}{2} = \frac{26.23 - 26.38}{2} = -0.075$$

$$\frac{\partial \rho}{\partial T}(33,4) \approx \frac{\rho(33,6)-\rho(33,4)}{2} = \frac{26-26.23}{2} = -0.115$$
$$\frac{\partial \rho}{\partial T}(33,6) \approx \frac{\rho(33,8)-\rho(33,6)}{2} = \frac{25.73-26}{2} = -0.135$$
$$\frac{\partial \rho}{\partial T}(33,8) \approx \frac{\rho(33,10)-\rho(33,8)}{2} = \frac{25.42-25.73}{2} = -0.155$$
$$\frac{\partial \rho}{\partial T}(33,10) \approx \frac{\rho(33,12)-\rho(33,10)}{2} = \frac{25.07-25.42}{2} = -0.175$$

These values indicate that $\frac{\partial \rho}{\partial T}(33,T)$ is a decreasing function of T, which means that the second derivative is negative, i.e., $\frac{\partial^2 \rho}{\partial T^2}(33,T) < 0$ and the graph of $\rho(33,T)$ is concave down.

In Exercises 57–62, compute the derivatives indicated.

57. $f(x,y) = 3x^2y - 6xy^4$, $\quad \dfrac{\partial^2 f}{\partial x^2}$ and $\dfrac{\partial^2 f}{\partial y^2}$

SOLUTION We first compute the partial derivatives $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$:

$$\frac{\partial f}{\partial x} = 6xy - 6y^4; \quad \frac{\partial f}{\partial y} = 3x^2 - 6x\cdot 4y^3 = 3x^2 - 24xy^3$$

We now differentiate $\frac{\partial f}{\partial x}$ with respect to x and $\frac{\partial f}{\partial y}$ with respect to y. We get

$$\frac{\partial^2 f}{\partial x^2} = \frac{\partial}{\partial x} f_x = 6y; \quad \frac{\partial^2 f}{\partial y^2} = \frac{\partial}{\partial y} f_y = -24x\cdot 3y^2 = -72xy^2.$$

58. $g(x,y) = \dfrac{xy}{x-y}$, $\quad \dfrac{\partial^2 g}{\partial x\,\partial y}$

SOLUTION By definition we have

$$\frac{\partial^2 g}{\partial x \partial y} = g_{yx} = \frac{\partial}{\partial x}\left(\frac{\partial g}{\partial y}\right)$$

Thus, we must find $\frac{\partial g}{\partial y}$:

$$\frac{\partial g}{\partial y} = x\frac{\partial}{\partial y}\left(\frac{y}{x-y}\right) = x\frac{1\cdot(x-y) - y\cdot(-1)}{(x-y)^2} = \frac{x^2}{(x-y)^2}$$

Differentiating $\frac{\partial g}{\partial y}$ with respect to x, using the Quotient Rule, we obtain

$$\frac{\partial^2 g}{\partial x \partial y} = \frac{\partial}{\partial x}\left(\frac{\partial g}{\partial y}\right) = \frac{\partial}{\partial x}\frac{x^2}{(x-y)^2} = \frac{2x(x-y)^2 - x^2\cdot 2(x-y)}{(x-y)^4} = -\frac{2xy}{(x-y)^3}$$

59. $h(u,v) = \dfrac{u}{u+4v}$, $\quad h_{vv}(u,v)$

SOLUTION We first note

$$\frac{\partial h}{\partial v} = \frac{-4u}{(u+4v)^2}$$

so thus

$$\frac{\partial h^2}{\partial v^2} = \frac{\partial}{\partial v}\left(\frac{-4u}{(u+4v)^2}\right) = \frac{32u}{(u+4v)^3}$$

60. $h(x,y) = \ln(x^3+y^3)$, $\quad h_{xy}(x,y)$

SOLUTION We first note that

$$\frac{\partial h}{\partial y} = \frac{3y^2}{x^3+y^3}$$

so thus

$$\frac{\partial^2 h}{\partial x \partial y} = \frac{\partial}{\partial x}\left(\frac{3y^2}{x^3 + y^3}\right) = \frac{-9x^2y^2}{(x^3 + y^3)^2}$$

61. $f(x, y) = x \ln(y^2)$, $\quad f_{yy}(2, 3)$

SOLUTION We find f_y using the Chain Rule:

$$f_y = \frac{\partial}{\partial y}(x \ln y^2) = x \frac{\partial}{\partial y} \ln y^2 = x \frac{1}{y^2} \cdot 2y = \frac{2x}{y}$$

We now differentiate f_y with respect to y, obtaining

$$f_{yy}(x, y) = \frac{\partial}{\partial y} f_y = 2x \frac{\partial}{\partial y}\left(\frac{1}{y}\right) = \frac{-2x}{y^2}.$$

The derivative at $(2, 3)$ is thus

$$f_{yy}(2, 3) = \frac{-2 \cdot 2}{3^2} = -\frac{4}{9}.$$

62. $g(x, y) = xe^{-xy}$, $\quad g_{xy}(-3, 2)$

SOLUTION We first compute:

$$\frac{\partial g}{\partial x} = x \cdot e^{-xy} \cdot (-y) + e^{-xy} = e^{-xy}(1 - xy)$$

so thus:

$$\frac{\partial^2 g}{\partial y \partial x} = \frac{\partial}{\partial y}(e^{-xy}(1 - xy)) = e^{-xy}(-x) + (1 - xy)e^{-xy} \cdot (-x) = -xe^{-xy}(2 - xy)$$

and

$$g_{xy}(-3, 2) = 3e^6(2 + 6) = 24e^6$$

63. Compute f_{xyxzy} for

$$f(x, y, z) = y \sin(xz) \sin(x + z) + (x + z^2) \tan y + x \tan\left(\frac{z + z^{-1}}{y - y^{-1}}\right)$$

Hint: Use a well-chosen order of differentiation on each term.

SOLUTION At the points where the derivatives are continuous, the partial derivative f_{xyxzy} may be performed in any order. To simplify the computation we first consider $f(x, y, z)$ as the sum of the following terms:

$$F(x, y, z) = y \sin(xz) \sin(x + z), \quad G(x, y, z) = (x + z^2) \tan y, \quad H(x, y, z) = x \tan\left(\frac{z + z^{-1}}{y - y^{-1}}\right)$$

so that

$$f(x, y, z) = F(x, y, z) + G(x, y, z) + H(x, y, z)$$

We can differentiate each in any order. First, let us work with $F(x, y, z) = y \sin(xz) \sin(x + z)$:

$$F_y(x, y, z) = \frac{\partial}{\partial y}(y \sin(xz) \sin(x + z)) = \sin(xz) \sin(x + z)$$

then

$$F_{yy}(x, y, z) = \frac{\partial}{\partial y}(F_y(x, y, z)) = 0$$

hence,

$$F_{yyxxz}(x, y, z) = 0$$

Next, let us work with $G(x, y, z) = (x + z^2) \tan y$:

$$G_x(x, y, z) = \frac{\partial}{\partial x}((x + z^2) \tan y) = \tan y$$

then

$$G_{xx}(x, y, z) = \frac{\partial}{\partial x}(G_x(x, y, z)) = 0$$

Hence

$$G_{xxyyz}(x, y, z) = 0$$

Finally, let us work with $H(x, y, z) = x \tan\left(\frac{z + z^{-1}}{y - y^{-1}}\right)$

$$H_x(x, y, z) = \frac{\partial}{\partial x}\left(x \tan\left(\frac{z + z^{-1}}{y - y^{-1}}\right)\right) = \tan\left(\frac{z + z^{-1}}{y - y^{-1}}\right)$$

then

$$H_{xx}(x, y, z) = \frac{\partial}{\partial x}(H_x(x, y, z)) = 0$$

hence,

$$H_{xxyyz}(x, y, z) = 0$$

Therefore, we can conclude that $f_{xyxzy}(x, y, z) = 0 + 0 + 0 = 0$.

64. Let

$$f(x, y, u, v) = \frac{x^2 + e^y v}{3y^2 + \ln(2 + u^2)}$$

What is the fastest way to show that $f_{uvxyvu}(x, y, u, v) = 0$ for all (x, y, u, v)?

SOLUTION We first differentiate with respect to v, obtaining

$$\begin{aligned} f_v(x, y, u, v) &= \frac{\partial}{\partial v}\left(\frac{x^2}{3y^2 + \ln(2 + u^2)}\right) + \frac{\partial}{\partial v}\left(\frac{e^y}{3y^2 + \ln(2 + u^2)} v\right) \\ &= 0 + \frac{e^y}{3y^2 + \ln(2 + u^2)} = \frac{e^y}{3y^2 + \ln(2 + u^2)} \end{aligned}$$

We now differentiate f_v with respect to x. Since f_v does not depend on x, we have

$$f_{vx}(x, y, u, v) = 0$$

Hence also,

$$f_{uvxyvu}(x, y, u, v) = \frac{\partial}{\partial u}\frac{\partial}{\partial y}\frac{\partial}{\partial v}\frac{\partial}{\partial u}(0) = 0$$

In Exercises 65–72, compute the derivative indicated.

65. $f(u, v) = \cos(u + v^2)$, $\quad f_{uuv}$

SOLUTION Using the Chain Rule, we have

$$\begin{aligned} f_u &= \frac{\partial}{\partial u}\cos(u + v^2) = -\sin(u + v^2) \cdot \frac{\partial}{\partial u}(u + v^2) = -\sin(u + v^2) \\ f_{uu} &= \frac{\partial}{\partial u}\big(-\sin(u + v^2)\big) = -\cos(u + v^2) \\ f_{uuv} &= \frac{\partial}{\partial v}\big(-\cos(u + v^2)\big) = \sin(u + v^2) \cdot \frac{\partial}{\partial v}(u + v^2) = 2v\sin(u + v^2) \end{aligned}$$

66. $g(x, y, z) = x^4 y^5 z^6$, $\quad g_{xxyz}$

SOLUTION For $g(x, y, z) = x^4 y^5 z^6$, we have

$$\begin{aligned} g_x &= y^5 z^6 \frac{\partial}{\partial x} x^4 = y^5 z^6 \cdot 4x^3 = 4x^3 y^5 z^6 \\ g_{xx} &= 4y^5 z^6 \frac{\partial}{\partial x} x^3 = 4y^5 z^6 \cdot 3x^2 = 12x^2 y^5 z^6 \end{aligned}$$

$$g_{xxy} = 12x^2z^6\frac{\partial}{\partial y}(y^5) = 12x^2z^6 \cdot 5y^4 = 60x^2y^4z^6$$

$$g_{xxyz} = 60x^2y^4\frac{\partial}{\partial z}z^6 = 60x^2y^4 \cdot 6x^5 = 360x^2y^4z^5$$

67. $F(r, s, t) = r(s^2 + t^2), \quad F_{rst}$

SOLUTION For $F(r, s, t) = r(s^2 + t^2)$, we have

$$F_r = s^2 + t^2$$
$$F_{rs} = 2s$$
$$F_{rst} = 0$$

68. $u(x, t) = t^{-1/2}e^{-(x^2/4t)}, \quad u_{xx}$

SOLUTION Using the Chain Rule we obtain

$$u_x = t^{-1/2}\frac{\partial}{\partial x}(e^{-x^2/4t}) = t^{-1/2} \cdot e^{-x^2/4t}\frac{\partial}{\partial x}\left(-\frac{x^2}{4t}\right) = t^{-1/2} \cdot e^{-x^2/4t} \cdot \frac{-2x}{4t} = -\frac{1}{2}xt^{-3/2}e^{-x^2/4t}$$

We now differentiate u_x with respect to x, using the Product Rule and the Chain Rule:

$$u_{xx} = -\frac{1}{2}t^{-3/2}\frac{\partial}{\partial x}\left(xe^{-x^2/4t}\right) = -\frac{1}{2}t^{-3/2}\left(1 \cdot e^{-x^2/4t} + x \cdot e^{-x^2/4t} \cdot \frac{-2x}{4t}\right)$$
$$= -\frac{1}{2}t^{-3/2}\left(e^{-x^2/4t} - \frac{x^2}{2t}e^{-x^2/4t}\right) = -\frac{1}{2}t^{-3/2}e^{-x^2/4t}\left(1 - \frac{x^2}{2t}\right)$$

69. $F(\theta, u, v) = \sinh(uv + \theta^2), \quad F_{uu\theta}$

SOLUTION We can compute:

$$F_u = v \cdot \cosh(uv + \theta^2)$$
$$F_{uu} = v^2 \cdot \sinh(uv + \theta^2)$$
$$F_{uu\theta} = 2\theta v^2 \cosh(uv + \theta^2)$$

70. $R(u, v, w) = \dfrac{u}{v + w}, \quad R_{uvw}$

SOLUTION We differentiate R with respect to u:

$$R_u = \frac{\partial}{\partial u}\left(\frac{u}{v + w}\right) = \frac{1}{v + w}$$

We now differentiate R_u with respect to v, using the Chain Rule:

$$R_{uv} = \frac{\partial}{\partial v}\frac{1}{v + w} = -\frac{1}{(v + w)^2}$$

Finally we differentiate R_{uv} with respect to w:

$$R_{uvw} = \frac{\partial}{\partial w}\left(-(v + w)^{-2}\right) = 2(v + w)^{-3} = \frac{2}{(v + w)^3}.$$

71. $g(x, y, z) = \sqrt{x^2 + y^2 + z^2}, \quad g_{xyz}$

SOLUTION Differentiating with respect to x, using the Chain Rule, we get

$$g_x = \frac{\partial}{\partial x}\sqrt{x^2 + y^2 + z^2} = \frac{1}{2\sqrt{x^2 + y^2 + z^2}}\frac{\partial}{\partial x}(x^2 + y^2 + z^2) = \frac{1}{2\sqrt{x^2 + y^2 + z^2}} \cdot 2x = \frac{x}{\sqrt{x^2 + y^2 + z^2}}$$

We now differentiate g_x with respect to y, using the Chain Rule. This gives

$$g_{xy} = x\frac{\partial}{\partial y}(x^2 + y^2 + z^2)^{-1/2} = x \cdot \left(-\frac{1}{2}\right)(x^2 + y^2 + z^2)^{-3/2} \cdot 2y = \frac{-xy}{(x^2 + y^2 + z^2)^{3/2}}$$

Finally, we differentiate g_{xy} with respect to z, obtaining

$$g_{xyz} = -xy\frac{\partial}{\partial z}(x^2+y^2+z^2)^{-3/2} = -xy\cdot\left(-\frac{3}{2}\right)(x^2+y^2+z^2)^{-5/2}\cdot 2z = \frac{3xyz}{(x^2+y^2+z^2)^{5/2}}$$

72. $u(x,t) = \operatorname{sech}^2(x-t), \quad u_{xxx}$

SOLUTION Using the Chain Rule we have

$$u_x = \frac{\partial}{\partial x}\operatorname{sech}^2(x-t) = 2\operatorname{sech}(x-t)\cdot\big(-\operatorname{sech}(x-t)\tanh(x-t)\big)\cdot\frac{\partial}{\partial x}(x-t) = -2\operatorname{sech}^2(x-t)\tanh(x-t)$$

We now use the Product Rule and the Chain Rule to differentiate u_x with respect to x:

$$\begin{aligned} u_{xx} &= -2\big[2\operatorname{sech}(x-t)\cdot\big(-\operatorname{sech}(x-t)\tanh(x-t)\big)\tanh(x-t) + \operatorname{sech}^2(x-t)\cdot\operatorname{sech}^2(x-t)\big] \\ &= 4\operatorname{sech}^2(x-t)\tanh^2(x-t) - 2\operatorname{sech}^4(x-t) = 2\operatorname{sech}^2(x-t)\big(2\tanh^2(x-t)-\operatorname{sech}^2(x-t)\big) \end{aligned}$$

We find u_{xxx}, using the Product Rule and the Chain Rule:

$$\begin{aligned} u_{xxx} &= 4\operatorname{sech}(x-t)\big(-\operatorname{sech}(x-t)\tanh(x-t)\big)\big(2\tanh^2(x-t)-\operatorname{sech}^2(x-t)\big) \\ &\quad + 2\operatorname{sech}^2(x-t)\big[4\tanh(x-t)\cdot\operatorname{sech}^2(x-t) - 2\operatorname{sech}(x-t)\big(-\operatorname{sech}(x-t)\tanh(x-t)\big)\big] \\ &= -8\operatorname{sech}^2(x-t)\tanh^3(x-t) + 4\operatorname{sech}^4(x-t)\tanh(x-t) + 12\operatorname{sech}^4(x-t)\tanh(x-t) \\ &= 16\operatorname{sech}^4(x-t)\tanh(x-t) - 8\operatorname{sech}^2(x-t)\tanh^3(x-t) \end{aligned}$$

73. Find a function such that $\dfrac{\partial f}{\partial x} = 2xy$ and $\dfrac{\partial f}{\partial y} = x^2$.

SOLUTION The function $f(x,y) = x^2y$ satisfies $\frac{\partial f}{\partial y} = x^2$ and $\frac{\partial f}{\partial x} = 2xy$.

74. Prove that there does not exist any function $f(x,y)$ such that $\dfrac{\partial f}{\partial x} = xy$ and $\dfrac{\partial f}{\partial y} = x^2$. *Hint:* Show that f cannot satisfy Clairaut's Theorem.

SOLUTION Suppose that there exists a function $f(x,y)$ such that $\frac{\partial f}{\partial x} = xy$ and $\frac{\partial f}{\partial y} = x^2$. Hence,

$$\begin{aligned} f_{xy} &= \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x}\right) = \frac{\partial}{\partial y}xy = x \\ f_{yx} &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial y}\right) = \frac{\partial}{\partial x}x^2 = 2x \end{aligned}$$

The mixed partials f_{xy} and f_{yx} are continuous everywhere, but $f_{xy} \neq f_{yx}$ for $x \neq 0$. This contradicts Clairaut's Theorem on Equality of Mixed Partials. We conclude that there does not exist any function $f(x,y)$ with the given partials.

75. Assume that f_{xy} and f_{yx} are continuous and that f_{yxx} exists. Show that f_{xyx} also exists and that $f_{yxx} = f_{xyx}$.

SOLUTION Since f_{xy} and f_{yx} are continuous, Clairaut's Theorem implies that

$$f_{xy} = f_{yx} \tag{1}$$

We are given that f_{yxx} exists. Using (1) we get

$$f_{yxx} = \frac{\partial}{\partial x}\frac{\partial}{\partial x}f_y = \frac{\partial}{\partial x}f_{yx} = \frac{\partial}{\partial x}f_{xy} = f_{xyx}$$

Therefore, f_{xyx} also exists and $f_{yxx} = f_{xyx}$.

76. Show that $u(x,t) = \sin(nx)\,e^{-n^2t}$ satisfies the heat equation for any constant n:

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2}$$ $\boxed{3}$

SOLUTION We compute $\frac{\partial u}{\partial t}$ using the Chain Rule:

$$\frac{\partial u}{\partial t} = \sin(nx)\frac{\partial}{\partial t}e^{-n^2t} = \sin(nx)e^{-n^2t}\frac{\partial}{\partial t}(-n^2t) = -n^2\sin(nx)e^{-n^2t}$$

We now find u_x:

$$u_x = e^{-n^2t}\frac{\partial}{\partial x}\sin(nx) = e^{-n^2t}\cos(nx)\cdot n = n\cdot\cos(nx)e^{-n^2t}$$

Differentiating u_x with respect to x gives

$$u_{xx} = ne^{-n^2t}\frac{\partial}{\partial x}\cos(nx) = ne^{-n^2t}\left(-\sin(nx)\frac{\partial}{\partial x}(nx)\right) = ne^{-n^2t}\big(-\sin(nx)\big)\cdot n = -n^2e^{-n^2t}\sin(nx)$$

We see that $u_t = u_{xx}$, therefore u satisfies the heat equation.

77. Find all values of A and B such that $f(x,t) = e^{Ax+Bt}$ satisfies Eq. (3).

SOLUTION We compute the following partials, using the Chain Rule:

$$\frac{\partial f}{\partial t} = \frac{\partial}{\partial t}(e^{Ax+Bt}) = e^{Ax+Bt}\frac{\partial}{\partial t}(Ax+Bt) = Be^{Ax+Bt}$$
$$\frac{\partial f}{\partial x} = \frac{\partial}{\partial x}(e^{Ax+Bt}) = e^{Ax+Bt}\frac{\partial}{\partial x}(Ax+Bt) = Ae^{Ax+Bt}$$
$$\frac{\partial^2 f}{\partial x^2} = \frac{\partial}{\partial x}(Ae^{Ax+Bt}) = A\frac{\partial}{\partial x}(e^{Ax+Bt}) = Ae^{Ax+Bt}\frac{\partial}{\partial x}(Ax+Bt) = A^2e^{Ax+Bt}$$

Substituting these partials in the differential equation (3), we get

$$Be^{Ax+Bt} = A^2e^{Ax+Bt}$$

We divide by the nonzero e^{Ax+Bt} to obtain

$$B = A^2$$

We conclude that $f(x,t) = e^{Ax+Bt}$ satisfies equation (5) if and only if $B = A^2$, where A is arbitrary.

78. The function

$$f(x,t) = \frac{1}{2\sqrt{\pi t}}e^{-x^2/4t}$$

describes the temperature profile along a metal rod at time $t > 0$ when a burst of heat is applied at the origin (see Example 11). A small bug sitting on the rod at distance x from the origin feels the temperature rise and fall as heat diffuses through the bar. Show that the bug feels the maximum temperature at time $t = \frac{1}{2}x^2$.

SOLUTION From the example in the text we see that:

$$\frac{\partial f}{\partial t} = -\frac{1}{4\sqrt{\pi}}t^{-3/2}e^{-x^2/4t} + \frac{1}{8\sqrt{\pi}}x^2t^{-5/2}e^{-x^2/4t}$$

We take this expression, in order to find the maximum, and set it equal to 0 and solve for t:

$$-\frac{1}{4\sqrt{\pi}}t^{-3/2}e^{-x^2/4t} + \frac{1}{8\sqrt{\pi}}x^2t^{-5/2}e^{-x^2/4t} = 0$$
$$e^{-x^2/4t}(-2t^{-3/2} + x^2t^{-5/2}) = 0$$
$$t^{-5/2}e^{-x^2/4t}(-2t + x^2) = 0$$

Then since the exponential factor is never equal to 0 and the $t^{-5/2}$ is not either, we only consider when

$$-2t + x^2 = 0 \quad\Rightarrow\quad t = \frac{1}{2}x^2$$

Since we are told that the bug experiences the rise and then the fall of the temperature, we are assured that $t = 1/2x^2$ is the point in time when the bug experiences the maximum temperature.

In Exercises 79–82, the ***Laplace operator*** Δ *is defined by* $\Delta f = f_{xx} + f_{yy}$. *A function* $u(x,y)$ *satisfying the Laplace equation* $\Delta u = 0$ *is called* ***harmonic***.

79. Show that the following functions are harmonic:

(a) $u(x,y) = x$

(b) $u(x,y) = e^x\cos y$

(c) $u(x,y) = \tan^{-1}\dfrac{y}{x}$

(d) $u(x,y) = \ln(x^2+y^2)$

SOLUTION

(a) We compute u_{xx} and u_{yy} for $u(x, y) = x$:

$$u_x = \frac{\partial}{\partial x}(x) = 1; \quad u_{xx} = \frac{\partial}{\partial x}(1) = 0$$

$$u_y = \frac{\partial}{\partial y}(x) = 0; \quad u_{yy} = \frac{\partial}{\partial y}(0) = 0$$

Since $u_{xx} + u_{yy} = 0$, u is harmonic.

(b) We compute the partial derivatives of $u(x, y) = e^x \cos y$:

$$u_x = \frac{\partial}{\partial x}\left(e^x \cos y\right) = \cos y \frac{\partial}{\partial x} e^x = (\cos y)e^x$$

$$u_y = \frac{\partial}{\partial y}\left(e^x \cos y\right) = e^x \frac{\partial}{\partial y} \cos y = -e^x \sin y$$

$$u_{xx} = \frac{\partial}{\partial x}\left((\cos y)e^x\right) = \cos y \frac{\partial}{\partial x} e^x = (\cos y)e^x$$

$$u_{yy} = \frac{\partial}{\partial y}\left(-e^x \sin y\right) = -e^x \frac{\partial}{\partial y} \sin y = -e^x \cos y$$

Thus,

$$u_{xx} + u_{yy} = (\cos y)e^x - e^x \cos y = 0$$

Hence $u(x, y) = e^x \cos y$ is harmonic.

(c) We compute the partial derivatives of $u(x, y) = \tan^{-1} \frac{y}{x}$ using the Chain Rule and the formula

$$\frac{d}{dt} \tan^{-1} t = \frac{1}{1+t^2}$$

We have

$$u_x = \frac{\partial}{\partial x} \tan^{-1} \frac{y}{x} = \frac{1}{1+(y/x)^2} \frac{\partial}{\partial x} \frac{y}{x} = \frac{1}{1+(y/x)^2} \left(\frac{-y}{x^2}\right) = -\frac{y}{x^2+y^2}$$

$$u_y = \frac{\partial}{\partial y} \tan^{-1} \frac{y}{x} = \frac{1}{1+(y/x)^2} \frac{\partial}{\partial y} \frac{y}{x} = \frac{1}{1+(y/x)^2} \left(\frac{1}{x}\right) = \frac{x}{x^2+y^2}$$

$$u_{xx} = \frac{\partial}{\partial x} \left(-\frac{y}{x^2+y^2}\right) = \frac{2xy}{(x^2+y^2)^2}$$

$$u_{yy} = \frac{\partial}{\partial y} \frac{x}{x^2+y^2} = -\frac{2xy}{(x^2+y^2)^2}$$

Therefore $u_{xx} + u_{xx} = 0$. This shows that $u(x, y) = \tan^{-1} \frac{y}{x}$ is harmonic.

(d) We compute the partial derivatives of $u(x, y) = \ln\left(x^2 + y^2\right)$ using the Chain Rule:

$$u_x = \frac{\partial}{\partial x} \ln(x^2+y^2) = \frac{1}{x^2+y^2} \cdot 2x = \frac{2x}{x^2+y^2}$$

$$u_y = \frac{\partial}{\partial y} \ln(x^2+y^2) = \frac{1}{x^2+y^2} \cdot 2y = \frac{2y}{x^2+y^2}$$

We now find u_{xx} and u_{yy} using the Quotient Rule:

$$u_{xx} = \frac{\partial}{\partial x} \frac{2x}{x^2+y^2} = \frac{2(x^2+y^2) - 2x \cdot 2x}{\left(x^2+y^2\right)^2} = \frac{2(y^2-x^2)}{\left(x^2+y^2\right)^2}$$

$$u_{yy} = \frac{\partial}{\partial y} \frac{2y}{x^2+y^2} = \frac{2(x^2+y^2) - 2y \cdot 2y}{\left(x^2+y^2\right)^2} = \frac{2(x^2-y^2)}{\left(x^2+y^2\right)^2}$$

Thus,

$$u_{xx} + u_{yy} = \frac{2(y^2-x^2)}{\left(x^2+y^2\right)^2} + \frac{2(x^2-y^2)}{\left(x^2+y^2\right)^2} = 0.$$

Therefore, $u(x, y) = \ln(x^2 + y^2)$ is harmonic.

80. Find all harmonic polynomials $u(x, y)$ of degree three, that is, $u(x, y) = ax^3 + bx^2y + cxy^2 + dy^3$.

SOLUTION We compute the first-order partials u_x and u_y and the second-order partials u_{xx} and u_{yy} of the given polynomial $u(x, y)$. This gives

$$\begin{aligned} u_x &= 3ax^2 + 2bxy + cy^2 \\ u_y &= bx^2 + 2cxy + 3dy^2 \\ u_{xx} &= 6ax + 2by \\ u_{yy} &= 2cx + 6dy \end{aligned}$$

The polynomial is harmonic if $u_{xx} + u_{yy} = 0$, that is, if for all x and y

$$6ax + 2by + 2cx + 6dy = 0$$

This equality holds for all x and y if and only if the coefficients of x and y are both zero. That is, $6a + 2c = 0$ (so $c = -3a$) and $2b + 6d = 0$ (so $b = -3d$). We conclude that the harmonic polynomials in the given form are

$$u(x, y) = ax^3 - 3dx^2y - 3axy^2 + dy^3$$

81. Show that if $u(x, y)$ is harmonic, then the partial derivatives $\partial u/\partial x$ and $\partial u/\partial y$ are harmonic.

SOLUTION We assume that the second-order partials are continuous, hence the partial differentiation may be performed in any order. By the given data, we have

$$u_{xx} + u_{yy} = 0 \tag{1}$$

We must show that

$$(u_x)_{xx} + (u_x)_{yy} = 0 \quad \text{and} \quad (u_y)_{xx} + (u_y)_{yy} = 0$$

We differentiate (1) with respect to x, obtaining

$$0 = (u_{xx})_x + (u_{yy})_x = u_{xxx} + u_{xyy} = (u_x)_{xx} + (u_x)_{yy} \tag{2}$$

We differentiate (1) with respect to y:

$$0 = (u_{xx})_y + (u_{yy})_y = u_{xxy} + u_{yyy} = u_{yxx} + u_{yyy} = (u_y)_{xx} + (u_y)_{yy} \tag{3}$$

Equalities (2) and (3) prove that u_x and u_y are harmonic.

82. Find all constants a, b such that $u(x, y) = \cos(ax)e^{by}$ is harmonic.

SOLUTION To determine if the functions $\cos(ax)e^{by}$ are harmonic, we compute the following derivatives:

$$\begin{aligned} (\cos ax)' = -a \sin ax \quad &\Rightarrow \quad (\cos ax)'' = -a^2 \cos ax \\ (e^{by})' = be^{by} \quad &\Rightarrow \quad (e^{by})'' = b^2 e^{by} = a^2 e^{by} \end{aligned}$$

Thus, we can conclude

$$\begin{aligned} u_{xx} &= \frac{\partial^2}{\partial x^2} \cos(ax)e^{by} = -a^2 \cos(ax)e^{by} = -a^2 u \\ u_{yy} &= \frac{\partial^2}{\partial y^2} \cos(ax)e^{by} = b^2 \cos(ax)e^{by} = b^2 u \end{aligned}$$

Thus, $u_{xx} + u_{yy} = (b^2 - a^2)u$, which equals 0 if and only if $a^2 = b^2$.

83. Show that $u(x, t) = \operatorname{sech}^2(x - t)$ satisfies the **Korteweg–deVries equation** (which arises in the study of water waves):

$$4u_t + u_{xxx} + 12uu_x = 0$$

SOLUTION In Exercise 72 we found the following derivatives:

$$\begin{aligned} u_x &= -2 \operatorname{sech}^2(x - t) \tanh(x - t) \\ u_{xxx} &= 16 \operatorname{sech}^4(x - t) \tanh(x - t) - 8 \operatorname{sech}^2(x - t) \tanh^3(x - t) \end{aligned}$$

Hence,

$$4u_t + u_{xxx} + 12uu_x = 8 \operatorname{sech}^2(x - t) \tanh(x - t) + 16 \operatorname{sech}^4(x - t) \tanh(x - t)$$

$$
\begin{aligned}
&- 8\operatorname{sech}^2(x-t)\tanh^3(x-t) - 24\operatorname{sech}^4(x-t)\tanh(x-t)\\
&= 8\operatorname{sech}^2(x-t)\left\{\tanh(x-t) - \tanh^3(x-t)\right\} - 8\operatorname{sech}^4(x-t)\tanh(x-t)\\
&= 8\operatorname{sech}^2(x-t)\tanh(x-t)\left\{1 - \tanh^2(x-t)\right\} - 8\operatorname{sech}^4(x-t)\tanh(x-t)\\
&= 8\operatorname{sech}^2(x-t)\tanh(x-t)\left\{\operatorname{sech}^2(x-t)\right\} - 8\operatorname{sech}^4(x-t)\tanh(x-t)\\
&= 0
\end{aligned}
$$

Further Insights and Challenges

84. Assumptions Matter This exercise shows that the hypotheses of Clairaut's Theorem are needed. Let

$$f(x, y) = xy\frac{x^2 - y^2}{x^2 + y^2}$$

for $(x, y) \neq (0, 0)$ and $f(0, 0) = 0$.

(a) Verify for $(x, y) \neq (0, 0)$:

$$f_x(x, y) = \frac{y(x^4 + 4x^2y^2 - y^4)}{(x^2 + y^2)^2}$$

$$f_y(x, y) = \frac{x(x^4 - 4x^2y^2 - y^4)}{(x^2 + y^2)^2}$$

(b) Use the limit definition of the partial derivative to show that $f_x(0, 0) = f_y(0, 0) = 0$ and that $f_{yx}(0, 0)$ and $f_{xy}(0, 0)$ both exist but are not equal.

(c) Show that for $(x, y) \neq (0, 0)$:

$$f_{xy}(x, y) = f_{yx}(x, y) = \frac{x^6 + 9x^4y^2 - 9x^2y^4 - y^6}{(x^2 + y^2)^3}$$

Show that f_{xy} is not continuous at $(0, 0)$. *Hint:* Show that $\lim_{h\to 0} f_{xy}(h, 0) \neq \lim_{h\to 0} f_{xy}(0, h)$.

(d) Explain why the result of part (b) does not contradict Clairaut's Theorem.

SOLUTION

(a) These are the partials for $(x, y) \neq (0, 0)$:

$$f_x(x, y) = \frac{y(x^4 + 4x^2y^2 - y^4)}{(x^2 + y^2)^2}$$

$$f_y(x, y) = \frac{x(x^4 - 4x^2y^2 - y^4)}{(x^2 + y^2)^2}$$

(b) Using the limit definition of the partial derivatives at the point $(0, 0)$ we have

$$f_x(0, 0) = \lim_{h\to 0}\frac{f(h, 0) - f(0, 0)}{h} = \lim_{h\to 0}\frac{h\cdot 0\frac{h^2-0^2}{h^2+0^2} - 0}{h} = \lim_{h\to 0}\frac{0}{h} = 0$$

$$f_y(0, 0) = \lim_{k\to 0}\frac{f(0, k) - f(0, 0)}{k} = \lim_{k\to 0}\frac{0\cdot k\frac{0^2-k^2}{0^2+k^2} - 0}{k} = \lim_{k\to 0}\frac{0}{k} = 0$$

We now use the derivatives in part (a) and the limit definition of the partial derivatives to compute $f_{yx}(0, 0)$ and $f_{xy}(0, 0)$. By the formulas in part (a), we have

$$f_y(0, 0) = 0, \quad f_y(h, 0) = \frac{h(h^4 - 0 - 0)}{(h^2 + 0)^2} = h$$

$$f_x(0, 0) = 0, \quad f_x(0, k) = \frac{k(0 + 0 - k^4)}{(0^2 + k^2)^2} = -k$$

Thus,

$$f_{yx}(0, 0) = \frac{\partial}{\partial x}f_y\bigg|_{(0,0)} = \lim_{h\to 0}\frac{f_y(h, 0) - f_y(0, 0)}{h} = \lim_{h\to 0}\frac{h - 0}{h} = \lim_{h\to 0} 1 = 1$$

$$f_{xy}(0,0) = \frac{\partial}{\partial y} f_x \bigg|_{(0,0)} = \lim_{k\to 0} \frac{f_x(0,k) - f_x(0,0)}{k} = \lim_{k\to 0} \frac{-k-0}{k} = \lim_{k\to 0}(-1) = -1$$

We see that the mixed partials at the point $(0,0)$ exist but are not equal.

(c) We verify that for $(x,y) \neq (0,0)$ the following derivatives hold:

$$f_{xy}(x,y) = f_{yx}(x,y) = \frac{x^6 + 9x^4y^2 - 9x^2y^4 - y^6}{(x^2+y^2)^3}$$

To show that f_{xy} is not continuous at $(0,0)$, we show that the limit $\lim_{(x,y)\to(0,0)} f_{xy}(x,y)$ does not exist. We compute the limit as (x,y) approaches the origin along the x-axis. Along this axis, $y = 0$; hence,

$$\lim_{\substack{(x,y)\to(0,0)\\ \text{along the } x\text{-axis}}} f_{xy}(x,y) = \lim_{h\to 0} f_{xy}(h,0) = \lim_{h\to 0} \frac{h^6 + 9h^4\cdot 0 - 9h^2\cdot 0 - 0}{(0+h^2)^3} = \lim_{h\to 0} 1 = 1$$

We compute the limit as (x,y) approaches the origin along the y-axis. Along this axis, $x = 0$, hence,

$$\lim_{\substack{(x,y)\to(0,0)\\ \text{along the } y\text{-axis}}} f_{xy}(x,y) = \lim_{h\to 0} f_{xy}(0,h) = \lim_{h\to 0} \frac{0+0+0-h^6}{(0+h^2)^3} = \lim_{h\to 0}(-1) = -1$$

Since the limits are not equal $f(x,y)$ does not approach one value as $(x,y) \to (0,0)$, hence the limit $\lim_{(x,y)\to(0,0)} f_{xy}(x,y)$ does not exist, and $f_{xy}(x,y)$ is not continuous at the origin.

(d) The result of part (b) does not contradict Clairaut's Theorem since f_{xy} is not continuous at the origin. The continuity of the mixed derivative is essential in Clairaut's Theorem.

14.4 Differentiability and Tangent Planes (LT Section 15.4)

Preliminary Questions

1. How is the linearization of $f(x,y)$ at (a,b) defined?

SOLUTION The linearization of $f(x,y)$ at (a,b) is the linear function

$$L(x,y) = f(a,b) + f_x(a,b)(x-a) + f_y(a,b)(y-b)$$

This function is the equation of the tangent plane to the surface $z = f(x,y)$ at $\big(a,b,f(a,b)\big)$.

2. Define local linearity for functions of two variables.

SOLUTION $f(x,y)$ is locally linear at (a,b) if

$$f(x,y) - L(x,y) = \epsilon(x,y)\sqrt{(x-a)^2 + (y-b)^2}$$

for all (x,y) in an open disk D containing (a,b), where $\epsilon(x,y)$ satisfies $\lim_{(x,y)\to(a,b)} \epsilon(x,y) = 0$.

In Exercises 3–5, assume that

$$f(2,3) = 8, \qquad f_x(2,3) = 5, \qquad f_y(2,3) = 7$$

3. Which of (a)–(b) is the linearization of f at $(2,3)$?

(a) $L(x,y) = 8 + 5x + 7y$

(b) $L(x,y) = 8 + 5(x-2) + 7(y-3)$

SOLUTION The linearization of f at $(2,3)$ is the following linear function:

$$L(x,y) = f(2,3) + f_x(2,3)(x-2) + f_y(2,3)(y-3)$$

That is,

$$L(x,y) = 8 + 5(x-2) + 7(y-3) = -23 + 5x + 7y$$

The function in (b) is the correct answer.

4. Estimate $f(2, 3.1)$.

SOLUTION We use the linear approximation

$$f(a+h, b+k) \approx f(a, b) + f_x(a, b)h + f_y(a, b)k$$

We let $(a, b) = (2, 3)$, $h = 0$, $k = 3.1 - 3 = 0.1$. Then,

$$f(2, 3.1) \approx f(2, 3) + f_x(2, 3) \cdot 0 + f_y(2, 3) \cdot 0.1 = 8 + 0 + 7 \cdot 0.1 = 8.7$$

We get the estimation $f(2, 3.1) \approx 8.7$.

5. Estimate Δf at $(2, 3)$ if $\Delta x = -0.3$ and $\Delta y = 0.2$.

SOLUTION The change in f can be estimated by the linear approximation as follows:

$$\Delta f \approx f_x(a, b)\Delta x + f_y(a, b)\Delta y$$
$$\Delta f \approx f_x(2, 3) \cdot (-0.3) + f_y(2, 3) \cdot 0.2$$

or

$$\Delta f \approx 5 \cdot (-0.3) + 7 \cdot 0.2 = -0.1$$

The estimated change is $\Delta f \approx -0.1$.

6. Which theorem allows us to conclude that $f(x, y) = x^3y^8$ is differentiable?

SOLUTION The function $f(x, y) = x^3y^8$ is a polynomial, hence $f_x(x, y)$ and $f_y(x, y)$ exist and are continuous. Therefore the Criterion for Differentiability implies that f is differentiable everywhere.

Exercises

1. Use Eq. (2) to find an equation of the tangent plane to the graph of $f(x, y) = 2x^2 - 4xy^2$ at $(-1, 2)$.

SOLUTION The equation of the tangent plane at the point $(-1, 2, 18)$ is

$$z = f(-1, 2) + f_x(-1, 2)(x+1) + f_y(-1, 2)(y-2) \tag{1}$$

We compute the function and its partial derivatives at the point $(-1, 2)$:

$$\begin{aligned} f(x, y) &= 2x^2 - 4xy^2 & & f(-1, 2) = 18 \\ f_x(x, y) &= 4x - 4y^2 & \Rightarrow \quad & f_x(-1, 2) = -20 \\ f_y(x, y) &= -8xy & & f_y(-1, 2) = 16 \end{aligned}$$

Substituting in (1) we obtain the following equation of the tangent plane:

$$z = 18 - 20(x+1) + 16(y-2) = -34 - 20x + 16y$$

That is,

$$z = -34 - 20x + 16y$$

2. Find the equation of the plane in Figure 9, which is tangent to the graph at $(x, y) = (1, 0.8)$.

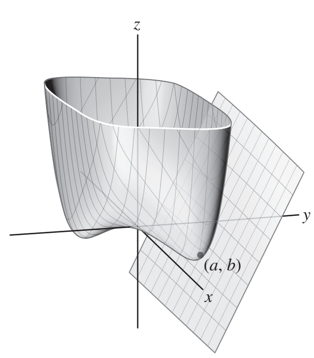

FIGURE 9 Graph of $f(x, y) = 0.2x^4 + y^6 - xy$.

SOLUTION We know that the equation of the tangent plane at the point $(1, 0.8)$ is:

$$z = f(1, 0.8) + f_x(1, 0.8)(x-1) + f_y(1, 0.8)(y-0.8)$$

We compute the function and its partial derivatives at the point $(1, 0.8)$:

$$\begin{aligned} f(x, y) &= 0.2x^4 + y^6 - xy &\Rightarrow\quad & f(1, 0.8) = -0.34 \\ f_x(x, y) &= 0.8x^3 - y &\Rightarrow\quad & f_x(1, 0.8) = 0 \\ f_y(x, y) &= 6y^5 - x &\Rightarrow\quad & f_y(1, 0.8) = 0.96608 \end{aligned}$$

Substituting in the equation of the tangent plane we obtain the following equation:

$$z = -0.34 + 0(x - 1) + 0.96608(y - 0.8)$$

That is,

$$z = 0.96608y - 1.112864$$

In Exercises 3–10, find an equation of the tangent plane at the given point.

3. $f(x, y) = x^2y + xy^3$, $(2, 1)$

SOLUTION The equation of the tangent plane at $(2, 1)$ is

$$z = f(2, 1) + f_x(2, 1)(x - 2) + f_y(2, 1)(y - 1) \tag{1}$$

We compute the values of f and its partial derivatives at $(2, 1)$:

$$\begin{aligned} f(x, y) &= x^2y + xy^3 & & f(2, 1) = 6 \\ f_x(x, y) &= 2xy + y^3 &\Rightarrow\quad & f_x(2, 1) = 5 \\ f_y(x, y) &= x^2 + 3xy^2 & & f_y(2, 1) = 10 \end{aligned}$$

We now substitute these values in (1) to obtain the following equation of the tangent plane:

$$z = 6 + 5(x - 2) + 10(y - 1) = 5x + 10y - 14$$

That is,

$$z = 5x + 10y - 14.$$

4. $f(x, y) = \dfrac{x}{\sqrt{y}}$, $(4, 4)$

SOLUTION The equation of the tangent plane at $(4, 4)$ is

$$z = f(4, 4) + f_x(4, 4)(x - 4) + f_y(4, 4)(y - 4) \tag{1}$$

We compute the values of f and its partial derivatives at $(4, 4)$:

$$\begin{aligned} f(x, y) &= \frac{x}{\sqrt{y}} & & f(4, 4) = 2 \\ f_x(x, y) &= \frac{1}{\sqrt{y}} &\Rightarrow\quad & f_x(4, 4) = \frac{1}{2} \\ f_y(x, y) &= x\frac{\partial}{\partial y}y^{-1/2} = x \cdot \left(-\frac{1}{2}\right)y^{-3/2} = -\frac{x}{2y^{3/2}} & & f_y(4, 4) = -\frac{1}{4} \end{aligned}$$

Substituting these values in (1) gives

$$z = 2 + \frac{1}{2}(x - 4) - \frac{1}{4}(y - 4) = \frac{1}{2}x - \frac{1}{4}y + 1.$$

5. $f(x, y) = x^2 + y^{-2}$, $(4, 1)$

SOLUTION The equation of the tangent plane at $(4, 1)$ is

$$z = f(4, 1) + f_x(4, 1)(x - 4) + f_y(4, 1)(y - 1) \tag{1}$$

We compute the values of f and its partial derivatives at $(4, 1)$:

$$\begin{aligned} f(x, y) &= x^2 + y^{-2} & & f(4, 1) = 17 \\ f_x(x, y) &= 2x &\Rightarrow\quad & f_x(4, 1) = 8 \\ f_y(x, y) &= -2y^{-3} & & f_y(4, 1) = -2 \end{aligned}$$

Substituting in (1) we obtain the following equation of the tangent plane:

$$z = 17 + 8(x-4) - 2(y-1) = 8x - 2y - 13.$$

6. $G(u, w) = \sin(uw), \quad \left(\frac{\pi}{6}, 1\right)$

SOLUTION The equation of the tangent plane at $\left(\frac{\pi}{6}, 1\right)$ is

$$z = f\left(\frac{\pi}{6}, 1\right) + f_u\left(\frac{\pi}{6}, 1\right)\left(u - \frac{\pi}{6}\right) + f_w\left(\frac{\pi}{6}, 1\right)(w-1) \tag{1}$$

We compute the following values:

$$\begin{aligned} f(u,w) &= \sin(uw) & & f\left(\frac{\pi}{6}, 1\right) = \sin\frac{\pi}{6} = \frac{1}{2} \\ f_u(u,w) &= w\cos(uw) & \Rightarrow\quad & f_u\left(\frac{\pi}{6}, 1\right) = 1 \cdot \cos\frac{\pi}{6} = \frac{\sqrt{3}}{2} \\ f_w(u,w) &= u\cos(uw) & & f_w\left(\frac{\pi}{6}, 1\right) = \frac{\pi}{6}\cos\frac{\pi}{6} = \frac{\sqrt{3}\pi}{12} \end{aligned}$$

Substituting in (1) gives the following equation of the tangent plane:

$$z = \frac{1}{2} + \frac{\sqrt{3}}{2}\left(u - \frac{\pi}{6}\right) + \frac{\sqrt{3}\pi}{12}(w-1)$$

That is,

$$z = \frac{\sqrt{3}}{2}u + \frac{\sqrt{3}\pi}{12}w + \frac{1}{2} - \frac{\sqrt{3}\pi}{6}.$$

7. $F(r, s) = r^2 s^{-1/2} + s^{-3}, \quad (2, 1)$

SOLUTION The equation of the tangent plane at (2, 1) is

$$z = f(2,1) + f_r(2,1)(r-2) + f_s(2,1)(s-1) \tag{1}$$

We compute f and its partial derivatives at (2, 1):

$$\begin{aligned} f(r,s) &= r^2 s^{-1/2} + s^{-3} & & f(2,1) = 5 \\ f_r(r,s) &= 2rs^{-1/2} & \Rightarrow\quad & f_r(2,1) = 4 \\ f_s(r,s) &= -\frac{1}{2}r^2 s^{-3/2} - 3s^{-4} & & f_s(2,1) = -5 \end{aligned}$$

We substitute these values in (1) to obtain the following equation of the tangent plane:

$$z = 5 + 4(r-2) - 5(s-1) = 4r - 5s + 2.$$

8. $g(x, y) = e^{x/y}, \quad (2, 1)$

SOLUTION The equation of the tangent plane at (2, 1) is:

$$z = g(2,1) + g_x(2,1)(x-2) + g_y(2,1)(y-1)$$

We compute g and its partial derivatives at (2, 1):

$$\begin{aligned} g(x,y) &= e^{x/y} & g(2,1) &= e^2 \\ g_x(x,y) &= \frac{1}{y}e^{x/y}, & g_x(2,1) &= e^2 \\ g_y(x,y) &= -\frac{x}{y^2}e^{x/y}, & g_y(2,1) &= -2e^2 \end{aligned}$$

We substitute these values in the tangent plane equation to obtain the following equation of the tangent plane:

$$z = e^2 + e^2(x-2) - 2e^2(y-1) = e^2x - 2e^2y + e^2 = e^2(x - 2y + 1)$$

9. $f(x, y) = \operatorname{sech}(x - y), \quad (\ln 4, \ln 2)$

SOLUTION The equation of the tangent plane at $(\ln 4, \ln 2)$ is:

$$z = f(\ln 4, \ln 2) + f_x(\ln 4, \ln 2)(x - \ln 4) + f_y(\ln 4, \ln 2)(y - \ln 2)$$

We compute f and its partial derivatives at $(\ln 4, \ln 2)$:

$$f(x, y) = \operatorname{sech}(x - y), \quad f(\ln 4, \ln 2) = \operatorname{sech}(\ln 2) = \frac{4}{5}$$

$$f_x(x, y) = -\tanh(x - y)\operatorname{sech}(x - y), \quad f_x(\ln 4, \ln 2) = -\tanh(\ln 2)\operatorname{sech}(\ln 2) = -\frac{12}{25}$$

$$f_y(x, y) = \tanh(x - y)\operatorname{sech}(x - y), \quad f_y(\ln 4, \ln 2) = \tanh(\ln 2)\operatorname{sech}(\ln 2) = \frac{12}{25}$$

We substitute these values in the tangent plane equation to obtain:

$$z = \frac{4}{5} - \frac{12}{25}(x - \ln 4) + \frac{12}{25}(x - \ln 2) = -\frac{4}{25}(3x - 3y - 5 - \ln 8)$$

10. $f(x, y) = \ln(4x^2 - y^2), \quad (1, 1)$

SOLUTION The equation of the tangent plane at $(1, 1)$ is

$$z = f(1, 1) + f_x(1, 1)(x - 1) + f_y(1, 1)(y - 1)$$

We compute the values of f and its partial derivatives at $(1, 1)$:

$$f(x, y) = \ln(4x^2 - y^2), \quad f(1, 1) = \ln 3$$

$$f_x(x, y) = \frac{8x}{4x^2 - y^2}, \quad f_x(1, 1) = \frac{8}{3}$$

$$f_y(x, y) = \frac{-2y}{4x^2 - y^2}, \quad f_y(1, 1) = -\frac{2}{3}$$

Substituting these values into the equation for the tangent plane we obtain:

$$z = \ln 3 + \frac{8}{3}(x - 1) - \frac{2}{3}(y - 1) = \frac{8}{3}x - \frac{2}{3}y + \ln 3 - 2$$

11. Find the points on the graph of $z = 3x^2 - 4y^2$ at which the vector $\mathbf{n} = \langle 3, 2, 2\rangle$ is normal to the tangent plane.

SOLUTION The equation of the tangent plane at the point $\big(a, b, f(a, b)\big)$ on the graph of $z = f(x, y)$ is

$$z = f(a, b) + f_x(a, b)(x - a) + f_y(a, b)(y - b)$$

or

$$f_x(a, b)(x - a) + f_y(a, b)(y - b) - z + f(a, b) = 0$$

Therefore, the following vector is normal to the plane:

$$\mathbf{v} = \big\langle f_x(a, b), f_y(a, b), -1\big\rangle$$

We compute the partial derivatives of the function $f(x, y) = 3x^2 - 4y^2$:

$$f_x(x, y) = 6x \quad \Rightarrow \quad f_x(a, b) = 6a$$

$$f_y(x, y) = -8y \quad \Rightarrow \quad f_y(a, b) = -8b$$

Therefore, the vector $\mathbf{v} = \langle 6a, -8b, -1\rangle$ is normal to the tangent plane at (a, b). Since we want $\mathbf{n} = \langle 3, 2, 2\rangle$ to be normal to the plane, the vectors $\mathbf{v}$ and $\mathbf{n}$ must be parallel. That is, the following must hold:

$$\frac{6a}{3} = \frac{-8b}{2} = -\frac{1}{2}$$

which implies that $a = -\frac{1}{4}$ and $b = \frac{1}{8}$. We compute the z-coordinate of the point:

$$z = 3 \cdot \left(-\frac{1}{4}\right)^2 - 4\left(\frac{1}{8}\right)^2 = \frac{1}{8}$$

The point on the graph at which the vector $\mathbf{n} = \langle 3, 2, 2\rangle$ is normal to the tangent plane is $\left(-\frac{1}{4}, \frac{1}{8}, \frac{1}{8}\right)$.

12. Find the points on the graph of $z = xy^3 + 8y^{-1}$ where the tangent plane is parallel to $2x + 7y + 2z = 0$.

SOLUTION The equation of the tangent plane at the point $(a, b, f(a, b))$ on the graph of $z = f(x, y)$ is

$$z = f(a, b) + f_x(a, b)(x - a) + f_y(a, b)(y - b)$$

or

$$f_x(a, b)(x - a) + f_y(a, b)(y - b) - z + f(a, b) = 0$$

Therefore, the following vector is normal to the plane:

$$\mathbf{v} = \left\langle f_x(a, b), f_y(a, b), -1 \right\rangle$$

We compute the partial derivatives of the function $z = xy^3 + 8y^{-1}$:

$$f_x(x, y) = y^3, \quad f_x(a, b) = b^3$$
$$f_y(x, y) = 3xy^2 - 8y^{-2}, \quad f_y(a, b) = 3ab^2 - 8b^{-2}$$

Therefore, the vector $\mathbf{v} = \left\langle b^3, 3ab^2 - 8b^{-2}, -1 \right\rangle$ is normal to the tangent plane at (a, b). For two planes to be parallel, the vectors $\mathbf{v}$ and $\mathbf{n}$ must be parallel. The corresponding normal vector here is $\mathbf{n} = \langle 2, 7, 2 \rangle$. The following must hold:

$$\frac{b^3}{2} = \frac{3ab^2 - 8b^{-2}}{7} = -\frac{1}{2}$$

which implies that $b = -1$ and $a = 3/2$. We compute the z-coordinate of the point:

$$z = \frac{3}{2}(-1)^3 + 8(-1)^{-1} = -\frac{19}{2}$$

The point on the graph at which the tangent plane is parallel to $2x + 7y + 2z = 0$ is $\left(\frac{3}{2}, -1, -\frac{19}{2}\right)$.

13. Find the linearization $L(x, y)$ of $f(x, y) = x^2y^3$ at $(a, b) = (2, 1)$. Use it to estimate $f(2.01, 1.02)$ and $f(1.97, 1.01)$ and compare with values obtained using a calculator.

SOLUTION

(a) We compute the value of the function and its partial derivatives at $(a, b) = (2, 1)$:

$$\begin{aligned} f(x, y) &= x^2y^3 & & f(2, 1) = 4 \\ f_x(x, y) &= 2xy^3 & \Rightarrow \quad & f_x(2, 1) = 4 \\ f_y(x, y) &= 3x^2y^2 & & f_y(2, 1) = 12 \end{aligned}$$

The linear approximation is therefore

$$L(x, y) = f(2, 1) + f_x(2, 1)(x - 2) + f_y(2, 1)(y - 1)$$
$$L(x, y) = 4 + 4(x - 2) + 12(y - 1) = -16 + 4x + 12y$$

(b) For $h = x - 2$ and $k = y - 1$ we have the following form of the linear approximation at $(a, b) = (2, 1)$:

$$L(x, y) = f(2, 1) + f_x(2, 1)h + f_y(2, 1)k = 4 + 4h + 12k$$

To approximate $f(2.01, 1.02)$ we set $h = 2.01 - 2 = 0.01$, $k = 1.02 - 1 = 0.02$ to obtain

$$L(2.01, 1.02) = 4 + 4 \cdot 0.01 + 12 \cdot 0.02 = 4.28$$

The actual value is

$$f(2.01, 1.02) = 2.01^2 \cdot 1.02^3 = 4.2874$$

To approximate $f(1.97, 1.01)$ we set $h = 1.97 - 2 = -0.03$, $k = 1.01 - 1 = 0.01$ to obtain

$$L(1.97, 1.01) = 4 + 4 \cdot (-0.03) + 12 \cdot 0.01 = 4.$$

The actual value is

$$f(1.97, 1.01) = 1.97^2 \cdot 1.01^3 = 3.998.$$

14. Write the linear approximation to $f(x, y) = x(1+y)^{-1}$ at $(a, b) = (8, 1)$ in the form

$$f(a+h, b+k) \approx f(a, b) + f_x(a, b)h + f_y(a, b)k$$

Use it to estimate $\frac{7.98}{2.02}$ and compare with the value obtained using a calculator.

SOLUTION We first compute the value of $f(x, y) = x(1+y)^{-1}$ and its partial derivatives at $(a, b) = (8, 1)$:

$$\begin{aligned} f(x, y) &= x(1+y)^{-1} &\Rightarrow\quad & f(8, 1) = 4 \\ f_x(x, y) &= (1+y)^{-1} &\Rightarrow\quad & f_x(8, 1) = \frac{1}{2} \\ f_y(x, y) &= -x(1+y)^{-2} &\Rightarrow\quad & f_y(8, 1) = -2 \end{aligned}$$

Hence,

$$f(8+h, 1+k) \approx 4 + \frac{1}{2}h - 2k \tag{1}$$

To estimate $\frac{7.98}{2.02} = \frac{7.98}{1+1.02}$ we set $h = 7.98 - 8 = -0.02$, $k = 1.02 - 1 = 0.02$ in the equation above to obtain

$$f(7.98, 1.02) = \frac{7.98}{2.02} \approx 4 + \frac{1}{2}(-0.02) - 2(0.02) = 3.95$$

The actual value is

$$\frac{7.98}{2.02} = 3.950495\ldots$$

15. Let $f(x, y) = x^3y^{-4}$. Use Eq. (4) to estimate the change

$$\Delta f = f(2.03, 0.9) - f(2, 1)$$

SOLUTION We compute the function and its partial derivatives at $(a, b) = (2, 1)$:

$$\begin{aligned} f(x, y) &= x^3y^{-4} & & f(2, 1) = 8 \\ f_x(x, y) &= 3x^2y^{-4} &\Rightarrow\quad & f_x(2, 1) = 12 \\ f_y(x, y) &= -4x^3y^{-5} & & f_y(2, 1) = -32 \end{aligned}$$

Also, $\Delta x = 2.03 - 2 = 0.03$ and $\Delta y = 0.9 - 1 = -0.1$. Therefore,

$$\begin{aligned} &\Delta f = f(2.03, 0.9) - f(2, 1) \approx f_x(2, 1)\Delta x + f_y\Delta y = 12 \cdot 0.03 + (-32) \cdot (-0.1) = 3.56 \\ &\Delta f \approx 3.56 \end{aligned}$$

16. Use the linear approximation to $f(x, y) = \sqrt{x/y}$ at $(9, 4)$ to estimate $\sqrt{9.1/3.9}$.

SOLUTION The linear approximation to $f(x, y) = \sqrt{\frac{x}{y}}$ at $(9, 4)$ is

$$f(9+h, 4+k) \approx f(9, 4) + f_x(9, 4)h + f_y(9, 4)k \tag{1}$$

We compute the function and its partial derivatives at $(9, 4)$:

$$\begin{aligned} f(x, y) &= x^{1/2}y^{-1/2} & & f(9, 4) = \frac{3}{2} \\ f_x(x, y) &= \frac{1}{2}x^{-1/2}y^{-1/2} &\Rightarrow\quad & f_x(9, 4) = \frac{1}{12} \\ f_y(x, y) &= -\frac{1}{2}x^{1/2}y^{-3/2} & & f_y(9, 4) = -\frac{3}{16} \end{aligned}$$

Substituting these values and $h = 0.1$, $k = -0.1$ in (1) gives the following estimation:

$$\sqrt{\frac{9.1}{3.9}} \approx \frac{3}{2} + \frac{1}{12} \cdot 0.1 - \frac{3}{16}(-0.1) \approx 1.5271$$

The value obtained by a calculator is $\sqrt{\frac{9.1}{3.9}} \approx 1.5275$. The error is 0.0004 and the percentage error is

$$\text{percentage error} \approx \frac{0.0004 \cdot 100}{1.5275} \approx 0.0262\%$$

17. Use the linear approximation of $f(x, y) = e^{x^2+y}$ at $(0, 0)$ to estimate $f(0.01, -0.02)$. Compare with the value obtained using a calculator.

SOLUTION The linear approximation of f at the point $(0, 0)$ is

$$f(h, k) \approx f(0, 0) + f_x(0, 0)h + f_y(0, 0)k \tag{1}$$

We first must compute f and its partial derivative at the point $(0, 0)$. Using the Chain Rule we obtain

$$\begin{aligned} f(x, y) &= e^{x^2+y} & & f(0, 0) = e^0 = 1 \\ f_x(x, y) &= 2xe^{x^2+y} & \Rightarrow \quad & f_x(0, 0) = 2 \cdot 0 \cdot e^0 = 0 \\ f_y(x, y) &= e^{x^2+y} & & f_y(0, 0) = e^0 = 1 \end{aligned}$$

We substitute these values and $h = 0.01$, $k = -0.02$ in (1) to obtain

$$f(0.01, -0.02) \approx 1 + 0 \cdot 0.01 + 1 \cdot (-0.02) = 0.98$$

The actual value is $f(0.01, -0.02) = e^{0.01^2-0.02} \approx 0.9803$.

18. Let $f(x, y) = x^2/(y^2 + 1)$. Use the linear approximation at an appropriate point (a, b) to estimate $f(4.01, 0.98)$.

SOLUTION We use the linear approximation at the point $(a, b) = (4, 1)$, which is the closest point with integer coordinates. That is,

$$f(4 + h, 1 + k) \approx f(4, 1) + f_x(4, 1)h + f_y(4, 1)k \tag{1}$$

We compute f and its partial derivatives at the point $(4, 1)$:

$$\begin{aligned} f(x, y) &= \frac{x^2}{y^2 + 1} & & f(4, 1) = 8 \\ f_x(x, y) &= \frac{2x}{y^2 + 1} & \Rightarrow \quad & f_x(4, 1) = 4 \\ f_y(x, y) &= x^2 \frac{\partial}{\partial y}\left(\frac{1}{y^2 + 1}\right) = x^2 \cdot \frac{-2y}{(y^2 + 1)^2} = \frac{-2x^2 y}{(y^2 + 1)^2} & & f_y(4, 1) = -8 \end{aligned}$$

Substituting these values and $h = 0.01$, $k = -0.02$ in (1) gives

$$f(4.01, 0.98) \approx 8 + 4 \cdot 0.01 + (-8)(-0.02) = 8.2$$

The actual value is

$$f(4.01, 0.98) = \frac{4.01^2}{0.98^2 + 1} = 8.202$$

19. Find the linearization of $f(x, y, z) = z\sqrt{x + y}$ at $(8, 4, 5)$.

SOLUTION The linear approximation of f at the point $(8, 4, 5)$ is:

$$f(x, y, z) \approx f(8, 4, 5) + f_x(8, 4, 5)(x - 8) + f_y(8, 4, 5)(y - 4) + f_z(8, 4, 5)(z - 5)$$

We compute the values of f and its partial derivatives at $(8, 4, 5)$:

$$\begin{aligned} f(x, y, z) &= z\sqrt{x + y}, & f(8, 4, 5) &= 5\sqrt{12} = 10\sqrt{3} \\ f_x(x, y, z) &= \frac{z}{2\sqrt{x + y}}, & f_x(8, 4, 5) &= \frac{5}{2\sqrt{12}} = \frac{5}{4\sqrt{3}} \\ f_y(x, y, z) &= \frac{z}{2\sqrt{x + y}}, & f_y(8, 4, 5) &= \frac{5}{2\sqrt{12}} = \frac{5}{4\sqrt{3}} \\ f_z(x, y, z) &= \sqrt{x + y}, & f_z(8, 4, 5) &= \sqrt{12} = 4\sqrt{3} \end{aligned}$$

Substituting these values we obtain the linearization:

$$\begin{aligned} f(x, y, z) &\approx 10\sqrt{3} + \frac{5}{4\sqrt{3}}(x - 8) + \frac{5}{4\sqrt{3}}(y - 4) + 4\sqrt{3}(z - 5) \\ &= \frac{5}{4\sqrt{3}}(x - 8) + \frac{5}{4\sqrt{3}}(y - 4) + 4\sqrt{3}z - 15\sqrt{3} \end{aligned}$$

20. Find the linearization to $f(x, y, z) = xy/z$ at the point $(2, 1, 2)$. Use it to estimate $f(2.05, 0.9, 2.01)$ and compare with the value obtained from a calculator.

SOLUTION The linear approximation to f at the point $(2, 1, 2)$ is:

$$f(x, y, z) \approx f(2, 1, 2) + f_x(2, 1, 2)(x - 2) + f_y(2, 1, 2)(y - 1) + f_z(2, 1, 2)(z - 2) \tag{1}$$

We compute the values of f and its partial derivatives at $(2, 1, 2)$:

$$\begin{array}{lcl} f(x, y, z) = \dfrac{xy}{z} & & f(2, 1, 2) = 1 \\ f_x(x, y, z) = \dfrac{y}{z} & \Rightarrow & f_x(2, 1, 2) = \dfrac{1}{2} \\ f_y(x, y, z) = \dfrac{x}{z} & & f_y(2, 1, 2) = 1 \\ f_z(x, y, z) = -\dfrac{xy}{z^2} & & f_z(2, 1, 2) = -\dfrac{1}{2} \end{array}$$

We substitute these values in (1) to obtain the following linear approximation:

$$\frac{xy}{z} \approx 1 + \frac{1}{2}(x - 2) + 1 \cdot (y - 1) - \frac{1}{2}(z - 2)$$
$$\frac{xy}{z} \approx \frac{1}{2}x + y - \frac{1}{2}z$$

To estimate $f(2.05, 0.9, 2.01)$ we will have:

$$f(2.05, 0.9, 2.01) \approx \frac{1}{2}(2.05) + 0.9 - \frac{1}{2}(2.01) = 0.92$$

Comparing this with the calculator value we get:

$$f(2.05, 0.9, 2.01) = \frac{2.05 \cdot 0.9}{2.01} \approx 0.9179$$

21. Estimate $f(2.1, 3.8)$ assuming that

$$f(2, 4) = 5, \qquad f_x(2, 4) = 0.3, \qquad f_y(2, 4) = -0.2$$

SOLUTION We use the linear approximation of f at the point $(2, 4)$, which is

$$f(2 + h, 4 + k) \approx f(2, 4) + f_x(2, 4)h + f_y(2, 4)k$$

Substituting the given values and $h = 0.1$, $k = -0.2$ we obtain the following approximation:

$$f(2.1, 3.8) \approx 5 + 0.3 \cdot 0.1 + 0.2 \cdot 0.2 = 5.07.$$

22. Estimate $f(1.02, 0.01, -0.03)$ assuming that

$$\begin{array}{ll} f(1, 0, 0) = -3, & f_x(1, 0, 0) = -2, \\ f_y(1, 0, 0) = 4, & f_z(1, 0, 0) = 2 \end{array}$$

SOLUTION The linear approximation at $(1, 0, 0)$ is

$$f(1 + h, k, l) \approx f(1, 0, 0) + f_x(1, 0, 0)h + f_y(1, 0, 0)k + f_z(1, 0, 0)l \tag{1}$$

We substitute $h = 0.02$, $k = 0.01$, $l = -0.03$ and the given values to obtain the following estimation:

$$f(1.02, 0.01, -0.03) \approx -3 + (-2) \cdot 0.02 + 4 \cdot 0.01 + 2(-0.03) = -3.06$$

That is,

$$f(1.02, 0.01, -0.03) \approx -3.06.$$

In Exercises 23–28, use the linear approximation to estimate the value. Compare with the value given by a calculator.

23. $(2.01)^3(1.02)^2$

SOLUTION The number $(2.01)^3(1.02)^2$ is a value of the function $f(x, y) = x^3y^2$. We use the li(8, near approximation at (2, 1), which is

$$f(2+h, 1+k) \approx f(2,1) + f_x(2,1)h + f_y(2,1)k \tag{1}$$

We compute the value of the function and its partial derivatives at (2, 1):

$$\begin{aligned} f(x,y) &= x^3y^2 & & f(2,1) = 8 \\ f_x(x,y) &= 3x^2y^2 & \Rightarrow \quad & f_x(2,1) = 12 \\ f_y(x,y) &= 2x^3y & & f_y(2,1) = 16 \end{aligned}$$

Substituting these values and $h = 0.01$, $k = 0.02$ in (1) gives the approximation

$$(2.01)^3(1.02)^2 \approx 8 + 12 \cdot 0.01 + 16 \cdot 0.02 = 8.44$$

The value given by a calculator is 8.4487. The error is 0.0087 and the percentage error is

$$\text{Percentage error} \approx \frac{0.0087 \cdot 100}{8.4487} = 0.103\%$$

24. $\dfrac{4.1}{7.9}$

SOLUTION The number $\frac{4.1}{7.9}$ is a value of the function $f(x, y) = xy^{-1}$. We use the linear approximation at the point (4, 8), which is

$$f(4+h, 8+k) \approx f(4,8) + f_x(4,8)h + f_y(4,8)k \tag{1}$$

We compute the values of the function and its partial derivatives at (4, 8):

$$\begin{aligned} f(x,y) &= xy^{-1} & & f(4,8) = \frac{1}{2} \\ f_x(x,y) &= y^{-1} & \Rightarrow \quad & f_x(4,8) = \frac{1}{8} \\ f_y(x,y) &= -xy^{-2} & & f_y(4,8) = -\frac{1}{16} \end{aligned}$$

We substitute these values and $h = 0.1$, $k = -0.1$ in (1) to obtain the following approximation:

$$\frac{4.1}{7.9} \approx \frac{1}{2} + \frac{1}{8} \cdot 0.1 - \frac{1}{16} \cdot (-0.1) = \frac{83}{160} = 0.51875$$

The value given by a calculator is $\frac{4.1}{7.9} \approx 0.51899$. The error is 0.00024 and the percentage error is at most

$$\text{Percentage error} \approx \frac{0.00024 \cdot 100}{0.51899} = 0.04625\%$$

25. $\sqrt{3.01^2 + 3.99^2}$

SOLUTION This is a value of the function $f(x, y) = \sqrt{x^2 + y^2}$. We use the linear approximation at the point (3, 4), which is

$$f(3+h, 4+k) \approx f(3,4) + f_x(3,4)h + f_y(3,4)k \tag{1}$$

Using the Chain Rule gives the following partial derivatives:

$$\begin{aligned} f(x,y) &= \sqrt{x^2+y^2} & & f(3,4) = 5 \\ f_x(x,y) &= \frac{2x}{2\sqrt{x^2+y^2}} = \frac{x}{\sqrt{x^2+y^2}} & \Rightarrow \quad & f_x(3,4) = \frac{3}{5} \\ f_y(x,y) &= \frac{2y}{2\sqrt{x^2+y^2}} = \frac{y}{\sqrt{x^2+y^2}} & & f_y(3,4) = \frac{4}{5} \end{aligned}$$

Substituting these values and $h = 0.01$, $k = -0.01$ in (1) gives the following approximation:

$$\sqrt{3.01^2 + 3.99^2} \approx 5 + \frac{3}{5} \cdot 0.01 + \frac{4}{5} \cdot (-0.01) = 4.998$$

The value given by a calculator is $\sqrt{3.01^2 + 3.99^2} \approx 4.99802$. The error is 0.00002 and the percentage error is at most

$$\text{Percentage error} \approx \frac{0.00002 \cdot 100}{4.99802} = 0.0004002\%$$

26. $\dfrac{0.98^2}{2.01^3 + 1}$

SOLUTION We use the linear approximation of the function $f(x, y) = \frac{x^2}{y^3+1}$ at the point $(1, 2)$, which is

$$f(1 + h, 2 + k) \approx f(1, 2) + f_x(1, 2)h + f_y(1, 2)k \tag{1}$$

We compute the values of f and its partial derivatives at $(1, 2)$. We get:

$$\begin{aligned} f(x, y) &= \frac{x^2}{y^3 + 1} & & & f(1, 2) &= \frac{1}{9} \\ f_x(x, y) &= \frac{2x}{y^3 + 1} & & \Rightarrow & f_x(1, 2) &= \frac{2}{9} \\ f_y(x, y) &= x^2 \cdot \frac{-1}{(y^3 + 1)^2} \cdot 3y^2 = \frac{-3x^2y^2}{(y^3 + 1)^2} & & & f_y(1, 2) &= -\frac{4}{27} \end{aligned}$$

Substituting these values and $h = -0.02$, $k = 0.01$ in (1) gives the following approximation:

$$\frac{0.98^2}{2.01^3 + 1} \approx \frac{1}{9} + \frac{2}{9}(-0.02) - \frac{4}{27} \cdot 0.01 \approx 0.1052$$

The value given by a calculator is $\frac{0.98^2}{2.01^3+1} \approx 0.1053$. The error is 0.0001 and the percentage error is at most

$$\text{Percentage error} \approx \frac{0.0001 \cdot 100}{0.1053} \approx 0.095\%$$

27. $\sqrt{(1.9)(2.02)(4.05)}$

SOLUTION We use the linear approximation of the function $f(x, y, z) = \sqrt{xyz}$ at the point $(2, 2, 4)$, which is

$$f(2 + h, 2 + k, 4 + l) \approx f(2, 2, 4) + f_x(2, 2, 4)h + f_y(2, 2, 4)k + f_z(2, 2, 4)l \tag{1}$$

We compute the values of the function and its partial derivatives at $(2, 2, 4)$:

$$\begin{aligned} f(x, y, z) &= \sqrt{xyz} & & & f(2, 2, 4) &= 4 \\ f_x(x, y, z) &= \frac{yz}{2\sqrt{xyz}} = \frac{1}{2}\sqrt{\frac{yz}{x}} & & \Rightarrow & f_x(2, 2, 4) &= 1 \\ f_y(x, y, z) &= \frac{xz}{2\sqrt{xyz}} = \frac{1}{2}\sqrt{\frac{xz}{y}} & & & f_y(2, 2, 4) &= 1 \\ f_z(x, y, z) &= \frac{xy}{2\sqrt{xyz}} = \frac{1}{2}\sqrt{\frac{xy}{z}} & & & f_z(2, 2, 4) &= \frac{1}{2} \end{aligned}$$

Substituting these values and $h = -0.1$, $k = 0.02$, $l = 0.05$ in (1) gives the following approximation:

$$\sqrt{(1.9)(2.02)(4.05)} = 4 + 1 \cdot (-0.1) + 1 \cdot 0.02 + \frac{1}{2}(0.05) = 3.945$$

The value given by a calculator is:

$$\sqrt{(1.9)(2.02)(4.05)} \approx 3.9426$$

28. $\dfrac{8.01}{\sqrt{(1.99)(2.01)}}$

SOLUTION We use the linear approximation of the function $f(x,y,z)=\frac{x}{\sqrt{yz}}$ at the point (8, 2, 2), which is

$$f(8+h,2+k,2+l)\approx f(8,2,2)+f_x(8,2,2)h+f_y(8,2,2)k+f_z(8,2,2)l \tag{1}$$

We compute the values of the function and its partial derivatives at (8, 2, 2). This gives

$$\begin{aligned}
f(x,y,z)&=\frac{x}{\sqrt{yz}} && f(8,2,2)=4\\
f_x(x,y,z)&=\frac{1}{\sqrt{yz}} && \Rightarrow\quad f_x(8,2,2)=\frac{1}{2}\\
f_y(x,y,z)&=x\frac{\partial}{\partial y}(yz)^{-1/2}=-\frac{1}{2}x(yz)^{-3/2}z=-\frac{1}{2}xy^{-3/2}z^{-1/2} && f_y(8,2,2)=-1\\
f_z(x,y,z)&=x\frac{\partial}{\partial z}(yz)^{-1/2}=-\frac{1}{2}x(yz)^{-3/2}y=-\frac{1}{2}xy^{-1/2}z^{-3/2} && f_z(8,2,2)=-1
\end{aligned}$$

Substituting these values and $h=0.01$, $k=-0.01$, $l=0.01$ in (1) gives the following approximation:

$$\frac{8.01}{\sqrt{(1.99)(2.01)}}=4+\frac{1}{2}\cdot 0.01-1\cdot(-0.01)-1\cdot 0.01=4.005$$

The value given by a calculator is 4.00505. The error is 0.00005 and the percentage error is at most

$$\text{Percentage error}\approx\frac{0.00005\cdot 100}{4.00505}\approx 0.00125\%$$

29. Find an equation of the tangent plane to $z=f(x,y)$ at $P=(1,2,10)$ assuming that

$$f(1,2)=10,\qquad f(1.1,2.01)=10.3,\qquad f(1.04,2.1)=9.7$$

SOLUTION The equation of the tangent plane at the point (1, 2) is

$$\begin{aligned}
z&=f(1,2)+f_x(1,2)(x-1)+f_y(1,2)(y-2)\\
z&=10+f_x(1,2)(x-1)+f_y(1,2)(y-2)
\end{aligned}\tag{1}$$

Since the values of the partial derivatives at (1, 2) are not given, we approximate them as follows:

$$\begin{aligned}
f_x(1,2)&\approx\frac{f(1.1,2)-f(1,2)}{0.1}\approx\frac{f(1.1,2.01)-f(1,2)}{0.1}=3\\
f_y(1,2)&\approx\frac{f(1,2.1)-f(1,2)}{0.1}\approx\frac{f(1.04,2.1)-f(1,2)}{0.1}=-3
\end{aligned}$$

Substituting in (1) gives the following approximation to the equation of the tangent plane:

$$z=10+3(x-1)-3(y-2)$$

That is, $z=3x-3y+13$.

30. Suppose that the plane tangent to $z=f(x,y)$ at $(-2,3,4)$ has equation $4x+2y+z=2$. Estimate $f(-2.1,3.1)$.

SOLUTION The tangent plane $z=2-4x-2y$ is also a linear approximation for f near $(-2,3)$, so we can thus calculate the following:

$$f(-2.1,3.1)\approx 2-4(-2.1)-2(3.1)=4.2$$

In Exercises 31–34, let $I=W/H^2$ denote the BMI described in Example 5.

31. A boy has weight $W=34$ kg and height $H=1.3$ m. Use the linear approximation to estimate the change in I if (W,H) changes to (36, 1.32).

SOLUTION Let $\Delta I=I(36,1.32)-I(34,1.3)$ denote the change in I. Using the linear approximation of I at the point (34, 1.3) we have

$$I(34+h,1.3+k)-I(34,1.3)\approx\frac{\partial I}{\partial W}(34,1.3)h+\frac{\partial I}{\partial H}(34,1.3)k$$

For $h=2$, $k=0.02$ we obtain

$$\Delta I\approx\frac{\partial I}{\partial W}(34,1.3)\cdot 2+\frac{\partial I}{\partial H}(34,1.3)\cdot 0.02 \tag{1}$$

We compute the partial derivatives in (1):

$$\frac{\partial I}{\partial W} = \frac{\partial}{\partial W}\frac{W}{H^2} = \frac{1}{H^2} \qquad \Rightarrow \quad \frac{\partial I}{\partial W}(34, 1.3) = 0.5917$$
$$\frac{\partial I}{\partial H} = W\frac{\partial}{\partial H}H^{-2} = W\cdot(-2H^{-3}) = \frac{-2W}{H^3} \quad \Rightarrow \quad \frac{\partial I}{\partial H}(34, 1.3) = -30.9513$$

Substituting the partial derivatives in (1) gives the following estimation of ΔI:

$$\Delta I \approx 0.5917\cdot 2 - 30.9513\cdot 0.02 = 0.5644$$

32. Suppose that $(W, H) = (34, 1.3)$. Use the linear approximation to estimate the increase in H required to keep I constant if W increases to 35.

SOLUTION The linear approximation of $I = \frac{W}{H^2}$ at the point (34, 1.3) is:

$$\Delta I = I(34+h, 1.3+k) - I(34, 1.3) \approx \frac{\partial I}{\partial W}(34, 1.3)h + \frac{\partial I}{\partial H}(34, 1.3)k \tag{1}$$

In the earlier exercise, we found that

$$\frac{\partial I}{\partial W}(34, 1.3) = 0.5917, \qquad \frac{\partial I}{\partial H}(34, 1.3) = -30.9513$$

We substitute these derivatives and $h = 1$ in (1), equate the resulting expression to zero and solve for k. This gives:

$$\Delta I \approx 0.5917\cdot 1 - 30.9513\cdot k = 0$$
$$0.5917 = 30.9513k \quad \Rightarrow \quad k = 0.0191$$

That is, for an increase in weight of 1 kg, the increase in height must be approximately 0.0191 meters (or 1.91 centimeters) in order to keep I constant.

33. (a) Show that $\Delta I \approx 0$ if $\Delta H/\Delta W \approx H/2W$.

(b) Suppose that $(W, H) = (25, 1.1)$. What increase in H will leave I (approximately) constant if W is increased by 1 kg?

SOLUTION

(a) The linear approximation implies that

$$\Delta I \approx \frac{\partial I}{\partial W}\Delta W + \frac{\partial I}{\partial H}\Delta H$$

Hence, $\Delta I \approx 0$ if

$$\frac{\partial I}{\partial W}\Delta W + \frac{\partial I}{\partial H}\Delta H = 0 \tag{1}$$

We compute the partial derivatives of $I = \frac{W}{H^2}$:

$$\frac{\partial I}{\partial W} = \frac{\partial}{\partial W}\left(\frac{W}{H^2}\right) = \frac{1}{H^2}$$
$$\frac{\partial I}{\partial H} = W\frac{\partial}{\partial H}(H^{-2}) = -2WH^{-3} = \frac{-2W}{H^3}$$

We substitute the partial derivatives in (1) to obtain

$$\frac{1}{H^2}\Delta W - \frac{2W}{H^3}\Delta H = 0$$

Hence,

$$\frac{1}{H^2}\Delta W = \frac{2W}{H^3}\Delta H$$

or

$$\frac{\Delta H}{\Delta W} = \frac{1}{H^2}\cdot\frac{H^3}{2W} = \frac{H}{2W}$$

(b) In part (a) we showed that if $\frac{\Delta H}{\Delta W} = \frac{H}{2W}$, then I remains approximately constant. We thus substitute $W = 25$, $H = 1.1$, $\Delta W = 1$, and solve for ΔH. This gives

$$\frac{\Delta H}{1} = \frac{1.1}{50} \quad \Rightarrow \quad \Delta H \approx 0.022 \text{ meters.}$$

That is, an increase of 0.022 meters in H will leave I approximately constant.

34. Estimate the change in height that will decrease I by 1 if $(W, H) = (25, 1.1)$, assuming that W remains constant.

SOLUTION If $\Delta W = 0$, then

$$\Delta I \approx -(2W/H^3)\Delta H = -1$$

This yields $\Delta H = H^3/2W = 1.1^3/50 \approx 0.027$ meters, or 2.7 cm

35. A cylinder of radius r and height h has volume $V = \pi r^2 h$.

(a) Use the linear approximation to show that

$$\frac{\Delta V}{V} \approx \frac{2\Delta r}{r} + \frac{\Delta h}{h}$$

(b) Estimate the percentage increase in V if r and h are each increased by 2%.

(c) The volume of a certain cylinder V is determined by measuring r and h. Which will lead to a greater error in V: a 1% error in r or a 1% error in h?

SOLUTION

(a) The linear approximation is

$$\Delta V \approx V_r \Delta r + V_h \Delta h \tag{1}$$

We compute the partial derivatives of $V = \pi r^2 h$:

$$V_r = \pi h \frac{\partial}{\partial r} r^2 = 2\pi h r$$

$$V_h = \pi r^2 \frac{\partial}{\partial h} h = \pi r^2$$

Substituting in (1) gives

$$\Delta V \approx 2\pi h r \Delta r + \pi r^2 \Delta h$$

We divide by $V = \pi r^2 h$ to obtain

$$\frac{\Delta V}{V} \approx \frac{2\pi h r \Delta r}{V} + \frac{\pi r^2 \Delta h}{V} = \frac{2\pi h r \Delta r}{\pi r^2 h} + \frac{\pi r^2 \Delta h}{\pi r^2 h} = \frac{2\Delta r}{r} + \frac{\Delta h}{h}$$

That is,

$$\frac{\Delta V}{V} \approx \frac{2\Delta r}{r} + \frac{\Delta h}{h}$$

(b) The percentage increase in V is, by part (a),

$$\frac{\Delta V}{V} \cdot 100 \approx 2\frac{\Delta r}{r} \cdot 100 + \frac{\Delta h}{h} \cdot 100$$

We are given that $\frac{\Delta r}{r} \cdot 100 = 2$ and $\frac{\Delta h}{h} \cdot 100 = 2$, hence the percentage increase in V is

$$\frac{\Delta V}{V} \cdot 100 = 2 \cdot 2 + 2 = 6\%$$

(c) The percentage error in V is

$$\frac{\Delta V}{V} \cdot 100 = 2\frac{\Delta r}{r} \cdot 100 + \frac{\Delta h}{h} \cdot 100$$

A 1% error in r implies that $\frac{\Delta r}{r} \cdot 100 = 1$. Assuming that there is no error in h, we get

$$\frac{\Delta V}{V} \cdot 100 = 2 \cdot 1 + 0 = 2\%$$

A 1% in h implies that $\frac{\Delta h}{h} \cdot 100 = 1$. Assuming that there is no error in r, we get

$$\frac{\Delta V}{V} \cdot 100 = 0 + 1 = 1\%$$

We conclude that a 1% error in r leads to a greater error in V than a 1% error in h.

36. Use the linear approximation to show that if $I = x^a y^b$, then

$$\frac{\Delta I}{I} \approx a\frac{\Delta x}{x} + b\frac{\Delta y}{y}$$

SOLUTION The linear approximation is

$$\Delta I \approx I_x \Delta x + I_y \Delta y \tag{1}$$

We compute the partial derivatives of $I = x^a y^b$:

$$\begin{cases} I_x = \mathrm{a}x^{a-1}y^b \\ I_y = bx^a y^{b-1} \end{cases}$$

substituting in (1) gives

$$\Delta I \approx ax^{a-1}y^b \Delta x + bx^a y^{b-1}\Delta y$$

We now divide by $I = x^a y^b$ to obtain

$$\frac{\Delta I}{I} \approx \frac{ax^{a-1}y^b\Delta x}{I} + \frac{bx^a y^{b-1}\Delta y}{I} = \frac{ax^{a-1}y^b\Delta x}{x^a y^b} + \frac{bx^a y^{b-1}\Delta y}{x^a y^b} = a\frac{\Delta x}{x} + b\frac{\Delta y}{y}$$

That is,

$$\frac{\Delta I}{I} \approx a\frac{\Delta x}{x} + b\frac{\Delta \mathrm{y}}{y}.$$

37. The monthly payment for a home loan is given by a function $f(P, r, N)$, where P is the principal (initial size of the loan), r the interest rate, and N is the length of the loan in months. Interest rates are expressed as a decimal: A 6% interest rate is denoted by $r = 0.06$. If $P = \$100{,}000$, $r = 0.06$, and $N = 240$ (a 20-year loan), then the monthly payment is $f(100{,}000, 0.06, 240) = 716.43$. Furthermore, at these values, we have

$$\frac{\partial f}{\partial P} = 0.0071, \qquad \frac{\partial f}{\partial r} = 5769, \qquad \frac{\partial f}{\partial N} = -1.5467$$

Estimate:

(a) The change in monthly payment per \$1000 increase in loan principal.
(b) The change in monthly payment if the interest rate increases to $r = 6.5\%$ and $r = 7\%$.
(c) The change in monthly payment if the length of the loan increases to 24 years.

SOLUTION

(a) The linear approximation to $f(P, r, N)$ is

$$\Delta f \approx \frac{\partial f}{\partial P}\Delta P + \frac{\partial f}{\partial r}\Delta r + \frac{\partial f}{\partial N}\Delta N$$

We are given that $\frac{\partial f}{\partial P} = 0.0071$, $\frac{\partial f}{\partial r} = 5769$, $\frac{\partial f}{\partial N} = -1.5467$, and $\Delta P = 1000$. Assuming that $\Delta r = 0$ and $\Delta N = 0$, we get

$$\Delta f \approx 0.0071 \cdot 1000 = 7.1$$

The change in monthly payment per thousand dollar increase in loan principal is \$7.1.

(b) By the given data, we have

$$\Delta f \approx 0.0071\Delta P + 5769\Delta r - 1.5467\Delta N \tag{1}$$

The interest rate 6.5% corresponds to $r = 0.065$, and the interest rate 7% corresponds to $r = 0.07$. In the first case $\Delta r = 0.065 - 0.06 = 0.005$ and in the second case $\Delta r = 0.07 - 0.06 = 0.01$. Substituting in (1), assuming that $\Delta P = 0$ and $\Delta N = 0$, gives

$$\Delta f = 5769 \cdot 0.005 = \$28.845$$

$$\Delta f = 5769 \cdot 0.01 = \$57.69$$

(c) We substitute $\Delta N = (24 - 20) \cdot 12 = 48$ months and $\Delta r = \Delta N = 0$ in (1) to obtain

$$\Delta f \approx -1.5467 \cdot 48 = -74.2416$$

The monthly payment will be reduced by \$74.2416.

38. Automobile traffic passes a point P on a road of width w ft at an average rate of R vehicles per second. Although the arrival of automobiles is irregular, traffic engineers have found that the average waiting time T until there is a gap in traffic of at least t seconds is approximately $T = te^{Rt}$ seconds. A pedestrian walking at a speed of 3.5 ft/s (5.1 mph) requires $t = w/3.5$ s to cross the road. Therefore, the average time the pedestrian will have to wait before crossing is $f(w, R) = (w/3.5)e^{wR/3.5}$ s.

(a) What is the pedestrian's average waiting time if $w = 25$ ft and $R = 0.2$ vehicle per second?

(b) Use the linear approximation to estimate the increase in waiting time if w is increased to 27 ft.

(c) Estimate the waiting time if the width is increased to 27 ft and R decreases to 0.18.

(d) What is the rate of increase in waiting time per 1-ft increase in width when $w = 30$ ft and $R = 0.3$ vehicle per second?

SOLUTION

(a) We are given that the average time the pedestrian will have to wait for a t-second gap in traffic is

$$f(w, R) = \frac{w}{3.5}e^{wR/3.5}$$

Substituting the values $w = 25$ and $R = 0.2$, we obtain

$$f(25, 0.2) = \frac{25}{3.5}e^{(25\cdot 0.2)/3.5} \approx 29.8 \text{ seconds}$$

(b) The linear approximation at $(w, R) = (25, 0.2)$ is,

$$\Delta f \approx f_w(25, 0.2)\Delta w + f_r(25, 0.2)\Delta R \tag{1}$$

We compute the partial derivatives. Using the Product Rule and the Chain Rule we have

$$f_w(w, R) = \frac{1}{3.5}\left(e^{wR/3.5} + we^{wR/3.5}\cdot\frac{R}{3.5}\right) = \frac{e^{wR/3.5}}{3.5}\left(1 + \frac{wR}{3.5}\right)$$

By the Chain Rule we get

$$f_R(w, R) = \frac{w}{3.5}e^{wR/3.5}\cdot\frac{w}{3.5} = \left(\frac{w}{3.5}\right)^2 e^{wR/3.5}$$

At the point $(25, 0.2)$ we have

$$f_w(25, 0.2) \approx 2.9; \quad f_R(25, 0.2) \approx 212.9 \tag{2}$$

Substituting these derivatives, $\Delta w = 27 - 25 = 2$, and $\Delta r = 0$ in (1) we get

$$\Delta f = 2.9 \cdot 2 = 5.8$$

An increase of 2 ft in w causes an increase of 5.8 seconds in waiting time.

(c) We substitute the derivatives in (2) with $\Delta w = 2$ and $\Delta r = 0.18 - 0.2 = -0.02$ in the linear approximation (1) to obtain

$$\Delta f \approx 2.9 \cdot 2 - 212.9 \cdot 0.02 \approx 1.54$$

That is, the waiting time is increased by approximately 1.54 seconds. Using part (a), the estimated waiting time is

$$f(25, 0.2) + 1.54 \approx 29.8 + 1.54 = 31.34 \text{ seconds}$$

(d) The rate of increase in waiting time per one foot increase in width, when $w = 30$ and $R = 0.3$, is $\frac{\partial f}{\partial w}(30, 0.3)$. Using the derivative obtained in part (b) we have

$$\frac{\partial f}{\partial w}(30, 0.3) = \frac{e^{9/3.5}}{3.5}\left(1 + \frac{9}{3.5}\right) \approx 13.35$$

39. The volume V of a right-circular cylinder is computed using the values 3.5 m for diameter and 6.2 m for height. Use the linear approximation to estimate the maximum error in V if each of these values has a possible error of at most 5%. Recall that $V = \frac{1}{3}\pi r^2 h$.

SOLUTION We denote by d and h the diameter and height of the cylinder, respectively. By the Formula for the Volume of a Cylinder we have

$$V = \pi\left(\frac{d}{2}\right)^2 h = \frac{\pi}{4}d^2 h$$

The linear approximation is

$$\Delta V \approx \frac{\partial V}{\partial d}\Delta d + \frac{\partial V}{\partial h}\Delta h \tag{1}$$

We compute the partial derivatives at $(d, h) = (3.5, 6.2)$:

$$\begin{aligned} \frac{\partial V}{\partial d}(d,h) &= \frac{\pi}{4}h\cdot 2d = \frac{\pi}{2}hd \\ \frac{\partial V}{\partial h}(d,h) &= \frac{\pi}{4}d^2 \end{aligned} \quad\Rightarrow\quad \begin{aligned} \frac{\partial V}{\partial d}(3.5, 6.2) &\approx 34.086 \\ \frac{\partial V}{\partial h}(3.5, 6.2) &= 9.621 \end{aligned}$$

Substituting these derivatives in (1) gives

$$\Delta V \approx 34.086\Delta d + 9.621\Delta h \tag{2}$$

We are given that the errors in the measurements of d and h are at most 5%. Hence,

$$\frac{\Delta d}{3.5} = 0.05 \quad\Rightarrow\quad \Delta d = 0.175$$

$$\frac{\Delta h}{6.2} = 0.05 \quad\Rightarrow\quad \Delta h = 0.31$$

Substituting in (2) we obtain

$$\Delta V \approx 34.086 \cdot 0.175 + 9.621 \cdot 0.31 \approx 8.948$$

The error in V is approximately 8.948 meters. The percentage error is at most

$$\frac{\Delta V \cdot 100}{V} = \frac{8.948 \cdot 100}{\frac{\pi}{4}\cdot 3.5^2 \cdot 6.2} = 15\%$$

Further Insights and Challenges

40. Show that if $f(x, y)$ is differentiable at (a, b), then the function of one variable $f(x, b)$ is differentiable at $x = a$. Use this to prove that $f(x, y) = \sqrt{x^2 + y^2}$ is *not* differentiable at $(0, 0)$.

SOLUTION If $f(x, y)$ is differentiable at (a, b), then the partial derivatives f_x and f_y both exist at (a, b), which means that (in particular) $\frac{d}{dx}f(x, b)$ exists at $x = a$, which means that $f(x, b)$ is differentiable at $x = a$. In our case, for $(a, b) = (0, 0)$ and $f(x, y) = \sqrt{x^2 + y^2}$, then $f(x, b) = f(x, 0) = \sqrt{x^2 + 0^2} = \sqrt{x^2} = |x|$, which is not differentiable at $x = 0$. Hence the original two-variable function $f(x, y) = \sqrt{x^2 + y^2}$ is *not* differentiable at $(0, 0)$.

41. This exercise shows directly (without using Theorem 1) that the function $f(x, y) = 5x + 4y^2$ from Example 1 is locally linear at $(a, b) = (2, 1)$.

(a) Show that $f(x, y) = L(x, y) + e(x, y)$ with $e(x, y) = 4(y - 1)^2$.

(b) Show that

$$0 \le \frac{e(x, y)}{\sqrt{(x-2)^2 + (y-1)^2}} \le 4|y - 1|$$

(c) Verify that $f(x, y)$ is locally linear.

SOLUTION According to Example 1,

$$L(x, y) = -4 + 5x + 8y$$

(a) We compute the difference:

$$\begin{aligned} f(x, y) - L(x, y) &= (5x + 4y^2) - (-4 + 5x + 8y) \\ &= 4y^2 - 8y + 4 = 4(y-1)^2 \end{aligned}$$

Therefore, $f(x, y) = L(x, y) + 4(y - 1)^2$.

(b) For $(x, y) \neq (2, 1)$, we consider

$$\frac{e(x, y)}{\sqrt{(x-2)^2 + (y-1)^2}} = \frac{4(y-1)^2}{\sqrt{(x-2)^2 + (y-1)^2}}$$

The following inequality holds

$$\frac{4(y-1)^2}{\sqrt{(x-2)^2 + (y-1)^2}} \le \frac{4(y-1)^2}{\sqrt{(y-1)^2}} = 4|y - 1|$$

because we have made the denominator smaller.

(c) We have

$$f(x, y) = L(x, y) + e(x, y)$$

where

$$0 \le \frac{e(x, y)}{\sqrt{(x-2)^2 + (y-1)^2}} \le 4|y-1|$$

We have $\lim_{(x,y)\to(2,1)} 4|y-1| = 0$, and therefore

$$\lim_{(x,y)\to(2,1)} e(x, y) = 0$$

by the Squeeze Theorem. This proves that $f(x, y)$ is locally linear at (2, 1).

42. Show directly, as in Exercise 41, that $f(x, y) = xy^2$ is differentiable at (0, 2).

SOLUTION

(a) Firstly, we need to find $L(x, y)$. We know from the text that

$$L(x, y) = f(0, 2) + f_x(0, 2)(x - 0) + f_y(0, 2)(y - 2)$$

Computing with the function and the partial derivatives we see

$$\begin{aligned} f(x, y) = xy^2 &\quad\Rightarrow\quad f(0, 2) = 0 \\ f_x(x, y) = y^2 &\quad\Rightarrow\quad f_x(0, 2) = 4 \\ f_y(x, y) = 2xy &\quad\Rightarrow\quad f_y(0, 2) = 0 \end{aligned}$$

Therefore we have

$$L(x, y) = 0 + 4(x - 0) + 0(y - 2) = 4x$$

Hence, using the methods from the previous exercise we have

$$e(x, y) = f(x, y) - L(x, y) = xy^2 - 4x = x(y^2 - 4)$$

and

$$f(x, y) = L(x, y) + x(y^2 - 4)$$

(b) For $(x, y) \ne (0, 2)$, consider

$$\frac{x(y^2-4)}{\sqrt{x^2 + (y-2)^2}}$$

The following inequality holds for all x values:

$$\frac{x(y^2-4)}{\sqrt{x^2 + (y-2)^2}} \le \frac{|x|(y^2-4)}{\sqrt{x^2 + (y-2)^2}} \le \frac{|x|(y^2-4)}{\sqrt{x^2}} = \frac{|x|(y^2-4)}{|x|} = y^2 - 4$$

(c) Then we have

$$f(x, y) = L(x, y) + e(x, y)$$

where

$$0 \le \frac{e(x, y)}{\sqrt{x^2 + (y-2)^2}} \le y^2 - 4$$

and easily we know $\lim_{(x,y)\to(0,2)} (y^2 - 4) = 0$, and therefore

$$\lim_{(x,y)\to(0,2)} \frac{e(x, y)}{\sqrt{x^2 + (y-2)^2}} = 0$$

by the Squeeze Theorem. Therefore $\lim_{(x,y)\to(0,0)} e(x, y) = 0$ as well. This proves that $f(x, y)$ is locally linear at the point (0, 2), and therefore, differentiable at (0, 2).

43. Differentiability Implies Continuity Use the definition of differentiability to prove that if f is differentiable at (a, b), then f is continuous at (a, b).

SOLUTION Suppose that f is differentiable at (a, b), then we know f is locally linear at (a, b), that is

$$f(x, y) = L(x, y) + e(x, y)$$

where $e(x, y)$ satisfies

$$\lim_{(x,y)\to(a,b)} \frac{e(x, y)}{\sqrt{(x-a)^2 + (y-b)^2}} = \lim_{(x,y)\to(a,b)} E(x, y) = 0$$

and

$$L(x, y) = f(a, b) + f_x(a, b)(x - a) + f_y(a, b)(y - b)$$

We would like to show $\lim_{(x,y)\to(a,b)} f(x, y) = f(a, b)$, then f would be continuous at (a, b). Consider the following computation:

$$\begin{aligned}
\lim_{(x,y)\to(a,b)} f(x, y) &= \lim_{(x,y)\to(a,b)} L(x, y) + e(x, y) \\
&= \lim_{(x,y)\to(a,b)} L(x, y) + E(x, y)\sqrt{(x-a)^2 + (y-b)^2} \\
&= \lim_{(x,y)\to(a,b)} f(a, b) + f_x(a, b)(x - a) + f_y(a, b)(y - b) + E(x, y)\sqrt{(x-a)^2 + (y-b)^2} \\
&= f(a, b) + 0 + 0 + 0 = f(a, b)
\end{aligned}$$

Therefore we have shown that if f is differentiable at (a, b) then f is continuous at (a, b).

44. Let $f(x)$ be a function of one variable defined near $x = a$. Given a number M, set

$$L(x) = f(a) + M(x - a), \qquad e(x) = f(x) - L(x)$$

Thus $f(x) = L(x) + e(x)$. We say that f is locally linear at $x = a$ if M can be chosen so that $\lim_{x\to a} \dfrac{e(x)}{|x-a|} = 0$.

(a) Show that if $f(x)$ is differentiable at $x = a$, then $f(x)$ is locally linear with $M = f'(a)$.

(b) Show conversely that if f is locally linear at $x = a$, then $f(x)$ is differentiable and $M = f'(a)$.

SOLUTION

(a) Suppose that f is differentiable at $x = a$. From single-variable calculus we also know that f is continuous and that

$$\lim_{x\to a} \frac{f(x) - f(a)}{x - a} = f'(a)$$

Then also, using methods of linear approximation from single variable calculus, we can write

$$L(x) = f(a) + f'(a)(x - a) \text{ with } M = f'(a)$$

Now to fulfill local linearity we need to show $\lim_{x\to a} \frac{e(x)}{|x-a|} = 0$. Let us note here that $\lim_{x\to a} \frac{e(x)}{|x-a|} = 0$ if and only if $\lim_{x\to a} \frac{e(x)}{x-a} = 0$. It will be enough to show, $\lim_{x\to a} \frac{e(x)}{x-a} = 0$.

Consider the following:

$$\begin{aligned}
\lim_{x\to a} \frac{e(x)}{x-a} &= \lim_{x\to a} \frac{f(x) - L(x)}{x - a} \\
&= \lim_{x\to a} \frac{f(x) - f(a) - f'(a)(x - a)}{x - a} \\
&= \lim_{x\to a} \frac{f(x) - f(a)}{x - a} - \lim_{x\to a} \frac{f'(a)(x - a)}{x - a} \\
&= \lim_{x\to a} \frac{f(x) - f(a)}{x - a} - \lim_{x\to a} f'(a) \\
&= f'(a) - f'(a) = 0
\end{aligned}$$

Therefore, f is locally linear at $x = a$.

(b) Now suppose that f is locally linear at $x = a$. By definition

$$f(x) = f(a) + M(x-a) + e(x)$$

Therefore,

$$\frac{f(x) - f(a)}{x-a} = M + \frac{e(x)}{x-a}$$

If $f(x)$ is locally linear, then (by definition), $\frac{e(x)}{x-a}$ tends to zero and thus the difference quotient for $f(x)$ approaches M. Therefore, $f'(a)$ exists and equals M.

45. Assumptions Matter Define $g(x, y) = 2xy(x+y)/(x^2+y^2)$ for $(x, y) \neq 0$ and $g(0, 0) = 0$. In this exercise, we show that $g(x, y)$ is continuous at (0, 0) and that $g_x(0, 0)$ and $g_y(0, 0)$ exist, but $g(x, y)$ is not differentiable at (0, 0).

(a) Show using polar coordinates that $g(x, y)$ is continuous at (0, 0).

(b) Use the limit definitions to show that $g_x(0, 0)$ and $g_y(0, 0)$ exist and that both are equal to zero.

(c) Show that the linearization of $g(x, y)$ at (0, 0) is $L(x, y) = 0$.

(d) Show that if $g(x, y)$ were locally linear at (0, 0), we would have $\lim_{h\to 0} \frac{g(h,h)}{h} = 0$. Then observe that this is not the case because $g(h, h) = 2h$. This shows that $g(x, y)$ is not locally linear at (0, 0) and, hence, not differentiable at (0, 0).

SOLUTION

(a) We would like to show $\lim_{(x,y)\to(0,0)} g(x, y) = g(0, 0)$. Consider the following, using polar coordinates, $x = r\cos\theta$ and $y = r\sin\theta$:

$$\begin{aligned}
\lim_{(x,y)\to(0,0)} \frac{2xy(x+y)}{x^2+y^2} &= \lim_{(r,\theta)\to(0,0)} \frac{2r^2\cos\theta\sin\theta(r\cos\theta + r\sin\theta)}{r^2\cos^2\theta + r^2\sin^2\theta} \\
&= \lim_{(r,\theta)\to(0,0)} \frac{2r^3\cos\theta\sin\theta(\cos\theta+\sin\theta)}{r^2} \\
&= \lim_{(r,\theta)\to(0,0)} 2r\cos\theta\sin\theta(\cos\theta+\sin\theta) = 0 = g(0,0)
\end{aligned}$$

Therefore $g(x, y)$ is continuous at (0, 0).

(b) Taking partial derivatives we have:

$$g_x(x, y) = \frac{2y^2(y-x)^2}{(x^2+y^2)^2}, \quad g_y(x, y) = \frac{2x^2(x-y)^2}{(x^2+y^2)^2}$$

But we need to use limit definitions for the partial derivatives. Consider the following:

$$\begin{aligned}
g_x(0, 0) &= \lim_{h\to 0} \frac{g(h,0) - g(0,0)}{h} \\
&= \lim_{h\to 0} \frac{1}{h}(0-0) = 0
\end{aligned}$$

$$\begin{aligned}
g_y(0, 0) &= \lim_{h\to 0} \frac{g(0,h) - g(0,0)}{h} \\
&= \lim_{h\to 0} \frac{1}{h}(0-0) = 0
\end{aligned}$$

Thus both partial derivatives exist and $g_x(0, 0) = 0$ and $g_y(0, 0) = 0$.

(c) We know that the linearization of g will be:

$$g(x, y) \approx g(0, 0) + g_x(0, 0)(x-0) + g_y(0, 0)(y-0)$$

We are given that $g(0, 0) = 0$. In part (b) we know $g_x(0, 0) = 0$ and $g_y(0, 0) = 0$. Substituting in these values in the linearization we have:

$$g(x, y) \approx 0 + 0 + 0 = 0$$

(d) We know if g were locally linear at (0, 0), we would have:

$$\lim_{h\to 0} \frac{g(h,h)}{h} = 0$$

However, we know:

$$g(h, h) = \frac{2h^2(2h)}{2h^2} = 2h, \quad \frac{g(h,h)}{h} = \frac{2h}{h} = 2$$

This is a contradiction, $g(x, y)$ is not locally linear at (0, 0) and hence, is not differentiable at (0, 0).

14.5 The Gradient and Directional Derivatives (LT Section 15.5)

Preliminary Questions

1. Which of the following is a possible value of the gradient ∇f of a function $f(x, y)$ of two variables?

(a) 5 **(b)** $\langle 3, 4\rangle$ **(c)** $\langle 3, 4, 5\rangle$

SOLUTION The gradient of $f(x, y)$ is a vector with two components, hence the possible value of the gradient $\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}\right\rangle$ is (b).

2. True or false? A differentiable function increases at the rate $\|\nabla f_P\|$ in the direction of ∇f_P.

SOLUTION The statement is true. The value $\|\nabla f_P\|$ is the rate of increase of f in the direction ∇f_P.

3. Describe the two main geometric properties of the gradient ∇f.

SOLUTION The gradient of f points in the direction of maximum rate of increase of f and is normal to the level curve (or surface) of f.

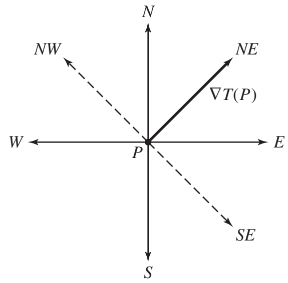
4. You are standing at a point where the temperature gradient vector is pointing in the northeast (NE) direction. In which direction(s) should you walk to avoid a change in temperature?

(a) NE **(b)** NW **(c)** SE **(d)** SW

SOLUTION The rate of change of the temperature T at a point P in the direction of a unit vector $\mathbf{u}$, is the directional derivative $D_{\mathbf{u}}T(P)$, which is given by the formula

$$D_{\mathbf{u}}T(P) = \|\nabla f_P\| \cos\theta$$

To avoid a change in temperature, we must choose the direction $\mathbf{u}$ so that $D_{\mathbf{u}}T(P) = 0$, that is, $\cos\theta = 0$, so $\theta = \frac{\pi}{2}$ or $\theta = \frac{3\pi}{2}$. Since the gradient at P is pointing NE, we should walk NW or SE to avoid a change in temperature. Thus, the answer is (b) and (c).



5. What is the rate of change of $f(x, y)$ at $(0, 0)$ in the direction making an angle of 45° with the x-axis if $\nabla f(0, 0) = \langle 2, 4\rangle$?

SOLUTION By the formula for directional derivatives, and using the unit vector $\langle 1/\sqrt{2}, 1/\sqrt{2}\rangle$, we get $\langle 2, 4\rangle \cdot \langle 1/\sqrt{2}, 1/\sqrt{2}\rangle = 6/\sqrt{2} = 3\sqrt{2}$.

Exercises

1. Let $f(x, y) = xy^2$ and $\mathbf{c}(t) = \left(\frac{1}{2}t^2, t^3\right)$.

(a) Calculate ∇f and $\mathbf{c}'(t)$.

(b) Use the Chain Rule for Paths to evaluate $\frac{d}{dt} f(\mathbf{c}(t))$ at $t = 1$ and $t = -1$.

SOLUTION

(a) We compute the partial derivatives of $f(x, y) = xy^2$:

$$\frac{\partial f}{\partial x} = y^2, \quad \frac{\partial f}{\partial y} = 2xy$$

The gradient vector is thus

$$\nabla f = \left\langle y^2, 2xy\right\rangle.$$

Also,

$$\mathbf{c}'(t) = \left\langle \left(\frac{1}{2}t^2\right)', \left(t^3\right)'\right\rangle = \left\langle t, 3t^2\right\rangle$$

(b) Using the Chain Rule gives

$$\frac{d}{dt} f(\mathbf{c}(t)) = \frac{d}{dt}\left(\frac{1}{2}t^2 \cdot t^6\right) = \frac{d}{dt}\left(\frac{1}{2}t^8\right) = 4t^7$$

Substituting $x = \frac{1}{2}t^2$ and $y = t^3$, we obtain

$$\frac{d}{dt} f(\mathbf{c}(t)) = t^6 \cdot t + 2 \cdot \frac{1}{2}t^2 \cdot 3 \cdot t^3 \cdot t^2 = 4t^7$$

At the point $t = 1$ and $t = -1$, we get

$$\frac{d}{dt}(f(\mathbf{c}(t)))\bigg|_{t=1} = 4 \cdot 1^7 = 4, \quad \frac{d}{dt}(f(\mathbf{c}(t)))\bigg|_{t=-1} = 4 \cdot (-1)^7 = -4.$$

2. Let $f(x, y) = e^{xy}$ and $\mathbf{c}(t) = (t^3, 1 + t)$.

(a) Calculate ∇f and $\mathbf{c}'(t)$.

(b) Use the Chain Rule for Paths to calculate $\frac{d}{dt} f(\mathbf{c}(t))$.

(c) Write out the composite $f(\mathbf{c}(t))$ as a function of t and differentiate. Check that the result agrees with part (b).

SOLUTION

(a) We first find the partial derivatives of $f(x, y) = e^{xy}$:

$$\frac{\partial f}{\partial x} = ye^{xy}, \quad \frac{\partial f}{\partial y} = xe^{xy}.$$

The gradient vector is thus

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \left\langle ye^{xy}, xe^{xy} \right\rangle$$

Differentiating $\mathbf{c}(t) = (t^3, 1 + t)$ componentwise, we obtain

$$\mathbf{c}'(t) = \left((t^3)', (1+t)'\right) = (3t^2, 1)$$

(b) We find $\frac{d}{dt} f(\mathbf{c}(t))$ using the Chain Rule and the results of part (a). This gives

$$\frac{d}{dt} f(\mathbf{c}(t)) = \frac{\partial f}{\partial x}\frac{dx}{dt} + \frac{\partial f}{\partial y}\frac{dy}{dt} = (ye^{xy}) \cdot 3t^2 + (xe^{xy}) \cdot 1$$

To write the answer in terms of t only, we substitute $x = t^3$ and $y = 1 + t$. This gives

$$\frac{d}{dt} f(\mathbf{c}(t)) = (1+t)e^{t^3+t^4} \cdot 3t^2 + (t^3)e^{t^3+t^4} = (3t^2 + 4t^3)e^{t^3+t^4}$$

(c) We substitute $x = t^3$, $y = 1 + t$ in $f(x, y) = e^{xy}$ to obtain the composite function $f(\mathbf{c}(t))$:

$$f(\mathbf{c}(t)) = e^{t^3+t^4}$$

We now differentiate the composite function to obtain

$$\frac{d}{dt} f(\mathbf{c}(t)) = \frac{d}{dt}\left(e^{t^3+t^4}\right) = (3t^2 + 4t^3)e^{t^3+t^4}$$

This result agrees with the result obtained in part (a).

3. Figure 14 shows the level curves of a function $f(x, y)$ and a path $\mathbf{c}(t)$, traversed in the direction indicated. State whether the derivative $\frac{d}{dt} f(\mathbf{c}(t))$ is positive, negative, or zero at points A–D.

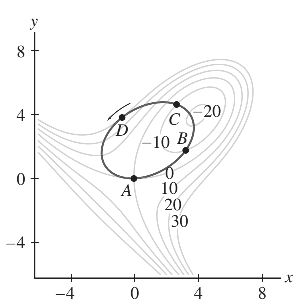


FIGURE 14

SOLUTION At points A and D, the path is (temporarily) tangent to one of the contour lines, which means that along the path $\mathbf{c}(t)$ the function $f(x, y)$ is (temporarily) constant, and so the derivative $\frac{d}{dt} f(\mathbf{c}(t))$ is zero. At point B, the path is moving from a higher contour (of -10) to a lower one (of -20), so the derivative is negative. At the point C, where the path moves from the contour of -10 towards the contour of value 0, the derivative is positive.

4. Let $f(x, y) = x^2 + y^2$ and $\mathbf{c}(t) = (\cos t, \sin t)$.

(a) Find $\dfrac{d}{dt} f(\mathbf{c}(t))$ without making any calculations. Explain.

(b) Verify your answer to (a) using the Chain Rule.

SOLUTION

(a) The level curves of $f(x, y)$ are the circles $x^2 + y^2 = \mathbf{c}^2$. Since $\mathbf{c}(t)$ is a parametrization of the unit circle, f has constant value 1 on $\mathbf{c}$. That is, $f(\mathbf{c}(t)) = 1$, which implies that $\frac{d}{dt} f(\mathbf{c}(t)) = 0$.

(b) We now find $\frac{d}{dt} f(\mathbf{c}(t))$ using the Chain Rule:

$$\frac{d}{dt} f(\mathbf{c}(t)) = \frac{\partial f}{\partial x}\frac{dx}{dt} + \frac{\partial f}{\partial y}\frac{dy}{dt} \tag{1}$$

We compute the derivatives involved in (1):

$$\frac{\partial f}{\partial x} = \frac{\partial}{\partial x}\left(x^2 + y^2\right) = 2x, \quad \frac{\partial f}{\partial y} = \frac{\partial}{\partial y}\left(x^2 + y^2\right) = 2y$$
$$\frac{dx}{dt} = \frac{d}{dt}(\cos t) = -\sin t, \quad \frac{dy}{dt} = \frac{d}{dt}(\sin t) = \cos t$$

Substituting the derivatives in (1) gives

$$\frac{d}{dt} f(\mathbf{c}(t)) = 2x(-\sin t) + 2y\cos t$$

Finally, we substitute $x = \cos t$ and $y = \sin t$ to obtain

$$\frac{d}{dt} f(\mathbf{c}(t)) = -2\cos t\sin t + 2\sin t\cos t = 0.$$

In Exercises 5–8, calculate the gradient.

5. $f(x, y) = \cos(x^2 + y)$

SOLUTION We find the partial derivatives using the Chain Rule:

$$\frac{\partial f}{\partial x} = -\sin\left(x^2 + y\right)\frac{\partial}{\partial x}\left(x^2 + y\right) = -2x\sin\left(x^2 + y\right)$$
$$\frac{\partial f}{\partial y} = -\sin\left(x^2 + y\right)\frac{\partial}{\partial y}\left(x^2 + y\right) = -\sin\left(x^2 + y\right)$$

The gradient vector is thus

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \left\langle -2x\sin\left(x^2 + y\right), -\sin\left(x^2 + y\right) \right\rangle = -\sin\left(x^2 + y\right)\langle 2x, 1\rangle$$

6. $g(x, y) = \dfrac{x}{x^2 + y^2}$

SOLUTION We compute the partial derivatives. We first find $\frac{\partial g}{\partial x}$ using the Quotient Rule:

$$\frac{\partial g}{\partial x} = \frac{1 \cdot \left(x^2 + y^2\right) - x \cdot 2x}{\left(x^2 + y^2\right)^2} = \frac{y^2 - x^2}{\left(x^2 + y^2\right)^2}$$

We compute $\frac{\partial g}{\partial y}$ using the Chain Rule:

$$\frac{\partial g}{\partial y} = x\frac{\partial}{\partial y}\frac{1}{x^2 + y^2} = x \cdot \frac{-1}{\left(x^2 + y^2\right)^2} \cdot 2y = \frac{-2xy}{\left(x^2 + y^2\right)^2}$$

The gradient vector is thus

$$\nabla g = \left\langle \frac{\partial g}{\partial x}, \frac{\partial g}{\partial y} \right\rangle = \left\langle \frac{y^2 - x^2}{\left(x^2 + y^2\right)^2}, \frac{-2xy}{\left(x^2 + y^2\right)^2} \right\rangle = \frac{1}{\left(x^2 + y^2\right)^2}\left\langle y^2 - x^2, -2xy \right\rangle.$$

7. $h(x, y, z) = xyz^{-3}$

SOLUTION We compute the partial derivatives of $h(x, y, z) = xyz^{-3}$, obtaining

$$\frac{\partial h}{\partial x} = yz^{-3}, \quad \frac{\partial h}{\partial y} = xz^{-3}, \quad \frac{\partial h}{\partial z} = xy \cdot \left(-3z^{-4}\right) = -3xyz^{-4}$$

The gradient vector is thus

$$\nabla h = \left\langle \frac{\partial h}{\partial x}, \frac{\partial h}{\partial y}, \frac{\partial h}{\partial z} \right\rangle = \left\langle yz^{-3}, xz^{-3}, -3xyz^{-4} \right\rangle.$$

8. $r(x, y, z, w) = xze^{yw}$

SOLUTION We find the partial derivatives of $r(x, y, z, w) = xze^{yw}$:

$$\frac{\partial r}{\partial x} = ze^{yw}, \quad \frac{\partial r}{\partial y} = xzwe^{yw}, \quad \frac{\partial r}{\partial z} = xe^{yw}, \quad \frac{\partial r}{\partial w} = xzye^{yw}$$

The gradient vector is thus

$$\nabla r = \left\langle \frac{\partial r}{\partial x}, \frac{\partial r}{\partial y}, \frac{\partial r}{\partial z}, \frac{\partial r}{\partial w} \right\rangle = \left\langle ze^{yw}, xzwe^{yw}, xe^{yw}, xzye^{yw} \right\rangle = e^{yw} \left\langle z, xzw, x, xzy \right\rangle$$

In Exercises 9–20, use the Chain Rule to calculate $\frac{d}{dt} f(\mathbf{c}(t))$.

9. $f(x, y) = 3x - 7y, \quad \mathbf{c}(t) = (\cos t, \sin t), \quad t = 0$

SOLUTION By the Chain Rule for paths, we have

$$\frac{d}{dt} f\,(\mathbf{c}(t)) = \nabla f_{\mathbf{c}(t)} \cdot \mathbf{c}'(t) \tag{1}$$

We compute the gradient and the derivative $\mathbf{c}'(t)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \langle 3, -7 \rangle, \quad \mathbf{c}'(t) = \langle -\sin t, \cos t \rangle$$

We determine these vectors at $t = 0$:

$$\mathbf{c}'(0) = \langle -\sin 0, \cos 0 \rangle = \langle 0, 1 \rangle$$

and since the gradient is a constant vector, we have

$$\nabla f_{\mathbf{c}(0)} = \nabla f_{(1,0)} = \langle 3, -7 \rangle$$

Substituting these vectors in (1) gives

$$\left. \frac{d}{dt} f\,(\mathbf{c}(t)) \right|_{t=0} = \langle 3, -7 \rangle \cdot \langle 0, 1 \rangle = 0 - 7 = -7$$

10. $f(x, y) = 3x - 7y, \quad \mathbf{c}(t) = (t^2, t^3), \quad t = 2$

SOLUTION We first compute the gradient and $\mathbf{c}'(t)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \langle 3, -7 \rangle, \quad \mathbf{c}'(t) = \left(2t, 3t^2\right)$$

At the point $t = 2$ we have

$$\nabla f_{\mathbf{c}(2)} = \langle 3, -7 \rangle, \quad \mathbf{c}'(2) = \langle 4, 12 \rangle$$

We now use the Chain Rule for paths to compute the following derivative:

$$\left. \frac{d}{dt} f\,(\mathbf{c}(t)) \right|_{t=2} = \nabla f_{\mathbf{c}(2)} \cdot \mathbf{c}'(2) = \langle 3, -7 \rangle \cdot \langle 4, 12 \rangle = -72$$

11. $f(x, y) = x^2 - 3xy, \quad \mathbf{c}(t) = (\cos t, \sin t), \quad t = 0$

SOLUTION By the Chain Rule For Paths we have

$$\frac{d}{dt} f(\mathbf{c}(t)) = \nabla f_{\mathbf{c}(t)} \cdot \mathbf{c}'(t) \tag{1}$$

We compute the gradient and $\mathbf{c}'(t)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \langle 2x - 3y, -3x \rangle$$
$$\mathbf{c}'(t) = \langle -\sin t, \cos t \rangle$$

At the point $t = 0$ we have

$$\mathbf{c}(0) = (\cos 0, \sin 0) = (1, 0)$$
$$\mathbf{c}'(0) = \langle -\sin 0, \cos 0 \rangle = \langle 0, 1 \rangle$$
$$\nabla f \bigg|_{\mathbf{c}(0)} = \nabla f_{(1,0)} = \langle 2 \cdot 1 - 3 \cdot 0, -3 \cdot 1 \rangle = \langle 2, -3 \rangle$$

Substituting in (1) we obtain

$$\frac{d}{dt} f(\mathbf{c}(t)) \bigg|_{t=0} = \langle 2, -3 \rangle \cdot \langle 0, 1 \rangle = -3$$

12. $f(x, y) = x^2 - 3xy, \quad \mathbf{c}(t) = (\cos t, \sin t), \quad t = \frac{\pi}{2}$

SOLUTION In the previous exercise we found that

$$\nabla f = \langle 2x - 3y, -3x \rangle, \quad \mathbf{c}'(t) = \langle -\sin t, \cos t \rangle$$

At the point $t = \frac{\pi}{2}$ we have

$$\mathbf{c}\left(\frac{\pi}{2}\right) = \left(\cos \frac{\pi}{2}, \sin \frac{\pi}{2}\right) = (0, 1)$$
$$\mathbf{c}'\left(\frac{\pi}{2}\right) = \left\langle -\sin \frac{\pi}{2}, \cos \frac{\pi}{2} \right\rangle = \langle -1, 0 \rangle$$
$$\nabla f_{\mathbf{c}\left(\frac{\pi}{2}\right)} = \nabla f_{(0,1)} = \langle 2 \cdot 0 - 3 \cdot 1, -3 \cdot 0 \rangle = \langle -3, 0 \rangle$$

We now use the Chain Rule for Paths to obtain

$$\frac{d}{dt} f(\mathbf{c}(t)) \bigg|_{t=\frac{\pi}{2}} = \nabla f_{\mathbf{c}\left(\frac{\pi}{2}\right)} \cdot \mathbf{c}'\left(\frac{\pi}{2}\right) = \langle -3, 0 \rangle \cdot \langle -1, 0 \rangle = 3 + 0 = 3$$

13. $f(x, y) = \sin(xy), \quad \mathbf{c}(t) = (e^{2t}, e^{3t}), \quad t = 0$

SOLUTION By the Chain Rule for Paths we have

$$\frac{d}{dt} f(\mathbf{c}(t)) = \nabla f_{\mathbf{c}(t)} \cdot \mathbf{c}'(t) \tag{1}$$

We compute the gradient and $\mathbf{c}'(t)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \langle y \cos(xy), x \cos(xy) \rangle$$
$$\mathbf{c}'(t) = \left\langle 2e^{2t}, 3e^{3t} \right\rangle$$

At the point $t = 0$ we have

$$\mathbf{c}(0) = \left(e^0, e^0\right) = (1, 1)$$
$$\mathbf{c}'(0) = \left\langle 2e^0, 3e^0 \right\rangle = \langle 2, 3 \rangle$$
$$\nabla f_{\mathbf{c}(0)} = \nabla f_{(1,1)} = \langle \cos 1, \cos 1 \rangle$$

Substituting the vectors in (1) we get

$$\frac{d}{dt} f(\mathbf{c}(t)) \bigg|_{t=0} = \langle \cos 1, \cos 1 \rangle \cdot \langle 2, 3 \rangle = 5 \cos 1$$

14. $f(x, y) = \cos(y - x)$, $\quad \mathbf{c}(t) = (e^t, e^{2t})$, $\quad t = \ln 3$

SOLUTION By the Chain Rule for Paths we have

$$\frac{d}{dt} f(\mathbf{c}(t)) = \nabla f_{\mathbf{c}(t)} \cdot \mathbf{c}'(t) \tag{1}$$

We compute the gradient and $\mathbf{c}'(t)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \left\langle 2xy^3, 3x^2y^2 \right\rangle$$
$$\mathbf{c}'(t) = \left\langle e^t, 2e^{2t} \right\rangle$$

At the point $t = \ln 3$ we have

$$\mathbf{c}(\ln 3) = \left(e^{\ln 3}, e^{2\ln 3}\right) = \left(3, 3^2\right) = (3, 9)$$
$$\mathbf{c}'(\ln 3) = \left\langle e^{\ln 3}, 2e^{2\ln 3}\right\rangle = \left\langle 3, 2 \cdot 3^2\right\rangle = \langle 3, 18\rangle$$
$$\nabla f_{\mathbf{c}(\ln 3)} = \nabla f_{(3,9)} = \left\langle 2 \cdot 3 \cdot 9^3, 3 \cdot 3^2 \cdot 9^2\right\rangle = 2187\,\langle 2, 1\rangle$$

Substituting the vectors in (1) we obtain

$$\left.\frac{d}{dt} f(\mathbf{c}(t))\right|_{t=\ln 3} = 2187\,\langle 2, 1\rangle \cdot \langle 3, 18\rangle = 52{,}488$$

15. $f(x, y) = x - xy$, $\quad \mathbf{c}(t) = (t^2, t^2 - 4t)$, $\quad t = 4$

SOLUTION We compute the gradient and $\mathbf{c}'(t)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \langle 1 - y, -x\rangle$$
$$\mathbf{c}'(t) = (2t, 2t - 4)$$

At the point $t = 4$ we have

$$\mathbf{c}(4) = \left(4^2, 4^2 - 4 \cdot 4\right) = (16, 0)$$
$$\mathbf{c}'(4) = \langle 2 \cdot 4, 2 \cdot 4 - 4\rangle = \langle 8, 4\rangle$$
$$\nabla f_{\mathbf{c}(4)} = \nabla f_{(16,0)} = \langle 1 - 0, -16\rangle = \langle 1, -16\rangle$$

We now use the Chain Rule for Paths to compute the following derivative:

$$\left.\frac{d}{dt} f(\mathbf{c}(t))\right|_{t=4} = \nabla f_{\mathbf{c}(4)} \cdot \mathbf{c}'(4) = \langle 1, -16\rangle \cdot \langle 8, 4\rangle = 8 - 64 = -56$$

16. $f(x, y) = xe^y$, $\quad \mathbf{c}(t) = (t^2, t^2 - 4t)$, $\quad t = 0$

SOLUTION We compute the gradient and $\mathbf{c}'(t)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \left\langle e^y, xe^y\right\rangle = e^y\,\langle 1, x\rangle$$
$$\mathbf{c}'(t) = \langle 2t, 2t - 4\rangle$$

At the point $t = 0$ we have

$$\mathbf{c}(0) = (0, 0)$$
$$\mathbf{c}'(0) = \langle 0, -4\rangle$$
$$\nabla f_{\mathbf{c}(0)} = \nabla f_{(0,0)} = e^0\,\langle 1, 0\rangle = \langle 1, 0\rangle$$

Using the Chain Rule for Paths we obtain the following derivative:

$$\left.\frac{d}{dt} f(\mathbf{c}(t))\right|_{t=0} = \nabla f_{\mathbf{c}(0)} \cdot \mathbf{c}'(0) = \langle 1, 0\rangle \cdot \langle 0, -4\rangle = 0$$

17. $f(x, y) = \ln x + \ln y, \quad \mathbf{c}(t) = (\cos t, t^2), \quad t = \frac{\pi}{4}$

SOLUTION We compute the gradient and $\mathbf{c}'(t)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \left\langle \frac{1}{x}, \frac{1}{y} \right\rangle$$
$$\mathbf{c}'(t) = \langle -\sin t, 2t \rangle$$

At the point $t = \frac{\pi}{4}$ we have

$$\mathbf{c}\left(\frac{\pi}{4}\right) = \left(\cos\frac{\pi}{4}, \left(\frac{\pi}{4}\right)^2\right) = \left(\frac{\sqrt{2}}{2}, \frac{\pi^2}{16}\right)$$
$$\mathbf{c}'\left(\frac{\pi}{4}\right) = \left\langle -\sin\frac{\pi}{4}, \frac{2\pi}{4} \right\rangle = \left\langle -\frac{\sqrt{2}}{2}, \frac{\pi}{2} \right\rangle$$
$$\nabla f_{\mathbf{c}\left(\frac{\pi}{4}\right)} = \nabla f_{\left(\frac{\sqrt{2}}{2}, \frac{\pi^2}{16}\right)} = \left\langle \sqrt{2}, \frac{16}{\pi^2} \right\rangle$$

Using the Chain Rule for Paths we obtain the following derivative:

$$\frac{d}{dt} f(\mathbf{c}(t))\Big|_{t=\frac{\pi}{4}} = \nabla f_{\mathbf{c}\left(\frac{\pi}{4}\right)} \cdot \mathbf{c}'\left(\frac{\pi}{4}\right) = \left\langle \sqrt{2}, \frac{16}{\pi^2} \right\rangle \cdot \left\langle -\frac{\sqrt{2}}{2}, \frac{\pi}{2} \right\rangle = -1 + \frac{8}{\pi} \approx 1.546$$

18. $g(x, y, z) = xye^z, \quad \mathbf{c}(t) = (t^2, t^3, t-1), \quad t = 1$

SOLUTION We compute the gradient and $\mathbf{c}'(t)$:

$$\nabla g = \left\langle \frac{\partial g}{\partial x}, \frac{\partial g}{\partial y}, \frac{\partial g}{\partial z} \right\rangle = \left\langle ye^z, xe^z, xye^z \right\rangle = e^z \langle y, x, xy \rangle$$
$$\mathbf{c}'(t) = \left\langle 2t, 3t^2, 1 \right\rangle$$

At the point $t = 1$ we have

$$\mathbf{c}(1) = (1, 1, 0)$$
$$\mathbf{c}'(1) = \langle 2, 3, 1 \rangle$$
$$\nabla g_{\mathbf{c}(1)} = \nabla g_{(1,1,0)} = e^0 \langle 1, 1, 1 \rangle = \langle 1, 1, 1 \rangle$$

Using the Chain Rule for Paths we obtain the following derivative:

$$\frac{d}{dt} g(\mathbf{c}(t))\Big|_{t=1} = \nabla g_{\mathbf{c}(1)} \cdot \mathbf{c}'(1) = \langle 1, 1, 1 \rangle \cdot \langle 2, 3, 1 \rangle = 2 + 3 + 1 = 6$$

19. $g(x, y, z) = xyz^{-1}, \quad \mathbf{c}(t) = (e^t, t, t^2), \quad t = 1$

SOLUTION By the Chain Rule for Paths we have

$$\frac{d}{dt} g(\mathbf{c}(t)) = \nabla g_{\mathbf{c}(t)} \cdot \mathbf{c}'(t) \tag{1}$$

We compute the gradient and $\mathbf{c}'(t)$:

$$\nabla g = \left\langle \frac{\partial g}{\partial x}, \frac{\partial g}{\partial y}, \frac{\partial g}{\partial z} \right\rangle = \left\langle yz^{-1}, xz^{-1}, -xyz^{-2} \right\rangle$$
$$\mathbf{c}'(t) = \left\langle e^t, 1, 2t \right\rangle$$

At the point $t = 1$ we have

$$\mathbf{c}(1) = (e, 1, 1)$$
$$\mathbf{c}'(1) = \langle e, 1, 2 \rangle$$
$$\nabla g_{\mathbf{c}(1)} = \nabla g_{(e,1,1)} = \langle 1, e, -e \rangle$$

Substituting the vectors in (1) gives the following derivative:

$$\frac{d}{dt} g(\mathbf{c}(t))\Big|_{t=1} = \langle 1, e, -e \rangle \cdot \langle e, 1, 2 \rangle = e + e - 2e = 0$$

20. $g(x, y, z, w) = x + 2y + 3z + 5w, \quad \mathbf{c}(t) = (t^2, t^3, t, t-2), \quad t = 1$

SOLUTION We compute the gradient and $\mathbf{c}'(t)$:

$$\nabla g = \left\langle \frac{\partial g}{\partial x}, \frac{\partial g}{\partial y}, \frac{\partial g}{\partial z}, \frac{\partial g}{\partial w} \right\rangle = \langle 1, 2, 3, 5 \rangle$$
$$\mathbf{c}'(t) = \left\langle 2t, 3t^2, 1, 1 \right\rangle$$

At the point $t = 1$ we have (notice that the gradient is a constant vector)

$$\nabla g_{\mathbf{c}(1)} = \langle 1, 2, 3, 5 \rangle$$
$$\mathbf{c}'(1) = \langle 2, 3, 1, 1 \rangle$$

We now use the Chain Rule for Paths to obtain the following derivative:

$$\frac{d}{dt} g\left(\mathbf{c}(t)\right)\bigg|_{t=1} = \nabla g_{\mathbf{c}(1)} \cdot \mathbf{c}'(1) = \langle 1, 2, 3, 5 \rangle \cdot \langle 2, 3, 1, 1 \rangle = 2 + 6 + 3 + 5 = 16$$

In Exercises 21–30, calculate the directional derivative in the direction of $\mathbf{v}$ *at the given point. Remember to normalize the direction vector or use Eq. (4).*

21. $f(x, y) = x^2 + y^3, \quad \mathbf{v} = \langle 4, 3 \rangle, \quad P = (1, 2)$

SOLUTION We first normalize the direction vector $\mathbf{v}$:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 4, 3 \rangle}{\sqrt{4^2 + 3^2}} = \left\langle \frac{4}{5}, \frac{3}{5} \right\rangle$$

We compute the gradient of $f(x, y) = x^2 + y^3$ at the given point:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \left\langle 2x, 3y^2 \right\rangle \quad \Rightarrow \quad \nabla f_{(1,2)} = \langle 2, 12 \rangle$$

Using the Theorem on Evaluating Directional Derivatives, we get

$$D_{\mathbf{u}} f(1, 2) = \nabla f_{(1,2)} \cdot \mathbf{u} = \langle 2, 12 \rangle \cdot \left\langle \frac{4}{5}, \frac{3}{5} \right\rangle = \frac{8}{5} + \frac{36}{5} = \frac{44}{5} = 8.8$$

22. $f(x, y) = x^2y^3, \quad \mathbf{v} = \mathbf{i} + \mathbf{j}, \quad P = (-2, 1)$

SOLUTION We normalize $\mathbf{v}$ to obtain a unit vector $\mathbf{u}$ in the direction of $\mathbf{v}$:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{2}}(\mathbf{i} + \mathbf{j}) = \frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}$$

We compute the gradient of $f(x, y) = x^2y^3$ at the point P:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \left\langle 2xy^3, 3x^2y^2 \right\rangle \quad \Rightarrow \quad \nabla f_{(-2,1)} = \langle -4, 12 \rangle = -4\mathbf{i} + 12\mathbf{j}$$

The directional derivative in the direction of $\mathbf{v}$ is therefore

$$D_{\mathbf{u}} f(-2, 1) = \nabla f_{(-2,1)} \cdot \mathbf{u} = (-4\mathbf{i} + 12\mathbf{j}) \cdot \left(\frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}\right) = -\frac{4}{\sqrt{2}} + \frac{12}{\sqrt{2}} = \frac{8}{\sqrt{2}} = 4\sqrt{2}$$

23. $f(x, y) = x^2y^3, \quad \mathbf{v} = \mathbf{i} + \mathbf{j}, \quad P = \left(\frac{1}{6}, 3\right)$

SOLUTION We normalize $\mathbf{v}$ to obtain a unit vector $\mathbf{u}$ in the direction of $\mathbf{v}$:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{2}}(\mathbf{i} + \mathbf{j}) = \frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}$$

We compute the gradient of $f(x, y) = x^2y^3$ at the point P:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \left\langle 2xy^3, 3x^2y^2 \right\rangle \quad \Rightarrow \quad \nabla f_{\left(\frac{1}{6},3\right)} = \left\langle 2 \cdot \frac{1}{6} \cdot 3^3, 3 \cdot \frac{1}{6^2} \cdot 3^2 \right\rangle = \left\langle 9, \frac{3}{4} \right\rangle = 9\mathbf{i} + \frac{3}{4}\mathbf{j}$$

The directional derivative in the direction $\mathbf{v}$ is thus

$$D_{\mathbf{u}} f\left(\frac{1}{6}, 3\right) = \nabla f_{\left(\frac{1}{6},3\right)} \cdot \mathbf{u} = \left(9\mathbf{i} + \frac{3}{4}\mathbf{j}\right) \cdot \left(\frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}\right) = \frac{9}{\sqrt{2}} + \frac{3}{4\sqrt{2}} = \frac{39}{4\sqrt{2}}$$

24. $f(x, y) = \sin(x - y)$, $\mathbf{v} = \langle 1, 1\rangle$, $P = \left(\frac{\pi}{2}, \frac{\pi}{6}\right)$

SOLUTION We normalize $\mathbf{v}$ to obtain a unit vector $\mathbf{u}$ in the direction $\mathbf{v}$:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{2}}\langle 1, 1\rangle$$

We compute the gradient of $f(x, y) = \sin(x - y)$ at the point P:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}\right\rangle = \langle \cos(x - y), -\cos(x - y)\rangle \quad \Rightarrow \quad \nabla f_{\left(\frac{\pi}{2}, \frac{\pi}{6}\right)} = \left\langle \cos\frac{\pi}{3}, -\cos\frac{\pi}{3}\right\rangle = \left\langle \frac{1}{2}, -\frac{1}{2}\right\rangle$$

The directional derivative in the direction $\mathbf{v}$ is thus

$$D_{\mathbf{u}} f(P) = \nabla f_{\left(\frac{\pi}{2}, \frac{\pi}{6}\right)} \cdot \mathbf{u} = \left\langle \frac{1}{2}, -\frac{1}{2}\right\rangle \cdot \frac{1}{\sqrt{2}}\langle 1, 1\rangle = 0$$

25. $f(x, y) = \tan^{-1}(xy)$, $\mathbf{v} = \langle 1, 1\rangle$, $P = (3, 4)$

SOLUTION We first normalize $\mathbf{v}$ to obtain a unit vector $\mathbf{u}$ in the direction $\mathbf{v}$:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{2}}\langle 1, 1\rangle$$

We compute the gradient of $f(x, y) = \tan^{-1}(xy)$ at the point $P = (3, 4)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}\right\rangle = \left\langle \frac{y}{1 + (xy)^2}, \frac{x}{1 + (xy)^2}\right\rangle = \frac{1}{1 + x^2y^2}\langle y, x\rangle$$

$$\nabla f_{(3,4)} = \frac{1}{1 + 3^2 \cdot 4^2}\langle 4, 3\rangle = \frac{1}{145}\langle 4, 3\rangle$$

Therefore, the directional derivative in the direction $\mathbf{v}$ is

$$D_{\mathbf{u}} f(3, 4) = \nabla f_{(3,4)} \cdot \mathbf{u} = \frac{1}{145}\langle 4, 3\rangle \cdot \frac{1}{\sqrt{2}}\langle 1, 1\rangle = \frac{1}{145\sqrt{2}}(4 + 3) = \frac{7}{145\sqrt{2}} = \frac{7\sqrt{2}}{290}$$

26. $f(x, y) = e^{xy - y^2}$, $\mathbf{v} = \langle 12, -5\rangle$, $P = (2, 2)$

SOLUTION We first normalize $\mathbf{v}$ to obtain a unit vector $\mathbf{u}$ in the direction $\mathbf{v}$:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 12, -5\rangle}{\sqrt{12^2 + (-5)^2}} = \frac{1}{13}\langle 12, -5\rangle$$

We compute the gradient of $f(x, y) = e^{xy - y^2}$ at the point $P = (2, 2)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}\right\rangle = \left\langle ye^{xy - y^2}, (x - 2y)e^{xy - y^2}\right\rangle = e^{xy - y^2}\langle y, x - 2y\rangle$$

$$\nabla f_{(2,2)} = e^0\langle 2, -2\rangle = \langle 2, -2\rangle$$

Therefore, the directional derivative in the direction $\mathbf{v}$ is thus

$$D_{\mathbf{u}} f(2, 2) = \nabla f_{(2,2)} \cdot \mathbf{u} = \langle 2, -2\rangle \cdot \frac{1}{13}\langle 12, -5\rangle = \frac{34}{13}$$

27. $f(x, y) = \ln(x^2 + y^2)$, $\mathbf{v} = 3\mathbf{i} - 2\mathbf{j}$, $P = (1, 0)$

SOLUTION We normalize $\mathbf{v}$ to obtain a unit vector $\mathbf{u}$ in the direction $\mathbf{v}$:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{1}{\sqrt{3^2 + (-2)^2}}(3\mathbf{i} - 2\mathbf{j}) = \frac{1}{\sqrt{13}}(3\mathbf{i} - 2\mathbf{j})$$

We compute the gradient of $f(x, y) = \ln\left(x^2 + y^2\right)$ at the point $P = (1, 0)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}\right\rangle = \left\langle \frac{2x}{x^2 + y^2}, \frac{2y}{x^2 + y^2}\right\rangle = \frac{2}{x^2 + y^2}\langle x, y\rangle$$

$$\nabla f_{(1,0)} = \frac{2}{1^2 + 0^2}\langle 1, 0\rangle = \langle 2, 0\rangle = 2\mathbf{i}$$

The directional derivative in the direction **v** is thus

$$D_{\mathbf{u}}f(1,0) = \nabla f_{(1,0)} \cdot \mathbf{u} = 2\mathbf{i} \cdot \frac{1}{\sqrt{13}}(3\mathbf{i} - 2\mathbf{j}) = \frac{6}{\sqrt{13}}$$

28. $g(x, y, z) = z^2 - xy^2, \quad \mathbf{v} = \langle -1, 2, 2 \rangle, \quad P = (2, 1, 3)$

SOLUTION We normalize **v** to obtain a unit vector **u** in the direction **v**:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle -1, 2, 2 \rangle}{\sqrt{(-1)^2 + 2^2 + 2^2}} = \frac{1}{3}\langle -1, 2, 2 \rangle$$

We compute the gradient of $f(x, y, z) = z^2 - xy^2$ at the point $P = (2, 1, 3)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \left\langle -y^2, -2xy, 2z \right\rangle \quad \Rightarrow \quad \nabla f_{(2,1,3)} = \langle -1, -4, 6 \rangle$$

The directional derivative in the direction **v** is thus

$$D_{\mathbf{u}}f(2,1,3) = \nabla f_{(2,1,3)} \cdot \mathbf{u} = \langle -1, -4, 6 \rangle \cdot \frac{1}{3}\langle -1, 2, 2 \rangle = \frac{1}{3}(1 - 8 + 12) = \frac{5}{3}$$

29. $g(x, y, z) = xe^{-yz}, \quad \mathbf{v} = \langle 1, 1, 1 \rangle, \quad P = (1, 2, 0)$

SOLUTION We first compute a unit vector **u** in the direction **v**:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 1, 1, 1 \rangle}{\sqrt{1^2 + 1^2 + 1^2}} = \frac{1}{\sqrt{3}}\langle 1, 1, 1 \rangle$$

We find the gradient of $f(x, y, z) = xe^{-yz}$ at the point $P = (1, 2, 0)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \left\langle e^{-yz}, -xze^{-yz}, -xye^{-yz} \right\rangle = e^{-yz}\langle 1, -xz, -xy \rangle$$

$$\nabla f_{(1,2,0)} = e^0 \langle 1, 0, -2 \rangle = \langle 1, 0, -2 \rangle$$

The directional derivative in the direction **v** is thus

$$D_{\mathbf{u}}f(1,2,0) = \nabla f_{(1,2,0)} \cdot \mathbf{u} = \langle 1, 0, -2 \rangle \cdot \frac{1}{\sqrt{3}}\langle 1, 1, 1 \rangle = \frac{1}{\sqrt{3}}(1 + 0 - 2) = -\frac{1}{\sqrt{3}}$$

30. $g(x, y, z) = x\ln(y + z), \quad \mathbf{v} = 2\mathbf{i} - \mathbf{j} + \mathbf{k}, \quad P = (2, e, e)$

SOLUTION We first find a unit vector **u** in the direction **v**:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{2\mathbf{i} - \mathbf{j} + \mathbf{k}}{\sqrt{2^2 + (-1)^2 + 1^2}} = \frac{1}{\sqrt{6}}(2\mathbf{i} - \mathbf{j} + \mathbf{k})$$

We compute the gradient of $f(x, y, z) = x\ln(y + z)$ at the point $P = (2, e, e)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \left\langle \ln(y+z), \frac{x}{y+z}, \frac{x}{y+z} \right\rangle$$

$$\nabla f_{(2,e,e)} = \left\langle \ln 2e, \frac{2}{2e}, \frac{2}{2e} \right\rangle = \left\langle \ln 2e, e^{-1}, e^{-1} \right\rangle = (\ln 2e)\mathbf{i} + e^{-1}\mathbf{j} + e^{-1}\mathbf{k}$$

The directional derivative in the direction **v** is thus

$$D_{\mathbf{u}}f(2,e,e) = \nabla f_{(2,e,e)} \cdot \mathbf{u} = \left((\ln 2e)\mathbf{i} + e^{-1}\mathbf{j} + e^{-1}\mathbf{k}\right) \cdot \frac{1}{\sqrt{6}}(2\mathbf{i} - \mathbf{j} + \mathbf{k})$$

$$= \frac{1}{\sqrt{6}}\left(2\ln(2e) - e^{-1} + e^{-1}\right) = \frac{2\ln 2e}{\sqrt{6}}$$

31. Find the directional derivative of $f(x, y) = x^2 + 4y^2$ at $P = (3, 2)$ in the direction pointing to the origin.

SOLUTION The direction vector is $\mathbf{v} = \overrightarrow{PO} = \langle -3, -2 \rangle$. A unit vector **u** in the direction **v** is obtained by normalizing **v**. That is,

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle -3, -2 \rangle}{\sqrt{3^2 + 2^2}} = \frac{-1}{\sqrt{13}}\langle 3, 2 \rangle$$

We compute the gradient of $f(x, y) = x^2 + 4y^2$ at the point $P = (3, 2)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \langle 2x, 8y \rangle \quad \Rightarrow \quad \nabla f_{(3,2)} = \langle 6, 16 \rangle$$

The directional derivative is thus

$$D_{\mathbf{u}} f(3, 2) = \nabla f_{(3,2)} \cdot \mathbf{u} = \langle 6, 16 \rangle \cdot \frac{-1}{\sqrt{13}} \langle 3, 2 \rangle = \frac{-50}{\sqrt{13}}$$

32. Find the directional derivative of $f(x, y, z) = xy + z^3$ at $P = (3, -2, -1)$ in the direction pointing to the origin.

SOLUTION The direction vector is $\mathbf{v} = \overrightarrow{PO} = \langle -3, 2, 1 \rangle$. We normalize $\mathbf{v}$ to obtain a unit vector $\mathbf{u}$ in the direction $\mathbf{v}$:

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle -3, 2, 1 \rangle}{\sqrt{9 + 4 + 1}} = \frac{1}{\sqrt{14}} \langle -3, 2, 1 \rangle$$

We compute the gradient of $f(x, y, z) = xy + z^3$ at P:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \left\langle y, x, 3z^2 \right\rangle \quad \Rightarrow \quad \nabla f_{(3,-2,-1)} = \langle -2, 3, 3 \rangle$$

The directional derivative is thus

$$D_{\mathbf{u}} f_{(3,-2,-1)} = \nabla f_{(3,-2,-1)} \cdot \mathbf{u} = \langle -2, 3, 3 \rangle \cdot \frac{1}{\sqrt{14}} \langle -3, 2, 1 \rangle = \frac{1}{\sqrt{14}}(6 + 6 + 3) = \frac{15}{\sqrt{14}}$$

33. A bug located at $(3, 9, 4)$ begins walking in a straight line toward $(5, 7, 3)$. At what rate is the bug's temperature changing if the temperature is $T(x, y, z) = xe^{y-z}$? Units are in meters and degrees Celsius.

SOLUTION The bug is walking in a straight line from the point $P = (3, 9, 4)$ towards $Q = (5, 7, 3)$, hence the rate of change in the temperature is the directional derivative in the direction of $\mathbf{v} = \overrightarrow{PQ}$. We first normalize $\mathbf{v}$ to obtain

$$\mathbf{v} = \overrightarrow{PQ} = \langle 5 - 3, 7 - 9, 3 - 4 \rangle = \langle 2, -2, -1 \rangle$$

$$\mathbf{u} = \frac{\mathbf{v}}{\|\mathbf{v}\|} = \frac{\langle 2, -2, -1 \rangle}{\sqrt{4 + 4 + 1}} = \frac{1}{3} \langle 2, -2, -1 \rangle$$

We compute the gradient of $T(x, y, z) = xe^{y-z}$ at $P = (3, 9, 4)$:

$$\nabla T = \left\langle \frac{\partial T}{\partial x}, \frac{\partial T}{\partial y}, \frac{\partial T}{\partial z} \right\rangle = \left\langle e^{y-z}, xe^{y-z}, -xe^{y-z} \right\rangle = e^{y-z} \langle 1, x, -x \rangle$$

$$\nabla T_{(3,9,4)} = e^{9-4} \langle 1, 3, -3 \rangle = e^5 \langle 1, 3, -3 \rangle$$

The rate of change of the bug's temperature at the starting point P is the directional derivative

$$D_{\mathbf{u}} f(P) = \nabla T_{(3,9,4)} \cdot \mathbf{u} = e^5 \langle 1, 3, -3 \rangle \cdot \frac{1}{3} \langle 2, -2, -1 \rangle = -\frac{e^5}{3} \approx -49.47$$

The answer is -49.47 degrees Celsius per meter.

34. The temperature at location (x, y) is $T(x, y) = 20 + 0.1(x^2 - xy)$ (degrees Celsius). Beginning at $(200, 0)$ at time $t = 0$ (seconds), a bug travels along a circle of radius 200 cm centered at the origin, at a speed of 3 cm/s. How fast is the temperature changing at time $t = \pi/3$?

SOLUTION First we should parametrize the circle the bug is walking along as:

$$\mathbf{r}(t) = \langle 200 \cos t, 200 \sin t \rangle, \ 0 \le t \le 2\pi$$

Then at $t = \pi/3$ then $x = 100$ and $y = 100\sqrt{3}$.

Next we need to calculate the velocity vector at $t = \pi/3$, using the parametrization for the circle we have

$$\mathbf{r}'(t) = \langle -200 \sin t, 200 \cos t \rangle \quad \Rightarrow \quad \mathbf{v} = \mathbf{r}'(\pi/3) = \left\langle -100\sqrt{3}, 100 \right\rangle$$

Now to normalize $\mathbf{v}$ we have

$$\mathbf{u} = \frac{1}{\sqrt{30000 + 10000}} \left\langle -100\sqrt{3}, 100 \right\rangle = \frac{1}{200} \left\langle -100\sqrt{3}, 100 \right\rangle = \left\langle -\frac{\sqrt{3}}{2}, \frac{1}{2} \right\rangle$$

We also need to compute the gradient of $T(x, y) = 20 + 0.1(x^2 - xy)$ at $t = \pi/3$ (or $x = 100$, $y = 100\sqrt{3}$):

$$\nabla T = \left\langle \frac{\partial T}{\partial x}, \frac{\partial T}{\partial y} \right\rangle = \langle 0.2x - 0.1y, -0.1x \rangle$$

$$\nabla T_{(100,100\sqrt{3})} = \left\langle 0.2(100) - 0.1(100\sqrt{3}), -0.1(100) \right\rangle = \left\langle 20 - 10\sqrt{3}, -10 \right\rangle$$

Then the rate of change of the bug's temperature at the point $t = \pi/3$ is the directional derivative:

$$D_{\mathbf{u}} f(\pi/3) = \nabla T_{(100,100\sqrt{3})} \cdot \mathbf{u} = \left\langle 20 - 10\sqrt{3}, -10 \right\rangle \cdot \left\langle -\frac{\sqrt{3}}{2}, \frac{1}{2} \right\rangle = 10 - 10\sqrt{3} \approx -7.32$$

So the temperature is changing at -7.32 degrees Celsius per second.

35. Suppose that $\nabla f_P = \langle 2, -4, 4 \rangle$. Is f increasing or decreasing at P in the direction $\mathbf{v} = \langle 2, 1, 3 \rangle$?

SOLUTION We compute the derivative of f at P with respect to $\mathbf{v}$:

$$D_{\mathbf{v}} f(P) = \nabla f_P \cdot \mathbf{v} = \langle 2, -4, 4 \rangle \cdot \langle 2, 1, 3 \rangle = 4 - 4 + 12 = 12 > 0$$

Since the derivative is positive, f is increasing at P in the direction of $\mathbf{v}$.

36. Let $f(x, y) = xe^{x^2 - y}$ and $P = (1, 1)$.

(a) Calculate $\|\nabla f_P\|$.

(b) Find the rate of change of f in the direction ∇f_P.

(c) Find the rate of change of f in the direction of a vector making an angle of 45° with ∇f_P.

SOLUTION

(a) We compute the gradient of $f(x, y) = xe^{x^2 - y}$. The partial derivatives are

$$\frac{\partial f}{\partial x} = 1 \cdot e^{x^2 - y} + xe^{x^2 - y} \cdot 2x = e^{x^2 - y}\left(1 + 2x^2\right)$$

$$\frac{\partial f}{\partial y} = -xe^{x^2 - y}$$

The gradient vector is thus

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \left\langle e^{x^2 - y}\left(1 + 2x^2\right), -xe^{x^2 - y} \right\rangle = e^{x^2 - y}\left\langle 1 + 2x^2, -x \right\rangle$$

At the point $P = (1, 1)$ we have

$$\nabla f_P = e^0 \langle 1 + 2, -1 \rangle = \langle 3, -1 \rangle \quad \Rightarrow \quad \|\nabla f_P\| = \sqrt{3^2 + (-1)^2} = \sqrt{10}$$

(b) The rate of change of f in the direction of the gradient vector is the length of the gradient, that is, $\|\nabla f_P\| = \sqrt{10}$.

(c) Let $\mathbf{e_v}$ be the unit vector making an angle of 45° with ∇f_P. The rate of change of f in the direction of $\mathbf{e_v}$ is the directional derivative of f in the direction $\mathbf{e_v}$, which is the following dot product:

$$D_{\mathbf{e_v}} f(P) = \nabla f_P \cdot \mathbf{e_v} = \|\nabla f_P\| \|\mathbf{e_v}\| \cos 45^\circ = \sqrt{10} \cdot 1 \cdot \frac{1}{\sqrt{2}} = \sqrt{5} \approx 2.236$$

37. Let $f(x, y, z) = \sin(xy + z)$ and $P = (0, -1, \pi)$. Calculate $D_{\mathbf{u}} f(P)$, where $\mathbf{u}$ is a unit vector making an angle $\theta = 30^\circ$ with ∇f_P.

SOLUTION The directional derivative $D_{\mathbf{u}} f(P)$ is the following dot product:

$$D_{\mathbf{u}} f(P) = \nabla f_P \cdot \mathbf{u}$$

Since $\mathbf{u}$ is a unit vector making an angle $\theta = 30^\circ$ with ∇f_P, we have by the properties of the dot product

$$D_{\mathbf{u}} f(P) = \|\nabla f_P\| \cdot \|\mathbf{u}\| \cos 30^\circ = \frac{\sqrt{3}}{2} \|\nabla f_P\| \tag{1}$$

We now must find the gradient at P and its length:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \langle y\cos(xy + z), x\cos(xy + z), \cos(xy + z) \rangle = \cos(xy + z) \langle y, x, 1 \rangle$$

$$\nabla f_{(0,-1,\pi)} = \cos \pi \langle -1, 0, 1 \rangle = -1 \langle -1, 0, 1 \rangle = \langle 1, 0, -1 \rangle$$

Hence,

$$\|\nabla f_{(0,-1,\pi)}\| = \sqrt{1^2 + 0^2 + (-1)^2} = \sqrt{2}$$

Substituting in (1) we get

$$D_{\mathbf{u}} f(P) = \frac{\sqrt{3}}{2}\sqrt{2} = \frac{\sqrt{6}}{2}.$$

38. Let $T(x, y)$ be the temperature at location (x, y). Assume that $\nabla T = \langle y - 4, x + 2y \rangle$. Let $\mathbf{c}(t) = (t^2, t)$ be a path in the plane. Find the values of t such that

$$\frac{d}{dt} T(\mathbf{c}(t)) = 0$$

SOLUTION By the Chain Rule for Paths we have

$$\frac{d}{dt} T\,(\mathbf{c}(t)) = \nabla T_{\mathbf{c}(t)} \cdot \mathbf{c}'(t) \qquad (1)$$

We compute the gradient vector ∇T for $x = t^2$ and $y = t$:

$$\nabla T = \left\langle t - 4, t^2 + 2t \right\rangle$$

Also $\mathbf{c}'(t) = \langle 2t, 1 \rangle$. Substituting in (1) gives

$$\frac{d}{dt} T\,(\mathbf{c}(t)) = \left\langle t - 4, t^2 + 2t \right\rangle \cdot \langle 2t, 1 \rangle = (t - 4) \cdot 2t + \left(t^2 + 2t\right) \cdot 1 = 3t^2 - 6t$$

We are asked to find the values of t such that

$$\frac{d}{dt} T\,(\mathbf{c}(t)) = 3t^2 - 6t = 0$$

We solve to obtain

$$3t^2 - 6t = 3t(t - 2) = 0 \quad \Rightarrow \quad t_1 = 0, \quad t_2 = 2$$

39. Find a vector normal to the surface $x^2 + y^2 - z^2 = 6$ at $P = (3, 1, 2)$.

SOLUTION The gradient ∇f_P is normal to the level curve $f(x, y, z) = x^2 + y^2 - z^2 = 6$ at P. We compute this vector:

$$\begin{aligned} f_x(x, y, z) &= 2x \\ f_y(x, y, z) &= 2y \quad \Rightarrow \quad \nabla f_P = \nabla f_{(3,1,2)} = \langle 6, 2, -4 \rangle \\ f_z(x, y, z) &= -2z \end{aligned}$$

The vector $\langle 6, 2, -4 \rangle$ is normal to the surface $x^2 + y^2 - z^2 = 6$ at P.

40. Find a vector normal to the surface $3z^3 + x^2 y - y^2 x = 1$ at $P = (1, -1, 1)$.

SOLUTION The gradient is normal to the level surfaces, that is ∇f_P is normal to the level surface $f(x, y, z) = 3z^3 + x^2 y - y^2 x = 1$. We compute the gradient vector at $P = (1, -1, 1)$:

$$\begin{aligned} \nabla f &= \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \left\langle 2xy - y^2, x^2 - 2yx, 9z^2 \right\rangle \\ \nabla f_P &= \langle -3, 3, 9 \rangle \end{aligned}$$

41. Find the two points on the ellipsoid

$$\frac{x^2}{4} + \frac{y^2}{9} + z^2 = 1$$

where the tangent plane is normal to $\mathbf{v} = \langle 1, 1, -2 \rangle$.

SOLUTION The gradient ∇f_P is normal to the level surface $f(x, y, z) = \frac{x^2}{4} + \frac{y^2}{9} + z^2 = 1$. If $\mathbf{v} = \langle 1, 1, -2 \rangle$ is also normal, then ∇f_P and $\mathbf{v}$ are parallel, that is, $\nabla f_P = k\mathbf{v}$ for some constant k. This yields the equation

$$\nabla f_P = \langle \frac{x}{2}, \frac{2y}{9}, 2z \rangle = k\,\langle 1, 1, -2 \rangle$$

Thus $x = 2k$, $y = 9k/2$, and $z = -k$. To determine k, substitute in the equation of the ellipsoid:

$$\frac{x^2}{4} + \frac{y^2}{9} + z^2 = \frac{(2k)^2}{4} + \frac{(9k/2)^2}{9} + (-k)^2 = 1$$

This yields $k^2 + \frac{9}{4}k^2 + k^2 = 1$ or $k = \pm 2/\sqrt{17}$. The two points are

$$(x, y, z) = (2k, \frac{9}{2}k, -k) = \pm\left(\frac{4}{\sqrt{17}}, \frac{9}{\sqrt{17}}, -\frac{2}{\sqrt{17}}\right)$$

In Exercises 42–45, find an equation of the tangent plane to the surface at the given point.

42. $x^2 + 3y^2 + 4z^2 = 20, \quad P = (2, 2, 1)$

SOLUTION The equation of the tangent plane is

$$\nabla f_P \cdot \langle x - 2, y - 2, z - 1\rangle = 0 \tag{1}$$

We compute the gradient of $f(x, y, z) = x^2 + 3y^2 + 4z^2$ at $P = (2, 2, 1)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right\rangle = \langle 2x, 6y, 8z\rangle$$

At the point P we have

$$\nabla f_P = \langle 2 \cdot 2, 6 \cdot 2, 8 \cdot 1\rangle = \langle 4, 12, 8\rangle$$

Substituting in (1) we obtain the following equation of the tangent plane:

$$\begin{aligned} \langle 4, 12, 8\rangle \cdot \langle x - 2, y - 2, z - 1\rangle &= 0 \\ 4(x - 2) + 12(y - 2) + 8(z - 1) &= 0 \\ x - 2 + 3(y - 2) + 2(z - 1) &= 0 \end{aligned}$$

or

$$x + 3y + 2z = 10$$

43. $xz + 2x^2y + y^2z^3 = 11, \quad P = (2, 1, 1)$

SOLUTION The equation of the tangent plane at P is

$$\nabla f_P \cdot \langle x - 2, y - 1, z - 1\rangle = 0 \tag{1}$$

We compute the gradient of $f(x, y, z) = xz + 2x^2y + y^2z^3$ at the point $P = (2, 1, 1)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right\rangle = \left\langle z + 4xy, 2x^2 + 2yz^3, x + 3y^2z^2\right\rangle$$

At the point P we have

$$\nabla f_P = \langle 9, 10, 5\rangle$$

Substituting in (1) we obtain the following equation of the tangent plane:

$$\begin{aligned} \langle 9, 10, 5\rangle \cdot \langle x - 2, y - 1, z - 1\rangle &= 0 \\ 9(x - 2) + 10(y - 1) + 5(z - 1) &= 0 \end{aligned}$$

or

$$9x + 10y + 5z = 33$$

44. $x^2 + z^2e^{y-x} = 13, \quad P = \left(2, 3, \frac{3}{\sqrt{e}}\right)$

SOLUTION We compute the gradient of $f(x, y, z) = x^2 + z^2e^{y-x}$ at the point $P = \left(2, 3, \frac{3}{\sqrt{e}}\right)$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right\rangle = \left\langle 2x - z^2e^{y-x}, z^2e^{y-x}, 2ze^{y-x}\right\rangle$$

At the point $P = \left(2, 3, \frac{3}{\sqrt{e}}\right)$ we have

$$\nabla f_P = \left\langle 4 - \frac{9}{e} \cdot e, \frac{9}{e} \cdot e, 2 \cdot \frac{3}{\sqrt{e}} \cdot e \right\rangle = \langle -5, 9, 6\sqrt{e} \rangle$$

The equation of the tangent plane at P is

$$\nabla f_P \cdot \left\langle x - 2, y - 3, z - \frac{3}{\sqrt{e}} \right\rangle = 0$$

That is,

$$-5(x-2) + 9(y-3) + 6\sqrt{e}\left(z - \frac{3}{\sqrt{e}}\right) = 0$$

or

$$-5x + 9y + 6\sqrt{e}z = 35$$

45. $\ln[1 + 4x^2 + 9y^4] - 0.1z^2 = 0, \quad P = (3, 1, 6.1876)$

SOLUTION The equation of the tangent plane at P is

$$\nabla f_P \cdot (x - 3, y - 1, z - 6.1876) = 0 \tag{1}$$

We compute the gradient of $f(x, y, z) = \ln(1 + 4x^2 + 9y^4) - 0.1z^2$ at the point P:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \left\langle \frac{8x}{1 + 4x^2 + 9y^4}, \frac{36y^3}{1 + 4x^2 + 9y^4}, -0.2z \right\rangle$$

At the point $P = (3, 1, 6.1876)$ we have

$$\nabla f_P = \left\langle \frac{24}{1 + 36 + 9}, \frac{36}{46}, -1.2375 \right\rangle = \langle 0.5217, 0.7826, -1.2375 \rangle$$

We substitute in (1) to obtain the following equation of the tangent plane:

$$0.5217(x-3) + 0.7826(y-1) - 1.2375(z - 6.1876) = 0$$

or

$$0.5217x + 0.7826y - 1.2375z = -5.309$$

46. Verify what is clear from Figure 15: Every tangent plane to the cone $x^2 + y^2 - z^2 = 0$ passes through the origin.

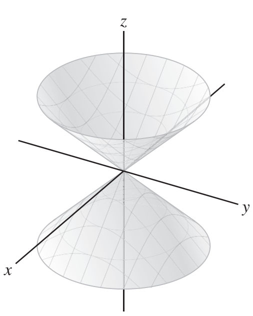

FIGURE 15 Graph of $x^2 + y^2 - z^2 = 0$.

SOLUTION The equation of the tangent plane to the surface $f(x, y, z) = x^2 + y^2 - z^2 = 0$ at the point $P = (x_0, y_0, z_0)$ on the surface is

$$\nabla f_P \cdot \langle x - x_0, y - y_0, z - z_0 \rangle \tag{1}$$

We compute the gradient of $f(x, y, z) = x^2 + y^2 - z^2$ at P:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \langle 2x, 2y, -2z \rangle$$

Hence,

$$\nabla f_P = \langle 2x_0, 2y_0, -2z_0 \rangle$$

Substituting in (1) we obtain the following equation of the tangent plane:

$$\langle 2x_0, 2y_0, -2z_0\rangle \cdot \langle x - x_0, y - y_0, z - z_0\rangle = 0$$
$$x_0(x - x_0) + y_0(y - y_0) - z_0(z - z_0) = 0$$
$$x_0x + y_0y - z_0z = x_0^2 + y_0^2 - z_0^2$$

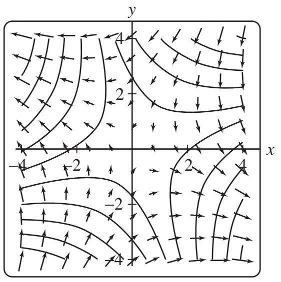
Since $P = (x_0, y_0, z_0)$ is on the surface, we have $x_0^2 + y_0^2 - z_0^2 = 0$. The equation of the tangent plane is thus

$$x_0x + y_0y - z_0z = 0$$

This plane passes through the origin.

47. CAS Use a computer algebra system to produce a contour plot of $f(x, y) = x^2 - 3xy + y - y^2$ together with its gradient vector field on the domain $[-4, 4] \times [-4, 4]$.

SOLUTION



48. Find a function $f(x, y, z)$ such that ∇f is the constant vector $\langle 1, 3, 1\rangle$.

SOLUTION The gradient of $f(x, y, z)$ must satisfy the equality

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \langle 1, 3, 1\rangle$$

Equating corresponding components gives

$$\frac{\partial f}{\partial x} = 1$$
$$\frac{\partial f}{\partial y} = 3$$
$$\frac{\partial f}{\partial z} = 1$$

One of the functions that satisfies these equalities is

$$f(x, y, z) = x + 3y + z$$

49. Find a function $f(x, y, z)$ such that $\nabla f = \langle 2x, 1, 2\rangle$.

SOLUTION The following equality must hold:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \langle 2x, 1, 2\rangle$$

Equating corresponding components gives

$$\frac{\partial f}{\partial x} = 2x$$
$$\frac{\partial f}{\partial y} = 1$$
$$\frac{\partial f}{\partial z} = 2$$

One of the functions that satisfies these equalities is $f(x, y, z) = x^2 + y + 2z$.

50. Find a function $f(x, y, z)$ such that $\nabla f = \langle x, y^2, z^3\rangle$.

SOLUTION The following equality must hold:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \left\langle x, y^2, z^3 \right\rangle$$

That is,

$$\frac{\partial f}{\partial x} = x$$
$$\frac{\partial f}{\partial y} = y^2$$
$$\frac{\partial f}{\partial z} = z^3$$

One of the functions that satisfies these equalities is

$$f(x, y, z) = \frac{1}{2}x^2 + \frac{1}{3}y^3 + \frac{1}{4}z^4$$

51. Find a function $f(x, y, z)$ such that $\nabla f = \langle z, 2y, x\rangle$.

SOLUTION $f(x, y, z) = xz + y^2$ is a good choice.

52. Find a function $f(x, y)$ such that $\nabla f = \langle y, x\rangle$.

SOLUTION We must find a function $f(x, y)$ such that

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle = \langle y, x\rangle$$

That is,

$$\frac{\partial f}{\partial x} = y, \quad \frac{\partial f}{\partial y} = x$$

We integrate the first equation with respect to x. Since y is treated as a constant, the constant of integration is a function of y. We get

$$f(x, y) = \int y\,dx = yx + g(y) \tag{1}$$

We differentiate f with respect to y and substitute in the second equation. This gives

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y}\left(yx + g(y)\right) = x + g'(y)$$

Hence,

$$x + g'(y) = x \quad \Rightarrow \quad g'(y) = 0 \quad \Rightarrow \quad g(y) = C$$

Substituting in (1) gives

$$f(x, y) = yx + C$$

One of the solutions is $f(x, y) = yx$ (obtained for $C = 0$).

53. Show that there does not exist a function $f(x, y)$ such that $\nabla f = \langle y^2, x\rangle$. *Hint:* Use Clairaut's Theorem $f_{xy} = f_{yx}$.

SOLUTION Suppose that for some differentiable function $f(x, y)$,

$$\nabla f = \langle f_x, f_y\rangle = \left\langle y^2, x\right\rangle$$

That is, $f_x = y^2$ and $f_y = x$. Therefore,

$$f_{xy} = \frac{\partial}{\partial y} f_x = \frac{\partial}{\partial y} y^2 = 2y \quad \text{and} \quad f_{yx} = \frac{\partial}{\partial x} f_y = \frac{\partial}{\partial x} x = 1$$

Since f_{xy} and f_{yx} are both continuous, they must be equal by Clairaut's Theorem. Since $f_{xy} \neq f_{yx}$ we conclude that such a function f does not exist.

54. Let $\Delta f = f(a+h, b+k) - f(a,b)$ be the change in f at $P = (a,b)$. Set $\Delta\mathbf{v} = \langle h, k\rangle$. Show that the linear approximation can be written

$$\Delta f \approx \nabla f_P \cdot \Delta\mathbf{v} \tag{8}$$

SOLUTION The linear approximation is

$$\Delta f \approx f_x(a,b)h + f_y(a,b)k = \left\langle f_x(a,b), f_y(a,b)\right\rangle \cdot \langle h, k\rangle = \nabla f_P \cdot \Delta\mathbf{v}$$

55. Use Eq. (8) to estimate

$$\Delta f = f(3.53, 8.98) - f(3.5, 9)$$

assuming that $\nabla f_{(3.5,9)} = \langle 2, -1\rangle$.

SOLUTION By Eq. (8),

$$\Delta f \approx \nabla f_P \cdot \Delta\mathbf{v}$$

The vector $\Delta\mathbf{v}$ is the following vector:

$$\Delta\mathbf{v} = \langle 3.53 - 3.5, 8.98 - 9\rangle = \langle 0.03, -0.02\rangle$$

Hence,

$$\Delta f \approx \nabla f_{(3,5,9)} \cdot \Delta\mathbf{v} = \langle 2, -1\rangle \cdot \langle 0.03, -0.02\rangle = 0.08$$

56. Find a unit vector $\mathbf{n}$ that is normal to the surface $z^2 - 2x^4 - y^4 = 16$ at $P = (2, 2, 8)$ that points in the direction of the xy-plane (in other words, if you travel in the direction of $\mathbf{n}$, you will eventually cross the xy-plane).

SOLUTION The gradient vector ∇f_P is normal to the surface $f(x,y,z) = z^2 - 2x^4 - y^4 = 16$ at P. We find this vector:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right\rangle = \left\langle -8x^3, -4y^3, 2z\right\rangle \quad \Rightarrow \quad \nabla f_{(2,2,8)} = \left\langle -8\cdot 2^3, -4\cdot 2^3, 2\cdot 8\right\rangle = \langle -64, -32, 16\rangle$$

We normalize to obtain a unit vector normal to the surface:

$$\frac{\nabla f_P}{\|\nabla f_P\|} = \frac{\langle -64, -32, 16\rangle}{\sqrt{(-64)^2 + 32^2 + 16^2}} = \frac{\langle -64, -32, 16\rangle}{16\sqrt{21}} = \frac{1}{\sqrt{21}}\langle -4, -2, 1\rangle$$

There are two unit normals to the surface at P, namely,

$$\mathbf{n} = \pm\frac{1}{\sqrt{21}}\langle -4, -2, 1\rangle$$

We need to find the normal that points in the direction of the xy-plane. Since the point $P = (2, 2, 8)$ is above the xy-plane, the normal we need has negative z-component. Hence,

$$\mathbf{n} = \frac{1}{\sqrt{21}}\langle 4, 2, -1\rangle$$

57. Suppose, in the previous exercise, that a particle located at the point $P = (2, 2, 8)$ travels toward the xy-plane in the direction normal to the surface.

(a) Through which point Q on the xy-plane will the particle pass?

(b) Suppose the axes are calibrated in centimeters. Determine the path $\mathbf{c}(t)$ of the particle if it travels at a constant speed of 8 cm/s. How long will it take the particle to reach Q?

SOLUTION

(a) The particle travels along the line through $P = (2, 2, 8)$ in the direction $\langle 4, 2, -1\rangle$. The vector parametrization of this line is

$$\mathbf{r}(t) = \langle 2, 2, 8\rangle + t\,\langle 4, 2, -1\rangle = \langle 2 + 4t, 2 + 2t, 8 - t\rangle \tag{1}$$

We must find the point where this line intersects the xy-plane. At this point the z-component is zero. Hence,

$$8 - t = 0 \quad \Rightarrow \quad t = 8$$

Substituting $t = 8$ in (1) we obtain

$$\mathbf{r}(8) = \langle 2 + 4\cdot 8, 2 + 2\cdot 8, 0\rangle = \langle 34, 18, 0\rangle$$

The particle will pass through the point $Q = (34, 18, 0)$ on the xy-plane.

(b) If $\mathbf{v}$ is a direction vector of the line PQ, so that $\|\mathbf{v}\| = 8$, the following parametrization of the line has constant speed 8:

$$\mathbf{c}(t) = \langle 2, 2, 8\rangle + t\mathbf{v}$$

(This has speed 8 because $\|\mathbf{c}'(t)\| = \|\mathbf{v}\| = 8$). In the previous exercise, we found the unit vector $\mathbf{n} = \frac{1}{\sqrt{21}}\langle 4, 2, -1\rangle$, therefore we use the direction vector $\mathbf{v} = 8\mathbf{n} = \frac{8}{\sqrt{21}}\langle 4, 2, -1\rangle$, obtaining the following parametrization of the line:

$$\mathbf{c}(t) = \langle 2, 2, 8\rangle + t \cdot \frac{8}{\sqrt{21}}\langle 4, 2, -1\rangle = \left\langle 2 + \frac{32}{\sqrt{21}}t, 2 + \frac{16}{\sqrt{21}}t, 8 - \frac{8t}{\sqrt{21}}\right\rangle$$

To find the time needed for the particle to reach Q if it travels along $\mathbf{c}(t)$, we first compute the distance $\overline{PQ}$:

$$\overline{PQ} = \sqrt{(34-2)^2 + (18-2)^2 + (0-8)^2} = \sqrt{1344} = 8\sqrt{21}$$

The time needed is thus

$$T = \frac{\overline{PQ}}{8} = \frac{8\sqrt{21}}{8} = \sqrt{21} \approx 4.58 \text{ s}$$

58. Let $f(x, y) = \tan^{-1}\frac{x}{y}$ and $\mathbf{u} = \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right\rangle$.

(a) Calculate the gradient of f.

(b) Calculate $D_{\mathbf{u}}f(1, 1)$ and $D_{\mathbf{u}}f(\sqrt{3}, 1)$.

(c) Show that the lines $y = mx$ for $m \neq 0$ are level curves for f.

(d) Verify that ∇f_P is orthogonal to the level curve through P for $P = (x, y) \neq (0, 0)$.

SOLUTION

(a) We compute the partial derivatives of $f(x, y) = \tan^{-1}\frac{x}{y}$. Using the Chain Rule we get

$$\frac{\partial f}{\partial x} = \frac{1}{1 + \left(\frac{x}{y}\right)^2} \cdot \frac{1}{y} = \frac{y}{x^2 + y^2}$$

$$\frac{\partial f}{\partial y} = \frac{1}{1 + \left(\frac{x}{y}\right)^2} \cdot \left(-\frac{x}{y^2}\right) = -\frac{x}{x^2 + y^2}$$

The gradient of f is thus

$$\nabla f = \left\langle \frac{y}{x^2 + y^2}, -\frac{x}{x^2 + y^2}\right\rangle = \frac{1}{x^2 + y^2}\langle y, -x\rangle$$

(b) By the Theorem on Evaluating Directional Derivatives,

$$D_{\mathbf{u}}f(a, b) = \nabla f_{(a,b)} \cdot \mathbf{u} \tag{1}$$

We find the values of the gradient at the two points:

$$\nabla f_{(1,1)} = \frac{1}{1^2 + 1^2}\langle 1, -1\rangle = \frac{1}{2}\langle 1, -1\rangle$$

$$\nabla f_{\left(\sqrt{3},1\right)} = \frac{1}{\left(\sqrt{3}\right)^2 + 1^2}\left\langle 1, -\sqrt{3}\right\rangle = \frac{1}{4}\left\langle 1, -\sqrt{3}\right\rangle$$

Substituting in (1) we obtain the following directional derivatives

$$D_{\mathbf{u}}f(1, 1) = \nabla f_{(1,1)} \cdot \mathbf{u} = \frac{1}{2}\langle 1, -1\rangle \cdot \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right\rangle = 0$$

$$D_{\mathbf{u}}f\left(\sqrt{3}, 1\right) = \nabla f_{\left(\sqrt{3},1\right)} \cdot \mathbf{u} = \frac{1}{4}\left\langle 1, -\sqrt{3}\right\rangle \cdot \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right\rangle = \frac{\sqrt{2}}{8}\left\langle 1, -\sqrt{3}\right\rangle \cdot \langle 1, 1\rangle$$

$$= \frac{\sqrt{2}}{8}\left(1 - \sqrt{3}\right) = \frac{\sqrt{2} - \sqrt{6}}{8}$$

(c) Note that f is not defined for $y = 0$. For $x = 0$, the level curve of f is the y-axis, and the gradient vector is $\langle \frac{1}{y}, 0\rangle$, which is perpendicular to the y-axis. For $y \neq 0$ and $x \neq 0$, the level curves of f are the curves where $f(x, y)$ is constant. That is,

$$\tan^{-1}\frac{x}{y} = k$$

$$\frac{x}{y} = \tan k \qquad (\text{for } k \neq 0)$$

$$y = \frac{1}{\tan k}x$$

We conclude that the lines $y = mx$, $m \neq 0$, are level curves for f.

(d) By part (c), the level curve through $P = (x_0, y_0)$ is the line $y = \frac{y_0}{x_0}x$. This line has a direction vector $\left\langle 1, \frac{y_0}{x_0}\right\rangle$. The gradient at P is, by part (a), $\nabla f_P = \frac{1}{x_0^2+y_0^2}\langle y_0, -x_0\rangle$. We verify that the two vectors are orthogonal:

$$\left(1, \frac{y_0}{x_0}\right)\cdot\nabla f_P = \left\langle 1, \frac{y_0}{x_0}\right\rangle\cdot\frac{1}{x_0^2+y_0^2}\langle y_0, -x_0\rangle = \frac{1}{x_0^2+y_0^2}\left(y_0 - \frac{x_0y_0}{x_0}\right) = 0$$

Since the dot products is zero, the two vectors are orthogonal as expected (Theorem 6).

59. Suppose that the intersection of two surfaces $F(x, y, z) = 0$ and $G(x, y, z) = 0$ is a curve $\mathcal{C}$, and let P be a point on $\mathcal{C}$. Explain why the vector $\mathbf{v} = \nabla F_P \times \nabla G_P$ is a direction vector for the tangent line to $\mathcal{C}$ at P.

SOLUTION The gradient ∇F_P is orthogonal to all the curves in the level surface $F(x, y, z) = 0$ passing through P. Similarly, ∇G_P is orthogonal to all the curves in the level surface $G(x, y, z) = 0$ passing through P. Therefore, both ∇F_P and ∇G_P are orthogonal to the intersection curve $\mathcal{C}$ at P, hence the cross product $\nabla F_P \times \nabla G_P$ is parallel to the tangent line to $\mathcal{C}$ at P.

60. Let $\mathcal{C}$ be the curve of intersection of the spheres $x^2 + y^2 + z^2 = 3$ and $(x-2)^2 + (y-2)^2 + z^2 = 3$. Use the result of Exercise 59 to find parametric equations of the tangent line to $\mathcal{C}$ at $P = (1, 1, 1)$.

SOLUTION The parametric equations of the tangent line to $\mathcal{C}$ at $P = (1, 1, 1)$ are

$$x = 1 + at, \quad y = 1 + bt, \quad z = 1 + ct \tag{1}$$

where $\mathbf{v} = \langle a, b, c\rangle$ is a direction vector for the line. By Exercise 59 $\mathbf{v}$ may be chosen as the following cross product:

$$\mathbf{v} = \nabla F_P \times \nabla G_P \tag{2}$$

where $F(x, y, z) = x^2 + y^2 + z^2$ and $G(x, y, z) = (x-2)^2 + (y-2)^2 + z^2$. We compute ∇F_P and ∇G_P:

$$\begin{aligned} F_x(x, y, z) &= 2x \\ F_y(x, y, z) &= 2y \quad \Rightarrow \quad \nabla F_P = \langle 2\cdot 1, 2\cdot 1, 2\cdot 1\rangle = \langle 2, 2, 2\rangle \\ F_z(x, y, z) &= 2z \end{aligned}$$

$$\begin{aligned} G_x(x, y, z) &= 2(x-2) \\ G_y(x, y, z) &= 2(y-2) \quad \Rightarrow \quad \nabla G_P = \langle 2(1-2), 2(1-2), 2\cdot 1\rangle = \langle -2, -2, 2\rangle \\ G_z(x, y, z) &= 2z \end{aligned}$$

Hence,

$$\mathbf{v} = \langle 2, 2, 2\rangle \times \langle -2, -2, 2\rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 2 & 2 \\ -2 & -2 & 2 \end{vmatrix} = (4+4)\mathbf{i} - (4+4)\mathbf{j} + (-4+4)\mathbf{k} = 8\mathbf{i} - 8\mathbf{j} = \langle 8, -8, 0\rangle$$

Therefore, $\mathbf{v} = \langle a, b, c\rangle = \langle 8, -8, 0\rangle$, yielding $a = 8$, $b = -8$, $c = 0$. Substituting in (1) gives the following equations of the tangent line: $x = 1 + 8t$, $y = 1 - 8t$, $z = 1$.

61. Let $\mathcal{C}$ be the curve obtained by intersecting the two surfaces $x^3 + 2xy + yz = 7$ and $3x^2 - yz = 1$. Find the parametric equations of the tangent line to $\mathcal{C}$ at $P = (1, 2, 1)$.

SOLUTION The parametric equations of the tangent line to $\mathcal{C}$ at $P = (1, 2, 1)$ are

$$x = 1 + at, \quad y = 2 + bt, \quad z = 1 + ct \tag{1}$$

where $\mathbf{v} = \langle a, b, c\rangle$ is a direction vector for the line. By Exercise 59, $\mathbf{v}$ may be chosen as the cross product:

$$\mathbf{v} = \nabla F_P \times \nabla G_P \tag{2}$$

where $F(x, y, z) = x^3 + 2xy + yz$ and $G(x, y, z) = 3x^2 - yz$. We compute the gradient vectors:

$$\begin{aligned} F_x(x, y, z) &= 3x^2 + 2y \qquad & F_x(1, 2, 1) &= 7 \\ F_y(x, y, z) &= 2x + z \quad \Rightarrow & F_y(1, 2, 1) &= 3 \quad \Rightarrow \quad \nabla F_P = \langle 7, 3, 2 \rangle \\ F_z(x, y, z) &= y & F_z(1, 2, 1) &= 2 \end{aligned}$$

$$\begin{aligned} G_x(x, y, z) &= 6x \qquad & G_x(1, 2, 1) &= 6 \\ G_y(x, y, z) &= -z \quad \Rightarrow & G_y(1, 2, 1) &= -1 \quad \Rightarrow \quad \nabla G_P = \langle 6, -1, -2 \rangle \\ G_z(x, y, z) &= -y & G_z(1, 2, 1) &= -2 \end{aligned}$$

Hence,

$$\mathbf{v} = \langle 7, 3, 2 \rangle \times \langle 6, -1, -2 \rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 7 & 3 & 2 \\ 6 & -1 & -2 \end{vmatrix} = -4\mathbf{i} + 26\mathbf{j} - 25\mathbf{k} = \langle -4, 26, -25 \rangle$$

Therefore, $\mathbf{v} = \langle a, b, c \rangle = \langle -4, 26, -25 \rangle$, so we obtain

$$a = -4, \quad b = 26, \quad c = -25.$$

Substituting in (1) gives the following parametric equations of the tangent line:

$$x = 1 - 4t, \quad y = 2 + 26t, \quad z = 1 - 25t.$$

62. Verify the linearity relations for gradients:
(a) $\nabla(f + g) = \nabla f + \nabla g$
(b) $\nabla(cf) = c\nabla f$

SOLUTION
(a) We use the linearity relations for partial derivative to write

$$\begin{aligned} \nabla(f + g) &= \left\langle (f+g)_x, (f+g)_y, (f+g)_z \right\rangle = \left\langle f_x + g_x, f_y + g_y, f_z + g_z \right\rangle \\ &= \left\langle f_x, f_y, f_z \right\rangle + \left\langle g_x, g_y, g_z \right\rangle = \nabla f + \nabla g \end{aligned}$$

(b) We use the linearity properties of partial derivatives to write

$$\nabla(cf) = \left\langle (cf)_x, (cf)_y, (cf)_z \right\rangle = \left\langle cf_x, cf_y, cf_z \right\rangle = c \left\langle f_x, f_y, f_z \right\rangle = c\nabla f$$

63. Prove the Chain Rule for Gradients (Theorem 1).

SOLUTION We must show that if $F(t)$ is a differentiable function of t and $f(x, y, z)$ is differentiable, then

$$\nabla F\left(f(x, y, z)\right) = F'\left(f(x, y, z)\right) \nabla f$$

Using the Chain Rule for partial derivatives we get

$$\begin{aligned} \nabla F\left(f(x, y, z)\right) &= \left\langle \frac{\partial}{\partial x} F\left(f(x, y, z)\right), \frac{\partial}{\partial y} F\left(f(x, y, z)\right), \frac{\partial}{\partial z} F\left(f(x, y, z)\right) \right\rangle \\ &= \left\langle \frac{dF}{dt} \cdot \frac{\partial f}{\partial x}, \frac{dF}{dt} \cdot \frac{\partial f}{\partial y}, \frac{dF}{dt} \cdot \frac{\partial f}{\partial z} \right\rangle = \frac{dF}{dt} \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = F'\left(f(x, y, z)\right) \nabla F \end{aligned}$$

64. Prove the Product Rule for Gradients (Theorem 1).

SOLUTION We must show that if $f(x, y, z)$ and $g(x, y, z)$ are differentiable, then

$$\nabla(fg) = f\nabla g + g\nabla f$$

Using the Product Rule for partial derivatives we get

$$\begin{aligned} \nabla(fg) &= \left\langle (fg)_x, (fg)_y, (fg)_z \right\rangle = \left\langle f_x g + f g_x, f_y g + f g_y, f_z g + f g_z \right\rangle \\ &= \left\langle f_x g, f_y g, f_z g \right\rangle + \left\langle f g_x, f g_y, f g_z \right\rangle = \left\langle f_x, f_y, f_z \right\rangle g + f \left\langle g_x, g_y, g_z \right\rangle = g\nabla f + f\nabla g \end{aligned}$$

Further Insights and Challenges

65. Let $\mathbf{u}$ be a unit vector. Show that the directional derivative $D_{\mathbf{u}} f$ is equal to the component of ∇f along $\mathbf{u}$.

SOLUTION The component of ∇f along $\mathbf{u}$ is $\nabla f \cdot \mathbf{u}$. By the Theorem on Evaluating Directional Derivatives, $D_{\mathbf{u}} f = \nabla f \cdot \mathbf{u}$, which is the component of ∇f along $\mathbf{u}$.

66. Let $f(x, y) = (xy)^{1/3}$.

(a) Use the limit definition to show that $f_x(0, 0) = f_y(0, 0) = 0$.

(b) Use the limit definition to show that the directional derivative $D_{\mathbf{u}} f(0, 0)$ does not exist for any unit vector $\mathbf{u}$ other than $\mathbf{i}$ and $\mathbf{j}$.

(c) Is f differentiable at $(0, 0)$?

SOLUTION

(a) By the limit definition and since $f(0, 0) = 0$, we have

$$f_x(0,0) = \lim_{h\to 0} \frac{f(h,0) - f(0,0)}{h} = \lim_{h\to 0} \frac{(h\cdot 0)^{1/3} - 0}{h} = \lim_{h\to 0} \frac{0}{h} = 0$$

$$f_y(0,0) = \lim_{h\to 0} \frac{f(0,h) - f(0,0)}{h} = \lim_{h\to 0} \frac{(0\cdot h)^{1/3} - 0}{h} = \lim_{h\to 0} \frac{0}{h} = 0$$

(b) By the limit definition of the directional derivative, and for $\mathbf{u} = \langle u_1, u_2 \rangle$ a unit vector, we have

$$D_{\mathbf{u}} f(0,0) = \lim_{t\to 0} \frac{f(tu_1, tu_2) - f(0,0)}{t} = \lim_{t\to 0} \frac{\left(t^2 u_1 u_2\right)^{1/3} - 0}{t} = \lim_{t\to 0} \frac{u_1 u_2}{t^{1/3}}$$

This limit does not exist unless $u_1 = 0$ or $u_2 = 0$. $u_1 = 0$ corresponds to the unit vector $\mathbf{j}$, and $u_2 = 0$ corresponds to the unit vector $\mathbf{i}$.

(c) If f was differentiable at $(0, 0)$, then $D_{\mathbf{u}} f(0, 0)$ would exist for any vector $\mathbf{u}$. Therefore, using the result obtained in part (b), f is not differentiable at $(0, 0)$.

67. Use the definition of differentiability to show that if $f(x, y)$ is differentiable at $(0, 0)$ and

$$f(0,0) = f_x(0,0) = f_y(0,0) = 0$$

then

$$\lim_{(x,y)\to(0,0)} \frac{f(x,y)}{\sqrt{x^2+y^2}} = 0 \qquad \boxed{9}$$

SOLUTION If $f(x, y)$ is differentiable at $(0, 0)$, then there exists a function $\epsilon(x, y)$ satisfying $\lim_{(x,y)\to(0,0)} \epsilon(x, y) = 0$ such that

$$f(x,y) = L(x,y) + \epsilon(x,y)\sqrt{x^2+y^2} \qquad (1)$$

Since $f(0, 0) = 0$, the linear function $L(x, y)$ is

$$L(x,y) = f(0,0) + f_x(0,0)x + f_y(0,0)y = f_x(0,0)x + f_y(0,0)y$$

Substituting in (1) gives

$$f(x,y) = f_x(0,0)x + f_y(0,0)y + \epsilon(x,y)\sqrt{x^2+y^2}$$

Therefore,

$$\lim_{(x,y)\to(0,0)} \frac{f(x,y) - f_x(0,0)x - f_y(0,0)y}{\sqrt{x^2+y^2}} = \lim_{(x,y)\to(0,0)} \epsilon(x,y) = 0$$

68. This exercise shows that there exists a function that is not differentiable at $(0, 0)$ even though all directional derivatives at $(0, 0)$ exist. Define $f(x, y) = x^2 y/(x^2 + y^2)$ for $(x, y) \neq 0$ and $f(0, 0) = 0$.

(a) Use the limit definition to show that $D_{\mathbf{v}} f(0, 0)$ exists for all vectors $\mathbf{v}$. Show that $f_x(0, 0) = f_y(0, 0) = 0$.

(b) Prove that f is *not* differentiable at $(0, 0)$ by showing that Eq. (9) does not hold.

SOLUTION

(a) Let $\mathbf{v} \neq \mathbf{0}$ be the vector $\mathbf{v} = \langle v_1, v_2 \rangle$. By the definition of the derivative $D_{\mathbf{v}} f(0, 0)$, we have

$$D_{\mathbf{v}} f(0,0) = \lim_{t \to 0} \frac{f(tv_1, tv_2) - f(0,0)}{t} = \lim_{t \to 0} \frac{\frac{(tv_1)^2 tv_2}{(tv_1)^2 + (tv_2)^2} - 0}{t}$$

$$= \lim_{t \to 0} \frac{t^3 v_1^2 v_2}{t^3 \left(v_1^2 + v_2^2\right)} = \lim_{t \to 0} \frac{v_1^2 v_2}{v_1^2 + v_2^2} = \frac{v_1^2 v_2}{v_1^2 + v_2^2} \tag{1}$$

Therefore $D_{\mathbf{v}} f(0, 0)$ exists for all vectors $\mathbf{v}$.

(b) In Exercise 67 we showed that if $f(x, y)$ is differentiable at $(0, 0)$ and $f(0, 0) = 0$, then

$$\lim_{(x,y) \to (0,0)} \frac{f(x, y) - f_x(0,0)x - f_y(0,0)y}{\sqrt{x^2 + y^2}} = 0$$

We now show that f does not satisfy the above equation. We first compute the partial derivatives $f_x(0, 0)$ and $f_y(0, 0)$. The partial derivatives f_x and f_y are the directional derivatives in the directions of $\mathbf{v} = \langle 1, 0 \rangle$ and $\mathbf{v} = \langle 0, 1 \rangle$, respectively. Substituting $v_1 = 1$, $v_2 = 0$ in (1) gives

$$f_x(0,0) = \frac{1^2 \cdot 0}{1^2 + 0^2} = 0$$

Substituting $v_1 = 0$, $v_2 = 1$ in (1) gives

$$f_y(0,0) = \frac{0^2 \cdot 1}{0^2 + 1^2} = 0$$

Also $f(0, 0) = 0$, therefore for $(x, y) \neq (0, 0)$ we have

$$\lim_{(x,y) \to (0,0)} \frac{f(x, y) - f_x(0,0)x - f_y(0,0)y}{\sqrt{x^2 + y^2}} = \lim_{(x,y) \to (0,0)} \frac{\frac{x^2 y}{x^2 + y^2} - 0x - 0y}{\sqrt{x^2 + y^2}} = \lim_{(x,y) \to (0,0)} \frac{x^2 y}{(x^2 + y^2)^{\frac{3}{2}}}$$

We compute the limit along the line $y = \sqrt{3}x$:

$$\lim_{\substack{(x,y) \to (0,0) \\ \text{along } y = \sqrt{3}x}} \frac{x^2 y}{(x^2 + y^2)^{3/2}} = \lim_{x \to 0} \frac{x^2 \sqrt{3}x}{\left(x^2 + \left(\sqrt{3}x\right)^2\right)^{3/2}} = \lim_{x \to 0} \frac{\sqrt{3}x^3}{\left(4x^2\right)^{3/2}} = \lim_{x \to 0} \frac{\sqrt{3}x^3}{8x^3} = \frac{\sqrt{3}}{8} \neq 0$$

Since this limit is not zero, f does not satisfy Eq. (9), hence f is not differentiable at $(0, 0)$.

69. Prove that if $f(x, y)$ is differentiable and $\nabla f_{(x,y)} = \mathbf{0}$ for all (x, y), then f is constant.

SOLUTION Since $\nabla f = \langle f_x, f_y \rangle = \langle 0, 0 \rangle$ for all (x, y), we have

$$f_x(x, y) = f_y(x, y) = 0 \text{ for all } (x, y) \tag{1}$$

Let $Q_0 = (x_0, y_0)$ be a fixed point and let $P = (x_1, y_1)$ be any other point. Let $\mathbf{c}(t) = \langle x(t), y(t) \rangle$ be a parametric equation of the line joining Q_0 and P, with $P = \mathbf{c}(t_1)$ and $Q_0 = \mathbf{c}(t_0)$. We define the following function:

$$F(t) = f(x(t), y(t))$$

$F(t)$ is defined for all t, since $f(x, y)$ is defined for all (x, y). By the Chain Rule we have

$$F'(t) = f_x(x(t), y(t)) \frac{dx}{dt} + f_y(x(t), y(t)) \frac{dy}{dt}$$

Combining with (1) we get $F'(t) = 0$ for all t. We conclude that $F(t) = \text{const}$. That is, f is constant on the line $\mathbf{c}(t)$. In particular, $f(P) = f(Q_0)$. Since P is any point, it follows that $f(x, y)$ is a constant function.

70. Prove the following Quotient Rule, where f, g are differentiable:

$$\nabla\left(\frac{f}{g}\right) = \frac{g\nabla f - f\nabla g}{g^2}$$

SOLUTION The Quotient Rule is valid for partial derivatives, therefore

$$\nabla\left(\frac{f}{g}\right) = \left\langle \frac{\partial}{\partial x}\left(\frac{f}{g}\right), \frac{\partial}{\partial y}\left(\frac{f}{g}\right), \frac{\partial}{\partial z}\left(\frac{f}{g}\right)\right\rangle = \left\langle \frac{g\frac{\partial f}{\partial x} - f\frac{\partial g}{\partial x}}{g^2}, \frac{g\frac{\partial f}{\partial y} - f\frac{\partial g}{\partial y}}{g^2}, \frac{g\frac{\partial f}{\partial z} - f\frac{\partial g}{\partial z}}{g^2}\right\rangle$$

$$= \left\langle \frac{g\frac{\partial f}{\partial x}}{g^2}, \frac{g\frac{\partial f}{\partial y}}{g^2}, \frac{g\frac{\partial f}{\partial z}}{g^2}\right\rangle - \left\langle \frac{f\frac{\partial g}{\partial x}}{g^2}, \frac{f\frac{\partial g}{\partial y}}{g^2}, \frac{f\frac{\partial g}{\partial z}}{g^2}\right\rangle = \frac{g}{g^2}\left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right\rangle - \frac{f}{g^2}\left\langle \frac{\partial g}{\partial x}, \frac{\partial g}{\partial y}, \frac{\partial g}{\partial z}\right\rangle$$

$$= \frac{g}{g^2}\nabla f - \frac{f}{g^2}\nabla g = \frac{g\nabla f - f\nabla g}{g^2}$$

In Exercises 71–73, a path $\mathbf{c}(t) = (x(t), y(t))$ *follows the gradient of a function* $f(x, y)$ *if the tangent vector* $\mathbf{c}'(t)$ *points in the direction of* ∇f *for all* t. *In other words,* $\mathbf{c}'(t) = k(t)\nabla f_{\mathbf{c}(t)}$ *for some positive function* $k(t)$. *Note that in this case,* $\mathbf{c}(t)$ *crosses each level curve of* $f(x, y)$ *at a right angle.*

71. Show that if the path $\mathbf{c}(t) = (x(t), y(t))$ follows the gradient of $f(x, y)$, then

$$\frac{y'(t)}{x'(t)} = \frac{f_y}{f_x}$$

SOLUTION Since $\mathbf{c}(t)$ follows the gradient of $f(x, y)$, we have

$$\mathbf{c}'(t) = k(t)\nabla f_{\mathbf{c}(t)} = k(t)\left\langle f_x(\mathbf{c}(t)), f_y(\mathbf{c}(t))\right\rangle$$

which implies that

$$x'(t) = k(t) f_x(\mathbf{c}(t)) \quad \text{and} \quad y'(t) = k(t) f_y(\mathbf{c}(t))$$

Hence,

$$\frac{y'(t)}{x'(t)} = \frac{k(t) f_y(\mathbf{c}(t))}{k(t) f_x(\mathbf{c}(t))} = \frac{f_y(\mathbf{c}(t))}{f_x(\mathbf{c}(t))}$$

or in short notation,

$$\frac{y'(t)}{x'(t)} = \frac{f_y}{f_x}$$

72. Find a path of the form $\mathbf{c}(t) = (t, g(t))$ passing through $(1, 2)$ that follows the gradient of $f(x, y) = 2x^2 + 8y^2$ (Figure 16). *Hint:* Use Separation of Variables.

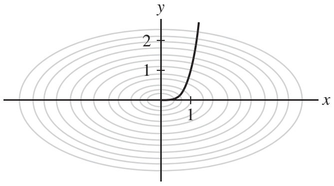


FIGURE 16 The path $\mathbf{c}(t)$ is orthogonal to the level curves of $f(x, y) = 2x^2 + 8y^2$.

SOLUTION By the previous exercise, if $\mathbf{c}(t) = (x(t), y(t))$ follows the gradient of f, then

$$\frac{dy}{dx} = \frac{y'(t)}{x'(t)} = \frac{f_y}{f_x} \tag{1}$$

We find the partial derivatives of f:

$$f_y = \frac{\partial}{\partial y}\left(2x^2 + 8y^2\right) = 16y, \quad f_x = \frac{\partial}{\partial x}\left(2x^2 + 8y^2\right) = 4x$$

Substituting in (1) we get

$$\frac{dy}{dx} = \frac{16y}{4x} = \frac{4y}{x}$$

We solve the differential equation using separation of variables. We obtain

$$\frac{dy}{y} = 4\frac{dx}{x}$$
$$\int \frac{dy}{y} = 4\int \frac{dx}{x}$$
$$\ln y = 4\ln x + c = \ln x^4 + c$$

or

$$y = e^{\ln x^4 + c} = e^c x^4$$

Denoting $k = e^c$, we obtain the following solution:

$$y = kx^4$$

The corresponding path may be parametrized using the parameter $x = t$ as

$$\mathbf{c}(t) = \left(t, kt^4\right) \tag{2}$$

Since we want the path to pass through $(1, 2)$, there must be a solution t for the equation

$$\left(t, kt^4\right) = (1, 2)$$

or

$$\begin{aligned} t &= 1 \\ kt^4 &= 2 \end{aligned} \quad \Rightarrow \quad k \cdot 1^4 = 2 \quad \Rightarrow \quad k = 2$$

Substituting in (2) we obtain the following path:

$$\mathbf{c}(t) = \left(t, 2t^4\right)$$

We now show that $\mathbf{c}$ follows the gradient of $f(x, y) = 2x^2 + 8y^2$. We have

$$\mathbf{c}'(t) = \left(1, 8t^3\right) \quad \text{and} \quad \nabla f = \langle f_x, f_y\rangle = \langle 4x, 16y\rangle$$

Therefore, $\nabla f_{\mathbf{c}(t)} = \left\langle 4t, 16 \cdot 2t^4\right\rangle = \left\langle 4t, 32t^4\right\rangle$, so we obtain

$$\mathbf{c}'(t) = \left(1, 8t^3\right) = \frac{1}{4t}\left\langle 4t, 32t^4\right\rangle = \frac{1}{4t}\nabla f_{\mathbf{c}(t)}, \quad t \neq 0$$

For $t = 0$, $\nabla f_{\mathbf{c}(0)} = \nabla f_{(0,0)} = \langle 0, 0\rangle$ and $\mathbf{c}'(0) = \langle 1, 0\rangle$. We conclude that $\mathbf{c}$ follows the gradient of f for $t \neq 0$.

73. CAS Find the curve $y = g(x)$ passing through $(0, 1)$ that crosses each level curve of $f(x, y) = y \sin x$ at a right angle. If you have a computer algebra system, graph $y = g(x)$ together with the level curves of f.

SOLUTION Using $f_x = y\cos x$, $f_y = \sin x$, and $y(0) = 1$, we get

$$\frac{dy}{dx} = \frac{\tan x}{y} \quad \Rightarrow \quad y(0) = 1$$

We solve the differential equation using separation of variables:

$$y\,dy = \tan x\,dx$$
$$\int y\,dy = \int \tan x\,dx$$
$$\frac{1}{2}y^2 = -\ln|\cos x| + k$$
$$y^2 = -2\ln|\cos x| + k = -\ln\left(\cos^2 x\right) + k$$
$$y = \pm\sqrt{-\ln\left(\cos^2 x\right) + k}$$

Since $y(0) = 1 > 0$, the appropriate sign is the positive sign. That is,

$$y = \sqrt{-\ln\left(\cos^2 x\right) + k} \tag{1}$$

We find the constant k by substituting $x = 0$, $y = 1$ and solve for k. This gives

$$1 = \sqrt{-\ln\left(\cos^2 0\right) + k} = \sqrt{-\ln 1 + k} = \sqrt{k}$$

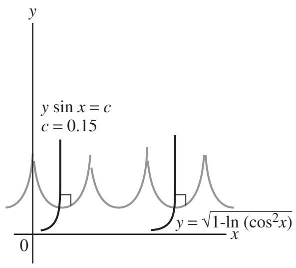
Hence,

$$k = 1$$

Substituting in (2) gives the following solution:

$$y = \sqrt{1 - \ln\left(\cos^2 x\right)} \tag{2}$$

The following figure shows the graph of the curve (3) together with some level curves of f.



14.6 The Chain Rule (LT Section 15.6)

Preliminary Questions

1. Let $f(x, y) = xy$, where $x = uv$ and $y = u + v$.

(a) What are the primary derivatives of f?

(b) What are the independent variables?

SOLUTION

(a) The primary derivatives of f are $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$.

(b) The independent variables are u and v, on which x and y depend.

In Questions 2 and 3, suppose that $f(u, v) = ue^v$, where $u = rs$ and $v = r + s$.

2. The composite function $f(u, v)$ is equal to:

(a) rse^{r+s} **(b)** re^s **(c)** rse^{rs}

SOLUTION The composite function $f(u, v)$ is obtained by replacing u and v in the formula for $f(u, v)$ by the corresponding functions $u = rs$ and $v = r + s$. This gives

$$f\left(u(r, s), v(r, s)\right) = u(r, s)e^{v(r,s)} = rse^{r+s}$$

Answer (a) is the correct answer.

3. What is the value of $f(u, v)$ at $(r, s) = (1, 1)$?

SOLUTION We compute $u = rs$ and $v = r + s$ at the point $(r, s) = (1, 1)$:

$$u(1, 1) = 1 \cdot 1 = 1; \quad v(1, 1) = 1 + 1 = 2$$

Substituting in $f(u, v) = ue^v$, we get

$$f(u, v)\Big|_{(r,s)=(1,1)} = 1 \cdot e^2 = e^2.$$

4. According to the Chain Rule, $\partial f/\partial r$ is equal to (choose the correct answer):

(a) $\frac{\partial f}{\partial x}\frac{\partial x}{\partial r} + \frac{\partial f}{\partial x}\frac{\partial x}{\partial s}$ **(b)** $\frac{\partial f}{\partial x}\frac{\partial x}{\partial r} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial r}$ **(c)** $\frac{\partial f}{\partial r}\frac{\partial r}{\partial x} + \frac{\partial f}{\partial s}\frac{\partial s}{\partial x}$

SOLUTION For a function $f(x, y)$ where $x = x(r, s)$ and $y = y(r, s)$, the Chain Rule states that the partial derivative $\frac{\partial f}{\partial r}$ is as given in (b). That is,

$$\frac{\partial f}{\partial x}\frac{\partial x}{\partial r} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial r}$$

5. Suppose that x, y, z are functions of the independent variables u, v, w. Which of the following terms appear in the Chain Rule expression for $\partial f/\partial w$?

(a) $\frac{\partial f}{\partial v}\frac{\partial x}{\partial v}$ **(b)** $\frac{\partial f}{\partial w}\frac{\partial w}{\partial x}$ **(c)** $\frac{\partial f}{\partial z}\frac{\partial z}{\partial w}$

SOLUTION By the Chain Rule, the derivative $\frac{\partial f}{\partial w}$ is

$$\frac{\partial f}{\partial w} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial w} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial w} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial w}$$

Therefore (c) is the only correct answer.

6. With notation as in the previous question, does $\partial x/\partial v$ appear in the Chain Rule expression for $\partial f/\partial u$?

SOLUTION The Chain Rule expression for $\frac{\partial f}{\partial u}$ is

$$\frac{\partial f}{\partial u} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial u} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial u}$$

The derivative $\frac{\partial x}{\partial v}$ does not appear in differentiating f with respect to the independent variable u.

Exercises

1. Let $f(x, y, z) = x^2y^3 + z^4$ and $x = s^2$, $y = st^2$, and $z = s^2t$.

(a) Calculate the primary derivatives $\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}$.

(b) Calculate $\frac{\partial x}{\partial s}, \frac{\partial y}{\partial s}, \frac{\partial z}{\partial s}$.

(c) Compute $\frac{\partial f}{\partial s}$ using the Chain Rule:

$$\frac{\partial f}{\partial s} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial s} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial s}$$

Express the answer in terms of the independent variables s, t.

SOLUTION

(a) The primary derivatives of $f(x, y, z) = x^2y^3 + z^4$ are

$$\frac{\partial f}{\partial x} = 2xy^3, \quad \frac{\partial f}{\partial y} = 3x^2y^2, \quad \frac{\partial f}{\partial z} = 4z^3$$

(b) The partial derivatives of x, y, and z with respect to s are

$$\frac{\partial x}{\partial s} = 2s, \quad \frac{\partial y}{\partial s} = t^2, \quad \frac{\partial z}{\partial s} = 2st$$

(c) We use the Chain Rule and the partial derivatives computed in parts (a) and (b) to find the following derivative:

$$\frac{\partial f}{\partial s} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial s} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial s} = 2xy^3 \cdot 2s + 3x^2y^2t^2 + 4z^3 \cdot 2st = 4xy^3s + 3x^2y^2t^2 + 8z^3st$$

To express the answer in terms of the independent variables s, t we substitute $x = s^2$, $y = st^2$, $z = s^2t$. This gives

$$\frac{\partial f}{\partial s} = 4s^2\left(st^2\right)^3 s + 3\left(s^2\right)^2\left(st^2\right)^2 t^2 + 8\left(s^2t\right)^3 st = 4s^6t^6 + 3s^6t^6 + 8s^7t^4 = 7s^6t^6 + 8s^7t^4.$$

2. Let $f(x, y) = x\cos(y)$ and $x = u^2 + v^2$ and $y = u - v$.

(a) Calculate the primary derivatives $\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}$.

(b) Use the Chain Rule to calculate $\partial f/\partial v$. Leave the answer in terms of both the dependent and the independent variables.

(c) Determine (x, y) for $(u, v) = (2, 1)$ and evaluate $\partial f/\partial v$ at $(u, v) = (2, 1)$.

SOLUTION

(a) The primary derivatives of $f(x, y) = x\cos(y)$ are

$$\frac{\partial f}{\partial x} = \cos(y), \quad \frac{\partial f}{\partial y} = -x\sin(y).$$

(b) By the Chain Rule, we have

$$\frac{\partial f}{\partial v}=\frac{\partial f}{\partial x}\frac{\partial x}{\partial v}+\frac{\partial f}{\partial y}\frac{\partial y}{\partial v} \tag{1}$$

We compute the partial derivatives $\frac{\partial x}{\partial v}$ and $\frac{\partial y}{\partial v}$:

$$\frac{\partial x}{\partial v}=2v, \quad \frac{\partial y}{\partial v}=-1.$$

Substituting these derivatives and the primary derivatives computed in part (a) in the Chain Rule (1) gives

$$\frac{\partial f}{\partial v}=\cos(y)\cdot 2v-x\sin(y)\cdot(-1)=2v\cos(y)+x\sin(y)$$

(c) We substitute $u=2$, $v=1$ in $x=u^2+v^2$ and $y=u-v$, and determine (x,y) for $(u,v)=(2,1)$. This gives

$$x=2^2+1^2=5, \quad y=2-1=1.$$

To find $\frac{\partial f}{\partial x}$ at $(u,v)=(2,1)$ we substitute $u=2$, $v=1$, $x=5$, and $y=1$ in $\frac{\partial f}{\partial v}$ computed in part (b). We obtain

$$\left.\frac{\partial f}{\partial v}\right|_{(u,v)=(2,1)}=2\cdot 1\cos 1+5\sin 1=2\cos 1+5\sin 1.$$

In Exercises 3–10, use the Chain Rule to calculate the partial derivatives. Express the answer in terms of the independent variables.

3. $\frac{\partial f}{\partial s}, \frac{\partial f}{\partial r}$; $f(x,y,z)=xy+z^2$, $x=s^2$, $y=2rs$, $z=r^2$

SOLUTION We perform the following steps:

Step 1. Compute the primary derivatives. The primary derivatives of $f(x,y,z)=xy+z^2$ are

$$\frac{\partial f}{\partial x}=y, \quad \frac{\partial f}{\partial y}=x, \quad \frac{\partial f}{\partial z}=2z$$

Step 2. Apply the Chain Rule. By the Chain Rule,

$$\frac{\partial f}{\partial s}=\frac{\partial f}{\partial x}\cdot\frac{\partial x}{\partial s}+\frac{\partial f}{\partial y}\cdot\frac{\partial y}{\partial s}+\frac{\partial f}{\partial z}\cdot\frac{\partial z}{\partial s} \tag{1}$$

$$\frac{\partial f}{\partial r}=\frac{\partial f}{\partial x}\cdot\frac{\partial x}{\partial r}+\frac{\partial f}{\partial y}\cdot\frac{\partial y}{\partial r}+\frac{\partial f}{\partial z}\cdot\frac{\partial z}{\partial r} \tag{2}$$

We compute the partial derivatives of x, y, z with respect to s and r:

$$\frac{\partial x}{\partial s}=2s, \quad \frac{\partial y}{\partial s}=2r, \quad \frac{\partial z}{\partial s}=0.$$

$$\frac{\partial x}{\partial r}=0, \quad \frac{\partial y}{\partial r}=2s, \quad \frac{\partial z}{\partial r}=2r.$$

Substituting these derivatives and the primary derivatives computed in step 1 in (1) and (2), we get

$$\frac{\partial f}{\partial s}=y\cdot 2s+x\cdot 2r+2z\cdot 0=2ys+2xr$$

$$\frac{\partial f}{\partial r}=y\cdot 0+x\cdot 2s+2z\cdot 2r=2xs+4zr$$

Step 3. Express the answer in terms of r and s. We substitute $x=s^2$, $y=2rs$, and $z=r^2$ in $\frac{\partial f}{\partial s}$ and $\frac{\partial f}{\partial r}$ in step 2, to obtain

$$\frac{\partial f}{\partial s}=2rs\cdot 2s+s^2\cdot 2r=4rs^2+2rs^2=6rs^2.$$

$$\frac{\partial f}{\partial r}=2s^2\cdot s+4r^2\cdot r=2s^3+4r^3.$$

4. $\frac{\partial f}{\partial r}, \frac{\partial f}{\partial t}$; $f(x,y,z)=xy+z^2$, $x=r+s-2t$, $y=3rt$, $z=s^2$

SOLUTION We use the following steps:

Step 1. Compute the primary derivatives. The primary derivatives of $f(x,y,z)=xy+z^2$ are

$$\frac{\partial f}{\partial x}=y, \quad \frac{\partial f}{\partial y}=x, \quad \frac{\partial f}{\partial z}=2z$$

Step 2. Apply the Chain Rule. By the Chain Rule,

$$\frac{\partial f}{\partial r} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial r} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial r} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial r} = y\frac{\partial x}{\partial r} + x\frac{\partial y}{\partial r} + 2z\frac{\partial z}{\partial r} \tag{1}$$

$$\frac{\partial f}{\partial t} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial t} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial t} = y\frac{\partial x}{\partial t} + x\frac{\partial y}{\partial t} + 2z\frac{\partial z}{\partial t} \tag{2}$$

We compute the partial derivatives of x, y with respect to r and t:

$$\frac{\partial x}{\partial r} = 1, \quad \frac{\partial y}{\partial r} = 3t, \quad \frac{\partial z}{\partial r} = 0$$

$$\frac{\partial x}{\partial t} = -2, \quad \frac{\partial y}{\partial t} = 3r, \quad \frac{\partial z}{\partial t} = 0$$

Substituting in (1) and (2), we get

$$\frac{\partial f}{\partial r} = y + 3tx + 2z \cdot 0 = y + 3xt$$

$$\frac{\partial f}{\partial t} = y \cdot (-2) + x \cdot 3r + 2z \cdot 0 = -2y + 3xr$$

Step 3. Express the answer in terms of r and t. We substitute $x = r + s - 2t$, $y = 3rt$, and $z = s^2$ in $\frac{\partial f}{\partial r}$ and $\frac{\partial f}{\partial t}$ obtained in step 2. This gives

$$\frac{\partial f}{\partial r} = 3rt + 3(r + s - 2t)t = 3rt + 3rt + 3st - 6t^2 = 6rt + 3st - 6t^2$$

$$\frac{\partial f}{\partial t} = -2 \cdot 3rt + 3(r + s - 2t)r = -6rt + 3r^2 + 3sr - 6tr = -12rt + 3rs + 3r^2$$

5. $\frac{\partial g}{\partial u}, \frac{\partial g}{\partial v}$; $g(x, y) = \cos(x - y)$, $x = 3u - 5v$, $y = -7u + 15v$

SOLUTION We use the following steps:

Step 1. Compute the primary derivatives. The primary derivatives of $g(x, y) = \cos(x - y)$ are:

$$\frac{\partial g}{\partial x} = -\sin(x - y), \quad \frac{\partial g}{\partial y} = \sin(x - y)$$

Step 2. Apply the Chain Rule. By the Chain Rule,

$$\frac{\partial g}{\partial u} = \frac{\partial g}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial g}{\partial y}\frac{\partial y}{\partial u} = -\sin(x - y)\frac{\partial x}{\partial u} + \sin(x - y)\frac{\partial y}{\partial u}$$

$$\frac{\partial g}{\partial v} = \frac{\partial g}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial g}{\partial y}\frac{\partial y}{\partial v} = -\sin(x - y)\frac{\partial x}{\partial v} + \sin(x - y)\frac{\partial y}{\partial v}$$

We compute the partial derivatives of x, y with respect to u and v:

$$\frac{\partial x}{\partial u} = 3, \quad \frac{\partial x}{\partial v} = -5$$

$$\frac{\partial y}{\partial u} = -7, \quad \frac{\partial y}{\partial v} = 15$$

substituting in the expressions above we have:

$$\frac{\partial g}{\partial u} = -\sin(x - y)(3) + \sin(x - y)(-7) = -10\sin(x - y)$$

$$\frac{\partial g}{\partial v} = -\sin(x - y)(-5) + \sin(x - y)(15) = 20\sin(x - y)$$

Step 3. Express the answer in terms of u and v. We substitute $x = 3u - 5v$ and $y = -7u + 15v$ in $\partial g/\partial u$ and $\partial g/\partial v$ found in step 2. This gives:

$$\frac{\partial g}{\partial u} = -10\sin(10u - 20v)$$

$$\frac{\partial g}{\partial v} = 20\sin(10u - 20v)$$

6. $\dfrac{\partial R}{\partial u}, \dfrac{\partial R}{\partial v}$; $R(x, y) = (3x + 4y)^5$, $x = u^2$, $y = uv$

SOLUTION We perform the following steps:

Step 1. Compute the primary derivatives. The primary derivatives of $R(x, y) = (3x + 4y)^5$ are:

$$\frac{\partial R}{\partial x} = 15(3x + 4y)^4, \quad \frac{\partial R}{\partial y} = 20(3x + 4y)^4$$

Step 2. Apply the Chain Rule. By the Chain Rule,

$$\frac{\partial R}{\partial u} = \frac{\partial R}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial R}{\partial y}\frac{\partial y}{\partial u} = 15(3x + 4y)^4 \frac{\partial x}{\partial u} + 20(3x + 4y)^4 \frac{\partial y}{\partial u}$$

$$\frac{\partial R}{\partial v} = \frac{\partial R}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial R}{\partial y}\frac{\partial y}{\partial v} = 15(3x + 4y)^4 \frac{\partial x}{\partial v} + 20(3x + 4y)^4 \frac{\partial y}{\partial v}$$

We compute the partial derivatives of x, y with respect to u and v:

$$\frac{\partial x}{\partial u} = 2u, \quad \frac{\partial x}{\partial v} = 0$$

$$\frac{\partial y}{\partial u} = v, \quad \frac{\partial y}{\partial v} = u$$

Substituting in the expressions above we get:

$$\frac{\partial R}{\partial u} = 15(3x + 4y)^4(2u) + 20(3x + 4y)^5(v) = 30(3x + 4y)^5(u) + 20v(3x + 4y)^5$$

$$\frac{\partial R}{\partial v} = 15(3x + 4y)^4(0) + 20(3x + 4y)^5(u) = 20(3x + 4y)^5(u)$$

Step 3. Express the answer in terms of u and v. We substitute $x = u^2$ and $y = uv$:

$$\frac{\partial R}{\partial u} = 30u(3u^2 + 4uv)^4 + 20v(3u^2 + 4uv)^4 = (3u^2 + 4uv)^4(30u + 20v)$$

$$\frac{\partial R}{\partial v} = 20u(3u^2 + 4uv)^4$$

7. $\dfrac{\partial F}{\partial y}$; $F(u, v) = e^{u+v}$, $u = x^2$, $v = xy$

SOLUTION We use the following steps:

Step 1. Compute the primary derivatives. The primary derivatives of $F(u, v) = e^{u+v}$ are

$$\frac{\partial f}{\partial u} = e^{u+v}, \quad \frac{\partial f}{\partial v} = e^{u+v}$$

Step 2. Apply the Chain Rule. By the Chain Rule,

$$\frac{\partial F}{\partial y} = \frac{\partial F}{\partial u}\frac{\partial u}{\partial y} + \frac{\partial F}{\partial v}\frac{\partial v}{\partial y} = e^{u+v}\frac{\partial u}{\partial y} + e^{u+v}\frac{\partial v}{\partial y} = e^{u+v}\left(\frac{\partial u}{\partial y} + \frac{\partial v}{\partial y}\right)$$

We compute the partial derivatives of u and v with respect to y:

$$\frac{\partial u}{\partial y} = 0, \quad \frac{\partial v}{\partial y} = x$$

We substitute to obtain

$$\frac{\partial F}{\partial y} = xe^{u+v} \tag{1}$$

Step 3. Express the answer in terms of x and y. We substitute $u = x^2$, $v = xy$ in (1) and (2), obtaining

$$\frac{\partial F}{\partial y} = xe^{x^2+xy}.$$

8. $\dfrac{\partial f}{\partial u}$; $f(x, y) = x^2 + y^2$, $x = e^{u+v}$, $y = u + v$

SOLUTION We use the following steps:

Step 1. Compute the primary derivatives. The primary derivatives of $f(x, y) = x^2 + y^2$ are

$$\frac{\partial f}{\partial x} = 2x, \quad \frac{\partial f}{\partial y} = 2y$$

Step 2. Apply the Chain Rule. By the Chain Rule,

$$\frac{\partial f}{\partial u} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial u} = 2x\frac{\partial x}{\partial u} + 2y\frac{\partial y}{\partial u}$$

We compute $\frac{\partial x}{\partial u}$ and $\frac{\partial y}{\partial u}$:

$$\frac{\partial x}{\partial u} = e^{u+v}, \quad \frac{\partial y}{\partial u} = 1$$

Hence,

$$\frac{\partial f}{\partial u} = 2xe^{u+v} + 2y \tag{1}$$

Step 3. Express the answer in terms of u and v. We substitute $x = e^{u+v}$ and $y = u + v$ in (1) to obtain

$$\frac{\partial f}{\partial u} = 2e^{u+v}e^{u+v} + 2(u + v) = 2\left(e^{2(u+v)} + u + v\right)$$

9. $\dfrac{\partial h}{\partial t_2}$; $h(x, y) = \dfrac{x}{y}$, $x = t_1 t_2$, $y = t_1^2 t_2$

SOLUTION We use the following steps:

Step 1. Compute the primary derivatives. The primary derivatives of $h(x, y) = \frac{x}{y}$ are

$$\frac{\partial h}{\partial x} = \frac{1}{y}, \quad \frac{\partial h}{\partial y} = -\frac{x}{y^2}$$

Step 2. Apply the Chain Rule. By the Chain Rule,

$$\frac{\partial h}{\partial t_2} = \frac{\partial h}{\partial x}\frac{\partial x}{\partial t_2} + \frac{\partial h}{\partial y}\frac{\partial y}{\partial t_2} = \frac{1}{y}\frac{\partial x}{\partial t_2} - \frac{x}{y^2}\frac{\partial y}{\partial t_2}$$

We compute the partial derivatives of x and y with respect to t_2:

$$\frac{\partial x}{\partial t_2} = t_1, \quad \frac{\partial y}{\partial t_2} = t_1^2$$

Hence,

$$\frac{\partial h}{\partial t_2} = \frac{t_1}{y} - \frac{x}{y^2}t_1^2$$

Step 3. Express the answer in terms of t_1 and t_2. We substitute $x = t_1 t_2$, $y = t_1^2 t_2$ in $\frac{\partial h}{\partial t_2}$ computed in step 2, to obtain

$$\frac{\partial h}{\partial t_2} = \frac{t_1}{t_1^2 t_2} - \frac{t_1 t_2 \cdot t_1^2}{\left(t_1^2 t_2\right)^2} = \frac{1}{t_1 t_2} - \frac{1}{t_1 t_2} = 0$$

Remark: Notice that $h\left(x(t_1, t_2), y(t_1, t_2)\right) = h(t_1, t_2) = \frac{t_1 t_2}{t_1^2 t_2} = \frac{1}{t_1}$. $h(t_1, t_2)$ is independent of t_2, hence $\frac{\partial h}{\partial t_2} = 0$ (as obtained in our computations).

10. $\dfrac{\partial f}{\partial \theta}$; $f(x, y, z) = xy - z^2$, $x = r\cos\theta$, $y = \cos^2\theta$, $z = r$

SOLUTION We use the following steps:

Step 1. Compute the primary derivatives. The primary derivatives of $f(x, y, z) = xy - z^2$ are

$$\frac{\partial f}{\partial x} = y, \quad \frac{\partial f}{\partial y} = x, \quad \frac{\partial f}{\partial z} = -2z$$

Step 2. Apply the Chain Rule. By the Chain Rule,

$$\frac{\partial f}{\partial \theta}=\frac{\partial f}{\partial x}\frac{\partial x}{\partial \theta}+\frac{\partial f}{\partial y}\frac{\partial y}{\partial \theta}+\frac{\partial f}{\partial z}\frac{\partial z}{\partial \theta}=y\frac{\partial x}{\partial \theta}+x\frac{\partial y}{\partial \theta}-2z\frac{\partial z}{\partial \theta}$$

We compute the partial derivatives of x, y, and z with respect to θ:

$$\frac{\partial x}{\partial \theta}=-r\sin\theta,\quad \frac{\partial y}{\partial \theta}=-2\cos\theta\sin\theta=-\sin 2\theta,\quad \frac{\partial z}{\partial \theta}=0$$

Step 3. Express the answer in terms of θ and r. We substitute $x=r\cos\theta$, $y=\cos^2\theta$, and $z=r$ in (1) to obtain

$$\frac{\partial f}{\partial \theta}=-r\cos^2\theta\sin\theta-r\cos\theta\sin 2\theta=-r\cdot\frac{1}{2}\cos\theta\sin 2\theta-r\cos\theta\sin 2\theta=-\frac{3}{2}\cos\theta\sin 2\theta$$

In Exercises 11–16, use the Chain Rule to evaluate the partial derivative at the point specified.

11. $\partial f/\partial u$ and $\partial f/\partial v$ at $(u,v)=(-1,-1)$, where $f(x,y,z)=x^3+yz^2$, $x=u^2+v$, $y=u+v^2$, $z=uv$.

SOLUTION The primary derivatives of $f(x,y,z)=x^3+yz^2$ are

$$\frac{\partial f}{\partial x}=3x^2,\quad \frac{\partial f}{\partial y}=z^2,\quad \frac{\partial f}{\partial z}=2yz$$

By the Chain Rule we have

$$\frac{\partial f}{\partial u}=\frac{\partial f}{\partial x}\frac{\partial x}{\partial u}+\frac{\partial f}{\partial y}\frac{\partial y}{\partial u}+\frac{\partial f}{\partial z}\frac{\partial z}{\partial u}=3x^2\frac{\partial x}{\partial u}+z^2\frac{\partial y}{\partial u}+2yz\frac{\partial z}{\partial u} \tag{1}$$

$$\frac{\partial f}{\partial v}=\frac{\partial f}{\partial x}\frac{\partial x}{\partial v}+\frac{\partial f}{\partial y}\frac{\partial y}{\partial v}+\frac{\partial f}{\partial z}\frac{\partial z}{\partial v}=3x^2\frac{\partial x}{\partial v}+z^2\frac{\partial y}{\partial v}+2yz\frac{\partial z}{\partial v} \tag{2}$$

We compute the partial derivatives of x, y, and z with respect to u and v:

$$\frac{\partial x}{\partial u}=2u,\quad \frac{\partial y}{\partial u}=1,\quad \frac{\partial z}{\partial u}=v$$

$$\frac{\partial x}{\partial v}=1,\quad \frac{\partial y}{\partial v}=2v,\quad \frac{\partial z}{\partial v}=u$$

Substituting in (1) and (2) we get

$$\frac{\partial f}{\partial u}=6x^2u+z^2+2yzv \tag{3}$$

$$\frac{\partial f}{\partial v}=3x^2+2vz^2+2yzu \tag{4}$$

We determine (x,y,z) for $(u,v)=(-1,-1)$:

$$x=(-1)^2-1=0,\quad y=-1+(-1)^2=0,\quad z=(-1)\cdot(-1)=1.$$

Finally, we substitute $(x,y,z)=(0,0,1)$ and $(u,v)=(-1,-1)$ in (3), (4) to obtain the following derivatives:

$$\left.\frac{\partial f}{\partial u}\right|_{(u,v)=(-1,-1)}=6\cdot 0^2\cdot(-1)+1^2+2\cdot 0\cdot 1\cdot(-1)=1$$

$$\left.\frac{\partial f}{\partial v}\right|_{(u,v)=(-1,-1)}=3\cdot 0^2+2\cdot(-1)\cdot 1^2+2\cdot 0\cdot 1\cdot(-1)=-2$$

12. $\partial f/\partial s$ at $(r,s)=(1,0)$, where $f(x,y)=\ln(xy)$, $x=3r+2s$, $y=5r+3s$.

SOLUTION The primary derivatives of $f(x,y)=\ln(xy)$ are

$$\frac{\partial f}{\partial x}=\frac{y}{xy}=\frac{1}{x},\quad \frac{\partial f}{\partial y}=\frac{x}{xy}=\frac{1}{y}$$

By the Chain Rule we have

$$\frac{\partial f}{\partial s}=\frac{\partial f}{\partial x}\frac{\partial x}{\partial s}+\frac{\partial f}{\partial y}\frac{\partial y}{\partial s}=\frac{1}{x}\frac{\partial x}{\partial s}+\frac{1}{y}\frac{\partial y}{\partial s} \tag{1}$$

We compute $\frac{\partial x}{\partial s}$ and $\frac{\partial y}{\partial s}$:

$$\frac{\partial x}{\partial s} = 2, \quad \frac{\partial y}{\partial s} = 3$$

Substituting in (1) we get

$$\frac{\partial f}{\partial s} = \frac{2}{x} + \frac{3}{y} \tag{2}$$

We now must determine (x, y) for $(s, r) = (1, 0)$:

$$x = 3 \cdot 0 + 2 \cdot 1 = 2, \quad y = 5 \cdot 0 + 3 \cdot 1 = 3$$

Substituting in (2) gives the following derivative:

$$\left.\frac{\partial f}{\partial s}\right|_{(s,r)=(1,0)} = \frac{2}{2} + \frac{3}{3} = 2$$

13. $\partial g/\partial\theta$ at $(r, \theta) = \left(2\sqrt{2}, \frac{\pi}{4}\right)$, where $g(x, y) = 1/(x + y^2)$, $x = r\sin\theta$, $y = r\cos\theta$.

SOLUTION We compute the primary derivatives of $g(x, y) = \frac{1}{x+y^2}$:

$$\frac{\partial g}{\partial x} = -\frac{1}{(x + y^2)^2}, \quad \frac{\partial g}{\partial y} = -\frac{2y}{(x + y^2)^2}$$

By the Chain Rule we have

$$\frac{\partial g}{\partial \theta} = \frac{\partial g}{\partial x}\frac{\partial x}{\partial \theta} + \frac{\partial g}{\partial y}\frac{\partial y}{\partial \theta} = -\frac{1}{(x + y^2)^2}\frac{\partial x}{\partial \theta} - \frac{2y}{(x + y^2)^2}\frac{\partial y}{\partial \theta} = -\frac{1}{(x + y^2)^2}\left(\frac{\partial x}{\partial \theta} + 2y\frac{\partial y}{\partial \theta}\right)$$

We find the partial derivatives $\frac{\partial x}{\partial \theta}$, $\frac{\partial y}{\partial \theta}$:

$$\frac{\partial x}{\partial \theta} = r\cos\theta, \quad \frac{\partial y}{\partial \theta} = -r\sin\theta$$

Hence,

$$\frac{\partial g}{\partial \theta} = -\frac{r}{(x + y^2)^2}(\cos\theta - 2y\sin\theta) \tag{1}$$

At the point $(r, \theta) = \left(2\sqrt{2}, \frac{\pi}{4}\right)$, we have $x = 2\sqrt{2}\sin\frac{\pi}{4} = 2$ and $y = 2\sqrt{2}\cos\frac{\pi}{4} = 2$. Substituting $(r, \theta) = \left(2\sqrt{2}, \frac{\pi}{4}\right)$ and $(x, y) = (2, 2)$ in (1) gives the following derivative:

$$\left.\frac{\partial g}{\partial \theta}\right|_{(r,\theta)=\left(2\sqrt{2}, \frac{\pi}{4}\right)} = \frac{-2\sqrt{2}}{(2 + 2^2)^2}\left(\cos\frac{\pi}{4} - 4\sin\frac{\pi}{4}\right) = \frac{-\sqrt{2}}{18}\left(\frac{1}{\sqrt{2}} - \frac{4}{\sqrt{2}}\right) = \frac{1}{6}.$$

14. $\partial g/\partial s$ at $s = 4$, where $g(x, y) = x^2 - y^2$, $x = s^2 + 1$, $y = 1 - 2s$.

SOLUTION We find the primary derivatives of $g(x, y) = x^2 - y^2$:

$$\frac{\partial g}{\partial x} = 2x, \quad \frac{\partial g}{\partial y} = -2y$$

Applying the Chain Rule gives

$$\frac{\partial g}{\partial s} = \frac{\partial g}{\partial x} \cdot \frac{dx}{ds} + \frac{\partial g}{\partial y} \cdot \frac{dy}{ds} = 2x\frac{dx}{ds} - 2y\frac{dy}{ds} \tag{1}$$

We compute $\frac{dx}{ds}$ and $\frac{dy}{ds}$:

$$\frac{dx}{ds} = 2s, \quad \frac{dy}{ds} = -2$$

Substituting in (1) we obtain

$$\frac{\partial g}{\partial s} = 4xs + 4y \tag{2}$$

We now determine (x, y) for $s = 4$:

$$x = 4^2 + 1 = 17, \quad y = 1 - 2 \cdot 4 = -7$$

Substituting $(x, y) = (17, -7)$ and $s = 4$ in (2) gives the following derivative:

$$\left.\frac{\partial g}{\partial s}\right|_{s=4} = 4 \cdot 17 \cdot 4 - 4 \cdot 7 = 244$$

15. $\partial g/\partial u$ at $(u, v) = (0, 1)$, where $g(x, y) = x^2 - y^2$, $x = e^u \cos v$, $y = e^u \sin v$.

SOLUTION The primary derivatives of $g(x, y) = x^2 - y^2$ are

$$\frac{\partial g}{\partial x} = 2x, \quad \frac{\partial g}{\partial y} = -2y$$

By the Chain Rule we have

$$\frac{\partial g}{\partial u} = \frac{\partial g}{\partial x} \cdot \frac{\partial x}{\partial u} + \frac{\partial g}{\partial y} \cdot \frac{\partial y}{\partial u} = 2x\frac{\partial x}{\partial u} - 2y\frac{\partial y}{\partial u} \tag{1}$$

We find $\frac{\partial x}{\partial u}$ and $\frac{\partial y}{\partial u}$:

$$\frac{\partial x}{\partial u} = e^u \cos v, \quad \frac{\partial y}{\partial u} = e^u \sin v$$

Substituting in (1) gives

$$\frac{\partial g}{\partial u} = 2xe^u \cos v - 2ye^u \sin v = 2e^u(x \cos v - y \sin v) \tag{2}$$

We determine (x, y) for $(u, v) = (0, 1)$:

$$x = e^0 \cos 1 = \cos 1, \quad y = e^0 \sin 1 = \sin 1$$

Finally, we substitute $(u, v) = (0, 1)$ and $(x, y) = (\cos 1, \sin 1)$ in (2) and use the identity $\cos^2\alpha - \sin^2\alpha = \cos 2\alpha$, to obtain the following derivative:

$$\left.\frac{\partial g}{\partial u}\right|_{(u,v)=(0,1)} = 2e^0\left(\cos^2 1 - \sin^2 1\right) = 2 \cdot \cos 2 \cdot 1 = 2\cos 2$$

16. $\frac{\partial h}{\partial q}$ at $(q, r) = (3, 2)$, where $h(u, v) = ue^v$, $u = q^3$, $v = qr^2$.

SOLUTION We first find the primary derivatives of $h(u, v) = ue^v$:

$$\frac{\partial h}{\partial u} = e^v, \quad \frac{\partial h}{\partial v} = ue^v$$

By the Chain Rule, we have

$$\frac{\partial h}{\partial q} = \frac{\partial h}{\partial u} \cdot \frac{\partial u}{\partial q} + \frac{\partial h}{\partial v} \cdot \frac{\partial v}{\partial q} = e^v\frac{\partial u}{\partial q} + ue^v\frac{\partial v}{\partial q} = e^v\left(\frac{\partial u}{\partial q} + u\frac{\partial v}{\partial q}\right) \tag{1}$$

We compute $\frac{\partial u}{\partial q}$ and $\frac{\partial v}{\partial q}$:

$$\frac{\partial u}{\partial q} = 3q^2, \quad \frac{\partial v}{\partial q} = r^2$$

Substituting in (1) gives

$$\frac{\partial h}{\partial q} = e^v\left(3q^2 + ur^2\right) \tag{2}$$

We now determine (u, v) for $(q, r) = (3, 2)$:

$$u = 3^3 = 27, \quad v = 3 \cdot 2^2 = 12$$

Substituting in (2) gives the following derivative:

$$\left.\frac{\partial h}{\partial q}\right|_{(q,r)=(3,2)} = e^{12}\left(3 \cdot 3^2 + 27 \cdot 2^2\right) = 135e^{12}$$

17. Jessica and Matthew are running toward the point P along the straight paths that make a fixed angle of θ (Figure 3). Suppose that Matthew runs with velocity v_a m/s and Jessica with velocity v_b m/s. Let $f(x, y)$ be the distance from Matthew to Jessica when Matthew is x meters from P and Jessica is y meters from P.

(a) Show that $f(x, y) = \sqrt{x^2 + y^2 - 2xy\cos\theta}$.

(b) Assume that $\theta = \pi/3$. Use the Chain Rule to determine the rate at which the distance between Matthew and Jessica is changing when $x = 30$, $y = 20$, $v_a = 4$ m/s, and $v_b = 3$ m/s.

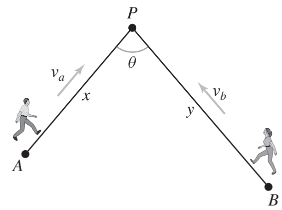


FIGURE 3

SOLUTION

(a) This is a simple application of the Law of Cosines. Connect points A and B in the diagram to form a line segment that we will call f. Then, the Law of Cosines says that $f^2 = x^2 + y^2 - 2xy\cos\theta$. By taking square roots, we find that $f = \sqrt{x^2 + y^2 - 2xy\cos\theta}$.

(b) Using the chain rule,

$$\frac{df}{dt} = \frac{\partial f}{\partial x}\frac{dx}{dt} + \frac{\partial f}{\partial y}\frac{dy}{dt}$$

so we get

$$\frac{df}{dt} = \frac{(x - y\cos\theta)dx/dt}{\sqrt{x^2 + y^2 - 2xy\cos\theta}} + \frac{(y - x\cos\theta)dy/dt}{\sqrt{x^2 + y^2 - 2xy\cos\theta}}$$

and using $x = 30$, $y = 20$, and $dx/dt = 4$, $dy/dt = 3$, we get

$$\frac{df}{dt} = \frac{180 - 170\cos\theta}{\sqrt{1300 - 1200\cos\theta}}$$

18. The Law of Cosines states that $c^2 = a^2 + b^2 - 2ab\cos\theta$, where a, b, c are the sides of a triangle and θ is the angle opposite the side of length c.

(a) Compute $\partial\theta/\partial a$, $\partial\theta/\partial b$, and $\partial\theta/\partial c$ using implicit differentiation.

(b) Suppose that $a = 10$, $b = 16$, $c = 22$. Estimate the change in θ if a and b are increased by 1 and c is increased by 2.

SOLUTION

(a) Let $F(a, b, c, \theta) = a^2 + b^2 - 2ab\cos\theta - c^2$. We use the formulas obtained by implicit differentiation (Eq. (7)) to write

$$\frac{\partial\theta}{\partial a} = -\frac{\frac{\partial F}{\partial a}}{\frac{\partial F}{\partial\theta}}, \quad \frac{\partial\theta}{\partial b} = -\frac{\frac{\partial F}{\partial b}}{\frac{\partial F}{\partial\theta}}, \quad \frac{\partial\theta}{\partial c} = -\frac{\frac{\partial F}{\partial c}}{\frac{\partial F}{\partial\theta}} \tag{1}$$

The partial derivatives of F are

$$\frac{\partial F}{\partial a} = 2a - 2b\cos\theta, \quad \frac{\partial F}{\partial b} = 2b - 2a\cos\theta, \quad \frac{\partial F}{\partial c} = -2c, \quad \frac{\partial F}{\partial\theta} = 2ab\sin\theta$$

Substituting these derivatives in (1), we obtain

$$\frac{\partial\theta}{\partial a} = -\frac{2a - 2b\cos\theta}{2ab\sin\theta} = -\frac{a - b\cos\theta}{ab\sin\theta}$$
$$\frac{\partial\theta}{\partial b} = -\frac{2b - 2a\cos\theta}{2ab\sin\theta} = -\frac{b - a\cos\theta}{ab\sin\theta}$$
$$\frac{\partial\theta}{\partial c} = -\frac{-2c}{2ab\sin\theta} = \frac{c}{ab\sin\theta}$$

(b) The linear approximation for θ is

$$\Delta\theta \approx \frac{\partial\theta}{\partial a}\Delta a + \frac{\partial\theta}{\partial b}\Delta b + \frac{\partial\theta}{\partial c}\Delta c = \frac{\partial\theta}{\partial a}\cdot 1 + \frac{\partial\theta}{\partial b}\cdot 1 + \frac{\partial\theta}{\partial c}\cdot 2 \tag{2}$$

We find the partial derivatives for $a = 10$, $b = 16$, $c = 22$. We first find θ using the relation $c^2 = a^2 + b^2 - 2ab\cos\theta$. This gives

$$22^2 = 10^2 + 16^2 - 2 \cdot 10 \cdot 16\cos\theta$$
$$484 = 356 - 320\cos\theta$$
$$\cos\theta = \frac{356 - 484}{320} = -0.4 \quad \Rightarrow \quad \theta \approx 1.98 \text{ rad}$$

We now substitute $(a, b, c, \theta) = (10, 16, 22, 1.98)$ in the partial derivatives of θ to obtain

$$\frac{\partial\theta}{\partial a} = -\frac{10 - 16\cos 1.98}{10 \cdot 16\sin 1.98} \approx -0.111$$
$$\frac{\partial\theta}{\partial b} = -\frac{16 - 10\cos 1.98}{10 \cdot 16\sin 1.98} \approx -0.136$$
$$\frac{\partial\theta}{\partial c} = \frac{22}{10 \cdot 16\sin 1.98} \approx 0.15$$

Substituting in (2) gives the following estimation for $\Delta\theta$:

$$\Delta\theta \approx -0.111 - 0.136 + 2 \cdot 0.15 = 0.053$$

We conclude that the angle θ will increase by approximately 0.053 rad.

19. Let $u = u(x, y)$, and let (r, θ) be polar coordinates. Verify the relation

$$\|\nabla u\|^2 = u_r^2 + \frac{1}{r^2}u_\theta^2 \qquad \boxed{8}$$

Hint: Compute the right-hand side by expressing u_θ and u_r in terms of u_x and u_y.

SOLUTION By the Chain Rule we have

$$u_\theta = u_x x_\theta + u_y y_\theta \tag{1}$$
$$u_r = u_x x_r + u_y y_r \tag{2}$$

Since $x = r\cos\theta$ and $y = r\sin\theta$, the partial derivatives of x and y with respect to r and θ are

$$x_\theta = -r\sin\theta, \quad y_\theta = r\cos\theta$$
$$x_r = \cos\theta, \quad y_r = \sin\theta$$

Substituting in (1) and (2) gives

$$u_\theta = (-r\sin\theta)u_x + (r\cos\theta)u_y \tag{3}$$
$$u_r = (\cos\theta)u_x + (\sin\theta)u_y \tag{4}$$

We now solve these equations for u_x and u_y in terms of u_θ and u_r. Multiplying (3) by $(-\sin\theta)$ and (4) by $r\cos\theta$ and adding the resulting equations gives

$$\begin{array}{rl} (-\sin\theta)u_\theta &= (r\sin^2\theta)u_x - (r\cos\theta\sin\theta)u_y \\ + \quad r\cos\theta u_r &= (r\cos^2\theta)u_x + (r\cos\theta\sin\theta)u_y \\ \hline (r\cos\theta)u_r - (\sin\theta)u_\theta &= ru_x \end{array}$$

or

$$u_x = (\cos\theta)u_r - \frac{\sin\theta}{r}u_\theta \tag{5}$$

Similarly, we multiply (3) by $\cos\theta$ and (4) by $r\sin\theta$ and add the resulting equations. We get

$$\begin{array}{rl} (\cos\theta)u_\theta &= (-r\sin\theta\cos\theta)u_x + \left(r\cos^2\theta\right)u_y \\ + \quad r\sin\theta u_r &= (r\sin\theta\cos\theta)u_x + (r\sin^2\theta)u_y \\ \hline (\cos\theta)u_\theta + (r\sin\theta)u_r &= ru_y \end{array}$$

or

$$u_y = (\sin\theta)u_r + \frac{\cos\theta}{r}u_\theta \tag{6}$$

We now use (5) and (6) to compute $\|\nabla u\|^2$ in terms of u_r and u_θ. We get

$$\begin{aligned}
\|\nabla u\|^2 = u_x^2 + u_y^2 &= \left((\cos\theta)u_r - \frac{\sin\theta}{r}u_\theta\right)^2 + \left((\sin\theta)u_r + \frac{\cos\theta}{r}u_\theta\right)^2 \\
&= \left(\cos^2\theta\right)u_r^2 - \frac{2\cos\theta\sin\theta}{r}u_r u_\theta + \frac{\sin^2\theta}{r^2}u_\theta^2 + \left(\sin^2\theta\right)u_r^2 + \frac{2\sin\theta\cos\theta}{r}u_r u_\theta + \frac{\cos^2\theta}{r^2}u_\theta^2 \\
&= \left(\cos^2\theta + \sin^2\theta\right)u_r^2 + \frac{1}{r^2}\left(\sin^2\theta + \cos^2\theta\right)u_\theta^2 = u_r^2 + \frac{1}{r^2}u_\theta^2
\end{aligned}$$

That is,

$$\|\nabla u\|^2 = u_r^2 + \frac{1}{r^2}u_\theta^2$$

20. Let $u(r,\theta) = r^2\cos^2\theta$. Use Eq. (8) to compute $\|\nabla u\|^2$. Then compute $\|\nabla u\|^2$ directly by observing that $u(x,y) = x^2$, and compare.

SOLUTION By Eq. (8) we have

$$\|\nabla u\|^2 = u_r^2 + \frac{1}{r^2}u_\theta^2$$

We compute the partial derivatives of $u(r,\theta) = r^2\cos^2\theta$:

$$u_r = 2r\cos^2\theta, \quad u_\theta = r^2 \cdot 2\cos\theta(-\sin\theta) = -2r^2\cos\theta\sin\theta$$

Substituting in Eq. (8) we get

$$\begin{aligned}
\|\nabla u\|^2 &= \left(2r\cos^2\theta\right)^2 + \frac{1}{r^2}\left(-2r^2\cos\theta\sin\theta\right)^2 = 4r^2\cos^4\theta + 4r^2\cos^2\theta\sin^2\theta \\
&= 4r^2\cos^2\theta(\cos^2\theta + \sin^2\theta) = 4r^2\cos^2\theta
\end{aligned}$$

That is,

$$\|\nabla u\|^2 = 4r^2\cos^2\theta \tag{1}$$

We now compute $\|\nabla u\|^2$ directly. We first express $u(r,\theta)$ as a function of x and y. Since $x = r\cos\theta$, we have

$$u(x,y) = x^2$$

Hence $u_x = 2x$, $u_y = 0$, so we obtain

$$\|\nabla u\|^2 = u_x^2 + u_y^2 = (2x)^2 + 0^2 = 4x^2 = 4(r\cos\theta)^2 = 4r^2\cos^2\theta$$

The answer agrees with the result in (1), as expected.

21. Let $x = s + t$ and $y = s - t$. Show that for any differentiable function $f(x,y)$,

$$\left(\frac{\partial f}{\partial x}\right)^2 - \left(\frac{\partial f}{\partial y}\right)^2 = \frac{\partial f}{\partial s}\frac{\partial f}{\partial t}$$

SOLUTION By the Chain Rule we have

$$\begin{aligned}
\frac{\partial f}{\partial s} &= \frac{\partial f}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial s} = \frac{\partial f}{\partial x}\cdot 1 + \frac{\partial f}{\partial y}\cdot 1 = \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} \\
\frac{\partial f}{\partial t} &= \frac{\partial f}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial t} = \frac{\partial f}{\partial x}\cdot 1 + \frac{\partial f}{\partial y}\cdot(-1) = \frac{\partial f}{\partial x} - \frac{\partial f}{\partial y}
\end{aligned}$$

Hence, using the algebraic identity $(a+b)(a-b) = a^2 - b^2$, we get

$$\frac{\partial f}{\partial s}\cdot\frac{\partial f}{\partial t} = \left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}\right)\cdot\left(\frac{\partial f}{\partial x} - \frac{\partial f}{\partial y}\right) = \left(\frac{\partial f}{\partial x}\right)^2 - \left(\frac{\partial f}{\partial y}\right)^2.$$

22. Express the derivatives

$$\frac{\partial f}{\partial \rho}, \frac{\partial f}{\partial \theta}, \frac{\partial f}{\partial \phi} \quad \text{in terms of} \quad \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}$$

where (ρ, θ, ϕ) are spherical coordinates.

SOLUTION The spherical coordinates are

$$x = \rho \sin\phi \cos\theta, \quad y = \rho \sin\phi \sin\theta, \quad z = \rho \cos\phi \tag{1}$$

We apply the Chain Rule to write

$$\begin{aligned}
\frac{\partial f}{\partial \rho} &= \frac{\partial f}{\partial x}\frac{\partial x}{\partial \rho} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial \rho} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial \rho}\\
\frac{\partial f}{\partial \theta} &= \frac{\partial f}{\partial x}\frac{\partial x}{\partial \theta} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial \theta} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial \theta}\\
\frac{\partial f}{\partial \phi} &= \frac{\partial f}{\partial x}\frac{\partial x}{\partial \phi} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial \phi} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial \phi}
\end{aligned} \tag{2}$$

We use (1) to compute the partial derivatives of x, y, and z with respect to ρ, θ, and ϕ. This gives

$$\begin{aligned}
&\frac{\partial x}{\partial \theta} = -\rho \sin\phi \sin\theta, \quad &&\frac{\partial y}{\partial \theta} = \rho \sin\phi \cos\theta, \quad &&\frac{\partial z}{\partial \theta} = 0\\
&\frac{\partial x}{\partial \phi} = \rho \cos\phi \cos\theta, \quad &&\frac{\partial y}{\partial \phi} = \rho \cos\phi \sin\theta, \quad &&\frac{\partial z}{\partial \phi} = -\rho \sin\phi\\
&\frac{\partial x}{\partial \rho} = \sin\phi \cos\theta, \quad &&\frac{\partial y}{\partial \rho} = \sin\phi \sin\theta, \quad &&\frac{\partial z}{\partial \rho} = \cos\phi
\end{aligned}$$

Substituting these derivatives in (2), we get

$$\begin{aligned}
\frac{\partial f}{\partial \rho} &= (\sin\phi\cos\theta)\frac{\partial f}{\partial x} + (\sin\phi\sin\theta)\frac{\partial f}{\partial y} + (\cos\phi)\frac{\partial f}{\partial z}\\
\frac{\partial f}{\partial \phi} &= (\rho\cos\phi\cos\theta)\frac{\partial f}{\partial x} + (\rho\cos\phi\sin\theta)\frac{\partial f}{\partial y} - (\rho\sin\phi)\frac{\partial f}{\partial z}\\
\frac{\partial f}{\partial \theta} &= (-\rho\sin\phi\sin\theta)\frac{\partial f}{\partial x} + (\rho\sin\phi\cos\theta)\frac{\partial f}{\partial y}
\end{aligned}$$

23. Suppose that z is defined implicitly as a function of x and y by the equation $F(x, y, z) = xz^2 + y^2z + xy - 1 = 0$.

(a) Calculate F_x, F_y, F_z.

(b) Use Eq. (7) to calculate $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$.

SOLUTION

(a) The partial derivatives of F are

$$F_x = z^2 + y, \quad F_y = 2yz + x, \quad F_z = 2xz + y^2$$

(b) By Eq. (7) we have

$$\begin{aligned}
\frac{\partial z}{\partial x} &= -\frac{F_x}{F_z} = -\frac{z^2 + y}{2xz + y^2}\\
\frac{\partial z}{\partial y} &= -\frac{F_y}{F_z} = -\frac{2yz + x}{2xz + y^2}
\end{aligned}$$

24. Calculate $\partial z/\partial x$ and $\partial z/\partial y$ at the points $(3, 2, 1)$ and $(3, 2, -1)$, where z is defined implicitly by the equation $z^4 + z^2x^2 - y - 8 = 0$.

SOLUTION For $F(x, y, z) = z^4 + z^2x^2 - y - 8 = 0$, we use the following equalities, (Eq. (7)):

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z}, \quad \frac{\partial z}{\partial y} = -\frac{F_y}{F_z} \tag{1}$$

The partial derivatives of F are

$$F_x = 2z^2x, \quad F_y = -1, \quad F_z = 4z^3 + 2zx^2$$

Substituting in (1) gives

$$\begin{aligned}
\frac{\partial z}{\partial x} &= -\frac{2z^2x}{4z^3 + 2zx^2} = -\frac{zx}{2z^2 + x^2}\\
\frac{\partial z}{\partial y} &= \frac{1}{4z^3 + 2zx^2}
\end{aligned}$$

At the point (3, 2, 1), we have

$$\left.\frac{\partial z}{\partial x}\right|_{(3,2,1)} = -\frac{1 \cdot 3}{2 \cdot 1^2 + 3^2} = -\frac{3}{11}, \quad \left.\frac{\partial z}{\partial y}\right|_{(3,2,1)} = \frac{1}{4 \cdot 1^3 + 2 \cdot 1 \cdot 3^2} = \frac{1}{22}$$

At the point (3, 2, −1), we have

$$\left.\frac{\partial z}{\partial x}\right|_{(3,2,-1)} = -\frac{-3}{2 \cdot (-1)^2 + 3^2} = \frac{3}{11}$$

$$\left.\frac{\partial z}{\partial y}\right|_{(3,2,-1)} = \frac{1}{4 \cdot (-1)^3 + 2 \cdot (-1) \cdot 3^2} = -\frac{1}{22}$$

In Exercises 25–30, calculate the partial derivative using implicit differentiation.

25. $\frac{\partial z}{\partial x}$, $\quad x^2y + y^2z + xz^2 = 10$

SOLUTION For $F(x, y, z) = x^2y + y^2z + xz^2 = 10$ we have

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} \tag{1}$$

We compute the partial derivatives of F:

$$F_x = 2xy + z^2, \quad F_z = y^2 + 2xz$$

Substituting in (1) gives the following derivative:

$$\frac{\partial z}{\partial x} = -\frac{2xy + z^2}{2xz + y^2}$$

26. $\frac{\partial w}{\partial z}$, $\quad x^2w + w^3 + wz^2 + 3yz = 0$

SOLUTION We find the partial derivatives F_w and F_z of

$$F(x, w, z) = x^2w + w^3 + wz^2 + 3yz$$
$$F_w = x^2 + 3w^2 + z^2, \quad F_z = 2wz + 3y$$

Using Eq. (7) we get

$$\frac{\partial w}{\partial z} = -\frac{F_z}{F_w} = -\frac{2wz + 3y}{x^2 + 3w^2 + z^2}.$$

27. $\frac{\partial z}{\partial y}$, $\quad e^{xy} + \sin(xz) + y = 0$

SOLUTION We use Eq. (7):

$$\frac{\partial z}{\partial y} = -\frac{F_y}{F_z} \tag{1}$$

The partial derivatives of $F(x, y, z) = e^{xy} + \sin(xz) + y$ are

$$F_y = xe^{xy} + 1, \quad F_z = x\cos(xz)$$

Substituting in (1), we get

$$\frac{\partial z}{\partial y} = -\frac{xe^{xy} + 1}{x\cos(xz)}$$

28. $\frac{\partial r}{\partial t}$ and $\frac{\partial t}{\partial r}$, $\quad r^2 = te^{s/r}$

SOLUTION We use the formulas obtained by implicit differentiation of $F(r, s, t) = r^2 - te^{s/r}$ (Eq. (7)):

$$\frac{\partial r}{\partial t} = -\frac{F_t}{F_r}, \quad \frac{\partial t}{\partial r} = -\frac{F_r}{F_t} \tag{1}$$

The partial derivatives of F are

$$F_r = 2r - te^{s/r}\left(-\frac{s}{r^2}\right) = 2r + \frac{st}{r^2}e^{s/r}$$

$$F_t = -e^{s/r}$$

Substituting in (1) gives

$$\frac{\partial r}{\partial t} = \frac{e^{s/r}}{2r + \frac{st}{r^2}e^{s/r}} = \frac{r^2 e^{s/r}}{2r^3 + ste^{s/r}}$$

$$\frac{\partial t}{\partial r} = \frac{2r + \frac{st}{r^2}e^{s/r}}{e^{s/r}} = \frac{2r^3 + ste^{s/r}}{r^2 e^{s/r}} = 2re^{-s/r} + \frac{st}{r^2}$$

29. $\frac{\partial w}{\partial y}$, $\quad \frac{1}{w^2 + x^2} + \frac{1}{w^2 + y^2} = 1$ at $(x, y, w) = (1, 1, 1)$

SOLUTION Using the formula obtained by implicit differentiation (Eq. (7)), we have

$$\frac{\partial w}{\partial y} = -\frac{F_y}{F_w} \tag{1}$$

We find the partial derivatives of $F(x, y, w) = \frac{1}{w^2+x^2} + \frac{1}{w^2+y^2} - 1$:

$$F_y = -\frac{2y}{\left(w^2 + y^2\right)^2}, \quad F_w = \frac{-2w}{\left(w^2 + x^2\right)^2} - \frac{2w}{\left(w^2 + y^2\right)^2}$$

We substitute in (1) to obtain

$$\frac{\partial w}{\partial y} = -\frac{\frac{-2y}{\left(w^2+y^2\right)^2}}{\frac{-2w}{\left(w^2+x^2\right)^2} - \frac{2w}{\left(w^2+y^2\right)^2}} = -\frac{y\left(w^2 + x^2\right)^2}{w\left(w^2 + y^2\right)^2 + w\left(w^2 + x^2\right)^2} = \frac{-y\left(w^2 + x^2\right)^2}{w\left(\left(w^2 + y^2\right)^2 + \left(w^2 + x^2\right)^2\right)}$$

30. $\partial U/\partial T$ and $\partial T/\partial U$, $\quad (TU - V)^2 \ln(W - UV) = 1$ at $(T, U, V, W) = (1, 1, 2, 4)$

SOLUTION Using the formulas obtained by implicit differentiation (Eq. (7)) we have,

$$\frac{\partial U}{\partial T} = -\frac{F_T}{F_U}, \quad \frac{\partial T}{\partial U} = -\frac{F_U}{F_T} \tag{1}$$

We compute the partial derivatives of $F(T, U, V, W) = (TU - V)^2 \ln(W - UV) - 1$:

$$F_T = 2U(TU - V)\ln(W - UV)$$

$$F_U = 2T(TU - V)\ln(W - UV) + (TU - V)^2 \cdot \frac{-V}{W - UV}$$

$$= (TU - V)\left(2T\ln(W - UV) - \frac{V(TU - V)}{W - UV}\right)$$

At the point $(T, U, V, W) = (1, 1, 2, 4)$ we have

$$F_T = 2(1 - 2)\ln(4 - 2) = -2\ln 2$$

$$F_U = (1 - 2)\left(2\ln(4 - 2) - \frac{2(1 - 2)}{4 - 2}\right) = (-2\ln 2 - 1) = -1 - 2\ln 2$$

Substituting in (1) we obtain

$$\left.\frac{\partial U}{\partial T}\right|_{(1,1,2,4)} = -\frac{2\ln 2}{1 + 2\ln 2}, \quad \left.\frac{\partial T}{\partial U}\right|_{(1,1,2,4)} = -\frac{1 + 2\ln 2}{2\ln 2}.$$

31. Let $\mathbf{r} = \langle x, y, z\rangle$ and $e_{\mathbf{r}} = \mathbf{r}/\|\mathbf{r}\|$. Show that if a function $f(x, y, z) = F(r)$ depends only on the distance from the origin $r = \|\mathbf{r}\| = \sqrt{x^2 + y^2 + z^2}$, then

$$\nabla f = F'(r)e_{\mathbf{r}}$$

SOLUTION The gradient of f is the following vector:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle$$

We must express this vector in terms of $\mathbf{r}$ and r. Using the Chain Rule, we have

$$\frac{\partial f}{\partial x} = F'(r)\frac{\partial r}{\partial x} = F'(r) \cdot \frac{2x}{2\sqrt{x^2+y^2+z^2}} = F'(r) \cdot \frac{x}{r}$$
$$\frac{\partial f}{\partial y} = F'(r)\frac{\partial r}{\partial y} = F'(r) \cdot \frac{2y}{2\sqrt{x^2+y^2+z^2}} = F'(r) \cdot \frac{y}{r}$$
$$\frac{\partial f}{\partial z} = F'(r)\frac{\partial r}{\partial z} = F'(r) \cdot \frac{2z}{2\sqrt{x^2+y^2+z^2}} = F'(r) \cdot \frac{z}{r}$$

Hence,

$$\nabla f = \left\langle F'(r)\frac{x}{r}, F'(r)\frac{y}{r}, F'(r)\frac{z}{r} \right\rangle = \frac{F'(r)}{r}\langle x, y, z\rangle = F'(r)\frac{\mathbf{r}}{\|\mathbf{r}\|} = F'(r)e_{\mathbf{r}}$$

32. Let $f(x, y, z) = e^{-x^2-y^2-z^2} = e^{-r^2}$, with r as in Exercise 31. Compute ∇f directly and using Eq. (9).

SOLUTION Direct computation gives

$$\nabla f = \langle f_x, f_y, f_z\rangle = \left\langle -2xe^{-x^2-y^2-z^2}, -2ye^{-x^2-y^2-z^2}, -2ze^{-x^2-y^2-z^2} \right\rangle$$
$$= -2e^{-(x^2+y^2+z^2)}\langle x, y, z\rangle = -2e^{-r^2}\mathbf{r}$$

We now compute the gradient using Eq. (9):

$$\nabla f = F'(r)\mathbf{e_r}$$

Since $F(r) = e^{-r^2}$, we have $F'(r) = -2re^{-r^2}$. Also, $e_r = \frac{\mathbf{r}}{\|\mathbf{r}\|}$. So we obtain

$$\nabla f = -2re^{-r^2} \cdot \frac{\mathbf{r}}{\|\mathbf{r}\|} = -2e^{-r^2}\mathbf{r}$$

Both answers agree, as expected.

33. Use Eq. (9) to compute $\nabla\left(\frac{1}{r}\right)$.

SOLUTION To compute $\nabla\left(\frac{1}{r}\right)$ using Eq. (9), we let $F(r) = \frac{1}{r}$:

$$F'(r) = -\frac{1}{r^2}$$

We obtain

$$\nabla\left(\frac{1}{r}\right) = F'(r)\mathbf{e_r} = -\frac{1}{r^2} \cdot \frac{\mathbf{r}}{\|\mathbf{r}\|} = -\frac{1}{r^3}\mathbf{r}$$

34. Use Eq. (9) to compute $\nabla(\ln r)$.

SOLUTION To compute $\nabla(\ln r)$ we let $F(r) = \ln r$, hence $F'(r) = \frac{1}{r}$. Thus,

$$\nabla(\ln r) = F'(r)\mathbf{e_r} = \frac{1}{r} \cdot \frac{\mathbf{r}}{\|\mathbf{r}\|} = \frac{1}{r^2}\mathbf{r}$$

35. Figure 4 shows the graph of the equation

$$F(x, y, z) = x^2 + y^2 - z^2 - 12x - 8z - 4 = 0$$

(a) Use the quadratic formula to solve for z as a function of x and y. This gives two formulas, depending on the choice of sign.

(b) Which formula defines the portion of the surface satisfying $z \geq -4$? Which formula defines the portion satisfying $z \leq -4$?

(c) Calculate $\partial z/\partial x$ using the formula $z = f(x, y)$ (for both choices of sign) and again via implicit differentiation. Verify that the two answers agree.

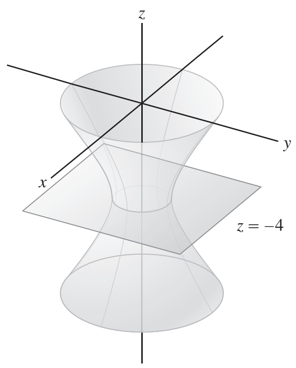

FIGURE 4 Graph of $x^2 + y^2 - z^2 - 12x - 8z - 4 = 0$.

SOLUTION

(a) We rewrite $F(x, y, z) = 0$ as a quadratic equation in the variable z:

$$z^2 + 8z + \left(4 + 12x - x^2 - y^2\right) = 0$$

We solve for z. The discriminant is

$$8^2 - 4\left(4 + 12x - x^2 - y^2\right) = 4x^2 + 4y^2 - 48x + 48 = 4\left(x^2 + y^2 - 12x + 12\right)$$

Hence,

$$z_{1,2} = \frac{-8 \pm \sqrt{4\left(x^2 + y^2 - 12x + 12\right)}}{2} = -4 \pm \sqrt{x^2 + y^2 - 12x + 12}$$

We obtain two functions:

$$z = -4 + \sqrt{x^2 + y^2 - 12x + 12}, \quad z = -4 - \sqrt{x^2 + y^2 - 12x + 12}$$

(b) The formula with the positive root defines the portion of the surface satisfying $z \ge -4$, and the formula with the negative root defines the portion satisfying $z \le -4$.

(c) Differentiating $z = -4 + \sqrt{x^2 + y^2 - 12x + 12}$ with respect to x, using the Chain Rule, gives

$$\frac{\partial z}{\partial x} = \frac{2x - 12}{2\sqrt{x^2 + y^2 - 12x + 12}} = \frac{x - 6}{\sqrt{x^2 + y^2 - 12x + 12}} \tag{1}$$

Alternatively, using the formula for $\frac{\partial z}{\partial x}$ obtained by implicit differentiation gives

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} \tag{2}$$

We find the partial derivatives of $F(x, y, z) = x^2 + y^2 - z^2 - 12x - 8z - 4$:

$$F_x = 2x - 12, \quad F_z = -2z - 8$$

Substituting in (2) gives

$$\frac{\partial z}{\partial x} = -\frac{2x - 12}{-2z - 8} = \frac{x - 6}{z + 4}$$

This result is the same as the result in (1), since $z = -4 + \sqrt{x^2 + y^2 - 12x + 12}$ implies that

$$\sqrt{x^2 + y^2 - 12x + 12} = z + 4$$

For $z = -4 - \sqrt{x^2 + y^2 - 12x + 12}$, differentiating with respect to x gives

$$\frac{\partial z}{\partial x} = -\frac{2x - 12}{2\sqrt{x^2 + y^2 - 12x + 12}} = \frac{x - 6}{-\sqrt{x^2 + y^2 - 12x + 12}} = \frac{x - 6}{z + 4}$$

which is equal to $-\frac{F_x}{F_z}$ computed above.

36. For all $x > 0$, there is a unique value $y = r(x)$ that solves the equation $y^3 + 4xy = 16$.

(a) Show that $dy/dx = -4y/(3y^2 + 4x)$.

(b) Let $g(x) = f(x, r(x))$, where $f(x, y)$ is a function satisfying

$$f_x(1, 2) = 8, \quad f_y(1, 2) = 10$$

Use the Chain Rule to calculate $g'(1)$. Note that $r(1) = 2$ because $(x, y) = (1, 2)$ satisfies $y^3 + 4xy = 16$.

SOLUTION

(a) Using implicit differentiation we see:

$$3y^2 \frac{dy}{dx} + 4x \frac{dy}{dx} + 4y = 0$$

$$\frac{dy}{dx}(3y^2 + 4x) = -4y$$

$$\frac{dy}{dx} = \frac{-4y}{3y^2 + 4x}$$

(b) Note that $r'(1) = -\dfrac{4(2)}{3(2)^2 + 4(1)} = -\dfrac{1}{2}$ Therefore,

$$g'(1) = f_x(1, 2) + f_y(1, 2) \cdot r'(1) = 8 + 10\left(-\frac{1}{2}\right) = 3$$

37. The pressure P, volume V, and temperature T of a van der Waals gas with n molecules (n constant) are related by the equation

$$\left(P + \frac{an^2}{V^2}\right)(V - nb) = nRT$$

where a, b, and R are constant. Calculate $\partial P/\partial T$ and $\partial V/\partial P$.

SOLUTION Let F be the following function:

$$F(P, V, T) = \left(P + \frac{an^2}{V^2}\right)(V - nb) - nRT$$

By Eq. (7),

$$\frac{\partial P}{\partial T} = -\frac{\frac{\partial F}{\partial T}}{\frac{\partial F}{\partial P}}, \quad \frac{\partial V}{\partial P} = -\frac{\frac{\partial F}{\partial P}}{\frac{\partial F}{\partial V}} \tag{1}$$

We compute the partial derivatives of F:

$$\frac{\partial F}{\partial P} = V - nb$$

$$\frac{\partial F}{\partial T} = -nR$$

$$\frac{\partial F}{\partial V} = -2an^2V^{-3}(V - nb) + \left(P + \frac{an^2}{V^2}\right) = P + \frac{2an^3b}{V^3} - \frac{an^2}{V^2}$$

Substituting in (1) gives

$$\frac{\partial P}{\partial T} = -\frac{-nR}{V - nb} = \frac{nR}{V - nb}$$

$$\frac{\partial V}{\partial P} = -\frac{V - nb}{P + \frac{2an^3b}{V^3} - \frac{an^2}{V^2}} = \frac{nbV^3 - V^4}{PV^3 + 2an^3b - an^2V}$$

38. When x, y, and z are related by an equation $F(x, y, z) = 0$, we sometimes write $(\partial z/\partial x)_y$ in place of $\partial z/\partial x$ to indicate that in the differentiation, z is treated as a function of x with y held constant (and similarly for the other variables).

(a) Use Eq. (7) to prove the **cyclic relation**

$$\left(\frac{\partial z}{\partial x}\right)_y \left(\frac{\partial x}{\partial y}\right)_z \left(\frac{\partial y}{\partial z}\right)_x = -1 \tag{10}$$

(b) Verify Eq. (10) for $F(x, y, z) = x + y + z = 0$.

(c) Verify the cyclic relation for the variables P, V, T in the ideal gas law $PV - nRT = 0$ (n and R are constants).

SOLUTION

(a) Using implicit differentiation for $F(x, y, z) = 0$, we have

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z}, \quad \frac{\partial x}{\partial y} = -\frac{F_y}{F_x}, \quad \frac{\partial y}{\partial z} = -\frac{F_z}{F_y}$$

Hence,

$$\frac{\partial z}{\partial x} \cdot \frac{\partial x}{\partial y} \cdot \frac{\partial y}{\partial z} = -\frac{F_x}{F_z} \cdot \frac{-F_y}{F_x} \cdot \frac{-F_z}{F_y} = -1$$

(b) For $F(x, y, z) = x + y + z = 0$ we have

$$x = -y - z, \quad y = -x - z, \quad z = -x - y$$

Hence,

$$\frac{\partial z}{\partial x} = -1, \quad \frac{\partial x}{\partial y} = -1, \quad \frac{\partial y}{\partial z} = -1$$

Eq. (10) holds since

$$\frac{\partial z}{\partial x} \cdot \frac{\partial x}{\partial y} \cdot \frac{\partial y}{\partial z} = (-1) \cdot (-1) \cdot (-1) = -1$$

(c) If $PV - nRT = 0$, then

$$T = \frac{PV}{nR}, \quad P = \frac{nRT}{V}, \quad V = \frac{nRT}{P}$$

Hence,

$$\frac{\partial T}{\partial V} = \frac{P}{nR}, \quad \frac{\partial V}{\partial P} = -\frac{nRT}{P^2}, \quad \frac{\partial P}{\partial T} = \frac{nR}{V}$$

We have

$$\frac{\partial T}{\partial V} \cdot \frac{\partial V}{\partial P} \cdot \frac{\partial P}{\partial T} = \frac{P}{nR} \cdot -\frac{nRT}{P^2} \cdot \frac{nR}{V} = -\frac{nRT}{PV}$$

and, since $PV = nRT$, we get

$$\frac{\partial T}{\partial V} \cdot \frac{\partial V}{\partial P} \cdot \frac{\partial P}{\partial T} = -\frac{PV}{PV} = -1$$

Similarly,

$$\frac{\partial T}{\partial P} \cdot \frac{\partial P}{\partial V} \cdot \frac{\partial V}{\partial T} = \frac{V}{nR} \cdot \left(-\frac{nRT}{V^2}\right) \cdot \frac{nR}{P} = -\frac{nRT}{VP} = -\frac{PV}{PV} = -1$$

39. Show that if $f(x)$ is differentiable and $c \neq 0$ is a constant, then $u(x, t) = f(x - ct)$ satisfies the so-called **advection equation**

$$\frac{\partial u}{\partial t} + c\frac{\partial u}{\partial x} = 0$$

SOLUTION For $s = x - ct$, we have $u(x, t) = f(s)$. We use the Chain Rule to compute $\frac{\partial u}{\partial t}$ and $\frac{\partial u}{\partial x}$:

$$\frac{\partial u}{\partial t} = f'(s)\frac{\partial s}{\partial t} = f'(s) \cdot (-c) = -cf'(s) \tag{1}$$

$$\frac{\partial u}{\partial x} = f'(s)\frac{\partial s}{\partial x} = f'(s) \cdot 1 = f'(s) \tag{2}$$

Equalities (1) and (2) imply that:

$$\frac{\partial u}{\partial t} = -c\frac{\partial u}{\partial x} \quad \text{or} \quad \frac{\partial u}{\partial t} + c\frac{\partial u}{\partial x} = 0$$

Further Insights and Challenges

In Exercises 40–43, a function $f(x, y, z)$ is called **homogeneous of degree n** *if $f(\lambda x, \lambda y, \lambda z) = \lambda^n f(x, y, z)$ for all $\lambda \in \mathbf{R}$.*

40. Show that the following functions are homogeneous and determine their degree.

(a) $f(x, y, z) = x^2y + xyz$

(b) $f(x, y, z) = 3x + 2y - 8z$

(c) $f(x, y, z) = \ln\left(\frac{xy}{z^2}\right)$

(d) $f(x, y, z) = z^4$

SOLUTION

(a) For $f(x, y, z) = x^2y + xyz$ we have

$$f(\lambda x, \lambda y, \lambda z) = (\lambda x)^2(\lambda y) + (\lambda x)(\lambda y)(\lambda z) = \lambda^3 x^2 y + \lambda^3 xyz = \lambda^3(x^2y + xyz) = \lambda^3 f(x, y, z)$$

Hence, f is homogeneous of degree 3.

(b) For $f(x, y, z) = 3x + 2y - 8z$ we have

$$f(\lambda x, \lambda y, \lambda z) = 3(\lambda x) + 2(\lambda y) - 8(\lambda z) = \lambda(3x + 2y - 8z) = \lambda f(x, y, z)$$

Hence, f is homogeneous of degree 1.

(c) For $f(x, y, z) = \ln\left(\frac{xy}{z^2}\right)$ we have, for $\lambda \neq 0$,

$$f(\lambda x, \lambda y, \lambda z) = \ln\left(\frac{(\lambda x)(\lambda y)}{(\lambda z)^2}\right) = \ln\left(\frac{\lambda^2 xy}{\lambda^2 z^2}\right) = \ln\left(\frac{xy}{z^2}\right) = f(x, y, z) = \lambda^0 f(x, y, z)$$

Thus, f is homogeneous of degree 0.

(d) For $f(z) = z^4$ we have

$$f(\lambda z) = (\lambda z)^4 = \lambda^4 z^4 = \lambda^4 f(z)$$

Hence, f is homogeneous of degree 4.

41. Prove that if $f(x, y, z)$ is homogeneous of degree n, then $f_x(x, y, z)$ is homogeneous of degree $n - 1$. *Hint:* Either use the limit definition or apply the Chain Rule to $f(\lambda x, \lambda y, \lambda z)$.

SOLUTION We are given that $f(\lambda x, \lambda y, \lambda z) = \lambda^n f(x, y, z)$ for all λ, and we must show that $f_x(\lambda x, \lambda y, \lambda z) = \lambda^{n-1} f_x(x, y, z)$. We use the limit definition of f_x. Since for all $\lambda \neq 0$, $\lambda h \to 0$ if and only if $h \to 0$, we get

$$\begin{aligned}
f_x(\lambda x, \lambda y, \lambda z) &= \lim_{h\to 0} \frac{f(\lambda x + \lambda h, \lambda y, \lambda z) - f(\lambda x, \lambda y, \lambda z)}{\lambda h} = \lim_{h\to 0} \frac{f(\lambda(x+h), \lambda y, \lambda z) - f(\lambda x, \lambda y, \lambda z)}{\lambda h} \\
&= \lim_{h\to 0} \frac{\lambda^n f(x+h, y, z) - \lambda^n f(x, y, z)}{\lambda h} = \lim_{h\to 0} \frac{\lambda^{n-1} f(x+h, y, z) - \lambda^{n-1} f(x, y, z)}{h} \\
&= \lambda^{n-1} \lim_{h\to 0} \frac{f(x+h, y, z) - f(x, y, z)}{h} = \lambda^{n-1} f_x(x, y, z)
\end{aligned}$$

Alternatively, we prove this property using the Chain Rule. We use the Chain Rule to differentiate the following equality with respect to x:

$$f(\lambda x, \lambda y, \lambda z) = \lambda^n f(x, y, z)$$

We get

$$f_x(\lambda x, \lambda y, \lambda z) \cdot \frac{\partial(\lambda x)}{\partial x} + f_y(\lambda x, \lambda y, \lambda z) \cdot \frac{\partial(\lambda y)}{\partial x} + f_z(\lambda x, \lambda y, \lambda z) \cdot \frac{\partial(\lambda z)}{\partial x} = \lambda^n f_x(x, y, z)$$

Since $\frac{\partial(\lambda y)}{\partial x} = \frac{\partial(\lambda z)}{\partial x} = 0$ and $\frac{\partial(\lambda x)}{\partial x} = \lambda$, we obtain for $\lambda \neq 0$,

$$\lambda f_x(\lambda x, \lambda y, \lambda z) = \lambda^n f_x(x, y, z) \quad \text{or} \quad f_x(\lambda x, \lambda y, \lambda z) = \lambda^{n-1} f_x(x, y, z)$$

42. Prove that if $f(x, y, z)$ is homogeneous of degree n, then

$$x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} + z\frac{\partial f}{\partial z} = nf \qquad \boxed{11}$$

Hint: Let $F(t) = f(tx, ty, tz)$ and calculate $F'(1)$ using the Chain Rule.

SOLUTION We use the Chain Rule to differentiate the function $F(t) = f(tx, ty, tz)$ with respect to t. This gives

$$F'(t) = \frac{\partial f}{\partial x} \cdot \frac{\partial (tx)}{\partial t} + \frac{\partial f}{\partial y} \cdot \frac{\partial (ty)}{\partial t} + \frac{\partial f}{\partial z} \cdot \frac{\partial (tz)}{\partial t} = x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} + z\frac{\partial f}{\partial z} \tag{1}$$

On the other hand, since f is homogeneous of degree n, we have

$$F(t) = f(tx, ty, tz) = t^n f(x, y, z)$$

Differentiating with respect to t we get

$$F'(t) = nt^{n-1} f(x, y, z) \tag{2}$$

By (1) and (2) we obtain

$$x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} + z\frac{\partial f}{\partial z} = nt^{n-1} f(x, y, z)$$

Substituting $t = 1$ gives

$$x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} + z\frac{\partial f}{\partial z} = nf$$

43. Verify Eq. (11) for the functions in Exercise 40.

SOLUTION Eq. (11) states that if f is homogeneous of degree n, then

$$x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} + z\frac{\partial f}{\partial z} = nf$$

(a) $f(x, y, z) = x^2y + xyz$. f is homogeneous of degree $n = 3$. The partial derivatives of f are

$$\frac{\partial f}{\partial x} = 2xy + yz, \quad \frac{\partial f}{\partial y} = x^2 + xz, \quad \frac{\partial f}{\partial z} = xy$$

Hence,

$$x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} + z\frac{\partial f}{\partial z} = x(2xy + yz) + y(x^2 + xz) + zxy = 3x^2y + 3xyz = 3(x^2y + xyz) = 3f(x, y, z)$$

(b) $f(x, y, z) = 3x + 2y - 8z$. f is homogeneous of degree $n = 1$. We have

$$x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} + z\frac{\partial f}{\partial z} = x \cdot 3 + y \cdot 2 + z \cdot (-8) = 3x + 2y - 8z = 1 \cdot f(x, y, z)$$

(c) $f(x, y, z) = \ln\left(\frac{xy}{z^2}\right)$. f is homogeneous of degree $n = 0$. The partial derivatives of f are

$$\frac{\partial f}{\partial x} = \frac{\frac{y}{z^2}}{\frac{xy}{z^2}} = \frac{1}{x}, \quad \frac{\partial f}{\partial y} = \frac{\frac{x}{z^2}}{\frac{xy}{z^2}} = \frac{1}{y}, \quad \frac{\partial f}{\partial z} = \frac{-2z^{-3}xy}{xyz^{-2}} = -\frac{2}{z}$$

Hence,

$$x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} + z\frac{\partial f}{\partial z} = x \cdot \frac{1}{x} + y \cdot \frac{1}{y} + z \cdot \left(-\frac{2}{z}\right) = 0 = 0 \cdot f(x, y, z)$$

(d) $f(x, y, z) = z^4$. f is homogeneous of degree $n = 4$. We have

$$x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} + z\frac{\partial f}{\partial z} = x \cdot 0 + y \cdot 0 + z \cdot 4z^3 = 4z^4 = 4f(x, y, z)$$

44. Suppose that $x = g(t, s)$, $y = h(t, s)$. Show that f_{tt} is equal to

$$f_{xx}\left(\frac{\partial x}{\partial t}\right)^2 + 2f_{xy}\left(\frac{\partial x}{\partial t}\right)\left(\frac{\partial y}{\partial t}\right) + f_{yy}\left(\frac{\partial y}{\partial t}\right)^2 + f_x\frac{\partial^2 x}{\partial t^2} + f_y\frac{\partial^2 y}{\partial t^2} \qquad \boxed{12}$$

SOLUTION We are given that $x = g(t, s)$, $y = h(t, s)$. We must compute f_{tt} for a function $f(x, y)$. We first compute f_t using the Chain Rule:

$$f_t = f_x\frac{\partial x}{\partial t} + f_y\frac{\partial y}{\partial t}$$

To find f_{tt} we differentiate the two sides with respect to t using the Product Rule. This gives

$$f_{tt} = \frac{\partial}{\partial t}(f_x)\frac{\partial x}{\partial t} + f_x\frac{\partial^2 x}{\partial t^2} + \frac{\partial}{\partial t}(f_y)\frac{\partial y}{\partial t} + f_y\frac{\partial^2 y}{\partial t^2} \tag{1}$$

By the Chain Rule,

$$\frac{\partial}{\partial t}(f_x) = f_{xx}\frac{\partial x}{\partial t} + f_{xy}\frac{\partial y}{\partial t}$$
$$\frac{\partial}{\partial t}(f_y) = f_{yx}\frac{\partial x}{\partial t} + f_{yy}\frac{\partial y}{\partial t}$$

Substituting in (1) we obtain

$$\begin{aligned} f_{tt} &= \left(f_{xx}\frac{\partial x}{\partial t} + f_{xy}\frac{\partial y}{\partial t}\right)\frac{\partial x}{\partial t} + f_x\frac{\partial^2 x}{\partial t^2} + \left(f_{yx}\frac{\partial x}{\partial t} + f_{yy}\frac{\partial y}{\partial t}\right)\frac{\partial y}{\partial t} + f_y\frac{\partial^2 y}{\partial t^2} \\ &= f_{xx}\left(\frac{\partial x}{\partial t}\right)^2 + f_{xy}\left(\frac{\partial y}{\partial t}\right)\left(\frac{\partial x}{\partial t}\right) + f_x\frac{\partial^2 x}{\partial t^2} + f_{yx}\left(\frac{\partial x}{\partial t}\right)\left(\frac{\partial y}{\partial t}\right) + f_{yy}\left(\frac{\partial y}{\partial t}\right)^2 + f_y\frac{\partial^2 y}{\partial t^2} \end{aligned}$$

If f_{xy} and f_{yx} are continuous, Clairaut's Theorem implies that $f_{xy} = f_{yx}$. Hence,

$$f_{tt} = f_{xx}\left(\frac{\partial x}{\partial t}\right)^2 + 2f_{xy}\left(\frac{\partial x}{\partial t}\right)\left(\frac{\partial y}{\partial t}\right) + f_{yy}\left(\frac{\partial y}{\partial t}\right)^2 + f_x\frac{\partial^2 x}{\partial t^2} + f_y\frac{\partial^2 y}{\partial t^2}$$

45. Let $r = \sqrt{x_1^2 + \cdots + x_n^2}$ and let $g(r)$ be a function of r. Prove the formulas

$$\frac{\partial g}{\partial x_i} = \frac{x_i}{r}g_r, \qquad \frac{\partial^2 g}{\partial x_i^2} = \frac{x_i^2}{r^2}g_{rr} + \frac{r^2 - x_i^2}{r^3}g_r$$

SOLUTION By the Chain Rule, we have

$$\frac{\partial g}{\partial x_i} = g'(r)\frac{\partial r}{\partial x_i} = g_r \cdot \frac{2x_i}{2\sqrt{x_1^2 + \cdots + x_n^2}} = g_r\frac{x_i}{r}$$

We differentiate $\frac{\partial g}{\partial x_i}$ with respect to x_i. Using the Product Rule we get

$$\frac{\partial^2 g}{\partial {x_i}^2} = \frac{\partial}{\partial x_i}(g_r) \cdot \frac{x_i}{r} + g_r\frac{\partial}{\partial x_i}\left(\frac{x_i}{r}\right) \tag{1}$$

We use the Chain Rule to compute $\frac{\partial}{\partial x_i}(g_r)$:

$$\frac{\partial}{\partial x_i}(g_r) = \frac{d}{dr}(g_r) \cdot \frac{\partial r}{\partial x_i} = g_{rr} \cdot \frac{2x_i}{2\sqrt{x_1^2 + \cdots + x_n^2}} = g_{rr} \cdot \frac{x_i}{r} \tag{2}$$

We compute $\frac{\partial}{\partial x_i} \cdot \left(\frac{x_i}{r}\right)$ using the Quotient Rule and the Chain Rule:

$$\frac{\partial}{\partial x_i} \cdot \left(\frac{x_i}{r}\right) = \frac{1 \cdot r - x_i \cdot \frac{\partial r}{\partial x_i}}{r^2} = \frac{r - x_i \cdot \frac{x_i}{r}}{r^2} = \frac{r^2 - x_i^2}{r^3} \tag{3}$$

Substituting (2) and (3) in (1), we obtain

$$\frac{\partial^2 g}{\partial {x_i}^2} = g_{\mathrm{rr}} \cdot \frac{x_i}{r} \cdot \frac{x_i}{r} + g_r\frac{r^2 - x_i^2}{r^3} = \frac{x_i^2}{r^2}g_{rr} + \frac{r^2 - x_i^2}{r^3}g_r$$

46. Prove that if $g(r)$ is a function of r as in Exercise 45, then

$$\frac{\partial^2 g}{\partial x_1^2} + \cdots + \frac{\partial^2 g}{\partial x_n^2} = g_{rr} + \frac{n-1}{r}g_r$$

SOLUTION In Exercise 45 we showed that

$$\frac{\partial^2 g}{\partial {x_i}^2} = \frac{x_i^2}{r^2}g_{rr} + \frac{r^2 - x_i^2}{r^3}g_r$$

Hence,

$$\begin{aligned}\frac{\partial^2 g}{\partial x_i{}^2}+\cdots+\frac{\partial^2 g}{\partial x_n{}^2}&=\left(\frac{x_1^2}{r^2}g_{rr}+\frac{r^2-x_1^2}{r^3}g_r\right)+\cdots+\left(\frac{x_n^2}{r^2}g_{rr}+\frac{r^2-x_n^2}{r^3}g_r\right)\\&=\frac{x_1^2+\cdots+x_n^2}{r^2}g_{rr}+\frac{1}{r^3}g_r\left((r^2-x_1^2)+\cdots+(r^2-x_n^2)\right)\\&=\frac{r^2}{r^2}g_{rr}+\frac{1}{r^3}g_r\left(nr^2-(x_1^2+\cdots+x_n^2)\right)\\&=g_{rr}+\frac{1}{r^3}g_r(nr^2-r^2)=g_{rr}+\frac{r^2}{r^3}g_r(n-1)=g_{rr}+\frac{n-1}{r}g_r\end{aligned}$$

In Exercises 47–51, the ***Laplace operator*** *is defined by* $\Delta f = f_{xx}+f_{yy}$. *A function* $f(x,y)$ *satisfying the Laplace equation* $\Delta f = 0$ *is called* ***harmonic***. *A function* $f(x,y)$ *is called* ***radial*** *if* $f(x,y)=g(r)$*, where* $r=\sqrt{x^2+y^2}$.

47. Use Eq. (12) to prove that in polar coordinates (r,θ),

$$\Delta f = f_{rr}+\frac{1}{r^2}f_{\theta\theta}+\frac{1}{r}f_r \qquad \boxed{13}$$

SOLUTION The polar coordinates are $x=r\cos\theta$, $y=r\sin\theta$. Hence,

$$\frac{\partial x}{\partial\theta}=-r\sin\theta,\quad \frac{\partial y}{\partial\theta}=r\cos\theta,\quad \frac{\partial x}{\partial r}=\cos\theta,\quad \frac{\partial y}{\partial r}=\sin\theta,$$
$$\frac{\partial^2 x}{\partial\theta^2}=-r\cos\theta,\quad \frac{\partial^2 y}{\partial\theta^2}=-r\sin\theta,\quad \frac{\partial^2 x}{\partial r^2}=\frac{\partial^2 y}{\partial r^2}=0$$

By Eq. (12) we have

$$\begin{aligned}f_{\theta\theta}&=f_{xx}\left(\frac{\partial x}{\partial\theta}\right)^2+f_{yy}\left(\frac{\partial y}{\partial\theta}\right)^2+2f_{xy}\left(\frac{\partial x}{\partial\theta}\right)\left(\frac{\partial y}{\partial\theta}\right)+f_x\frac{\partial^2 x}{\partial\theta^2}+f_y\frac{\partial^2 y}{\partial\theta^2}\\&=f_{xx}\left(r^2\sin^2\theta\right)+f_{yy}\left(r^2\cos^2\theta\right)-\left(2r^2\sin\theta\cos\theta\right)f_{xy}-(r\cos\theta)f_x-(r\sin\theta)f_y\end{aligned}\tag{1}$$

and

$$\begin{aligned}f_{rr}&=f_{xx}\left(\frac{\partial x}{\partial r}\right)^2+f_{yy}\left(\frac{\partial y}{\partial r}\right)^2+2f_{xy}\left(\frac{\partial x}{\partial r}\right)\left(\frac{\partial y}{\partial r}\right)+f_x\frac{\partial^2 x}{\partial r^2}+f_y\frac{\partial^2 y}{\partial r^2}\\&=f_{xx}\left(\cos^2\theta\right)+f_{yy}\left(\sin^2\theta\right)+(2\cos\theta\sin\theta)f_{xy}\end{aligned}\tag{2}$$

$$f_r=f_x\frac{\partial x}{\partial r}+f_y\frac{\partial y}{\partial r}=f_x(\cos\theta)+f_y(\sin\theta)\tag{3}$$

We now compute the right-hand side of the equality we need to prove. Using (1), (2), and (3), we obtain

$$\begin{aligned}f_{rr}+\frac{1}{r^2}f_{\theta\theta}+\frac{1}{r}f_r&=f_{xx}\left(\cos^2\theta\right)+f_{yy}\left(\sin^2\theta\right)+(2\cos\theta\sin\theta)f_{xy}+f_{xx}\left(\sin^2\theta\right)\\&\quad+f_{yy}\left(\cos^2\theta\right)-(2\sin\theta\cos\theta)f_{xy}-\frac{\cos\theta}{r}f_x-\frac{\sin\theta}{r}f_y+f_x\frac{\cos\theta}{r}+f_y\frac{\sin\theta}{r}\\&=f_{xx}\left(\cos^2\theta+\sin^2\theta\right)+f_{yy}\left(\sin^2\theta+\cos^2\theta\right)\\&=f_{xx}+f_{yy}=\Delta f\end{aligned}$$

We thus showed that

$$\Delta f = f_{rr}+\frac{1}{r^2}f_{\theta\theta}+\frac{1}{r}f_r$$

48. Use Eq. (13) to show that $f(x,y)=\ln r$ is harmonic.

SOLUTION We must show that $f(r,\theta)=\ln r$ satisfies

$$\Delta f = f_{rr}+\frac{1}{r^2}f_{\theta\theta}+\frac{1}{r}f_r=0$$

We compute the derivatives of $f(r,\theta) = \ln r$:

$$f_r = \frac{1}{r}, \quad f_{rr} = -\frac{1}{r^2}, \quad f_\theta = 0, \quad f_{\theta\theta} = 0$$

Hence,

$$\Delta f = f_{rr} + \frac{1}{r^2} f_{\theta\theta} + \frac{1}{r} f_r = -\frac{1}{r^2} + \frac{1}{r^2} \cdot 0 + \frac{1}{r} \cdot \frac{1}{r} = -\frac{1}{r^2} + \frac{1}{r^2} = 0$$

Since $\Delta f = 0$, f is harmonic.

49. Verify that $f(x,y) = x$ and $f(x,y) = y$ are harmonic using both the rectangular and polar expressions for Δf.

SOLUTION We must show that $\Delta f = 0$.

(a) Using the rectangular expression for Δf:

$$\Delta f = f_{xx} + f_{yy}$$

For $f(x,y) = x$ we have $f_x = 1$, $f_y = 0$, hence, $f_{xx} = 0$, $f_{yy} = 0$. Therefore $\Delta f = f_{xx} + f_{yy} = 0 + 0 = 0$. For $f(x,y) = y$ we have $f_y = 1$, $f_x = 0$, hence, $f_{xx} = 0$, $f_{yy} = 0$, and again, $\Delta f = f_{xx} + f_{yy} = 0 + 0 = 0$.

(b) Using the polar expression for Δf,

$$\Delta f = f_{rr} + \frac{1}{r^2} f_{\theta\theta} + \frac{1}{r} f_r \tag{1}$$

Since $x = r\cos\theta$, we have $f(r,\theta) = x = r\cos\theta$. Hence,

$$f_r = \cos\theta, \quad f_\theta = -r\sin\theta, \quad f_{rr} = 0, \quad f_{\theta\theta} = -r\cos\theta$$

We now show that $\Delta f = 0$:

$$\Delta f = f_{rr} + \frac{1}{r^2} f_{\theta\theta} + \frac{1}{r} f_r = 0 + \frac{1}{r^2} \cdot (-r\cos\theta) + \frac{1}{r}\cos\theta = 0$$

Similarly, since $y = r\sin\theta$, we have $f(r,\theta) = y = r\sin\theta$. Hence,

$$f_r = \sin\theta, \quad f_\theta = r\cos\theta, \quad f_{rr} = 0, \quad f_{\theta\theta} = -r\sin\theta$$

Substituting in (1) gives

$$\Delta f = 0 + \frac{1}{r^2}(-r\sin\theta) + \frac{1}{r}\sin\theta = 0$$

50. Verify that $f(x,y) = \tan^{-1}\frac{y}{x}$ is harmonic using both the rectangular and polar expressions for Δf.

SOLUTION

(a) Using the rectangular expression for Δf:

$$\Delta f = f_{xx} + f_{yy}$$

We compute the partial derivatives of $f(x,y) = \tan^{-1}\left(\frac{y}{x}\right)$. Using the Chain Rule we get

$$f_x = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \left(-\frac{y}{x^2}\right) = -\frac{y}{x^2 + y^2}$$

$$f_y = \frac{1}{1 + \left(\frac{y}{x}\right)^2} \cdot \frac{1}{x} = \frac{x}{x^2 + y^2}$$

$$f_{xx} = -\frac{-y}{\left(x^2 + y^2\right)^2} \cdot 2x = \frac{2xy}{\left(x^2 + y^2\right)^2}$$

$$f_{yy} = \frac{-x}{\left(x^2 + y^2\right)^2} \cdot 2y = \frac{-2xy}{\left(x^2 + y^2\right)^2}$$

Hence,

$$f_{xx} + f_{yy} = \frac{2xy}{\left(x^2 + y^2\right)^2} - \frac{2xy}{\left(x^2 + y^2\right)^2} = 0$$

(b) Using the polar expression for Δf,

$$\Delta f = f_{rr} + \frac{1}{r^2} f_{\theta\theta} + \frac{1}{r} f_r \tag{1}$$

Since $\frac{y}{x} = \frac{r\sin\theta}{r\cos\theta} = \tan\theta$, we have $f(x, y) = \tan^{-1}\left(\frac{y}{x}\right) = \tan^{-1}(\theta) = \theta$. We compute the partial derivatives:

$$f_r = 0, \quad f_\theta = 1, \quad f_{rr} = 0, \quad f_{\theta\theta} = 0.$$

Substituting in (1), we get

$$\Delta f = 0 + \frac{1}{r^2} \cdot 0 + \frac{1}{r} \cdot 0 = 0$$

51. Use the Product Rule to show that

$$f_{rr} + \frac{1}{r} f_r = r^{-1} \frac{\partial}{\partial r}\left(r \frac{\partial f}{\partial r}\right)$$

Use this formula to show that if f is a radial harmonic function, then $r f_r = C$ for some constant C. Conclude that $f(x, y) = C \ln r + b$ for some constant b.

SOLUTION We show that $f_{rr} + \frac{1}{r} f_r = r^{-1} \frac{\partial}{\partial r}\left(r \frac{\partial f}{\partial r}\right)$. We use the Product Rule to compute the following derivative:

$$\frac{\partial}{\partial r}\left(r \frac{\partial f}{\partial r}\right) = 1 \cdot \frac{\partial f}{\partial r} + r \frac{\partial}{\partial r}\left(\frac{\partial f}{\partial r}\right) = \frac{\partial f}{\partial r} + r \frac{\partial^2 f}{\partial r^2} = f_r + r f_{rr} = r\left(f_{rr} + \frac{1}{r} f_r\right)$$

Hence,

$$f_{rr} + \frac{1}{r} f_r = r^{-1} \frac{\partial}{\partial r}\left(r \frac{\partial f}{\partial r}\right) \tag{1}$$

Now, suppose that $f(x, y)$ is a radial harmonic function. Since f is radial, $f(x, y) = g(r)$, therefore $f_{\theta\theta} = 0$. Substituting in the polar expressions for Δf gives

$$\Delta f = f_{rr} + \frac{1}{r^2} f_{\theta\theta} + \frac{1}{r} f_r = f_{rr} + \frac{1}{r} f_r = 0$$

Combining with (1), we get

$$r^{-1} \frac{\partial}{\partial r}\left(r \frac{\partial f}{\partial r}\right) = 0 \quad \text{or} \quad \frac{\partial}{\partial r}\left(r \frac{\partial f}{\partial r}\right) = 0$$

yielding

$$r \frac{\partial f}{\partial r} = C \quad \Rightarrow \quad f_r = \frac{C}{r}$$

We now integrate the two sides to obtain

$$\int f_r \, dr = \int \frac{C}{r} \, dr \quad \text{or} \quad f(r) = C \ln r + b.$$

14.7 Optimization in Several Variables (LT Section 15.7)

Preliminary Questions

1. The functions $f(x, y) = x^2 + y^2$ and $g(x, y) = x^2 - y^2$ both have a critical point at (0, 0). How is the behavior of the two functions at the critical point different?

SOLUTION Let $f(x, y) = x^2 + y^2$ and $g(x, y) = x^2 - y^2$. In the domain $\mathbf{R}^2$, the partial derivatives of f and g are

$$f_x = 2x, \quad f_{xx} = 2, \quad f_y = 2y, \quad f_{yy} = 2, \quad f_{xy} = 0$$
$$g_x = 2x, \quad g_{xx} = 2, \quad g_y = -2y, \quad g_{yy} = -2, \quad g_{xy} = 0$$

Therefore, $f_x = f_y = 0$ at $(0, 0)$ and $g_x = g_y = 0$ at $(0, 0)$. That is, the two functions have one critical point, which is the origin. Since the discriminant of f is $D = 4 > 0$, $f_{xx} > 0$, and the discriminant of g is $D = -4 < 0$, f has a local minimum (which is also a global minimum) at the origin, whereas g has a saddle point there. Moreover, since $\lim_{y\to\infty} g(0, y) = -\infty$ and $\lim_{x\to\infty} g(x, 0) = \infty$, g does not have global extrema on the plane. Similarly, f does not have a global maximum but does have a global minimum, which is $f(0, 0) = 0$.

2. Identify the points indicated in the contour maps as local minima, local maxima, saddle points, or neither (Figure 15).

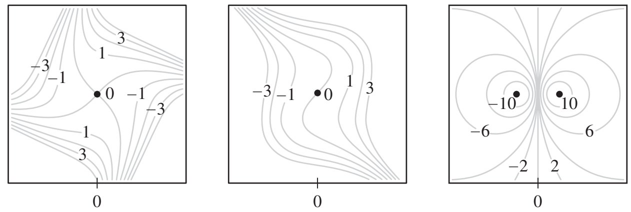

FIGURE 15

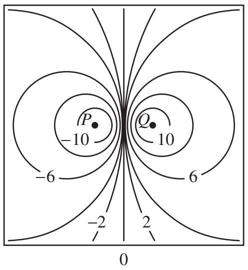
SOLUTION If $f(P)$ is a local minimum or maximum, then the nearby level curves are closed curves encircling P. In Figure (C), f increases in all directions emanating from P and decreases in all directions emanating from Q. Hence, f has a local minimum at P and local maximum at Q.



In Figure (A), the level curves through the point R consist of two intersecting lines that divide the neighborhood near R into four regions. f is decreasing in some directions and increasing in other directions. Therefore, R is a saddle point.

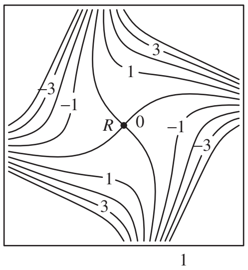


Figure (A)

Point S in Figure (B) is neither a local extremum nor a saddle point of f.

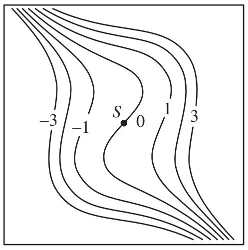

Figure (B)

3. Let $f(x, y)$ be a continuous function on a domain $\mathcal{D}$ in $\mathbf{R}^2$. Determine which of the following statements are true:

(a) If $\mathcal{D}$ is closed and bounded, then f takes on a maximum value on $\mathcal{D}$.

(b) If $\mathcal{D}$ is neither closed nor bounded, then f does not take on a maximum value of $\mathcal{D}$.

(c) $f(x, y)$ need not have a maximum value on the domain $\mathcal{D}$ defined by $0 \le x \le 1, 0 \le y \le 1$.

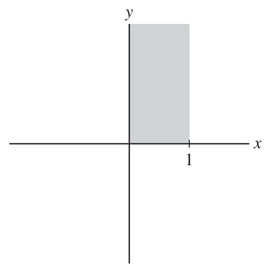
(d) A continuous function takes on neither a minimum nor a maximum value on the open quadrant

$$\{(x, y) : x > 0, y > 0\}$$

SOLUTION

(a) This statement is true. It follows by the Theorem on Existence of Global Extrema.

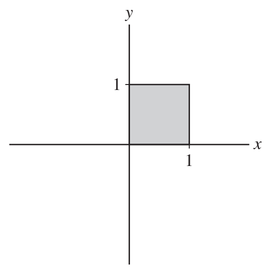
(b) The statement is false. Consider the constant function $f(x, y) = 2$ in the following domain:



$$D = \{(x, y) : 0 < x \leq 1,\ 0 \leq y < \infty\}$$

Obviously f is continuous and D is neither closed nor bounded. However, f takes on a maximum value (which is 2) on D.

(c) The domain $D = \{(x, y) : 0 \leq x, y \leq 1\}$ is the following rectangle:



$$D = \{(x, y) : 0 \leq x, y \leq 1\}$$

D is closed and bounded, hence f takes on a maximum value on D. Thus the statement is false.

(d) The statement is false. The constant function $f(x, y) = c$ takes on minimum and maximum values on the open quadrant.

Exercises

1. Let $P = (a, b)$ be a critical point of $f(x, y) = x^2 + y^4 - 4xy$.

(a) First use $f_x(x, y) = 0$ to show that $a = 2b$. Then use $f_y(x, y) = 0$ to show that $P = (0, 0)$, $(2\sqrt{2}, \sqrt{2})$, or $(-2\sqrt{2}, -\sqrt{2})$.

(b) Referring to Figure 16, determine the local minima and saddle points of $f(x, y)$ and find the absolute minimum value of $f(x, y)$.

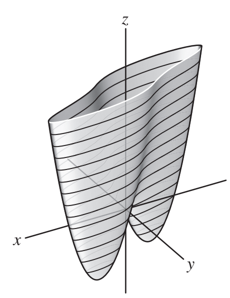


FIGURE 16

SOLUTION

(a) We find the partial derivatives:

$$f_x(x, y) = \frac{\partial}{\partial x}\left(x^2 + y^4 - 4xy\right) = 2x - 4y$$

$$f_y(x, y) = \frac{\partial}{\partial y}\left(x^2 + y^4 - 4xy\right) = 4y^3 - 4x$$

Since $P = (a, b)$ is a critical point, $f_x(a, b) = 0$. That is,

$$2a - 4b = 0 \quad \Rightarrow \quad a = 2b$$

Also $f_y(a, b) = 0$, hence,

$$4b^3 - 4a = 0 \quad \Rightarrow \quad a = b^3$$

We obtain the following equations for the critical points (a, b):

$$\begin{cases} a = 2b \\ a = b^3 \end{cases}$$

Equating the two equations, we get

$$2b = b^3$$

$$b^3 - 2b = b(b^2 - 2) = 0 \quad \Rightarrow \quad \begin{cases} b_1 = 0 \\ b_2 = \sqrt{2} \\ b_3 = -\sqrt{2} \end{cases}$$

Since $a = 2b$, we have $a_1 = 0$, $a_2 = 2\sqrt{2}$, $a_3 = -2\sqrt{2}$. The critical points are thus

$$P_1 = (0, 0), \quad P_2 = \left(2\sqrt{2}, \sqrt{2}\right), \quad P_3 = \left(-2\sqrt{2}, -\sqrt{2}\right)$$

(b) Referring to Figure 14, we see that $P_1 = (0, 0)$ is a saddle point and $P_2 = \left(2\sqrt{2}, \sqrt{2}\right)$, $P_3 = \left(-2\sqrt{2}, -\sqrt{2}\right)$ are local minima. The absolute minimum value of f is -4.

2. Find the critical points of the functions

$$f(x, y) = x^2 + 2y^2 - 4y + 6x, \qquad g(x, y) = x^2 - 12xy + y$$

Use the Second Derivative Test to determine the local minimum, local maximum, and saddle points. Match $f(x, y)$ and $g(x, y)$ with their graphs in Figure 17.

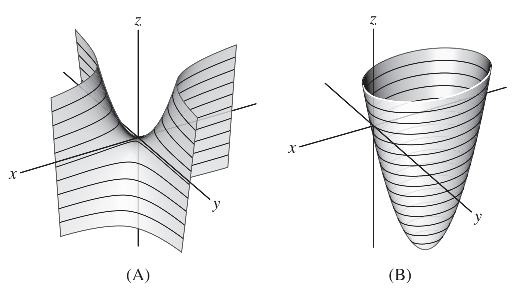

FIGURE 17

SOLUTION

Step 1. Find the critical points. We set the first partial derivatives equal to zero and solve:

$$\begin{aligned} f_x &= 2x + 6 = 0 \\ f_y &= 4y - 4 \end{aligned} \quad \Rightarrow \quad \begin{aligned} x &= -3 \\ y &= 1 \end{aligned}$$

The critical point is $(-3, 1)$.

$$\begin{aligned} g_x &= 2x - 12y = 0 \\ g_y &= -12x + 1 = 0 \end{aligned} \quad \Rightarrow \quad \begin{aligned} y &= \frac{1}{72} \\ x &= \frac{1}{12} \end{aligned}$$

The critical point is $\left(\frac{1}{12}, \frac{1}{72}\right)$.

Step 2. Compute the Discriminant. We compute the second-order partial derivatives:

$$f_{xx} = 2$$
$$f_{yy} = 4$$
$$f_{xy} = 0$$

The discriminant is $D(x, y) = f_{xx} f_{yy} - f_{xy}^2 = 2 \cdot 4 - 0^2 = 8$.

$$g_{xx} = 2$$
$$g_{yy} = 0$$
$$g_{xy} = -12$$

The discriminant is $D(x, y) = g_{xx} g_{yy} - g_{xy}^2 = 2 \cdot 0 - 144 = -144$.

Step 3. Apply the Second Derivative Test.

For f, we have $D > 0$ and $f_{xx} > 0$, therefore $f(-3, 1)$ is a local minimum.
For g, we have $D < 0$, hence $g\left(\frac{1}{12}, \frac{1}{72}\right)$ is a saddle point.

The graph in Figure 17(A) has a saddle point, therefore it is the graph of $g(x, y)$. The graph in Figure 17(B) corresponds to $f(x, y)$, since it has a local minimum.

3. Find the critical points of

$$f(x, y) = 8y^4 + x^2 + xy - 3y^2 - y^3$$

Use the contour map in Figure 18 to determine their nature (local minimum, local maximum, or saddle point).

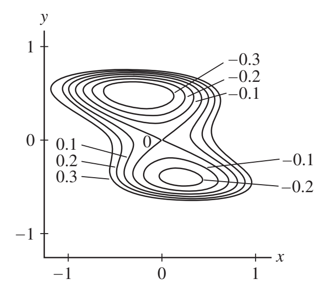

FIGURE 18 Contour map of $f(x, y) = 8y^4 + x^2 + xy - 3y^2 - y^3$.

SOLUTION The critical points are the solutions of $f_x = 0$ and $f_y = 0$. That is,

$$f_x(x, y) = 2x + y = 0$$
$$f_y(x, y) = 32y^3 + x - 6y - 3y^2 = 0$$

The first equation gives $y = -2x$. We substitute in the second equation and solve for x. This gives

$$32(-2x)^3 + x - 6(-2x) - 3(-2x)^2 = 0$$
$$-256x^3 + 13x - 12x^2 = 0$$
$$-x(256x^2 + 12x - 13) = 0$$

Hence $x = 0$ or $256x^2 + 12x - 13 = 0$. Solving the quadratic,

$$x_{1,2} = \frac{-12 \pm \sqrt{12^2 - 4 \cdot 256 \cdot (-13)}}{512} = \frac{-12 \pm 116}{512} \quad \Rightarrow \quad x = \frac{13}{64} \quad \text{or} \quad -\frac{1}{4}$$

Substituting in $y = -2x$ gives the y-coordinates of the critical points. The critical points are thus

$$(0, 0), \quad \left(\frac{13}{64}, -\frac{13}{32}\right), \quad \left(-\frac{1}{4}, \frac{1}{2}\right)$$

We now use the contour map to determine the type of each critical point. The level curves through $(0, 0)$ consist of two intersecting lines that divide the neighborhood near $(0, 0)$ into four regions. The function is decreasing in the y direction and increasing in the x-direction. Therefore, $(0, 0)$ is a saddle point. The level curves near the critical points $\left(\frac{13}{64}, -\frac{13}{32}\right)$ and $\left(-\frac{1}{4}, \frac{1}{2}\right)$ are closed curves encircling the points, hence these are local minima or maxima. The graph shows that both $\left(\frac{13}{64}, -\frac{13}{32}\right)$ and $\left(-\frac{1}{4}, \frac{1}{2}\right)$ are local minima.

4. Use the contour map in Figure 19 to determine whether the critical points A, B, C, D are local minima, local maxima, or saddle points.

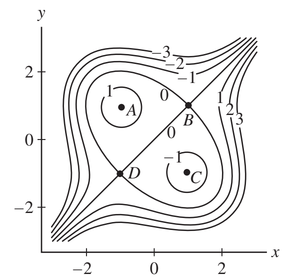

FIGURE 19

SOLUTION The nearby level curves at A and C are closed curves encircling A and C. As we move towards A the function increases in all directions, while moving towards C the function decreases in all directions. We conclude that the function has a local maximum at A and a local minimum at C. The level curves through B and D consist of two curves intersecting at these points respectively. These curves divide the neighborhoods near B and D into four regions. In some of the regions the function is increasing and in others it is decreasing as we move towards B or D. This implies that B and D are saddle points.

5. Let $f(x, y) = y^2x - yx^2 + xy$.

(a) Show that the critical points (x, y) satisfy the equations

$$y(y - 2x + 1) = 0, \qquad x(2y - x + 1) = 0$$

(b) Show that f has four critical points.

(c) Use the second derivative to determine the nature of the critical points.

SOLUTION

(a) The critical points are the solutions of the two equations $f_x(x, y) = 0$ and $f_y(x, y) = 0$. That is,

$$\begin{aligned} f_x(x, y) &= y^2 - 2yx + y = 0 \\ f_y(x, y) &= 2yx - x^2 + x = 0 \end{aligned} \quad \Rightarrow \quad \begin{aligned} y(y - 2x + 1) &= 0 \\ x(2y - x + 1) &= 0 \end{aligned}$$

(b) We find the critical points by solving the equations obtained in part (a):

$$y(y - 2x + 1) = 0 \tag{1}$$

$$x(2y - x + 1) = 0 \tag{2}$$

Equation (1) implies that $y = 0$ or $y = 2x - 1$. Substituting $y = 0$ in (2) and solving for x gives

$$x(-x + 1) = 0 \quad \Rightarrow \quad x = 0 \quad \text{or} \quad x = 1$$

We obtain the solutions $(0, 0)$ and $(1, 0)$. We now substitute $y = 2x - 1$ in (2) and solve for x. We get

$$\begin{aligned} x(4x - 2 - x + 1) &= 0 \\ x(3x - 1) &= 0 \quad \Rightarrow \quad x = 0 \quad \text{or} \quad x = \frac{1}{3} \end{aligned}$$

We compute the y-coordinate, using $y = 2x - 1$:

$$\begin{aligned} y &= 2 \cdot 0 - 1 = -1 \\ y &= 2 \cdot \frac{1}{3} - 1 = -\frac{1}{3} \end{aligned}$$

We obtain the solutions $(0, -1)$ and $\left(\frac{1}{3}, -\frac{1}{3}\right)$. To summarize, the critical points are $(0, 0)$, $(1, 0)$, $(0, -1)$, and $\left(\frac{1}{3}, -\frac{1}{3}\right)$. Three of the critical points have at least one zero coordinate, and one has two nonzero coordinates.

(c) We compute the second-order partial derivatives:

$$\begin{aligned} f_{xx}(x, y) &= \frac{\partial}{\partial x}(y^2 - 2yx + y) = -2y \\ f_{yy}(x, y) &= \frac{\partial}{\partial y}(2yx - x^2 + x) = 2x \end{aligned}$$

$$f_{xy}(x, y) = \frac{\partial}{\partial y}(y^2 - 2yx + y) = 2y - 2x + 1$$

The discriminant is

$$D(x, y) = f_{xx} f_{yy} - f_{xy}^2 = -2y \cdot 2x - (2y - 2x + 1)^2 = -4xy - (2y - 2x + 1)^2$$

We now apply the Second Derivative Test. We first compute the discriminants at the critical points:

$$\begin{aligned}
D(0, 0) &= -1 < 0 \\
D(1, 0) &= -1 < 0 \\
D(0, -1) &= -1 < 0 \\
D\left(\frac{1}{3}, -\frac{1}{3}\right) &= -4 \cdot \frac{1}{3}\left(-\frac{1}{3}\right) - \left(-\frac{2}{3} - \frac{2}{3} + 1\right)^2 = \frac{1}{3} > 0, \\
f_{xx}\left(\frac{1}{3}, -\frac{1}{3}\right) &= -2 \cdot \left(-\frac{1}{3}\right) = \frac{2}{3} > 0
\end{aligned}$$

The Second Derivative Test implies that the points $(0, 0)$, $(1, 0)$, and $(0, -1)$ are saddle points, and $f\left(\frac{1}{3}, -\frac{1}{3}\right)$ is a local minimum.

6. Show that $f(x, y) = \sqrt{x^2 + y^2}$ has one critical point P and that f is nondifferentiable at P. Does f take on a minimum, maximum, or saddle point at P?

SOLUTION Since $f(x, y) = \sqrt{x^2 + y^2} \geq 0$ and $f(0, 0) = 0$, $f(0, 0)$ is an absolute minimum value. To find the critical point of f we first find the first derivatives:

$$\begin{aligned}
f_x(x, y) &= \frac{\partial}{\partial x}\left(\sqrt{x^2 + y^2}\right) = \frac{2x}{2\sqrt{x^2 + y^2}} = \frac{x}{\sqrt{x^2 + y^2}} \\
f_y(x, y) &= \frac{\partial}{\partial y}\left(\sqrt{x^2 + y^2}\right) = \frac{2y}{2\sqrt{x^2 + y^2}} = \frac{y}{\sqrt{x^2 + y^2}}
\end{aligned}$$

Since f_x and f_y do not exist at $(0, 0)$ and the equations $f_x(x, y) = 0$ and $f_y(x, y) = 0$ have no solutions, the only critical point is $P = (0, 0)$, a point where f is non-differentiable (and is the absolute minimum).

In Exercises 7–23, find the critical points of the function. Then use the Second Derivative Test to determine whether they are local minima, local maxima, or saddle points (or state that the test fails).

7. $f(x, y) = x^2 + y^2 - xy + x$

SOLUTION

Step 1. Find the critical points. We set the first-order partial derivatives of $f(x, y) = x^2 + y^2 - xy + x$ equal to zero and solve:

$$f_x(x, y) = 2x - y + 1 = 0 \tag{1}$$

$$f_y(x, y) = 2y - x = 0 \tag{2}$$

Equation (2) implies that $x = 2y$. Substituting in (1) and solving for y gives

$$2 \cdot 2y - y + 1 = 0 \quad \Rightarrow \quad 3y = -1 \quad \Rightarrow \quad y = -\frac{1}{3}$$

The corresponding value of x is $x = 2 \cdot \left(-\frac{1}{3}\right) = -\frac{2}{3}$. The critical point is $\left(-\frac{2}{3}, -\frac{1}{3}\right)$.

Step 2. Compute the Discriminant. We find the second-order partials:

$$f_{xx}(x, y) = 2, \quad f_{yy}(x, y) = 2, \quad f_{xy}(x, y) = -1$$

The discriminant is

$$D(x, y) = f_{xx} f_{yy} - f_{xy}^2 = 2 \cdot 2 - (-1)^2 = 3$$

Step 3. Applying the Second Derivative Test. We have

$$D\left(-\frac{2}{3}, -\frac{1}{3}\right) = 3 > 0 \quad \text{and} \quad f_{xx}\left(-\frac{2}{3}, -\frac{1}{3}\right) = 2 > 0$$

The Second Derivative Test implies that $f\left(-\frac{2}{3}, -\frac{1}{3}\right)$ is a local minimum.

8. $f(x, y) = x^3 - xy + y^3$

SOLUTION

Step 1. Find the critical points. We set the first-order partial derivatives of $f(x, y) = x^3 - xy + y^3$ equal to zero and solve:

$$f_x(x, y) = 3x^2 - y = 0 \qquad (1)$$
$$f_y(x, y) = -x + 3y^2 = 0 \qquad (2)$$

Equation (1) implies that $y = 3x^2$. Substituting in equation (2) and solving for x gives

$$-x + 3(3x^2)^2 = 0$$
$$-x + 27x^4 = x(-1 + 27x^3) = 0 \quad \Rightarrow \quad x = 0, \quad x = \frac{1}{3}$$

The y-coordinates are $y = 3 \cdot 0^2 = 0$ and $y = 3 \cdot \left(\frac{1}{3}\right)^2 = \frac{1}{3}$. The critical points are thus $(0, 0)$ and $\left(\frac{1}{3}, \frac{1}{3}\right)$.

Step 2. Compute the Discriminant. We find the second-order partials:

$$f_{xx}(x, y) = 6x, \quad f_{yy}(x, y) = 6y, \quad f_{xy}(x, y) = -1$$

The discriminant is

$$D(x, y) = f_{xx}f_{yy} - f_{xy}^2 = 6x \cdot 6y - (-1)^2 = 36xy - 1$$

Step 3. Apply the Second Derivative Test. We have

$$D(0, 0) = -1 < 0$$
$$D\left(\frac{1}{3}, \frac{1}{3}\right) = 36 \cdot \frac{1}{3} \cdot \frac{1}{3} - 1 = 3 > 0, \quad f_{xx}\left(\frac{1}{3}, \frac{1}{3}\right) = 6 \cdot \frac{1}{3} = 2 > 0$$

Thus, $(0, 0)$ is a saddle point, whereas $f\left(\frac{1}{3}, \frac{1}{3}\right)$ is a local minimum.

9. $f(x, y) = x^3 + 2xy - 2y^2 - 10x$

SOLUTION

Step 1. Find the critical points. We set the first-order partial derivatives of $f(x, y) = x^3 + 2xy - 2y^2 - 10x$ equal to zero and solve:

$$f_x(x, y) = 3x^2 + 2y - 10 = 0 \qquad (1)$$
$$f_y(x, y) = 2x - 4y = 0 \qquad (2)$$

Equation (2) implies that $x = 2y$. We substitute in (1) and solve for y. This gives

$$3 \cdot (2y)^2 + 2y - 10 = 0$$
$$12y^2 + 2y - 10 = 0$$
$$6y^2 + y - 5 = 0$$
$$y_{1,2} = \frac{-1 \pm \sqrt{1 - 4 \cdot 6 \cdot (-5)}}{12} = \frac{-1 \pm 11}{12} \quad \Rightarrow \quad y_1 = -1 \quad \text{and} \quad y_2 = \frac{5}{6}$$

We find the x-coordinates using $x = 2y$:

$$x_1 = 2 \cdot (-1) = -2, \quad x_2 = 2 \cdot \frac{5}{6} = \frac{5}{3}$$

The critical points are thus $(-2, -1)$ and $\left(\frac{5}{3}, \frac{5}{6}\right)$.

Step 2. Compute the Discriminant. We find the second-order partials:

$$f_{xx}(x, y) = 6x, \quad f_{yy}(x, y) = -4, \quad f_{xy}(x, y) = 2$$

The discriminant is

$$D(x, y) = f_{xx}f_{yy} - f_{xy}^2 = 6x \cdot (-4) - 2^2 = -24x - 4$$

Step 3. Apply the Second Derivative Test. We have

$$D(-2,-1) = -24 \cdot (-2) - 4 = 44 > 0,$$
$$f_{xx}(-2,-1) = 6 \cdot (-2) = -12 < 0$$
$$D\left(\frac{5}{3}, \frac{5}{6}\right) = -24 \cdot \frac{5}{3} - 4 = -44 < 0$$

We conclude that $f(-2,-1)$ is a local maximum and $\left(\frac{5}{3}, \frac{5}{6}\right)$ is a saddle point.

10. $f(x, y) = x^3y + 12x^2 - 8y$

SOLUTION

Step 1. Find the critical points. We set the first-order partial derivatives of $f(x, y) = x^3y + 12x^2 - 8y$ equal to zero and solve:

$$f_x(x, y) = 3x^2y + 24x = 3x(xy + 8) = 0 \qquad (1)$$
$$f_y(x, y) = x^3 - 8 = 0 \qquad (2)$$

Equation (2) implies that $x = 2$. We substitute in equation (1) and solve for y to obtain

$$6(2y + 8) = 0 \quad \text{or} \quad y = -4$$

The critical point is $(2, -4)$.

Step 2. Compute the Discriminant. We find the second-order partials:

$$f_{xx}(x, y) = 6xy + 24, \quad f_{yy} = 0, \quad f_{xy} = 3x^2$$

The discriminant is thus

$$D(x, y) = f_{xx}f_{yy} - f_{xy}^2 = -9x^4$$

Step 3. Apply the Second Derivative Test. We have

$$D(2, -4) = -9 \cdot 2^4 < 0$$

Hence $(2, -4)$ is a saddle point.

11. $f(x, y) = 4x - 3x^3 - 2xy^2$

SOLUTION

Step 1. Find the critical points. We set the first-order derivatives of $f(x, y) = 4x - 3x^3 - 2xy^2$ equal to zero and solve:

$$f_x(x, y) = 4 - 9x^2 - 2y^2 = 0 \qquad (1)$$
$$f_y(x, y) = -4xy = 0 \qquad (2)$$

Equation (2) implies that $x = 0$ or $y = 0$. If $x = 0$, then equation (1) gives

$$4 - 2y^2 = 0 \quad \Rightarrow \quad y^2 = 2 \quad \Rightarrow \quad y = \sqrt{2}, \quad y = -\sqrt{2}$$

If $y = 0$, then equation (1) gives

$$4 - 9x^2 = 0 \quad \Rightarrow \quad 9x^2 = 4 \quad \Rightarrow \quad x = \frac{2}{3}, \quad x = -\frac{2}{3}$$

The critical points are therefore

$$\left(0, \sqrt{2}\right), \quad \left(0, -\sqrt{2}\right), \quad \left(\frac{2}{3}, 0\right), \quad \left(-\frac{2}{3}, 0\right)$$

Step 2. Compute the discriminant. The second-order partials are

$$f_{xx}(x, y) = -18x, \quad f_{yy}(x, y) = -4x, \quad f_{xy} = -4y$$

The discriminant is thus

$$D(x, y) = f_{xx}f_{yy} - f_{xy}^2 = -18x \cdot (-4x) - (-4y)^2 = 72x^2 - 16y^2$$

Step 3. Apply the Second Derivative Test. We have

$$D\left(0,\sqrt{2}\right) = -32 < 0$$
$$D\left(0,-\sqrt{2}\right) = -32 < 0$$
$$D\left(\frac{2}{3},0\right) = 72\cdot\frac{4}{9} = 32 > 0,$$
$$f_{xx}\left(\frac{2}{3},0\right) = -18\cdot\frac{2}{3} = -12 < 0$$
$$D\left(-\frac{2}{3},0\right) = 72\cdot\frac{4}{9} = 32 > 0,$$
$$f_{xx}\left(-\frac{2}{3},0\right) = -18\cdot\left(-\frac{2}{3}\right) = 12 > 0$$

The Second Derivative Test implies that the points $\left(0,\pm\sqrt{2}\right)$ are the saddle points, $f\left(\frac{2}{3},0\right)$ is a local maximum, and $f\left(-\frac{2}{3},0\right)$ is a local minimum.

12. $f(x,y) = x^3 + y^4 - 6x - 2y^2$

SOLUTION

Step 1. Find the critical points. We set the first-order derivatives of $f(x,y) = x^3 + y^4 - 6x - 2y^2$ equal to zero and solve:

$$f_x(x,y) = 3x^2 - 6 = 0, \quad f_y(x,y) = 4y^3 - 4y = 0 \quad \text{or} \quad 4y(y^2-1) = 0$$

The first equation implies that $x = \pm\sqrt{2}$, and the second equation implies that $y = 0$ or $y = \pm 1$. The critical points are therefore

$$\left(\sqrt{2},0\right), \quad \left(\sqrt{2},1\right), \quad \left(\sqrt{2},-1\right), \quad \left(-\sqrt{2},0\right), \quad \left(-\sqrt{2},1\right), \quad \left(-\sqrt{2},-1\right)$$

Step 2. Compute the discriminant. We find the second-order partials:

$$f_{xx}(x,y) = 6x, \quad f_{yy}(x,y) = 12y^2 - 4, \quad f_{xy} = 0$$

The discriminant is

$$D(x,y) = f_{xx}f_{yy} - f_{xy}^2 = 6x\cdot 4(3y^2-1) - 0^2 = 24x(3y^2-1)$$

Step 3. Apply the Second Derivative Test. We have

$$D\left(\sqrt{2},0\right) = -24\sqrt{2} < 0$$
$$D\left(\sqrt{2},1\right) = 48\sqrt{2} > 0,\ f_{xx}\left(\sqrt{2},1\right) = 6\sqrt{2} > 0$$
$$D\left(\sqrt{2},-1\right) = 48\sqrt{2} > 0,\ f_{xx}\left(\sqrt{2},-1\right) = 6\sqrt{2} > 0$$
$$D\left(-\sqrt{2},0\right) = 24\sqrt{2} > 0,\ f_{xx}\left(-\sqrt{2},0\right) = -6\sqrt{2} < 0$$
$$D\left(-\sqrt{2},1\right) = -48\sqrt{2} < 0$$
$$D\left(-\sqrt{2},-1\right) = -48\sqrt{2} < 0$$

By the Second Derivative Test we obtain the following conclusions: $\left(\sqrt{2},0\right)$, $\left(-\sqrt{2},1\right)$, and $\left(-\sqrt{2},-1\right)$ are saddle points; $f\left(\sqrt{2},1\right)$ and $f\left(\sqrt{2},-1\right)$ are local minima; and $f\left(-\sqrt{2},0\right)$ is a local maximum.

13. $f(x,y) = x^4 + y^4 - 4xy$

SOLUTION

Step 1. Find the critical points. We set the first-order derivatives of $f(x,y) = x^4 + y^4 - 4xy$ equal to zero and solve:

$$f_x(x,y) = 4x^3 - 4y = 0, \quad f_y(x,y) = 4y^3 - 4x = 0 \tag{1}$$

Equation (1) implies that $y = x^3$. Substituting in (2) and solving for x, we obtain

$$(x^3)^3 - x = x^9 - x = x(x^8 - 1) = 0 \quad \Rightarrow \quad x = 0, \quad x = 1, \quad x = -1$$

The corresponding y coordinates are

$$y = 0^3 = 0, \quad y = 1^3 = 1, \quad y = (-1)^3 = -1$$

The critical points are therefore

$$(0,0), \quad (1,1), \quad (-1,-1)$$

Step 2. Compute the discriminant. We find the second-order partials:

$$f_{xx}(x,y) = 12x^2, \quad f_{yy}(x,y) = 12y^2, \quad f_{xy}(x,y) = -4$$

The discriminant is thus

$$D(x,y) = f_{xx}f_{yy} - f_{xy}^2 = 12x^2 \cdot 12y^2 - (-4)^2 = 144x^2y^2 - 16$$

Step 3. Apply the Second Derivative Test. We have

$$\begin{aligned} D(0,0) &= -16 < 0 \\ D(1,1) &= 144 - 16 = 128 > 0, \quad f_{xx}(1,1) = 12 > 0 \\ D(-1,-1) &= 144 - 16 = 128 > 0, \quad f_{xx}(-1,-1) = 12 > 0 \end{aligned}$$

We conclude that $(0,0)$ is a saddle point, whereas $f(1,1)$ and $f(-1,-1)$ are local minima.

14. $f(x,y) = e^{x^2-y^2+4y}$

SOLUTION

Step 1. Find the critical points. We set the first partials of $f(x,y) = e^{x^2-y^2+4y}$ equal to zero and solve:

$$f_x(x,y) = 2xe^{x^2-y^2+4y} = 0, \quad f_y(x,y) = (-2y+4)e^{x^2-y^2+4y} = 0$$

Since $e^{x^2-y^2+4y} \neq 0$, the first equation gives $x = 0$ and the second equation gives $-2y + 4 = 0$ or $y = 2$. We obtain the critical point $(0,2)$.

Step 2. Compute the discriminant. We find the second-order partials:

$$\begin{aligned} f_{xx}(x,y) &= \frac{\partial}{\partial x}\left(2xe^{x^2-y^2+4y}\right) = 2e^{x^2-y^2+4y} + 2xe^{x^2-y^2+4y} \cdot 2x = 2e^{x^2-y^2+4y}(1+2x^2) \\ f_{yy}(x,y) &= \frac{\partial}{\partial y}\left((-2y+4)e^{x^2-y^2+4y}\right) = -2e^{x^2-y^2+4y} + (-2y+4)e^{x^2-y^2+4y} \cdot (-2y+4) \\ &= 2e^{x^2-y^2+4y}(-1 + (-y+2)(-2y+4)) = 2e^{x^2-y^2+4y}\left(2y^2 - 8y + 7\right) \\ f_{xy}(x,y) &= \frac{\partial}{\partial y}\left(2xe^{x^2-y^2+4y}\right) = 2xe^{x^2-y^2+4y}(-2y+4) = 4x(2-y)e^{x^2-y^2+4y} \end{aligned}$$

The discriminant is

$$D(x,y) = f_{xx}f_{yy} - f_{xy}^2 = 4e^{2\left(x^2-y^2+4y\right)}\left(1+2x^2\right)\left(2y^2-8y+7\right) - 16x^2(2-y)^2e^{2\left(x^2-y^2+4y\right)}$$

Step 3. Apply the Second Derivative Test. We have

$$D(0,2) = -4e^8 < 0$$

Therefore, $(0,2)$ is a saddle point.

15. $f(x,y) = xye^{-x^2-y^2}$

SOLUTION

Step 1. Find the critical points. We compute the partial derivatives of $f(x,y) = xye^{-x^2-y^2}$, using the Product Rule and the Chain Rule:

$$\begin{aligned} f_x(x,y,z) &= y\left(1 \cdot e^{-x^2-y^2} + xe^{-x^2-y^2} \cdot (-2x)\right) = ye^{-x^2-y^2}\left(1 - 2x^2\right) \\ f_y(x,y,z) &= x\left(1 \cdot e^{-x^2-y^2} + ye^{-x^2-y^2} \cdot (-2y)\right) = xe^{-x^2-y^2}\left(1 - 2y^2\right) \end{aligned}$$

We set the partial derivatives equal to zero and solve to find the critical points. This gives

$$ye^{-x^2-y^2}\left(1-2x^2\right)=0$$
$$xe^{-x^2-y^2}\left(1-2y^2\right)=0$$

Since $e^{-x^2-y^2}\neq 0$, the first equation gives $y=0$ or $1-2x^2=0$, that is, $y=0$, $x=\frac{1}{\sqrt{2}}$, $x=-\frac{1}{\sqrt{2}}$. We substitute each of these values in the second equation and solve to obtain

$$y=0:\quad xe^{-x^2}=0 \quad\Rightarrow\quad x=0$$
$$x=\frac{1}{\sqrt{2}}:\quad \frac{1}{\sqrt{2}}e^{-\frac{1}{2}-y^2}\left(1-2y^2\right)=0 \quad\Rightarrow\quad 1-2y^2=0 \quad\Rightarrow\quad y=\pm\frac{1}{\sqrt{2}}$$
$$x=-\frac{1}{\sqrt{2}}:\quad -\frac{1}{\sqrt{2}}e^{-\frac{1}{2}-y^2}\left(1-2y^2\right)=0 \quad\Rightarrow\quad 1-2y^2=0 \quad\Rightarrow\quad y=\pm\frac{1}{\sqrt{2}}$$

We obtain the following critical points: (0, 0),

$$\left(\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}}\right),\quad \left(\frac{1}{\sqrt{2}},-\frac{1}{\sqrt{2}}\right),\quad \left(-\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}}\right),\quad \left(-\frac{1}{\sqrt{2}},-\frac{1}{\sqrt{2}}\right)$$

Step 2. Compute the second-order partials.

$$f_{xx}(x,y)=y\frac{\partial}{\partial x}\left(e^{-x^2-y^2}\left(1-2x^2\right)\right)=y\left(e^{-x^2-y^2}(-2x)\left(1-2x^2\right)+e^{-x^2-y^2}(-4x)\right)$$
$$=-2xye^{-x^2-y^2}\left(3-2x^2\right)$$
$$f_{yy}(x,y)=x\frac{\partial}{\partial y}\left(e^{-x^2-y^2}\left(1-2y^2\right)\right)=x\left(e^{-x^2-y^2}(-2y)\left(1-2y^2\right)+e^{-x^2-y^2}(-4y)\right)$$
$$=-2yxe^{-x^2-y^2}\left(3-2y^2\right)$$
$$f_{xy}(x,y)=\frac{\partial}{\partial y}f_x=\left(1-2x^2\right)\frac{\partial}{\partial y}\left(ye^{-x^2-y^2}\right)=\left(1-2x^2\right)\left(1\cdot e^{-x^2-y^2}+ye^{-x^2-y^2}(-2y)\right)$$
$$=e^{-x^2-y^2}\left(1-2x^2\right)\left(1-2y^2\right)$$

The discriminant is

$$D(x,y)=f_{xx}f_{yy}-f_{xy}^2$$

Step 3. Apply the Second Derivative Test. We construct the following table:

Critical Point	f_{xx}	f_{yy}	f_{xy}	D	Type
$(0,0)$	0	0	1	-1	$D<0$, saddle point
$\left(\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}}\right)$	$-\frac{2}{e}$	$-\frac{2}{e}$	0	$\frac{4}{e^2}$	$D>0$, $f_{xx}<0$ local maximum
$\left(\frac{1}{\sqrt{2}},-\frac{1}{\sqrt{2}}\right)$	$\frac{2}{e}$	$\frac{2}{e}$	0	$\frac{4}{e^2}$	$D>0$, $f_{xx}>0$ local minimum
$\left(-\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}}\right)$	$\frac{2}{e}$	$\frac{2}{e}$	0	$\frac{4}{e^2}$	$D>0$, $f_{xx}>0$ local minimum
$\left(-\frac{1}{\sqrt{2}},-\frac{1}{\sqrt{2}}\right)$	$-\frac{2}{e}$	$-\frac{2}{e}$	0	$\frac{4}{e^2}$	$D>0$, $f_{xx}<0$ local maximum

16. $f(x,y)=e^x-xe^y$

SOLUTION

Step 1. Find the critical points. We set the first-order derivatives of $f(x,y)=e^x-xe^y$ equal to zero and solve:

$$f_x(x,y)=e^x-e^y=0$$
$$f_y(x,y)=-xe^y=0$$

Since $e^y\neq 0$, the second equation gives $x=0$. Substituting in the first equation, we get

$$e^0-e^y=1-e^y=0 \quad\Rightarrow\quad e^y=1 \quad\Rightarrow\quad y=0$$

The critical point is (0, 0).

Step 2. Compute the discriminant. We find the second-order partial derivatives:

$$f_{xx}(x, y) = \frac{\partial}{\partial x}\left(e^x - e^y\right) = e^x$$

$$f_{yy}(x, y) = \frac{\partial}{\partial y}\left(-xe^y\right) = -xe^y$$

$$f_{xy}(x, y) = \frac{\partial}{\partial y}\left(e^x - e^y\right) = -e^y$$

The discriminant is

$$D(x, y) = f_{xx} f_{yy} - f_{xy}^2 = -xe^{x+y} - e^{2y}$$

Step 3. Apply the Second Derivative Test. We have

$$D(0, 0) = 0 - e^0 = -1 < 0$$

The point (0, 0) is a saddle point.

17. $f(x, y) = \sin(x + y) - \cos x$

SOLUTION

Step 1. Find the critical points. We set the first-order derivatives of $f(x, y) = \sin(x + y) - \cos x$ equal to zero and solve:

$$f_x(x, y) = \cos(x + y) + \sin x = 0$$

$$f_y(x, y) = \cos(x + y) = 0$$

First consider the second equation, $\cos(x + y) = 0$ this is when

$$x + y = \frac{(2k+1)\pi}{2} \to y = \frac{(2k+1)\pi}{2} - x \text{ where } k \text{ is an integer}$$

Then setting the two equations equal to one another we gain $\sin x = 0$ which are the values:

$$x = 0, \pm\pi, \pm 2\pi, \cdots = \pm k\pi \text{ where } k \text{ is an integer.}$$

Thus we have:

$$x = k\pi \text{ and } y = \frac{(2n+1)\pi}{2} \text{ where } n, k \text{ are integers}$$

Step 2. Compute the discriminant. We find the second-order partial derivatives:

$$f_{xx}(x, y) = -\sin(x + y) + \cos x, \quad f_{yy}(x, y) = -\sin(x + y), \quad f_{xy}(x, y) = -\sin(x + y)$$

The discriminant is:

$$D(x, y) = f_{xx} f_{yy} - f_{xy}^2 = (-\sin(x + y) + \cos x)(-\sin(x + y)) - \sin^2(x + y) = -\cos(x)\sin(x + y)$$

Step 3. Apply the Second Derivative Test. We have

$$D = \begin{cases} +1, & \text{if } y = \frac{4n+3}{2}\pi \\ -1, & y = \frac{4n+1}{2}\pi \end{cases}$$

Therefore, the points $\left(k\pi, \frac{4n+1}{2}\pi\right)$ are saddle points since $D < 0$.

Since $D > 0$ for the points $\left(k\pi, \frac{4n+3}{2}\pi\right)$, we need to examine f_{xx}. The results show:

$$f_{xx} > 0 \text{ if } k \text{ is even and } f_{xx} < 0 \text{ if } k \text{ is odd}$$

Thus:

$$\left(k\pi, \frac{4n+3}{2}\pi\right) \text{ are local minima if } k \text{ is even}$$

while

$$\left(k\pi, \frac{4n+3}{2}\pi\right) \text{ are local maxima if } k \text{ is odd}$$

18. $f(x, y) = x\ln(x + y)$

SOLUTION

Step 1. Find the critical points. We set the first-order partial derivatives of $f(x, y) = x\ln(x + y)$ equal to zero and solve:

$$f_x(x, y) = \ln(x + y) + x \cdot \frac{1}{x + y} = \ln(x + y) + \frac{x}{x + y} = 0$$
$$f_y(x, y) = \frac{x}{x + y} = 0$$

The second equation implies $x = 0$. Substituting in the first equation gives

$$\ln y + 0 = 0 \quad \Rightarrow \quad \ln y = 0 \quad \Rightarrow \quad y = 1.$$

We obtain the critical point $(0, 1)$. f_x and f_y do not exist at the points where $x + y = 0$, but these points are not in the domain of f, hence they are not critical points. The critical point is thus $(0, 1)$.

Step 2. Compute the discriminant. We find the second-order derivatives:

$$f_{xx} = \frac{\partial}{\partial x}\left(\ln(x + y) + \frac{x}{x + y}\right) = \frac{1}{x + y} + \frac{1 \cdot (x + y) - x \cdot 1}{(x + y)^2} = \frac{1}{x + y} + \frac{y}{(x + y)^2} = \frac{x + 2y}{(x + y)^2}$$
$$f_{yy} = \frac{\partial}{\partial y}\left(\frac{x}{x + y}\right) = -\frac{x}{(x + y)^2}$$
$$f_{xy} = f_{yx} = \frac{\partial}{\partial x}\left(\frac{x}{x + y}\right) = \frac{1 \cdot (x + y) - x \cdot 1}{(x + y)^2} = \frac{y}{(x + y)^2}$$

The discriminant is

$$D(x, y) = f_{xx}f_{yy} - f_{xy}^2 = -\frac{x(x + 2y)}{(x + y)^4} - \frac{y^2}{(x + y)^4}$$

Step 3. Apply the Second Derivative Test. We have

$$D(0, 1) = 0 - \frac{1^2}{(0 + 1)^4} = -1 < 0$$

Therefore, $(0, 1)$ is a saddle point.

19. $f(x, y) = \ln x + 2\ln y - x - 4y$

SOLUTION

Step 1. Find the critical points. We set the first-order partials of $f(x, y) = \ln x + 2\ln y - x - 4y$ equal to zero and solve:

$$f_x(x, y) = \frac{1}{x} - 1 = 0, \quad f_y(x, y) = \frac{2}{y} - 4 = 0$$

The first equation gives $x = 1$, and the second equation gives $y = \frac{1}{2}$. We obtain the critical point $\left(1, \frac{1}{2}\right)$. Notice that f_x and f_y do not exist if $x = 0$ or $y = 0$, respectively, but these are not critical points since they are not in the domain of f. The critical point is thus $\left(1, \frac{1}{2}\right)$.

Step 2. Compute the discriminant. We find the second-order partials:

$$f_{xx}(x, y) = -\frac{1}{x^2}, \quad f_{yy}(x, y) = -\frac{2}{y^2}, \quad f_{xy}(x, y) = 0$$

The discriminant is

$$D(x, y) = f_{xx}f_{yy} - f_{xy}^2 = \frac{2}{x^2y^2}$$

Step 3. Apply the Second Derivative Test. We have

$$D\left(1, \frac{1}{2}\right) = \frac{2}{1^2 \cdot \left(\frac{1}{2}\right)^2} = 8 > 0, \quad f_{xx}\left(1, \frac{1}{2}\right) = -\frac{1}{1^2} = -1 < 0$$

We conclude that $f\left(1, \frac{1}{2}\right)$ is a local maximum.

20. $f(x, y) = (x + y)\ln(x^2 + y^2)$

SOLUTION

Step 1. Find the critical points. We set the partial derivatives of $f(x, y) = (x + y)\ln(x^2 + y^2)$ equal to zero and solve.

$$f_x(x + y) = \frac{2x(x + y)}{x^2 + y^2} + \ln(x^2 + y^2) = 0, \quad f_y(x, y) = \frac{2y(x + y)}{x^2 + y^2} + \ln(x^2 + y^2) = 0$$

and note that

$$2x(x + y) = 2y(x + y) \quad \Rightarrow \quad 2(x + y)(x - y) = 0$$

So critical points satisfy $x = \pm y$.

If $x = y$ we would have

$$\frac{2y(2y)}{2y^2} + \ln(2y^2) = 0 \quad \Rightarrow \quad \ln(2y^2) = -2 \quad \Rightarrow \quad y = \pm\frac{1}{e\sqrt{2}}$$

If $x = -y$ we would have

$$\frac{2y(0)}{2y^2} + \ln(2y^2) = 0 \quad \Rightarrow \quad \ln(2y^2) = 0 \quad \Rightarrow \quad y = \pm\frac{1}{\sqrt{2}}$$

Our critical points are:

$$\left(\frac{1}{e\sqrt{2}}, \frac{1}{e\sqrt{2}}\right), \quad \left(-\frac{1}{e\sqrt{2}}, -\frac{1}{e\sqrt{2}}\right), \quad \left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right), \quad \left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)$$

Step 2. Compute the discriminant. We compute the second-order partial derivatives

$$f_{xx}(x, y) = \frac{4x}{x^2 + y^2} + \frac{2(x + y)}{x^2 + y^2} - \frac{4x^2(x + y)}{(x^2 + y^2)^2}$$

$$f_{xy}(x, y) = \frac{2y}{x^2 + y^2} + \frac{2x}{x^2 + y^2} - \frac{4xy(x + y)}{(x^2 + y^2)^2}$$

$$f_{yy}(x, y) = \frac{4y}{x^2 + y^2} + \frac{2(x + y)}{x^2 + y^2} - \frac{4y^2(x + y)}{(x^2 + y^2)^2}$$

Step 3. Apply the Second Derivative Test. We can form the table

Critical point	f_{xx}	f_{yy}	f_{xy}	D	Type
$\left(\frac{1}{e\sqrt{2}}, \frac{1}{e\sqrt{2}}\right)$	$2e\sqrt{2}$	$2e\sqrt{2}$	0	$8e^2$	local minimum
$\left(-\frac{1}{e\sqrt{2}}, -\frac{1}{e\sqrt{2}}\right)$	$-2e\sqrt{2}$	$-2e\sqrt{2}$	0	$8e^2$	local maximum
$\left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right)$	$2\sqrt{2}$	$-2\sqrt{2}$	0	-8	saddle point
$\left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)$	$-2\sqrt{2}$	$2\sqrt{2}$	0	-8	saddle point

21. $f(x, y) = x - y^2 - \ln(x + y)$

SOLUTION

Step 1. Find the critical points. We set the partial derivatives of $f(x, y) = x - y^2 - \ln(x + y)$ equal to zero and solve.

$$f_x(x, y) = 1 - \frac{1}{x + y} = 0, \quad f_y(x, y) = -2y - \frac{1}{x + y} = 0$$

The first equation implies that $\frac{1}{x+y} = 1$. Substituting in the second equation gives

$$-2y - 1 = 0 \quad \Rightarrow \quad 2y = -1 \quad \Rightarrow \quad y = -\frac{1}{2}$$

We substitute $y = -\frac{1}{2}$ in the first equation and solve for x:

$$1 - \frac{1}{x - \frac{1}{2}} = 0 \quad \Rightarrow \quad x - \frac{1}{2} = 1 \quad \Rightarrow \quad x = \frac{3}{2}$$

We obtain the critical point $\left(\frac{3}{2}, -\frac{1}{2}\right)$. Notice that although f_x and f_y do not exist where $x + y = 0$, these are not critical points since f is not defined at these points.

Step 2. Compute the discriminant. We compute the second-order partial derivatives:

$$f_{xx}(x, y) = \frac{\partial}{\partial x}\left(1 - \frac{1}{x+y}\right) = \frac{1}{(x+y)^2}$$

$$f_{yy}(x, y) = \frac{\partial}{\partial y}\left(-2y - \frac{1}{x+y}\right) = -2 + \frac{1}{(x+y)^2}$$

$$f_{xy}(x, y) = \frac{\partial}{\partial y}\left(1 - \frac{1}{x+y}\right) = \frac{1}{(x+y)^2}$$

The discriminant is

$$D(x, y) = f_{xx}f_{yy} - f_{xy}^2 = \frac{1}{(x+y)^2}\left(-2 + \frac{1}{(x+y)^2}\right) - \frac{1}{(x+y)^4} = \frac{-2}{(x+y)^2}$$

Step 3. Apply the Second Derivative Test. We have

$$D\left(\frac{3}{2}, -\frac{1}{2}\right) = \frac{-2}{\left(\frac{3}{2} - \frac{1}{2}\right)^2} = -2 < 0$$

We conclude that $\left(\frac{3}{2}, -\frac{1}{2}\right)$ is a saddle point.

22. $f(x, y) = (x - y)e^{x^2 - y^2}$

SOLUTION Find the critical points. We set the partial derivatives of $f(x, y) = (x - y)e^{x^2 - y^2}$ equal to zero and solve:

$$f_x(x, y) = e^{x^2-y^2} + (x - y)e^{x^2-y^2} \cdot 2x = e^{x^2-y^2}\left(2x^2 - 2xy + 1\right) = 0$$

$$f_y(x, y) = -e^{x^2-y^2} + (x - y)e^{x^2-y^2} \cdot (-2y) = e^{x^2-y^2}\left(2y^2 - 2xy - 1\right) = 0$$

Since $e^{x^2-y^2} \neq 0$, we have the following equations:

$$2x^2 - 2xy + 1 = 0$$
$$2y^2 - 2xy - 1 = 0$$

We add and subtract the two equations to obtain the following equations:

$$2\left(x^2 + y^2\right) - 4xy = 0$$

$$2\left(x^2 - y^2\right) + 2 = 0$$

The first equation can be rewritten as $x^2 - 2xy + y^2 = 0$ or $(x - y)^2 = 0$, yielding $x = y$. Substituting in the second equation gives $2 = 0$, we conclude that the two equations have no solutions, that is, there are no critical points (notice that f_x and f_y exist everywhere). Since local minima and local maxima can occur only at critical points, it follows that $f(x, y) = (x - y)e^{x^2-y^2}$ does not have local minima or local maxima.

23. $f(x, y) = (x + 3y)e^{y - x^2}$

SOLUTION

Step 1. Find the critical points. We compute the partial derivatives of $f(x, y) = (x + 3y)e^{y-x^2}$, using the Product Rule and the Chain Rule:

$$f_x(x, y) = 1 \cdot e^{y-x^2} + (x + 3y)e^{y-x^2} \cdot (-2x) = e^{y-x^2}\left(1 - 2x^2 - 6xy\right)$$

$$f_y(x, y) = 3e^{y-x^2} + (x + 3y)e^{y-x^2} \cdot 1 = e^{y-x^2}(3 + x + 3y)$$

We set the partial derivatives equal to zero and solve to find the critical points:

$$e^{y-x^2}\left(1 - 2x^2 - 6xy\right) = 0$$

$$e^{y-x^2}(3 + x + 3y) = 0$$

Since $e^{y-x^2} \neq 0$, we obtain the following equations:

$$1 - 2x^2 - 6xy = 0$$
$$3 + x + 3y = 0$$

The second equation gives $x = -3(1 + y)$. We substitute for x in the first equation and solve for y:

$$1 - 2 \cdot 9(1+y)^2 + 18(1+y)y = 0$$
$$1 - 18\left(1 + 2y + y^2\right) + 18\left(y + y^2\right) = 0$$
$$-17 - 18y = 0 \quad \Rightarrow \quad y = -\frac{17}{18}, \quad x = -3\left(1 - \frac{17}{18}\right) = -\frac{1}{6}$$

The critical point is $\left(-\frac{1}{6}, -\frac{17}{18}\right)$.

Step 2. Compute the second-order partials.

$$f_{xx}(x, y) = \frac{\partial}{\partial x} f_x = e^{y-x^2}(-2x)\left(1 - 2x^2 - 6xy\right) + e^{y-x^2}(-4x - 6y) = 2e^{y-x^2}\left(2x^3 + 6x^2y - 3x - 3y\right)$$
$$f_{yy}(x, y) = \frac{\partial}{\partial y} f_y = e^{y-x^2}(3 + x + 3y) + e^{y-x^2} \cdot 3 = e^{y-x^2}(6 + x + 3y)$$
$$f_{xy}(x, y) = \frac{\partial}{\partial x} f_y = e^{y-x^2}(-2x)(3 + x + 3y) + e^{y-x^2} \cdot 1 = e^{y-x^2}\left(1 - 6xy - 2x^2 - 6x\right)$$

The discriminant is

$$D(x, y) = f_{xx} f_{yy} - f_{xy}^2$$

Step 3. Apply the Second Derivative Test. We obtain the following table:

Critical Point	f_{xx}	f_{yy}	f_{xy}	D	Type
$\left(-\frac{1}{6}, -\frac{17}{18}\right)$	2.4	1.13	0.38	2.57	$D > 0$, $f_{xx} > 0$, local minimum

24. Show that $f(x, y) = x^2$ has infinitely many critical points (as a function of two variables) and that the Second Derivative Test fails for all of them. What is the minimum value of f? Does $f(x, y)$ have any local maxima?

SOLUTION First if we solve for critical points we get

$$f_x(x, y) = 2x, \quad f_y(x, y) = 0$$

Thus setting each equal to zero only yields $x = 0$ and y can be any real number. The list of critical points is

$(0, r)$ where r is any real number.

Now computing the second-order partials for the discriminant we get

$$f_{xx}(x, y) = 2, \quad f_{xy}(x, y) = 0, \quad f_{yy}(x, y) = 0$$

Therefore, $D = 0$. This means that the Second Derivative Test is inconclusive for every critical point, it fails.

Finally this function does have a minimum value of 0 since the smallest any square can be is 0. Since x can get arbitrarily large, this function has no maximum value, and no local maxima.

25. Prove that the function $f(x, y) = \frac{1}{3}x^3 + \frac{2}{3}y^{3/2} - xy$ satisfies $f(x, y) \geq 0$ for $x \geq 0$ and $y \geq 0$.

(a) First, verify that the set of critical points of f is the parabola $y = x^2$ and that the Second Derivative Test fails for these points.

(b) Show that for fixed b, the function $g(x) = f(x, b)$ is concave up for $x > 0$ with a critical point at $x = b^{1/2}$.

(c) Conclude that $f(a, b) \geq f(b^{1/2}, b) = 0$ for all $a, b \geq 0$.

SOLUTION

(a) To find the critical points, we need the first-order partial derivatives, set them equal to zero and solve:

$$f_x(x, y) = x^2 - y = 0, \quad f_y(x, y) = y^{1/2} - x = 0$$

This gives us:

$$y = x^2$$

as the solution set for the critical points.

Now to compute the discriminant, we need the second-order partials

$$f_{xx}(x, y) = 2x, \quad f_{yy}(x, y) = \frac{1}{2}y^{-1/2}, \quad f_{xy}(x, y) = -1$$

Thus the discriminant is

$$D(x, y) = \frac{x}{\sqrt{y}} - 1$$

Since $y = x^2$ is the solution set for the critical points we see:

$$D(x, y) = 1 - 1 = 0$$

Therefore the Second Derivative Test is inconclusive and fails us.

(b) If we fix a value b and consider $g(x) = f(x, b) = \frac{1}{3}x^3 + \frac{2}{3}b^{3/2} - bx$ to find the concavity, we see

$$g'(x) = x^2 - b, \quad g''(x) = 2x$$

Then certainly, for $x > 0$, this function is concave up. The critical point will occur at the point when $x^2 - b = 0$ or $x = b^{1/2}$.

(c) Now, since for fixed b, we know that $g(x) = f(x, b)$ is concave up if $x > 0$, and the critical point is $x = b^{1/2}$. Therefore

$$f(a, b) \geq f(b^{1/2}, b) = 0 \text{ for all } b \geq 0$$

26. Let $f(x, y) = (x^2 + y^2)e^{-x^2-y^2}$.

(a) Where does f take on its minimum value? Do not use calculus to answer this question.

(b) Verify that the set of critical points of f consists of the origin $(0, 0)$ and the unit circle $x^2 + y^2 = 1$.

(c) The Second Derivative Test fails for points on the unit circle (this can be checked by some lengthy algebra). Prove, however, that f takes on its maximum value on the unit circle by analyzing the function $g(t) = te^{-t}$ for $t > 0$.

SOLUTION

(a) We know that $e^{-(x^2+y^2)}$ is always positive and greater than 0, and $x^2 + y^2 \geq 0$, therefore the minimum is reached when $x^2 + y^2 = 0$ and the only point where this occurs is at $(0, 0)$.

(b) Find the critical points. We set the first-order derivatives equal to zero and solve:

$$f_x(x, y) = 2xe^{-x^2-y^2} + (x^2 + y^2)e^{-x^2-y^2} \cdot (-2x) = 2xe^{-x^2-y^2}(1 - x^2 - y^2) = 0$$
$$f_y(x, y) = 2ye^{-x^2-y^2} + (x^2 + y^2)e^{-x^2-y^2} \cdot (-2y) = 2ye^{-x^2-y^2}(1 - x^2 - y^2) = 0$$

Since $e^{-x^2-y^2} \neq 0$, the first equation gives $x = 0$ or $x^2 + y^2 = 1$. We substitute $x = 0$ in the second equation and solve for y:

$$2ye^{-y^2}(1 - y^2) = 0$$

Since $e^{-y^2} \neq 0$, the solutions are $y = 0$ or $y = \pm 1$. The corresponding points are $(0, 0)$, $(0, 1)$, $(0, -1)$. The solution $x^2 + y^2 = 1$ also satisfies the second equation. We conclude that there are infinitely many critical points, namely, the points on the unit circle $x^2 + y^2 = 1$ and its center $(0, 0)$.

(c) For the given function we can define $t = x^2 + y^2$ to obtain the function $g(t) = te^{-t}$. The critical point of $g(t)$ is

$$g'(t) = e^{-t} - te^{-t} = (1 - t)e^{-t} = 0 \quad \Rightarrow \quad t = 1$$

We find the second derivative at the critical point:

$$g''(t) = \frac{d}{dt}\left[(1 - t)e^{-t}\right] = -e^{-t} + (1 - t)e^{-t}(-1) = (t - 2)e^{-t}$$

Therefore, by the Second Derivative Test for functions of one variable, $t = 1$ gives a local maximum. Also, the value of $f(x, y)$ at all the points on the unit circle is the same:

$$f(x, y) = (x^2 + y^2)e^{-(x^2+y^2)} = te^{-t} = e^{-1} \text{ when } t = 1$$

It follows that at the points on the unit circle $x^2 + y^2 = 1$, $f(x, y)$ has local maxima.

27. CAS Use a computer algebra system to find a numerical approximation to the critical point of

$$f(x, y) = (1 - x + x^2)e^{y^2} + (1 - y + y^2)e^{x^2}$$

Apply the Second Derivative Test to confirm that it corresponds to a local minimum as in Figure 20.

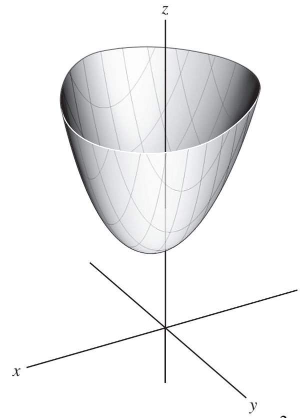

FIGURE 20 Plot of $f(x, y) = (1 - x + x^2)e^{y^2} + (1 - y + y^2)e^{x^2}$.

SOLUTION The critical points are the solutions of $f_x(x, y) = 0$ and $f_y(x, y) = 0$. We compute the partial derivatives:

$$f_x(x, y) = (-1 + 2x)e^{y^2} + \left(1 - y + y^2\right)e^{x^2} \cdot 2x$$
$$f_y(x, y) = \left(1 - x + x^2\right)e^{y^2} \cdot 2y + (-1 + 2y)e^{x^2}$$

Hence, the critical points are the solutions of the following equations:

$$(2x - 1)e^{y^2} + 2x\left(1 - y + y^2\right)e^{x^2} = 0$$
$$(2y - 1)e^{x^2} + 2y\left(1 - x + x^2\right)e^{y^2} = 0$$

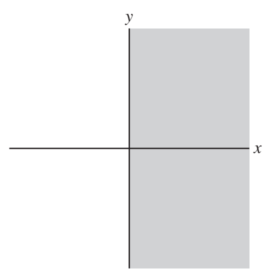
Using a CAS we obtain the following solution: $x = y = 0.27788$, which from the figure is a local minimum.

28. Which of the following domains are closed and which are bounded?

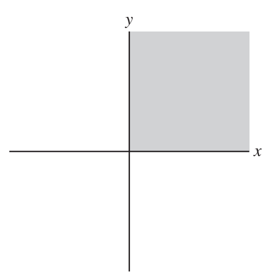
(a) $\{(x, y) \in \mathbf{R}^2 : x^2 + y^2 \le 1\}$
(b) $\{(x, y) \in \mathbf{R}^2 : x^2 + y^2 < 1\}$
(c) $\{(x, y) \in \mathbf{R}^2 : x \ge 0\}$
(d) $\{(x, y) \in \mathbf{R}^2 : x > 0, y > 0\}$
(e) $\{(x, y) \in \mathbf{R}^2 : 1 \le x \le 4, 5 \le y \le 10\}$
(f) $\{(x, y) \in \mathbf{R}^2 : x > 0, x^2 + y^2 \le 10\}$

SOLUTION

(a) $\{(x, y) \in \mathbf{R}^2 : x^2 + y^2 \le 1\}$: This domain is bounded since it is contained, for instance, in the disk $x^2 + y^2 < 2$. The domain is also closed since it contains all of its boundary points, which are the points on the unit circle $x^2 + y^2 = 1$.
(b) $\{(x, y) \in \mathbf{R}^2 : x^2 + y^2 < 1\}$: The domain is contained in the disk $x^2 + y^2 < 1$, hence it is bounded. It is not closed since its boundary $x^2 + y^2 = 1$ is not contained in the domain.
(c) $\{(x, y) \in \mathbf{R}^2 : x \ge 0\}$:

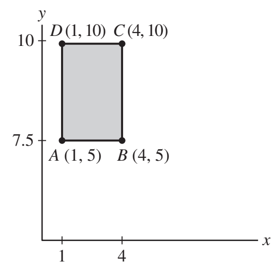


This domain is not contained in any disk, hence it is not bounded. However, the domain contains its boundary $x = 0$ (the y-axis), hence it is closed.
(d) $\{(x, y) \in \mathbf{R}^2 : x > 0, y > 0\}$:



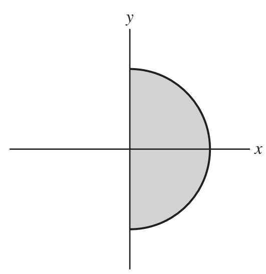
The domain is not contained in any disk, hence it is not bounded. The boundary is the positive x and y axes, and it is not contained in the domain, therefore the domain is not closed.

(e) $\{(x, y) \in \mathbf{R}^2 : 1 \leq x \leq 4, 5 \leq y \leq 10\}$:



This domain is contained in the disk $x^2 + y^2 \leq 11^2$, hence it is bounded. Moreover, the domain contains its boundary, which consists of the segments AB, BC, CD, AD shown in the figure, therefore the domain is closed.

(f) $\{(x, y) \in \mathbf{R}^2 : x > 0, x^2 + y^2 \leq 10\}$:



This domain is bounded since it is contained in the disk $x^2 + y^2 \leq 10$. It is not closed since the part $\{(0, y) \in \mathbf{R}^2 : |y| \leq \sqrt{10}\}$ of its boundary is not contained in the domain.

In Exercises 29–32, determine the global extreme values of the function on the given set without using calculus.

29. $f(x, y) = x + y, \quad 0 \leq x \leq 1, \quad 0 \leq y \leq 1$

SOLUTION The sum $x + y$ is maximum when $x = 1$ and $y = 1$, and it is minimum when $x = 0$ and $y = 0$. Therefore, the global maximum of f on the given set is $f(1, 1) = 1 + 1 = 2$ and the global minimum is $f(0, 0) = 0 + 0 = 0$.

30. $f(x, y) = 2x - y, \quad 0 \leq x \leq 1, \quad 0 \leq y \leq 3$

SOLUTION f is maximum when x is maximum and y is minimum, that is $x = 1$ and $y = 0$. f is minimum when x is minimum and y is maximum, that is, $x = 0$, $y = 3$. Therefore, the global maximum of f in the set is $f(1, 0) = 2 \cdot 1 - 0 = 2$ and the global minimum is $f(0, 3) = 2 \cdot 0 - 3 = -3$.

31. $f(x, y) = (x^2 + y^2 + 1)^{-1}, \quad 0 \leq x \leq 3, \quad 0 \leq y \leq 5$

SOLUTION $f(x, y) = \frac{1}{x^2+y^2+1}$ is maximum when x^2 and y^2 are minimum, that is, when $x = y = 0$. f is minimum when x^2 and y^2 are maximum, that is, when $x = 3$ and $y = 5$. Therefore, the global maximum of f on the given set is $f(0, 0) = (0^2 + 0^2 + 1)^{-1} = 1$, and the global minimum is $f(3, 5) = (3^2 + 5^2 + 1)^{-1} = \frac{1}{35}$.

32. $f(x, y) = e^{-x^2-y^2}, \quad x^2 + y^2 \leq 1$

SOLUTION The function $f(x, y) = e^{-(x^2+y^2)} = \frac{1}{e^{x^2+y^2}}$ is maximum when $e^{x^2+y^2}$ is minimum, that is, when $x^2 + y^2$ is minimum. The minimum value of $x^2 + y^2$ on the given set is zero, obtained at $x = 0$ and $y = 0$. We conclude that the maximum value of f on the given set is

$$f(0, 0) = e^{-0^2-0^2} = e^0 = 1$$

f is minimum when $x^2 + y^2$ is maximum, that is, when $x^2 + y^2 = 1$. Thus, the minimum value of f on the given disk is obtained on the boundary of the disk, and it is $e^{-1} = \frac{1}{e}$.

33. Assumptions Matter Show that $f(x, y) = xy$ does not have a global minimum or a global maximum on the domain

$$\mathcal{D} = \{(x, y) : 0 < x < 1, 0 < y < 1\}$$

Explain why this does not contradict Theorem 3.

SOLUTION The largest and smallest values of f on the closed square $0 \le x, y \le 1$ are $f(1,1) = 1$ and $f(0,0) = 0$. However, on the open square $0 < x, y < 1$, f can never attain these maximum and minimum values, since the boundary (and in particular the points $(1,1)$ and $(-1,-1)$) are not included in the domain. This does not contradict Theorem 3 since the domain is open.

34. Find a continuous function that does not have a global maximum on the domain $\mathcal{D} = \{(x, y) : x + y \ge 0, x + y \le 1\}$. Explain why this does not contradict Theorem 3.

SOLUTION Consider the continuous function $f(x, y) = x$. Taking first partial derivatives we have

$$f_x = x, \quad f_y = 0$$

and second-order partials we have

$$f_{xx} = 1, \quad f_{yy} = 0, \quad f_{xy} = 0$$

Already we can see that

$$D = f_{xx} f_{yy} - f_{xy}^2 = 0$$

So the Second Derivative Test is going to be inconclusive. (In fact, there are no critical points)

Considering this function over the domain, $\mathcal{D} = \{(x, y) : x + y \ge 0, x + y \le 1\}$, we see that $f(x, y) = x$ is in the strip formed between to the two lines $y = -x$ and $y = 1 - x$. We can make $f(x, y) = x$ arbitrarily large within this region. In fact, we can see that $\lim_{x \to -\infty} f(x, y)$ is arbitrarily large. This does not contradict the theorem in the text, because the domain $\mathcal{D}$ is an bounded domain, in that for any integer n, we can see that the open interval $(-n, n + 0.5)$ is contained in this region.

35. Find the maximum of

$$f(x, y) = x + y - x^2 - y^2 - xy$$

on the square, $0 \le x \le 2$, $0 \le y \le 2$ (Figure 21).

(a) First, locate the critical point of f in the square, and evaluate f at this point.

(b) On the bottom edge of the square, $y = 0$ and $f(x, 0) = x - x^2$. Find the extreme values of f on the bottom edge.

(c) Find the extreme values of f on the remaining edges.

(d) Find the largest among the values computed in (a), (b), and (c).

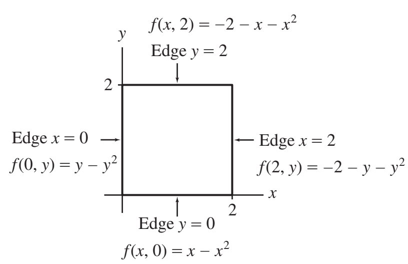


FIGURE 21 The function $f(x, y) = x + y - x^2 - y^2 - xy$ on the boundary segments of the square $0 \le x \le 2$, $0 \le y \le 2$.

SOLUTION

(a) To find the critical points, we look at the first-order partial derivatives set equal to zero and solve:

$$f_x(x, y) = 1 - 2x - y = 0, \quad f_y(x, y) = 1 - 2y - x = 0$$

This gives $y = 1 - 2x$ and $x = 1 - 2y$, solving simultaneously we see $y = 1/3$ and $x = 1/3$. The critical point is $(1/3, 1/3)$, subsequently, $f(1/3, 1/3) = 1/3$.

(b) To find the extreme points of $f(x, 0) = x - x^2$ we take the first derivative and set it equal to zero and solve:

$$f'(x, 0) = 1 - 2x = 0 \to x = 1/2$$

Thus the extreme value on the bottom edge of the square is

$$f(1/2, 0) = 1/4$$

(c) Now to find the extreme values on the other edges of the square.

First, let us use $x = 0$: $f(0, y) = y - y^2$. Taking the first derivative and setting equal to 0 gives us:

$$f'(0, y) = 1 - 2y = 0, \to y = 1/2$$

Therefore, the extreme value along $x = 0$ is $f(0, 1/2) = 1/4$.

Next, let us use $y = 2$: $f(x, 2) = -x^2 - x - 2$. Take the first derivative and setting equal to 0 gives us:

$$f'(x, 2) = -2x - 1 = 0, \to x = -1/2$$

Therefore, the extreme value along $y = 2$ is $f(-1/2, 2) = -7/4$.

Finally, let us use $x = 2$: $f(2, y) = -2 - y - y^2$. Take the first derivative and setting equal to 0 gives us:

$$f'(2, y) = -1 - 2y = 0, \to y = -1/2$$

Therefore, the extreme value along $x = 2$ is $f(2, -1/2) = -7/4$.

(d) Out of all the values we computed in parts (a), (b), and (c), $1/3$ is the largest. This value occurs at the point $(1/3, 1/3)$.

36. Find the maximum of $f(x, y) = y^2 + xy - x^2$ on the square $0 \le x \le 2$, $0 \le y \le 2$.

SOLUTION

(a) First, locate the critical point of f in the square, and evaluate f at this point.

Taking first-order partial derivatives and setting them equal to 0 to solve, we have:

$$f_x = y - 2x = 0, \quad f_y = 2y + x = 0$$

Thus $2x = y$ and we can write

$$4x + x = 0 \quad \Rightarrow \quad x = 0 \text{ and } y = 0$$

Therefore our critical point is $(0, 0)$ and note here that $f(0, 0) = 0$.

(b) Find the extreme values of f on the edges of the square, namely $x = 0, 2$ and $y = 0, 2$.

First if $x = 0$, then $f(0, y) = y^2$ and $f' = 2y$. Setting the derivative equal to 0 to solve we see $y = 0$. An extreme value occurs at the point $(0, 0)$, which was already accounted for in the step above. We also must examine the endpoints on the interval $(0, 0)$ and $(0, 2)$. Using this we have:

$$f(0, 0) = 0, \quad f(0, 2) = 4$$

Next, if $x = 2$, then $f(2, y) = y^2 + 2y - 4$ and $f' = 2y + 2$. Setting the derivative equal to 0 to solve, we see $y = -1$, but this value is not on our square, so we remove it from consideration. The endpoints along this line segment are $(2, 0)$ and $(2, 2)$. Using these we have

$$f(2, 0) = 4, \quad f(2, 2) = 4$$

Next, if $y = 0$, then $f(x, 0) = -x^2$ and $f' = -2x$. Setting the derivative equal to 0 to solve, we see $x = 0$. This value has already been accounted for in part (a). Checking the endpoints of this line segment means examining the points $(0, 0)$ and $(2, 0)$. Both have been accounted for in steps above.

Finally, if $y = 2$, then $f(x, 2) = 4 + 2x - x^2$ and $f' = 2 - 2x$. Setting this derivative equal to 0 to solve, we see $x = 1$. Evaluating at the point $(1, 2)$ we have $f(1, 2) = 5$. The endpoints of this line segment are $(0, 2)$ and $(2, 2)$, both have been accounted for in steps above.

(c) Find the largest among the values computed in (a) and (b).

The maximum occurs at critical point f on the top edge, where $f(x, 2) = 4 + 2x - x^2$. The critical point is $(x, y) = (1, 2)$ and $f(1, 2) = 5$.

In Exercises 37–43, determine the global extreme values of the function on the given domain.

37. $f(x, y) = x^3 - 2y, \quad 0 \le x \le 1, \quad 0 \le y \le 1$

SOLUTION We use the following steps.

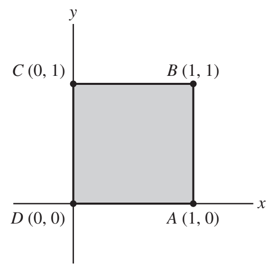
Step 1. Find the critical points. We set the first derivative equal to zero and solve:

$$f_x(x, y) = 3x^2 = 0, \quad f_y(x, y) = -2$$

The two equations have no solutions, hence there are no critical points.

Step 2. Check the boundary. The extreme values occur either at the critical points or at a point on the boundary of the domain. Since there are no critical points, the extreme values occur at boundary points. We consider each edge of the square $0 \le x, y \le 1$ separately.

The segment $\overline{OA}$: On this segment $y = 0$, $0 \le x \le 1$, and f takes the values $f(x, 0) = x^3$. The minimum value is $f(0, 0) = 0$ and the maximum value is $f(1, 0) = 1$.



The segment $\overline{AB}$: On this segment $x = 1$, $0 \le y \le 1$, and f takes the values $f(1, y) = 1 - 2y$. The minimum value is $f(1, 1) = 1 - 2 \cdot 1 = -1$ and the maximum value is $f(1, 0) = 1 - 2 \cdot 0 = 1$.

The segment $\overline{BC}$: On this segment $y = 1$, $0 \le x \le 1$, and f takes the values $f(x, 1) = x^3 - 2$. The minimum value is $f(0, 1) = 0^3 - 2 = -2$ and the maximum value is $f(1, 1) = 1^3 - 2 = -1$.

The segment $\overline{OC}$: On this segment $x = 0$, $0 \le y \le 1$, and f takes the values $f(0, y) = -2y$. The minimum value is $f(0, 1) = -2 \cdot 1 = -2$ and the maximum value is $f(0, 0) = -2 \cdot 0 = 0$.

Step 3. Conclusions. The values obtained in the previous steps are

$$f(0,0) = 0, \quad f(1,0) = 1, \quad f(1,1) = -1, \quad f(0,1) = -2$$

The smallest value is $f(0, 1) = -2$ and it is the global minimum of f on the square. The global maximum is the largest value $f(1, 0) = 1$.

38. $f(x, y) = 5x - 3y, \quad y \ge x - 2, \quad y \ge -x - 2, \quad y \le 3$

SOLUTION

Step 1. Find the critical points. We set the first partial derivatives equal to zero and solve:

$$f_x(x, y) = 5, \quad f_y(x, y) = -3$$

When we set each equal to zero, we have no solutions, hence there are no critical points.

Step 2. Check the boundary. The extreme values occur either at the critical points or at a point on the boundary of the domain. The edges of the boundary are defined by the line $y = x - 2$, the line $y = -x - 2$, and the line $y = 3$. This is the triangle with vertices $(0, -2)$, $(5, 3)$, $(-5, 3)$.

On the line $y = x - 2$ we have:

$$f(x, x - 2) = 5x - 3(x - 2) = 2x + 6 \text{ and } f' = 2$$

This means that the function is always increasing and the minimum occurs at the point $(0, -2)$ and the maximum occurs at the vertex $(5, 3)$:

$$f(0, -2) = 6, \quad f(5, 3) = 16$$

On the line $y = -x - 2$ we have:

$$f(x, -x - 2) = 5x - 3(-x - 2) = 8x + 6 \text{ and } f' = 8$$

This means that the function is always increasing and the minimum occurs at the point $(-5, 3)$ and the maximum occurs at the vertex $(0, -2)$:

$$f(-5, 3) = -34, \quad f(0, -2) = 6$$

On the line $y = 3$ we have:

$$f(x, 3) = 5x - 9 \text{ and } f' = 5$$

This means that the function is always increasing and the minimum occurs at the point $(-5, 3)$ and the maximum occurs at the vertex $(5, 3)$:

$$f(-5, 3) = -34, \quad f(5, 3) = 16$$

Step 3. Conclusions. The values obtained in the previous steps are:

$$f(0, -2) = 6, \quad f(-5, 3) = -34, \quad f(5, 3) = 16$$

The maximum value is 16 and it occurs at the point $(5, 3)$ and the minimum value is -34 and it occurs at the point $(-5, 3)$.

39. $f(x, y) = x^2 + 2y^2, \quad 0 \le x \le 1, \quad 0 \le y \le 1$

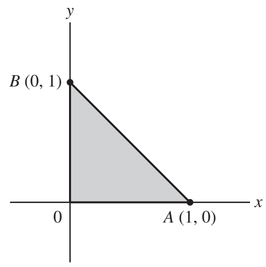
SOLUTION The sum $x^2 + 2y^2$ is maximum at the point $(1, 1)$, where x^2 and y^2 are maximum. It is minimum if $x = y = 0$, that is, at the point $(0, 0)$. Hence,

$$\text{Global maximum} = f(1, 1) = 1^2 + 2 \cdot 1^2 = 3$$
$$\text{Global minimum} = f(0, 0) = 0^2 + 2 \cdot 0^2 = 0$$

40. $f(x, y) = x^3 + x^2 y + 2y^2, \quad x, y \ge 0, \quad x + y \le 1$

SOLUTION We use the following steps.

Step 1. Examine the critical points. We find the critical points of $f(x, y) = x^3 + x^2 y + 2y^2$ in the interior of the domain (the standard region in the figure).



We set the partial derivatives of f equal to zero and solve:

$$f_x(x, y) = 3x^2 + 2xy = x(3x + 2y) = 0$$
$$f_y(x, y) = x^2 + 4y = 0$$

The first equation gives $x = 0$ or $y = -\frac{3}{2}x$. Substituting $x = 0$ in the second equation gives $4y = 0$ or $y = 0$. We obtain the critical point $(0, 0)$. We now substitute $y = -\frac{3}{2}x$ in the second equation and solve for x:

$$x^2 + 4 \cdot \left(-\frac{3}{2}x\right) = x^2 - 6x = x(x - 6) = 0 \quad \Rightarrow \quad x = 0, \quad x = 6$$

We get the critical points $(0, 0)$ and $(6, -9)$. None of the critical points $(0, 0)$ and $(6, -9)$ is in the interior of the domain.

Step 2. Check the boundary. The boundary consists of the three segments $\overline{OA}$, $\overline{OB}$, and $\overline{AB}$ shown in the figure. We consider each part of the boundary separately.

The segment $\overline{OA}$: On this segment $y = 0$, $0 \le x \le 1$, and $f(x, y) = f(x, 0) = x^3$. The minimum value is $f(0, 0) = 0^3 = 0$ and the maximum value is $f(1, 0) = 1^3 = 1$.
The segment $\overline{OB}$: On this segment $x = 0$, $0 \le y \le 1$, and $f(x, y) = f(0, y) = 2y^2$. The minimum value is $f(0, 0) = 2 \cdot 0^2 = 0$ and the maximum value is $f(0, 1) = 2 \cdot 1^2 = 2$.
The segment $\overline{AB}$: On this segment $y = 1 - x$, $0 \le x \le 1$, and

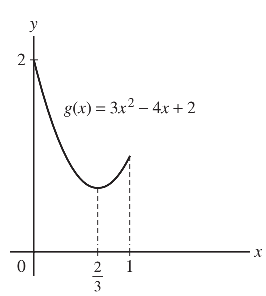
$$f(x, y) = x^3 + x^2(1 - x) + 2(1 - x)^2 = x^3 + x^2 - x^3 + 2\left(1 - 2x + x^2\right) = 3x^2 - 4x + 2$$

We find the extreme values of $g(x) = 3x^2 - 4x + 2$ in the interval $0 \le x \le 1$. With the aid of the graph of $g(x)$, and with setting the derivative g' equal to 0, we find that the minimum value is

$$g\left(\frac{2}{3}\right) = f\left(\frac{2}{3}, \frac{1}{3}\right) = 3 \cdot \left(\frac{2}{3}\right)^2 - 4 \cdot \frac{2}{3} + 2 = \frac{2}{3}$$

and the maximum value is

$$g(0) = f(0, 1) = 3 \cdot 0^2 - 4 \cdot 0 + 2 = 2$$



Step 3. Conclusions. We compare the values of $f(x, y)$ at the points obtained in step (2), and determine the global extrema of $f(x, y)$. This gives

$$f(0,0) = 0, \quad f(1,0) = 1, \quad f(0,1) = 2, \quad f\left(\frac{2}{3}, \frac{1}{3}\right) = \frac{2}{3}$$

We conclude that the global minimum of f in the given domain is $f(0,0) = 0$ and the global maximum is $f(0,1) = 2$.

41. $f(x, y) = x^3 + y^3 - 3xy, \quad 0 \le x \le 1, \quad 0 \le y \le 1$

SOLUTION We use the following steps.

Step 1. Examine the critical points in the interior of the domain. We set the partial derivatives equal to zero and solve:

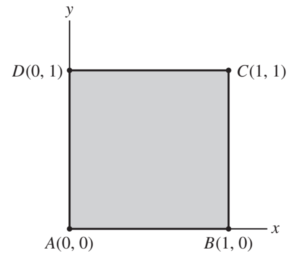
$$f_x(x, y) = 3x^2 - 3y = 0$$
$$f_y(x, y) = 3y^2 - 3x = 0$$

The first equation gives $y = x^2$. We substitute in the second equation and solve for x:

$$3\left(x^2\right)^2 - 3x = 0$$
$$3x^4 - 3x = 3x\left(x^3 - 1\right) = 0 \quad \Rightarrow \quad x = 0, \quad y = 0^2 = 0$$
$$\text{or} \quad x = 1, \quad y = 1^2 = 1$$

The critical points (0, 0) and (1, 1) are not in the interior of the domain.

Step 2. Find the extreme values on the boundary. We consider each part of the boundary separately.



The edge $\overline{AB}$: On this edge, $y = 0$, $0 \le x \le 1$, and $f(x, 0) = x^3$. The maximum value is obtained at $x = 1$ and the minimum value is obtained at $x = 0$. The corresponding extreme points are (1, 0) and (0, 0).

The edge $\overline{BC}$: On this edge $x = 1$, $0 \le y \le 1$, and $f(1, y) = y^3 - 3y + 1$. The critical points are $\frac{d}{dy}\left(y^3 - 3y + 1\right) = 3y^2 - 3 = 0$, that is, $y = \pm 1$. The point in the given domain is $y = 1$. The candidates for extreme values are thus $y = 1$ and $y = 0$, giving the points (1, 1) and (1, 0).

The edge $\overline{DC}$: On this edge $y = 1$, $0 \le x \le 1$, and $f(x, 1) = x^3 - 3x + 1$. Replacing the values of x and y in the previous solutions we get the points (1, 1) and (0, 1).

The edge $\overline{AD}$: On this edge $x = 0$, $0 \le y \le 1$, and $f(0, y) = y^3$. Replacing the values of x and y obtained for the edge $\overline{AB}$, we get (0, 1) and (0, 0).

By Theorem 3, the extreme values occur either at a critical point in the interior of the square or at a point on the boundary of the square. Since there are no critical points in the interior of the square, the candidates for extreme values are the following points:

$$(0,0), \quad (1,0), \quad (1,1), \quad (0,1)$$

We compute $f(x, y) = x^3 + y^3 - 3xy$ at these points:

$$f(0,0) = 0^3 + 0^3 - 3 \cdot 0 = 0$$
$$f(1,0) = 1^3 + 0^3 - 3 \cdot 1 \cdot 0 = 1$$
$$f(1,1) = 1^3 + 1^3 - 3 \cdot 1 \cdot 1 = -1$$
$$f(0,1) = 0^3 + 1^3 - 3 \cdot 0 \cdot 1 = 1$$

We conclude that in the given domain, the global maximum is $f(1,0) = f(0,1) = 1$ and the global minimum is $f(1,1) = -1$.

42. $f(x, y) = x^2 + y^2 - 2x - 4y, \quad x \geq 0, \quad 0 \leq y \leq 3, \quad y \geq x$

SOLUTION We use the following steps:

Step 1. Examine the critical points in the interior of the domain. We set the partial derivatives equal to zero and solve:

$$f_x(x, y) = 2x - 2, \quad f_y(x, y) = 2y - 4$$

Setting each equal to zero and solving we get: $x = 1$ and $y = 2$. Evaluating at the point $(1, 2)$ we see:

$$f(1, 2) = -5$$

Step 2. Find the extreme values on the boundary. We consider each part of the boundary separately. The region that is described is the triangle bounded by the lines $x = 0$, $y = 3$, and $y = x$ with vertices $(0, 0)$, $(3, 3)$, $(0, 3)$.

First consider the line $x = 0$:

$$f(0, y) = y^2 - 4y \quad \Rightarrow \quad f' = 2y - 4$$

Setting f' equal to zero and solving we get $y = 2$. So we must consider the point $(0, 2)$:

$$f(0, 2) = -4$$

We must also consider the endpoints of this line segment, $(0, 0)$ and $(0, 3)$:

$$f(0, 0) = 0, \quad f(0, 3) = -3$$

Next, consider the line $y = 3$:

$$f(x, 3) = x^2 + 9 - 2x - 12 = x^2 - 2x - 3 \quad \Rightarrow \quad f' = 2x - 2$$

Setting f' equal to zero and solving we get $x = 1$. So we must also consider the point $(1, 3)$:

$$f(1, 3) = -4$$

We must also consider the endpoints of this line segment, $(0, 3)$ and $(3, 3)$:

$$f(0, 3) = -3, \quad f(3, 3) = 0$$

Finally, consider the line $y = x$:

$$f(x, x) = x^2 + x^2 - 2x - 4x = 2x^2 - 6x \quad \Rightarrow \quad f' = 4x - 6$$

Setting f' equal to zero and solving, we get $x = 3/2$. So we must also consider the point $(3/2, 3/2)$:

$$f(3/2, 3/2) = -\frac{9}{2}$$

We have already examined the endpoints of this line segment in the steps above.

Step 3. Conclusions. The points that we have considered in this problem are

$$f(1, 2) = -5, \quad f(0, 2) = -4, \quad f(1, 3) = -4, \quad f(3/2, 3/2) = -\frac{9}{2}$$

$$f(0, 0) = 0, \quad f(0, 3) = -3, \quad f(3, 3) = 0$$

Therefore the minimum value is -5 and occurs at the point $(1, 2)$ and the maximum value is 0 and occurs in two places, at the points $(0, 0)$ and $(3, 3)$.

43. $f(x, y) = (4y^2 - x^2)e^{-x^2-y^2}, \quad x^2 + y^2 \leq 2$

SOLUTION We use the following steps.

Step 1. Examine the critical points. We compute the partial derivatives of $f(x, y) = \left(4y^2 - x^2\right) e^{-x^2-y^2}$, set them equal to zero and solve. This gives

$$f_x(x, y) = -2xe^{-x^2-y^2} + \left(4y^2 - x^2\right) e^{-x^2-y^2} \cdot (-2x) = -2xe^{-x^2-y^2} \left(1 + 4y^2 - x^2\right) = 0$$

$$f_y(x, y) = 8ye^{-x^2-y^2} + \left(4y^2 - x^2\right) e^{-x^2-y^2} \cdot (-2y) = -2ye^{-x^2-y^2} \left(-4 + 4y^2 - x^2\right) = 0$$

Since $e^{-x^2-y^2} \neq 0$, the first equation gives $x = 0$ or $x^2 = 1 + 4y^2$. Substituting $x = 0$ in the second equation gives

$$-2ye^{-y^2} \left(-4 + 4y^2\right) = 0.$$

Since $e^{-y^2} \neq 0$, we get

$$y\left(-1+y^2\right) = y(y-1)(y+1) = 0 \quad \Rightarrow \quad y=0, \quad y=1, \quad y=-1$$

We obtain the three points $(0,0)$, $(0,-1)$, $(0,1)$. We now substitute $x^2 = 1+4y^2$ in the second equation and solve for y:

$$-2ye^{-1-5y^2}\left(-4+4y^2-1-4y^2\right) = 0$$

$$-2ye^{-1-5y^2}\cdot(-5) = 0 \quad \Rightarrow \quad y=0$$

The corresponding values of x are obtained from

$$x^2 = 1+4\cdot 0^2 = 1 \quad \Rightarrow \quad x = \pm 1$$

We obtain the solutions $(1,0)$ and $(-1,0)$. We conclude that the critical points are

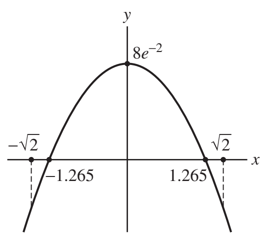
$$(0,0), \quad (0,-1), \quad (0,1), \quad (1,0), \quad \text{and} \quad (-1,0).$$

All of these points are in the interior $x^2+y^2<2$ of the given disk.

Step 2. Check the boundary. The boundary is the circle $x^2+y^2=2$. On this set $y^2 = 2-x^2$, hence the function $f(x,y)$ takes the values

$$f(x,y)\Big|_{x^2+y^2=2} = g(x) = \left(4\left(2-x^2\right)-x^2\right)e^{-2} = \left(-5x^2+8\right)e^{-2}$$

That is, $g(x) = -5e^{-2}x^2 + 8e^{-2}$. We determine the interval of x. Since $x^2+y^2=2$, we have $0 \le x^2 \le 2$ or $-\sqrt{2} \le x \le \sqrt{2}$.



We thus must find the extreme values of $g(x) = -5e^{-2}x^2 + 8e^{-2}$ on the interval $-\sqrt{2} \le x \le \sqrt{2}$. With the aid of the graph of $g(x)$, we conclude that the maximum value is $g(0) = 8e^{-2}$ and the minimum value is

$$g\left(-\sqrt{2}\right) = g\left(\sqrt{2}\right) = -5e^{-2}\left(\pm\sqrt{2}\right)^2 + 8e^{-2} = -10e^{-2} + 8e^{-2} = -2e^{-2} \approx -0.271$$

We conclude that the points on the boundary with largest and smallest values of f are

$$f\left(0, \pm\sqrt{2}\right) = 8e^{-2} \approx 1.083, \quad f\left(\pm\sqrt{2}, 0\right) = -2e^{-2} \approx -0.271$$

Step 3. Conclusions. The extreme values either occur at the critical points or at the points on the boundary, found in step 2. We compare the values of f at these points:

$$f(0,0) = 0$$
$$f(0,-1) = 4e^{-1} \approx 1.472$$
$$f(0,1) = 4e^{-1} \approx 1.472$$
$$f(1,0) = -e^{-1} \approx -0.368$$
$$f(-1,0) = -e^{-1} \approx -0.368$$
$$f\left(0, \pm\sqrt{2}\right) \approx 1.083$$
$$f\left(\pm\sqrt{2}, 0\right) \approx -0.271$$

We conclude that the global minimum is $f(1,0) = f(-1,0) = -0.368$ and the global maximum is $f(0,-1) = f(0,1) = 1.472$.

44. Find the maximum volume of a box inscribed in the tetrahedron bounded by the coordinate planes and the plane

$$x + \frac{1}{2}y + \frac{1}{3}z = 1$$

SOLUTION To maximize volume of a rectangular box we must consider the volume, $V = xyz$. But since the constraint is $x + \frac{1}{2}y + \frac{1}{3}z = 1$, we can solve this for z and get:

$$z = 3 - 3x - \frac{3}{2}y \quad \Rightarrow \quad V(x, y) = xy\left(3 - 3x - \frac{3}{2}y\right) = 3xy - 3x^2y - \frac{3}{2}xy^2$$

Now to maximize $V(x, y)$. First to find the critical points, we take the first-order partial derivatives, set them equal to zero, and solve:

$$V_x(x, y) = 3y - 6xy - \frac{3}{2}y^2 = 0, \quad V_y(x, y) = 3x - 3x^2 - 3xy = 0$$

Using the equation $V_y = 0$ we see:

$$3x - 3x^2 - 3xy = 0 \quad \Rightarrow \quad x - x^2 - xy = 0 \quad \Rightarrow \quad xy = x - x^2 \quad \Rightarrow \quad y = 1 - x \text{ or } x = 0$$

We can ignore $x = 0$, because this value would produce a box having volume 0. Using this information in the first equation, $V_x = 0$, we see

$$3y - 6xy - \frac{3}{2}y^2 = 0 \quad \Rightarrow \quad 3(1 - x) - 6x(1 - x) - \frac{3}{2}(1 - x)^2 = 0 \quad \Rightarrow \quad \frac{9}{2}x^2 - 6x + \frac{3}{2} = 0$$

Clearing this equation of fractions we have

$$3x^2 - 4x + 1 = 0 \quad \Rightarrow \quad (3x - 1)(x - 1) = 0 \quad \Rightarrow \quad x = \frac{1}{3}, 1$$

Using this information we see:

$$x = \frac{1}{3} \quad \Rightarrow \quad y = 1 - \frac{1}{3} = \frac{2}{3}$$

$$x = 1 \quad \Rightarrow \quad y = 1 - 1 = 0$$

We know that $y \neq 0$, otherwise, volume of the box will be 0 (which is not maximized). In fact, it makes no sense to use any of the coordinate plane boundaries for critical points because the resultant volume will be 0.

Therefore we examine the point where $x = \frac{1}{3}$ and $y = \frac{2}{3}$. To find z we use $z = 3 - 3x - \frac{3}{2}y$:

$$z = 3 - 3 \cdot \frac{1}{3} - \frac{3}{2} \cdot \frac{2}{3} = 1$$

Hence the maximum volume of the box is

$$V = xyz = \frac{1}{3} \cdot \frac{2}{3} \cdot 1 = \frac{2}{9} \text{ cubic units}$$

45. Find the maximum volume of the largest box of the type shown in Figure 22, with one corner at the origin and the opposite corner at a point $P = (x, y, z)$ on the paraboloid

$$z = 1 - \frac{x^2}{4} - \frac{y^2}{9} \quad \text{with } x, y, z \geq 0$$

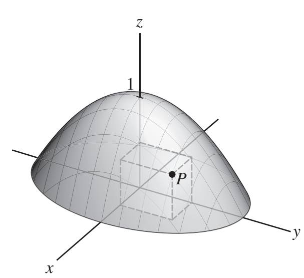


FIGURE 22

SOLUTION To maximize the volume of a rectangular box, start with the relation $V = xyz$ and using the paraboloid equation we see

$$z = 1 - \frac{x^2}{4} - \frac{y^2}{9} \quad \Rightarrow \quad V(x, y) = xy\left(1 - \frac{x^2}{4} - \frac{y^2}{9}\right)$$

Therefore we will consider

$$V(x, y) = xy - \frac{1}{4}x^3y - \frac{1}{9}xy^3$$

First to find the critical points, we take the first-order partial derivatives and set them equal to zero, and solve:

$$V_x(x, y) = y - \frac{3}{4}x^2y - \frac{1}{9}y^3, \quad V_y(x, y) = x - \frac{1}{4}x^3 - \frac{1}{3}xy^2$$

Using the equation $V_y = 0$ we see

$$x - \frac{1}{4}x^3 - \frac{1}{3}xy^2 = 0 \quad \Rightarrow \quad x = 0, \quad y^2 = 3 - \frac{3}{4}x^2 \quad \Rightarrow \quad y = \sqrt{3 - \frac{3}{4}x^2}$$

(Note here, we can ignore the value $x = 0$, since it produces a box having zero volume.)

Using this relation in the first equation, $V_x = 0$, we see:

$$\sqrt{3 - \frac{3}{4}x^2} - \frac{3}{4}x^2\sqrt{3 - \frac{3}{4}x^2} - \frac{1}{9}\left(3 - \frac{3}{4}x^2\right)^{3/2} = 0$$

Factoring we see:

$$\sqrt{3 - \frac{3}{4}x^2}\left[1 - \frac{3}{4}x^2 - \frac{1}{9}\left(3 - \frac{3}{4}x^2\right)\right] = 0$$

and thus

$$3 - \frac{3}{4}x^2 = 0 \quad \Rightarrow \quad x^2 = 4 \quad \Rightarrow \quad x = \pm 2$$

or

$$1 - \frac{3}{4}x^2 - \frac{1}{3} + \frac{1}{12}x^2 = 0 \quad \Rightarrow \quad \frac{2}{3} - \frac{2}{3}x^2 = 0 \quad \Rightarrow \quad x = \pm 1$$

Since the governing equation $f(x, y)$ is a paraboloid, that is symmetric about the z-axis, we need only consider the point when $x = 2$ or $x = 1$.

Therefore, since $y = \sqrt{3 - \frac{3}{4}x^2}$ and $z = 1 - \frac{1}{4}x^2 - \frac{1}{9}y^2$, we have, if $x = 2$

$$y = \sqrt{3 - \frac{3}{4} \cdot 4} = 0 \quad \Rightarrow \quad z = 1 - \frac{1}{4} \cdot 4 - \frac{1}{9} \cdot 0 = 0$$

This will give a box having zero volume - not a maximum volume at all.

Using $x = 1$, and $y = \sqrt{3 - \frac{3}{4}x^2}$, $z = 1 - \frac{1}{4}x^2 - \frac{1}{9}y^2$, we have

$$y = \sqrt{3 - \frac{3}{4}} = \frac{3}{2}, \quad z = 1 - \frac{1}{4} \cdot 1^2 - \frac{1}{9} \cdot \frac{9}{4} = \frac{1}{2}$$

Therefore, the box having maximum volume has dimensions, $x = 1$, $y = 3/2$, and $z = 1/2$ and maximum value for the volume:

$$V = xyz = 1 \cdot \frac{3}{2} \cdot \frac{1}{2} = \frac{3}{4}$$

46. Find the point on the plane

$$z = x + y + 1$$

closest to the point $P = (1, 0, 0)$. *Hint:* Minimize the square of the distance.

SOLUTION Using the hint given in the text, minimize the function

$$f(x, y, z) = (x - 1)^2 + y^2 + (x + y + 1)^2$$

We get, after taking first-order partial derivatives and setting them equal to zero to solve:

$$f_x = 2(x-1) + 2(x+y+1) = 0, \quad f_y = 2y + 2(x+y+1) = 0$$

This gives $y = x - 1$ and $2(x-1) + 2(2x) = 0$ or $x = 1/3$.

Therefore, since $x = 1/3$, then $y = x - 1 = 1/3 - 1 = -2/3$ and $z = x + y + 1 = 1/3 - 2/3 + 1 = 2/3$. The point closest to the point $P(1, 0, 0)$ is the point $(1/3, -2/3, 2/3)$.

47. Show that the sum of the squares of the distances from a point $P = (c, d)$ to n fixed points $(a_1, b_1), \dots, (a_n, b_n)$ is minimized when c is the average of the x-coordinates a_i and d is the average of the y-coordinates b_i.

SOLUTION First we must form the sum of the squares of the distances from a point $P(c, d)$ to n fixed points. For instance, the square of the distance from (c, d) to (a_1, b_1) would be:

$$(c - a_1)^2 + (d - b_1)^2$$

using this pattern, the sum in question would be

$$S = \sum_{i=1}^{n} [(c - a_i)^2 + (d - b_i)^2$$

Using the methods discussed in this section of the text, we want to minimize the sum S. We will examine the first-order partial derivatives with respect to c and d and set them equal to zero and solve:

$$S_c = \sum_{i=1}^{n} 2(c - a_i) = 0, \quad S_d = \sum_{i=1}^{n} 2(d - b_i) = 0$$

Consider first the following:

$$\sum_{i=1}^{n} 2(c - a_i) = 0 \quad \Rightarrow \quad \sum_{i=1}^{n} (c - a_i) = 0 \quad \Rightarrow \quad \sum_{i=1}^{n} c - \sum_{i=1}^{n} a_i = 0$$

Therefore

$$\sum_{i=1}^{n} c = \sum_{i=1}^{n} a_i \quad \Rightarrow \quad n \cdot c = \sum_{i=1}^{n} a_i \quad \Rightarrow \quad c = \frac{1}{n} \sum_{i=1}^{n} a_i$$

Similarly we can examine $S_d = 0$ to see

$$\sum_{i=1}^{n} 2(d - b_i) = 0 \quad \Rightarrow \quad \sum_{i=1}^{n} (d - b_i) = 0 \quad \Rightarrow \quad \sum_{i=1}^{n} d - \sum_{i=1}^{n} b_i = 0$$

and

$$\sum_{i=1}^{n} d = \sum_{i=1}^{n} b_i \quad \Rightarrow \quad n \cdot d = \sum_{i=1}^{n} b_i \quad \Rightarrow \quad d = \frac{1}{n} \sum_{i=1}^{n} b_i$$

Therefore, the sum is minimized when c is the average of the x-coordinates a_i and d is the average of the y-coordinates b_i.

48. Show that the rectangular box (including the top and bottom) with fixed volume $V = 27$ m^3 and smallest possible surface area is a cube (Figure 23).

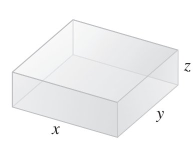

FIGURE 23 Rectangular box with sides x, y, z.

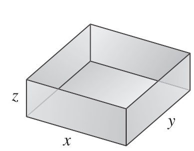
SOLUTION

Step 1. Find a function to be maximized. The surface area of the box with sides lengths x, y, z is

$$S = 2(xz + yz + xy) \tag{1}$$



We express the surface area in terms of x and y alone using the equation $V = xyz$ for the volume of the box. This equation implies that $z = \frac{V}{xy}$, hence by (1) we get

$$S = S(x, y) = 2\left(x \cdot \frac{V}{xy} + y \cdot \frac{V}{xy} + xy\right) = 2\left(\frac{V}{y} + \frac{V}{x} + xy\right) = \frac{2V}{y} + \frac{2V}{x} + 2xy$$

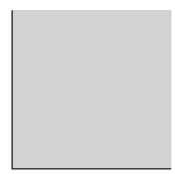
That is,

$$S = \frac{2V}{y} + \frac{2V}{x} + 2xy$$

Step 2. Determine the domain. The variables x and y express lengths, therefore, they must be nonnegative. Also, S is not defined if $x = 0$ or $y = 0$, therefore the domain is

$$D = \{(x, y) : x > 0, y > 0\}$$

We must find the minimum value of S on D. Because this domain is neither closed nor bounded, we have no guarantee that an absolute minimum exists. However, it can be proved (see later Justifications) that S has a minimum value on D, hence it must occur at a critical point in D.



Differentiating $S = \frac{2V}{y} + \frac{2V}{x} + 2xy$ and equating the partial derivatives to zero, we get

$$S_x(x, y) = -\frac{2V}{x^2} + 2y = 0, \quad S_y(x, y) = -\frac{2V}{y^2} + 2x = 0$$

The first equation gives $y = \frac{V}{x^2}$. Substituting in the second equation yields

$$2x - \frac{2V}{\frac{V^2}{x^4}} = 2x - \frac{2x^4}{V} = 2x\left(1 - \frac{x^3}{V}\right) = 0$$

The solutions are $x = 0$ and $x = \sqrt[3]{V}$. The solution $x = 0$ is not contained in D, hence the only solution in D is $x = \sqrt[3]{V}$. The corresponding value of y is obtained from $y = \frac{V}{x^2}$:

$$y = \frac{V}{\left(\sqrt[3]{V}\right)^2} = \frac{V}{V^{2/3}} = \sqrt[3]{V}$$

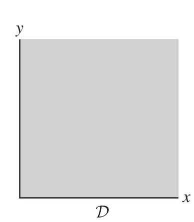
The critical point is $\left(\sqrt[3]{V}, \sqrt[3]{V}\right)$. We find the value of z, using $z = \frac{V}{xy}$:

$$z = \frac{V}{\sqrt[3]{V}\sqrt[3]{V}} = \frac{V}{V^{2/3}} = \sqrt[3]{V}$$

But how can we show that this critical point is a minumum? We provide two justifications.

Justification 1: Using the second derivative test, we have $S_{xx} = 4V/x^3$, so $S_{xx}(\sqrt[3]{V}) = 4$; $S_{yy} = 4V/y^3$, so $S_{yy}(\sqrt[3]{V}) = 4$; and $S_{xy} = 2$. Thus, $D = 4 \cdot 4 - 2^2 = 12 > 0$, and since $S_{xx} > 0$, we do indeed have a minimum surface area. This makes sense, because when x or y go to 0 or to ∞, then S (which is $2V/x + 2V/y + 2xy$) clearly goes to ∞.

Justification 2: We show that the function $S(X, Y) = \frac{2V}{y} + \frac{2V}{x} + 2xy$ has a minimum value in the domain $D = \{(x, y) : x > 0, y > 0\}$.



We denote by a_0 the value of $S(x, y)$ at the point $(2, 2)$ in D:

$$S(2, 2) = 2V + 8 = a_0 > 8$$

The following inequalities hold in D:

$$S(x, y) = \frac{V}{x} + \frac{V}{y} + 2xy \geq \frac{V}{x} \tag{2}$$

$$S(x, y) = \frac{V}{x} + \frac{V}{y} + 2xy \geq \frac{V}{y} \tag{3}$$

$$S(x, y) = \frac{V}{x} + \frac{V}{y} + 2xy \geq 2xy \tag{4}$$

Since $\lim_{x\to 0+} \frac{V}{x} = \infty$, it follows by (1) that there exists $0 < r_1 < 1$ such that, for all $0 < x < r_1$ and for all values of y,

$$S(x, y) > a_0$$

Since $\lim_{y\to 0+} \frac{V}{y} = \infty$, it follows by (2) that there exists $0 < r_2 < 1$ such that, for all $0 < y < r_1$ and for all values of x,

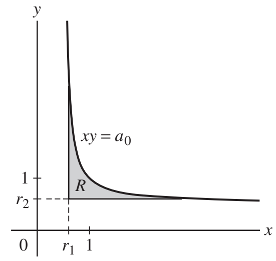
$$S(x, y) > a_0$$

By (3) it follows that if $xy > a_0$ then

$$S(x, y) > 2a_0 > a_0$$

We define the following domain:

$$R = \{(x, y) : x \geq r_1, y \geq r_2, xy \leq a_0\}$$



R is closed and bounded and $S(x, y)$ is continuous in R, therefore S has a minimum value in R.

We now show that this minimum is also the minimum value of S in D. First notice that, by the above considerations, $S(x, y) > a_0$ for all (x, y) outside R. At the point $(2, 2)$, $S(2, 2) = a_0$, and this point is in R, since $2 \geq r_1$, $2 \geq r_2$ (recall that $0 < r_1, r_2 < 1$) and $2 \cdot 2 = 4 < 8 < a_0$. Therefore, the minimum value of $S(x, y)$ in R is also the minimum value of S in D. We thus proved that S attains a minimum value on D.

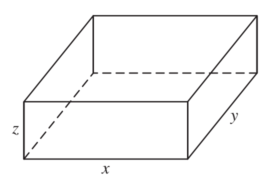
49. Consider a rectangular box B that has a bottom and sides but no top and has minimal surface area among all boxes with fixed volume V.

(a) Do you think B is a cube as in the solution to Exercise 48? If not, how would its shape differ from a cube?

(b) Find the dimensions of B and compare with your response to (a).

SOLUTION

(a) Each of the variables x and y is the length of a side of three faces (for example, x is the length of the front, back, and bottom sides), whereas z is the length of a side of four faces.

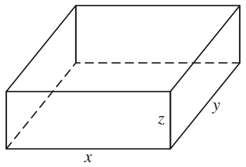


Therefore, the variables x, y, and z do not have equal influence on the surface area. We expect that in the box B with minimal surface area, z is smaller than $\sqrt[3]{V}$, which is the side of a cube with volume V (also we would expect $x = y$).

(b) We must find the dimensions of the box B, with fixed volume V and with smallest possible surface area, when the top is not included.

Step 1. Find a function to be minimized. The surface area of the box with sides lengths x, y, z when the top is not included is

$$S = 2xz + 2yz + xy \tag{1}$$



To express the surface in terms of x and y only, we use the formula for the volume of the box, $V = xyz$, giving $z = \frac{V}{xy}$. We substitute in (1) to obtain

$$S = 2x \cdot \frac{V}{xy} + 2y \cdot \frac{V}{xy} + xy = \frac{2V}{y} + \frac{2V}{x} + xy$$

That is,

$$S = \frac{2V}{y} + \frac{2V}{x} + xy.$$

Step 2. Determine the domain. The variables x, y denote lengths, hence they must be nonnegative. Moreover, S is not defined for $x = 0$ or $y = 0$. Since there are no other limitations on the variables, the domain is

$$D = \{(x, y) : x > 0, y > 0\}$$

We must find the minimum value of S on D. Because this domain is neither closed nor bounded, we are not sure that a minimum value exists. However, it can be proved (in like manner as in Exercise 48) that S does have a minimum value on D. This value occurs at a critical point in D, hence we set the partial derivatives equal to zero and solve. This gives

$$S_x(x, y) = -\frac{2V}{x^2} + y = 0$$
$$S_y(x, y) = -\frac{2V}{y^2} + x = 0$$

The first equation gives $y = \frac{2V}{x^2}$. Substituting in the second equation yields

$$x - \frac{2V}{\frac{4V^2}{x^4}} = x - \frac{x^4}{2V} = x\left(1 - \frac{x^3}{2V}\right) = 0$$

The solutions are $x = 0$ and $x = (2V)^{1/3}$. The solution $x = 0$ is not included in D, so the only solution is $x = (2V)^{1/3}$.
We find the value of y using $y = \frac{2V}{x^2}$:

$$y = \frac{2V}{(2V)^{2/3}} = (2V)^{1/3}$$

We conclude that the critical point, which is the point where the minimum value of S in D occurs, is $\left((2V)^{1/3}, (2V)^{1/3}\right)$. We find the corresponding value of z using $z = \frac{V}{xy}$. We get

$$z = \frac{V}{(2V)^{1/3}(2V)^{1/3}} = \frac{V}{2^{2/3}V^{2/3}} = \frac{V^{1/3}}{2^{2/3}} = \left(\frac{V}{4}\right)^{1/3}$$

We conclude that the sizes of the box with minimum surface area are

width: $x = (2V)^{1/3}$;
length: $y = (2V)^{1/3}$;
height: $z = \left(\frac{V}{4}\right)^{1/3}$.

We see that z is smaller than x and y as predicted.

50. Given n data points $(x_1, y_1), \dots, (x_n, y_n)$, the **linear least-squares fit** is the linear function

$$f(x) = mx + b$$

that minimizes the sum of the squares (Figure 24):

$$E(m, b) = \sum_{j=1}^{n} (y_j - f(x_j))^2$$

Show that the minimum value of E occurs for m and b satisfying the two equations

$$m\left(\sum_{j=1}^{n} x_j\right) + bn = \sum_{j=1}^{n} y_j$$

$$m\sum_{j=1}^{n} x_j^2 + b\sum_{j=1}^{n} x_j = \sum_{j=1}^{n} x_j y_j$$

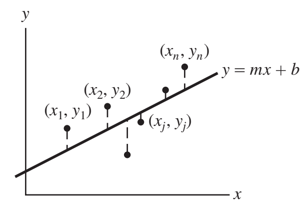


FIGURE 24 The linear least-squares fit minimizes the sum of the squares of the vertical distances from the data points to the line.

SOLUTION We first find the critical points of $E(m,b) = \sum_{j=1}^{n}\left(y_j - mx_j - b\right)^2$. Setting the partial derivatives equal to zero, we get

$$E_m(m,b) = 2\sum_{j=1}^{n}\left(y_j - mx_j - b\right)\cdot\left(-x_j\right) = -2\sum_{j=1}^{n} x_j\cdot\left(y_j - mx_j - b\right) = 0$$

$$E_b(m,b) = 2\sum_{j=1}^{n}\left(y_j - mx_j - b\right)\cdot(-1) = -2\sum_{j=1}^{n}\left(y_j - mx_j - b\right)$$

$$= -2\left(\sum_{j=1}^{n}\left(y_j - mx_j\right) - nb\right) = 0$$

We obtain the following equations:

$$\sum_{j=1}^{n} x_j\cdot y_j - m\sum_{j=1}^{n} x_j^2 - b\sum_{j=1}^{n} x_j = 0$$

$$\sum_{j=1}^{n} y_j - m\sum_{j=1}^{n} x_j - bn = 0$$

or

$$m\sum_{j=1}^{n} x_j^2 + b\sum_{j=1}^{n} x_j = \sum_{j=1}^{n} x_j\cdot y_j \tag{1}$$

$$m\sum_{j=1}^{n} x_j + bn = \sum_{j=1}^{n} y_j \tag{2}$$

By Theorem 3 the minimum value of $E(m,b)$ (if it exists) occurs at a critical point, which is the solution of equations (1) and (2). It can be shown (see justification) that $E(m,b)$ has a minimum value, hence E is minimized by the solution of (1) and (2).

Justification: We show that $E(m,b) = \sum_{j=1}^{n}\left(y_j - mx_j - b\right)^2$ has a minimum value. Let (m_0, b_0) be any point and $E(m_0, b_0) = E_0$. Since $E(m,b)$ is increasing without bound as $|m| \to \infty$ and $|b| \to \infty$, there exists a number $R > 0$ such that

$$E(m,b) > E_0 \text{ if } |m| > R \text{ and } |b| > R \tag{3}$$

The domain $D = \{(m,b) : |m| \le R \text{ and } |b| \le R\}$ is closed and bounded and $E(m,b)$ is continuous on D, hence E has a minimum value E_M on D. The point (m_0, b_0) is in D (since $E(m,b) > E_0$ for all points (m,b) that are not in D), hence

$$E_M \le E(m_0, b_0) = E_0 \tag{4}$$

It follows by (1) and (2) that E_M is the minimum value of $E(m,b)$ on the entire mb-plane.

51. The power (in microwatts) of a laser is measured as a function of current (in milliamps). Find the linear least-squares fit (Exercise 50) for the data points.

Current (mA)	1.0	1.1	1.2	1.3	1.4	1.5
Laser power (μW)	0.52	0.56	0.82	0.78	1.23	1.50

SOLUTION By Exercise 50, the coefficients of the linear least-square fit $f(x) = mx + b$ are determined by the following equations:

$$m\sum_{j=1}^{n} x_j + bn = \sum_{j=1}^{n} y_j$$

$$m\sum_{j=1}^{n} x_j^2 + b\sum_{j=1}^{n} x_j = \sum_{j=1}^{n} x_j \cdot y_j \tag{1}$$

In our case there are $n = 6$ data points:

$$(x_1, y_1) = (1, 0.52), (x_2, y_2) = (1.1, 0.56),$$
$$(x_3, y_3) = (1.2, 0.82), (x_4, y_4) = (1.3, 0.78),$$
$$(x_5, y_5) = (1.4, 1.23), (x_6, y_6) = (1.5, 1.50).$$

We compute the sums in (1):

$$\sum_{j=1}^{6} x_j = 1 + 1.1 + 1.2 + 1.3 + 1.4 + 1.5 = 7.5$$

$$\sum_{j=1}^{6} y_j = 0.52 + 0.56 + 0.82 + 0.78 + 1.23 + 1.50 = 5.41$$

$$\sum_{j=1}^{6} x_j^2 = 1^2 + 1.1^2 + 1.2^2 + 1.3^2 + 1.4^2 + 1.5^2 = 9.55$$

$$\sum_{j=1}^{6} x_j \cdot y_j = 1 \cdot 0.52 + 1.1 \cdot 0.56 + 1.2 \cdot 0.82 + 1.3 \cdot 0.78 + 1.4 \cdot 1.23 + 1.5 \cdot 1.50 = 7.106$$

Substituting in (1) gives the following equations:

$$7.5m + 6b = 5.41$$
$$9.55m + 7.5b = 7.106 \tag{2}$$

We multiply the first equation by 9.55 and the second by (-7.5), then add the resulting equations. This gives

$$\begin{array}{r} 71.625m + 57.3b = 51.6655 \\ + \ -71.625m - 56.25b = -53.295 \\ \hline 1.05b = -1.6295 \end{array} \quad \Rightarrow \quad b = -1.5519$$

We now substitute $b = -1.5519$ in the first equation in (2) and solve for m:

$$\begin{aligned} 7.5m + 6 \cdot (-1.5519) &= 5.41 \\ 7.5m &= 14.7214 \end{aligned} \quad \Rightarrow \quad m = 1.9629$$

The linear least squares fit $f(x) = mx + b$ is thus

$$f(x) = 1.9629x - 1.5519.$$

52. Let $A = (a, b)$ be a fixed point in the plane, and let $f_A(P)$ be the distance from A to the point $P = (x, y)$. For $P \neq A$, let $\mathbf{e}_{AP}$ be the unit vector pointing from A to P (Figure 25):

$$\mathbf{e}_{AP} = \frac{\overrightarrow{AP}}{\|\overrightarrow{AP}\|}$$

Show that

$$\nabla f_A(P) = \mathbf{e}_{AP}$$

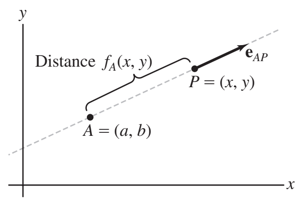

FIGURE 25 The distance from A to P increases most rapidly in the direction $\mathbf{e}_{AP}$.

SOLUTION Note that we can derive this result without calculation: Because $\nabla f_A(P)$ points in the direction of maximal increase, it must point directly away from A at P, and because the distance $f_A(x, y)$ increases at a rate of one as you move away from A along the line through A and P, $\nabla f_A(P)$ must be a unit vector.

Further Insights and Challenges

53. In this exercise, we prove that for all $x, y \geq 0$:

$$\frac{1}{\alpha}x^\alpha + \frac{1}{\beta}x^\beta \geq xy$$

where $\alpha \geq 1$ and $\beta \geq 1$ are numbers such that $\alpha^{-1} + \beta^{-1} = 1$. To do this, we prove that the function

$$f(x, y) = \alpha^{-1}x^\alpha + \beta^{-1}y^\beta - xy$$

satisfies $f(x, y) \geq 0$ for all $x, y \geq 0$.

(a) Show that the set of critical points of $f(x, y)$ is the curve $y = x^{\alpha-1}$ (Figure 26). Note that this curve can also be described as $x = y^{\beta-1}$. What is the value of $f(x, y)$ at points on this curve?

(b) Verify that the Second Derivative Test fails. Show, however, that for fixed $b > 0$, the function $g(x) = f(x, b)$ is concave up with a critical point at $x = b^{\beta-1}$.

(c) Conclude that for all $x > 0$, $f(x, b) \geq f(b^{\beta-1}, b) = 0$.

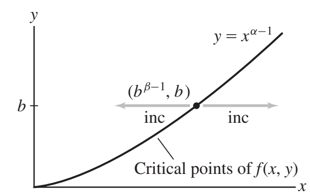

FIGURE 26 The critical points of $f(x, y) = \alpha^{-1}x^\alpha + \beta^{-1}y^\beta - xy$ form a curve $y = x^{\alpha-1}$.

SOLUTION We define the following function:

$$f(x, y) = \frac{1}{\alpha}x^\alpha + \frac{1}{\beta}y^\beta - xy$$

Notice that $f(0, 0) = 0$.

(a) Determine the critical points for $f(x, y) = f(x, y) = \alpha^{-1}x^\alpha + \beta^{-1}y^\beta - xy$. First, take the first-order partial derivatives and set them equal to zero to solve:

$$f_x = \alpha^{-1} \cdot \alpha x^{\alpha-1} - y = x^{\alpha-1} - y = 0, \quad f_y = \beta^{-1} \cdot \beta y^{\beta-1} - x = y^{\beta-1} - x = 0$$

This means that $y = x^{\alpha-1}$ and simultaneously $x = y^{\beta-1}$. Note here that we are guaranteed that the set of points satisfying both equations is nonempty because $1/\alpha + 1/\beta = 1$.

Now to compute the value of $f(x, y)$ at these points:

$$f(x, y) = f(x, x^{\alpha-1}) = \alpha^{-1}x^\alpha + \beta^{-1}(x^{\alpha-1})^\beta - x(x^{\alpha-1}) = \left(\frac{1}{\alpha} - 1\right)x^\alpha + \frac{1}{\beta}x^{\alpha\beta-\beta}$$

But remember that $\alpha^{-1} + \beta^{-1} = 1$ so we can say

$$\frac{1}{\alpha} + \frac{1}{\beta} = 1, \quad \beta + \alpha = \alpha\beta$$

Using these relations we see:

$$f(x, y) = f(x, x^{\alpha-1}) = \left(\frac{1}{\alpha} - 1\right)x^{\alpha} + \frac{1}{\beta}x^{\alpha\beta-\beta} = -\frac{1}{\beta}x^{\alpha} + \frac{1}{\beta}x^{\alpha} = 0$$

or similarly,

$$f(x, y) = f(y^{\beta-1}, y) = \frac{1}{\alpha}y^{\alpha\beta-\alpha} + \left(\frac{1}{\beta} - 1\right)y^{\beta} = \frac{1}{\alpha}y^{\beta} - \frac{1}{\alpha}y^{\beta} = 0$$

(b) Now computing the second-order partial derivatives we get

$$f_{xx} = (\alpha - 1)x^{\alpha-2}, \quad f_{yy} = (\beta - 1)y^{\beta-2}, \quad f_{xy} = -1$$

Therefore we can write the discriminant (while using the relations about α and β above):

$$D = f_{xx}f_{yy} - f_{xy}^2 = (\alpha - 1)(\beta - 1)x^{\alpha-2}y^{\beta-2} - 1 = x^{\alpha-2}y^{\beta-2} - 1$$

Evaluating this expression at the critical points when $y = x^{\alpha-1}$ we see

$$D(x, x^{\alpha-1}) = x^{\alpha-2}(x^{\alpha-1})^{\beta-2} - 1 = x^{\alpha-2}x^{\alpha\beta-\beta-2\alpha+2} - 1 = x^{\alpha-2+\alpha\beta-\beta-2\alpha+2} - 1 = x^0 - 1 = 0$$

Thus the Second Derivative Test is inconclusive and fails.

Instead, if we fix $b > 0$, consider the function

$$g(x) = f(x, b) = \frac{1}{\alpha}x^{\alpha} + \frac{1}{\beta}b^{\beta} - bx$$

Therefore, taking the first derivative and setting it equal to zero to solve, we see

$$g'(x) = x^{\alpha-1} - b = 0 \quad \Rightarrow \quad b = x^{\alpha-1}$$

In order to solve this for x, note here that $(\alpha - 1)(\beta - 1) = 1$ so then $\frac{1}{\alpha-1} = \beta - 1$ and

$$b = x^{\alpha-1} \quad \Rightarrow \quad x = b^{1/(\alpha-1)} \quad \Rightarrow \quad x = b^{\beta-1}$$

Since

$$g''(x) = (\alpha - 1)x^{\alpha-2}, \quad \alpha \geq 1$$

then $g''(x) \geq 0$ for all x. Therefore, $g(x)$ is concave up with critical point $x = b^{\beta-1}$.

(c) From our work in part (b), we can conclude, for all $x > 0$, then

$$f(x, b) \geq f(b^{\beta-1}, b) = 0$$

54. The following problem was posed by Pierre de Fermat: Given three points $A = (a_1, a_2)$, $B = (b_1, b_2)$, and $C = (c_1, c_2)$ in the plane, find the point $P = (x, y)$ that minimizes the sum of the distances

$$f(x, y) = AP + BP + CP$$

Let **e**, **f**, **g** be the unit vectors pointing from P to the points A, B, C as in Figure 27.

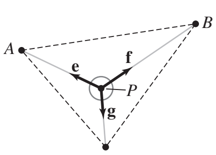
(a) Use Exercise 52 to show that the condition $\nabla f(P) = 0$ is equivalent to

$$\mathbf{e} + \mathbf{f} + \mathbf{g} = 0 \qquad \boxed{3}$$

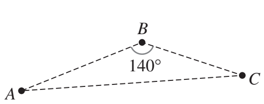
(b) Show that $f(x, y)$ is differentiable except at points A, B, C. Conclude that the minimum of $f(x, y)$ occurs either at a point P satisfying Eq. (3) or at one of the points A, B, or C.

(c) Prove that Eq. (3) holds if and only if P is the **Fermat point**, defined as the point P for which the angles between the segments $\overline{AP}$, $\overline{BP}$, $\overline{CP}$ are all 120° (Figure 27).

(d) Show that the Fermat point does not exist if one of the angles in $\triangle ABC$ is $> 120°$. Where does the minimum occur in this case?



(A) P is the Fermat point (the angles between **e**, **f**, and **g** are all 120°).

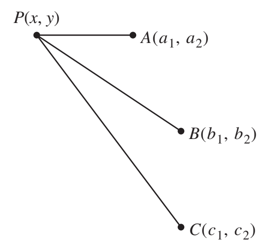


(B) Fermat point does not exist.

FIGURE 27

SOLUTION Let us examine part (b) first.

(b)



Using the formula for the length of a segment we obtain

$$f(x, y) = \sqrt{(x-a_1)^2 + (y-a_2)^2} + \sqrt{(x-b_1)^2 + (y-b_2)^2} + \sqrt{(x-c_1)^2 + (y-c_2)^2}$$

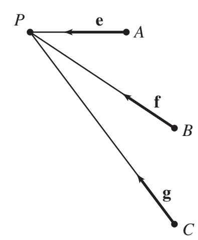
We compute the partial derivatives of f:

$$f_x(x, y) = \frac{x-a_1}{\sqrt{(x-a_1)^2 + (y-a_2)^2}} + \frac{x-b_1}{\sqrt{(x-b_1)^2 + (y-b_2)^2}} + \frac{x-c_1}{\sqrt{(x-c_1)^2 + (y-c_2)^2}} \tag{1}$$

$$f_y(x, y) = \frac{y-a_2}{\sqrt{(x-a_1)^2 + (y-a_2)^2}} + \frac{y-b_2}{\sqrt{(x-b_1)^2 + (y-b_2)^2}} + \frac{y-c_2}{\sqrt{(x-c_1)^2 + (y-c_2)^2}} \tag{2}$$

For all (x, y) other then (a_1, a_2), (b_1, b_2), (c_1, c_2) the partial derivatives are continuous, therefore the Criterion for Differentiability implies that f is differentiable at all points other than A, B, and C.

(a)



We compute the unit vectors $\mathbf{e}$, $\mathbf{f}$, and $\mathbf{g}$:

$$\mathbf{e} = \frac{\langle x-a_1, y-a_2\rangle}{\sqrt{(x-a_1)^2 + (y-a_2)^2}}$$

$$\mathbf{f} = \frac{\langle x-b_1, y-b_2\rangle}{\sqrt{(x-b_1)^2 + (y-b_2)^2}}$$

$$\mathbf{g} = \frac{\langle x-c_1, y-c_2\rangle}{\sqrt{(x-c_1)^2 + (y-c_2)^2}}$$

We write the condition $\mathbf{e} + \mathbf{f} + \mathbf{g} = \mathbf{0}$:

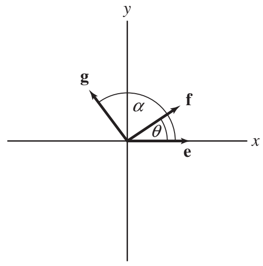
$$\begin{aligned}
\mathbf{e} + \mathbf{f} + \mathbf{g} &= \frac{\langle x-a_1, y-a_2\rangle}{\sqrt{(x-a_1)^2 + (y-a_2)^2}} + \frac{\langle x-b_1, y-b_2\rangle}{\sqrt{(x-b_1)^2 + (y-b_2)^2}} + \frac{\langle x-c_1, y-c_2\rangle}{\sqrt{(x-c_1)^2 + (y-c_2)^2}} \\
&= \Bigg\langle \frac{x-a_1}{\sqrt{(x-a_1)^2 + (y-a_2)^2}} + \frac{x-b_1}{\sqrt{(x-b_1)^2 + (y-b_2)^2}} + \frac{x-c_1}{\sqrt{(x-c_1)^2 + (y-c_2)^2}}, \\
&\quad \frac{y-a_2}{\sqrt{(x-a_1)^2 + (y-a_2)^2}} + \frac{y-b_2}{\sqrt{(x-b_1)^2 + (y-b_2)^2}} + \frac{y-c_2}{\sqrt{(x-c_1)^2 + (y-c_2)^2}} \Bigg\rangle
\end{aligned}$$

Combining with (1) and (2) we get

$$\mathbf{e}+\mathbf{f}+\mathbf{g}=\left\langle f_x(x,y), f_y(x,y)\right\rangle=\nabla f$$

Therefore, the condition $\nabla f=\mathbf{0}$ is equivalent to $\mathbf{e}+\mathbf{f}+\mathbf{g}=\mathbf{0}$.

(c) We now show that Eq. (3) holds if and only if the mutual angles between the unit vectors are all 120°. We place the axes so that the positive x-axis is in the direction of e.



Let θ and α be the angles that $\mathbf{f}$ and $\mathbf{g}$ make with $\mathbf{e}$, respectively. Hence,

$$\mathbf{e}=\langle 1,0\rangle, \mathbf{f}=\langle\cos\theta,\sin\theta\rangle, \mathbf{g}=\langle\cos\alpha,\sin\alpha\rangle$$

Substituting in $\mathbf{e}+\mathbf{f}+\mathbf{g}=\mathbf{0}$ we have

$$\langle\cos\theta+\cos\alpha+1, \sin\theta+\sin\alpha\rangle=\langle 0,0\rangle$$

or

$$\begin{aligned}\cos\theta+\cos\alpha+1&=0\\ \sin\theta+\sin\alpha&=0\end{aligned}$$

The second equation implies that

$$\sin\theta=-\sin\alpha=\sin(180+\alpha)$$

The solutions for $0\le\alpha,\theta\le 360$ are

$$\theta=180+\alpha,\quad \theta=360-\alpha$$

We substitute each solution in the first equation and solve for α. This gives

$$\begin{array}{ll}\underline{\theta=180+\alpha} & \underline{\theta=360^\circ-\alpha}\\ \cos(180+\alpha)+\cos\alpha+1=0 & \cos(360^\circ-\alpha)+\cos\alpha+1=0\\ -\cos\alpha+\cos\alpha+1=0 & \cos\alpha+\cos\alpha+1=0\\ 1=0 & 2\cos\alpha=-1\\ & \cos\alpha=-\frac{1}{2}\end{array}$$

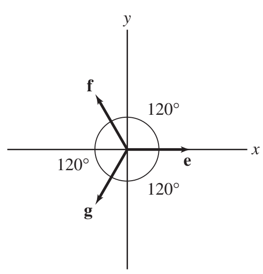
$$\Rightarrow\quad \begin{array}{ll}\alpha=120^\circ & \alpha=240^\circ\\ \theta=360^\circ-\alpha=240^\circ & \theta=360^\circ-\alpha=120^\circ\end{array}$$

We obtain the following vectors:

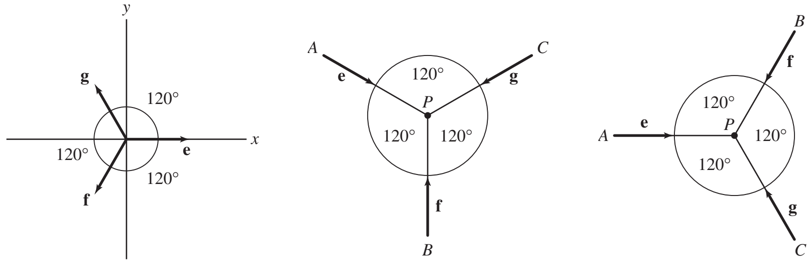
$$\mathbf{e}=\langle 1,0\rangle,\quad \mathbf{f}=\left\langle\cos 240^\circ,\sin 240^\circ\right\rangle,\quad \mathbf{g}=\left\langle\cos 120^\circ,\sin 120^\circ\right\rangle$$

or

$$\mathbf{e}=\langle 1,0\rangle,\quad \mathbf{f}=\left\langle\cos 120^\circ,\sin 120^\circ\right\rangle,\quad \mathbf{g}=\left\langle\cos 240^\circ,\sin 240^\circ\right\rangle$$



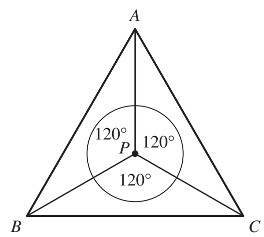
or



In either case the angles between the vectors are 120°.

Now we see $f(x, y)$ has the minimum value at a critical point:

The critical points are the points where f_x and f_y are 0 or do not exist, that is, the points A, B, C and the point where $\nabla f = \mathbf{0}$, which according to part (b) is the Fermat point. We now show that if the Fermat point P exists, then $f(P) \le f(A), f(B), f(C)$.



Suppose that the Fermat point P exists. The values of f at the critical points are

$$\begin{aligned} f(A) &= \overline{AB} + \overline{AC} \\ f(B) &= \overline{AB} + \overline{BC} \\ f(C) &= \overline{AC} + \overline{BC} \\ f(P) &= \overline{AP} + \overline{BP} + \overline{PC} \end{aligned}$$

We show that $f(P) \le f(A)$. Similarly it can be shown that also $f(P) \le f(B)$ and $f(P) \le f(C)$. By the Cosine Theorem for the triangles ABP and ACP we have

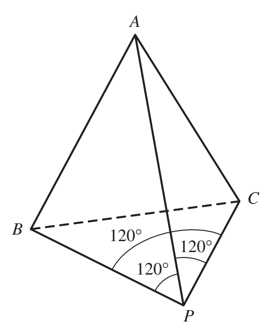
$$\overline{AB} = \sqrt{\overline{AP}^2 + \overline{BP}^2 - 2\overline{AP} \cdot \overline{BP} \cos 120^\circ} = \sqrt{\overline{AP}^2 + \overline{BP}^2 + \overline{AP} \cdot \overline{BP}}$$
$$\overline{AC} = \sqrt{\overline{AP}^2 + \overline{CP}^2 - 2\overline{AP} \cdot \overline{PC} \cos 120^\circ} = \sqrt{\overline{AP}^2 + \overline{CP}^2 + \overline{AP} \cdot \overline{PC}}$$

Hence

$$\begin{aligned} f(A) = \overline{AB} + \overline{AC} &= \sqrt{\overline{AP}^2 + \overline{BP}^2 + \overline{AP} \cdot \overline{BP}} + \sqrt{\overline{AP}^2 + \overline{CP}^2 + \overline{AP} \cdot \overline{PC}} \\ &\ge \overline{AP} + \overline{BP} + \overline{PC} = f(P) \end{aligned}$$

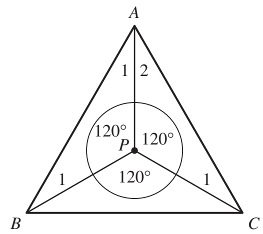
The last inequality can be verified by squaring and transferring sides. It's best to use a computer to help with the algebra; it's a daunting task to do by hand.

(d) We show that if one of the angles of ΔABC is $\ge 120°$, then the Fermat point does not exist. Notice that the Fermat point (if it exists) must fall inside the triangle ABC.



P cannot lie outside ΔABC

Suppose the Fermat point P exists.



We sum the angles in the triangles ABP and ACP, obtaining

$$\sphericalangle A_1 + \sphericalangle B_1 + 120^\circ = 180^\circ \quad \Rightarrow \quad \sphericalangle A_1 = 60^\circ - \sphericalangle B_1$$
$$\sphericalangle A_2 + \sphericalangle C_1 + 120^\circ = 180^\circ \quad \Rightarrow \quad \sphericalangle A_2 = 60^\circ - \sphericalangle C_1$$

Therefore,

$$\sphericalangle A = \sphericalangle A_1 + \sphericalangle A_2 = \left(60^\circ - \sphericalangle B_1\right) + \left(60^\circ - \sphericalangle C_1\right) = 120^\circ - (\sphericalangle B_1 + \sphericalangle C_1) < 120^\circ$$

We thus showed that if the Fermat point exists, then $\sphericalangle A < 120^\circ$. Similarly, one shows also that $\sphericalangle B$ and $\sphericalangle C$ must be smaller than 120°. We conclude that if one of the angles in ΔABC is equal or greater than 120°, then the Fermat point does not exist. In that case, the minimum value of $f(x, y)$ occurs at a point where f_x or f_y do not exist, that is, at one of the points A, B, or C.

14.8 Lagrange Multipliers: Optimizing with a Constraint (LT Section 15.8)

Preliminary Questions

1. Suppose that the maximum of $f(x, y)$ subject to the constraint $g(x, y) = 0$ occurs at a point $P = (a, b)$ such that $\nabla f_P \neq 0$. Which of the following statements is true?

(a) ∇f_P is tangent to $g(x, y) = 0$ at P.

(b) ∇f_P is orthogonal to $g(x, y) = 0$ at P.

SOLUTION

(a) Since the maximum of f subject to the constraint occurs at P, it follows by Theorem 1 that ∇f_P and ∇g_P are parallel vectors. The gradient ∇g_P is orthogonal to $g(x, y) = 0$ at P, hence ∇f_P is also orthogonal to this curve at P. We conclude that statement (b) is false (yet the statement can be true if $\nabla f_P = (0, 0)$).

(b) This statement is true by the reasoning given in the previous part.

2. Figure 9 shows a constraint $g(x, y) = 0$ and the level curves of a function f. In each case, determine whether f has a local minimum, a local maximum, or neither at the labeled point.

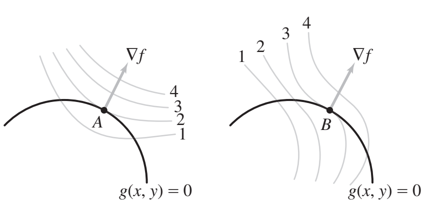


FIGURE 9

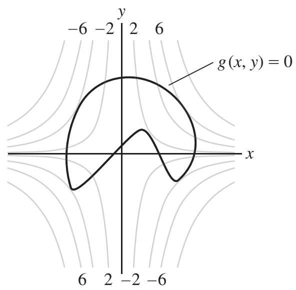
SOLUTION The level curve $f(x, y) = 2$ is tangent to the constraint curve at the point A. A close level curve that intersects the constraint curve is $f(x, y) = 1$, hence we may assume that f has a local maximum 2 under the constraint at A. The level curve $f(x, y) = 3$ is tangent to the constraint curve. However, in approaching B under the constraint, from one side f is increasing and from the other side f is decreasing. Therefore, $f(B)$ is neither local minimum nor local maximum of f under the constraint.

3. On the contour map in Figure 10:

(a) Identify the points where $\nabla f = \lambda \nabla g$ for some scalar λ.

(b) Identify the minimum and maximum values of $f(x, y)$ subject to $g(x, y) = 0$.

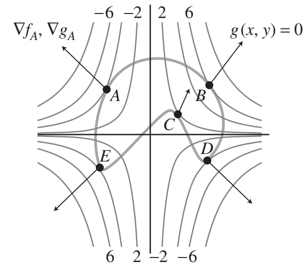


Contour plot of $f(x, y)$
(contour interval 2)

FIGURE 10 Contour map of $f(x, y)$; contour interval 2.

SOLUTION

(a) The gradient ∇g is orthogonal to the constraint curve $g(x, y) = 0$, and ∇f is orthogonal to the level curves of f. These two vectors are parallel at the points where the level curve of f is tangent to the constraint curve. These are the points A, B, C, D, E in the figure:



(b) The minimum and maximum occur where the level curve of f is tangent to the constraint curve. The level curves tangent to the constraint curve are

$$f(A) = -4, \quad f(C) = 2, \quad f(B) = 6, \quad f(D) = -4, \quad f(E) = 4$$

Therefore the global minimum of f under the constraint is -4 and the global maximum is 6.

Exercises

In this exercise set, use the method of Lagrange multipliers unless otherwise stated.

1. Find the extreme values of the function $f(x, y) = 2x + 4y$ subject to the constraint $g(x, y) = x^2 + y^2 - 5 = 0$.

(a) Show that the Lagrange equation $\nabla f = \lambda \nabla g$ gives $\lambda x = 1$ and $\lambda y = 2$.

(b) Show that these equations imply $\lambda \neq 0$ and $y = 2x$.

(c) Use the constraint equation to determine the possible critical points (x, y).

(d) Evaluate $f(x, y)$ at the critical points and determine the minimum and maximum values.

SOLUTION

(a) The Lagrange equations are determined by the equality $\nabla f = \lambda \nabla g$. We find them:

$$\nabla f = \langle f_x, f_y \rangle = \langle 2, 4 \rangle, \quad \nabla g = \langle g_x, g_y \rangle = \langle 2x, 2y \rangle$$

Hence,

$$\langle 2, 4 \rangle = \lambda \langle 2x, 2y \rangle$$

or

$$\begin{aligned} \lambda(2x) &= 2 \\ \lambda(2y) &= 4 \end{aligned} \quad \Rightarrow \quad \begin{aligned} \lambda x &= 1 \\ \lambda y &= 2 \end{aligned}$$

(b) The Lagrange equations in part (a) imply that $\lambda \neq 0$. The first equation implies that $x = \frac{1}{\lambda}$ and the second equation gives $y = \frac{2}{\lambda}$. Therefore $y = 2x$.

(c) We substitute $y = 2x$ in the constraint equation $x^2 + y^2 - 5 = 0$ and solve for x and y. This gives

$$x^2 + (2x)^2 - 5 = 0$$
$$5x^2 = 5$$
$$x^2 = 1 \quad \Rightarrow \quad x_1 = -1, \quad x_2 = 1$$

Since $y = 2x$, we have $y_1 = 2x_1 = -2$, $y_2 = 2x_2 = 2$. The critical points are thus

$$(-1, -2) \quad \text{and} \quad (1, 2).$$

Extreme values can also occur at the points where $\nabla g = \langle 2x, 2y \rangle = \langle 0, 0 \rangle$. However, $(0, 0)$ is not on the constraint.

(d) We evaluate $f(x, y) = 2x + 4y$ at the critical points, obtaining

$$f(-1, -2) = 2 \cdot (-1) + 4 \cdot (-2) = -10$$
$$f(1, 2) = 2 \cdot 1 + 4 \cdot 2 = 10$$

Since f is continuous and the graph of $g = 0$ is closed and bounded, global minimum and maximum points exist. So according to Theorem 1, we conclude that the maximum of $f(x, y)$ on the constraint is 10 and the minimum is -10.

2. Find the extreme values of $f(x, y) = x^2 + 2y^2$ subject to the constraint $g(x, y) = 4x - 6y = 25$.

(a) Show that the Lagrange equations yield $2x = 4\lambda$, $4y = -6\lambda$.

(b) Show that if $x = 0$ or $y = 0$, then the Lagrange equations give $x = y = 0$. Since $(0, 0)$ does not satisfy the constraint, you may assume that x and y are nonzero.

(c) Use the Lagrange equations to show that $y = -\frac{3}{4}x$.

(d) Substitute in the constraint equation to show that there is a unique critical point P.

(e) Does P correspond to a minimum or maximum value of f? Refer to Figure 11 to justify your answer. *Hint:* Do the values of $f(x, y)$ increase or decrease as (x, y) moves away from P along the line $g(x, y) = 0$?

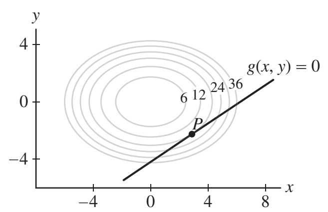


FIGURE 11 Level curves of $f(x, y) = x^2 + 2y^2$ and graph of the constraint $g(x, y) = 4x - 6y - 25 = 0$.

SOLUTION

(a) The gradients ∇f and ∇g are

$$\nabla f = \langle 2x, 4y \rangle, \quad \nabla g = \langle 4, -6 \rangle$$

The Lagrange equations are thus

$$\nabla f = \lambda \nabla g$$
$$\langle 2x, 4y \rangle = \lambda \langle 4, -6 \rangle$$

or

$$2x = 4\lambda$$
$$4y = -6\lambda$$

(b) If $x = 0$, the first equation gives $0 = 4\lambda$ or $\lambda = 0$. Substituting in the second equation gives $4y = 0$ or $y = 0$. Similarly, if $y = 0$, the second equation implies that $\lambda = 0$, hence by the first equation also $x = 0$. That is, if $x = 0$, then $y = 0$ and if $y = 0$ also $x = 0$. The point $(0, 0)$ does not satisfy the equation of the constraint, hence we may assume that $x \neq 0$ and $y \neq 0$.

(c) The first equation in part (a) gives $\lambda = \frac{x}{2}$. Substituting in the second equation we get

$$4y = -6 \cdot \frac{x}{2} = -3x \quad \Rightarrow \quad y = -\frac{3}{4}x$$

(d) We substitute $y = -\frac{3}{4}x$ in the constraint $4x - 6y = 25$ and solve for x and y. This gives

$$\begin{aligned} 4x - 6\left(-\frac{3}{4}x\right) &= 25 \\ 4x + \frac{9}{2}x &= 25 \\ 17x = 50 \quad &\Rightarrow \quad x = \frac{50}{17}, \quad y = -\frac{3}{4}\cdot\frac{50}{17} = -\frac{75}{34} \end{aligned}$$

We conclude that there is a unique critical point, which is $\left(\frac{50}{17}, -\frac{75}{34}\right)$.

(e) We now refer to Figure 11. As (x, y) moves away from P along the line $g(x, y) = 0$, the values of $f(x, y)$ increase, hence P corresponds to a minimum value of f.

3. Apply the method of Lagrange multipliers to the function $f(x, y) = (x^2 + 1)y$ subject to the constraint $x^2 + y^2 = 5$. *Hint:* First show that $y \neq 0$; then treat the cases $x = 0$ and $x \neq 0$ separately.

SOLUTION We first write out the Lagrange Equations. We have $\nabla f = \left\langle 2xy, x^2 + 1\right\rangle$ and $\nabla g = \langle 2x, 2y\rangle$. Hence, the Lagrange Condition for $\nabla g \neq 0$ is

$$\begin{aligned} \nabla f &= \lambda \nabla g \\ \left\langle 2xy, x^2 + 1\right\rangle &= \lambda\,\langle 2x, 2y\rangle \end{aligned}$$

We obtain the following equations:

$$\begin{aligned} 2xy &= \lambda(2x) \\ x^2 + 1 &= \lambda(2y) \end{aligned} \quad \Rightarrow \quad \begin{aligned} 2x(y - \lambda) &= 0 \\ x^2 + 1 &= 2\lambda y \end{aligned} \tag{1}$$

The second equation implies that $y \neq 0$, since there is no real value of x such that $x^2 + 1 = 0$. Likewise, $\lambda \neq 0$. The solutions of the first equation are $x = 0$ and $y = \lambda$.

Case 1: $x = 0$. Substituting $x = 0$ in the second equation gives $2\lambda y = 1$, or $y = \frac{1}{2\lambda}$. We substitute $x = 0$, $y = \frac{1}{2\lambda}$ (recall that $\lambda \neq 0$) in the constraint to obtain

$$0^2 + \frac{1}{4\lambda^2} = 5 \quad \Rightarrow \quad 4\lambda^2 = \frac{1}{5} \quad \Rightarrow \quad \lambda = \pm\frac{1}{\sqrt{20}} = \pm\frac{1}{2\sqrt{5}}$$

The corresponding values of y are

$$y = \frac{1}{2\cdot\frac{1}{2\sqrt{5}}} = \sqrt{5} \quad \text{and} \quad y = \frac{1}{2\cdot\left(-\frac{1}{2\sqrt{5}}\right)} = -\sqrt{5}$$

We obtain the critical points:

$$\left(0, \sqrt{5}\right) \quad \text{and} \quad \left(0, -\sqrt{5}\right)$$

Case 2: $x \neq 0$. Then the first equation in (1) implies $y = \lambda$. Substituting in the second equation gives

$$x^2 + 1 = 2\lambda^2 \quad \Rightarrow \quad x^2 = 2\lambda^2 - 1$$

We now substitute $y = \lambda$ and $x^2 = 2\lambda^2 - 1$ in the constraint $x^2 + y^2 = 5$ to obtain

$$\begin{aligned} 2\lambda^2 - 1 + \lambda^2 &= 5 \\ 3\lambda^2 &= 6 \\ \lambda^2 = 2 \quad &\Rightarrow \quad \lambda = \pm\sqrt{2} \end{aligned}$$

The solution (x, y) are thus

$$\begin{aligned} \lambda = \sqrt{2}: &\quad y = \sqrt{2}, \quad x = \pm\sqrt{2\cdot 2 - 1} = \pm\sqrt{3} \\ \lambda = -\sqrt{2}: &\quad y = -\sqrt{2}, \quad x = \pm\sqrt{2\cdot 2 - 1} = \pm\sqrt{3} \end{aligned}$$

We obtain the critical points:

$$\left(\sqrt{3}, \sqrt{2}\right), \quad \left(-\sqrt{3}, \sqrt{2}\right), \quad \left(\sqrt{3}, -\sqrt{2}\right), \quad \left(-\sqrt{3}, -\sqrt{2}\right)$$

We conclude that the critical points are

$$\left(0, \sqrt{5}\right), \quad \left(0, -\sqrt{5}\right), \quad \left(\sqrt{3}, \sqrt{2}\right), \quad \left(-\sqrt{3}, \sqrt{2}\right), \quad \left(\sqrt{3}, -\sqrt{2}\right), \quad \left(-\sqrt{3}, -\sqrt{2}\right).$$

We now calculate $f(x, y) = \left(x^2 + 1\right) y$ at the critical points:

$$f\left(0, \sqrt{5}\right) = \sqrt{5} \approx 2.24$$
$$f\left(0, -\sqrt{5}\right) = -\sqrt{5} \approx -2.24$$
$$f\left(\sqrt{3}, \sqrt{2}\right) = f\left(-\sqrt{3}, \sqrt{2}\right) = 4\sqrt{2} \approx 5.66$$
$$f\left(\sqrt{3}, -\sqrt{2}\right) = f\left(-\sqrt{3}, -\sqrt{2}\right) = -4\sqrt{2} \approx -5.66$$

Since the constraint gives a closed and bounded curve, f achieves a minimum and a maximum under it. We conclude that the maximum of $f(x, y)$ on the constraint is $4\sqrt{2}$ and the minimum is $-4\sqrt{2}$.

In Exercises 4–13, find the minimum and maximum values of the function subject to the given constraint.

4. $f(x, y) = 2x + 3y, \quad x^2 + y^2 = 4$

SOLUTION We find the extreme values of $f(x, y) = 2x + 3y$ under the constraint $g(x, y) = x^2 + y^2 - 4 = 0$.

Step 1. Write the Lagrange Equations. We have $\nabla f = \langle 2, 3\rangle$ and $\nabla g = \langle 2x, 2y\rangle$, hence the Lagrange Condition is

$$\nabla f = \lambda \nabla g$$
$$\langle 2, 3\rangle = \lambda \langle 2x, 2y\rangle$$

The corresponding equations are

$$2 = \lambda(2x)$$
$$3 = \lambda(2y)$$

Step 2. Solve for x and y using the constraint. The two equations imply that $x \neq 0$ and $y \neq 0$, hence

$$\lambda = \frac{1}{x} \quad \text{and} \quad \lambda = \frac{3}{2y}$$

The two expressions for λ must be equal, so we obtain

$$\frac{1}{x} = \frac{3}{2y} \quad \Rightarrow \quad y = \frac{3}{2}x$$

We now substitute $y = \frac{3}{2}x$ in the constraint equation $x^2 + y^2 = 4$ and solve for x and y:

$$x^2 + \left(\frac{3}{2}x\right)^2 = 4$$
$$x^2 + \frac{9}{4}x^2 = 4$$
$$13x^2 = 16 \quad \Rightarrow \quad x_1 = \frac{4}{\sqrt{13}}, \quad x_2 = -\frac{4}{\sqrt{13}}$$

Since $y = \frac{3}{2}x$, the corresponding values of y are

$$y_1 = \frac{3}{2} \cdot \frac{4}{\sqrt{13}} = \frac{6}{\sqrt{13}}, \quad y_2 = \frac{3}{2} \cdot \left(-\frac{4}{\sqrt{13}}\right) = -\frac{6}{\sqrt{13}}$$

We obtain the critical points:

$$\left(\frac{4}{\sqrt{13}}, \frac{6}{\sqrt{13}}\right), \quad \left(-\frac{4}{\sqrt{13}}, -\frac{6}{\sqrt{13}}\right)$$

Extreme points may occur also where $\nabla g = \langle 2x, 2y\rangle = \langle 0, 0\rangle$. However, the point $(0, 0)$ is not on the constraint.

Step 3. Calculate f at the critical points. We evaluate $f(x, y) = 2x + 3y$ at the critical points:

$$f\left(\frac{4}{\sqrt{13}}, \frac{6}{\sqrt{13}}\right) = \frac{8}{\sqrt{13}} + \frac{18}{\sqrt{13}} = \frac{26}{\sqrt{13}} \approx 7.21$$
$$f\left(-\frac{4}{\sqrt{13}}, -\frac{6}{\sqrt{13}}\right) = -\frac{8}{\sqrt{13}} - \frac{18}{\sqrt{13}} = -\frac{26}{\sqrt{13}} \approx -7.21$$

We conclude that the maximum of f on the constraint is about 7.21 and the minimum is about -7.21.

5. $f(x, y) = x^2 + y^2, \quad 2x + 3y = 6$

SOLUTION We find the extreme values of $f(x, y) = x^2 + y^2$ under the constraint $g(x, y) = 2x + 3y - 6 = 0$.
Step 1. Write out the Lagrange Equations. The gradients of f and g are $\nabla f = \langle 2x, 2y\rangle$ and $\nabla g = \langle 2, 3\rangle$. The Lagrange Condition is

$$\nabla f = \lambda \nabla g$$
$$\langle 2x, 2y\rangle = \lambda \langle 2, 3\rangle$$

We obtain the following equations:

$$2x = \lambda \cdot 2$$
$$2y = \lambda \cdot 3$$

Step 2. Solve for λ in terms of x and y. Notice that if $x = 0$, then the first equation gives $\lambda = 0$, therefore by the second equation also $y = 0$. The point $(0, 0)$ does not satisfy the constraint. Similarly, if $y = 0$ also $x = 0$. We therefore may assume that $x \neq 0$ and $y \neq 0$ and obtain by the two equations:

$$\lambda = x \quad \text{and} \quad \lambda = \frac{2}{3}y.$$

Step 3. Solve for x and y using the constraint. Equating the two expressions for λ gives

$$x = \frac{2}{3}y \quad \Rightarrow \quad y = \frac{3}{2}x$$

We substitute $y = \frac{3}{2}x$ in the constraint $2x + 3y = 6$ and solve for x and y:

$$2x + 3 \cdot \frac{3}{2}x = 6$$
$$13x = 12 \quad \Rightarrow \quad x = \frac{12}{13}, \quad y = \frac{3}{2} \cdot \frac{12}{13} = \frac{18}{13}$$

We obtain the critical point $\left(\frac{12}{13}, \frac{18}{13}\right)$.
Step 4. Calculate f at the critical point. We evaluate $f(x, y) = x^2 + y^2$ at the critical point:

$$f\left(\frac{12}{13}, \frac{18}{13}\right) = \left(\frac{12}{13}\right)^2 + \left(\frac{18}{13}\right)^2 = \frac{468}{169} \approx 2.77$$

Rewriting the constraint as $y = -\frac{2}{3}x + 2$, we see that as $|x| \to +\infty$ then so does $|y|$, and hence $x^2 + y^2$ is increasing without bound on the constraint as $|x| \to \infty$. We conclude that the value $468/169$ is the minimum value of f under the constraint, rather than the maximum value.

6. $f(x, y) = 4x^2 + 9y^2, \quad xy = 4$

SOLUTION We find the extreme values of $f(x, y) = 4x^2 + 9y^2$ under the constraint $g(x, y) = xy - 4 = 0$.
Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \langle 8x, 18y\rangle$ and $\nabla g = \langle y, x\rangle$, hence the Lagrange condition is

$$\nabla f = \lambda \nabla g$$
$$\langle 8x, 18y\rangle = \lambda \langle y, x\rangle$$

or

$$8x = \lambda y$$
$$18y = \lambda x$$

Step 2. Solve for λ in terms of x and y. We may assume that $x \neq 0$ and $y \neq 0$, since the points with $x = 0$ or $y = 0$ do not satisfy the constraint. The two equations give

$$\lambda = \frac{8x}{y} \quad \text{and} \quad \lambda = \frac{18y}{x}$$

Step 3. Solve for x and y using the constraint. We equate the two expressions for λ to obtain

$$\frac{8x}{y} = \frac{18y}{x} \quad \Rightarrow \quad 8x^2 = 18y^2 \quad \Rightarrow \quad y = \pm\frac{2}{3}x$$

The constraint $xy = 4$ implies that x and y have the same sign, hence $y = \frac{2}{3}x$. We substitute $y = \frac{2}{3}x$ in the constraint and solve for x and y:

$$x \cdot \frac{2}{3}x = 4 \quad \Rightarrow \quad x^2 = 6 \quad \Rightarrow \quad x_1 = \sqrt{6}, \quad x_2 = -\sqrt{6}$$

The corresponding values of y are obtained by $y = \frac{2}{3}x$:

$$y_1 = \frac{2}{3}\sqrt{6} = 2\sqrt{\frac{2}{3}}, \quad y_2 = \frac{2}{3} \cdot \left(-\sqrt{6}\right) = -2\sqrt{\frac{2}{3}}$$

The critical points are thus

$$\left(\sqrt{6}, 2\sqrt{\frac{2}{3}}\right), \quad \left(-\sqrt{6}, -2\sqrt{\frac{2}{3}}\right)$$

Extreme values can also occur at the point where $\nabla g = \langle y, x\rangle = \langle 0, 0, \rangle$. However, the point $(0, 0)$ is not on the constraint.
Step 4. Calculate f at the critical points. We evaluate $f(x, y) = 4x^2 + 9y^2$ at the critical points:

$$f\left(\sqrt{6}, 2\sqrt{\frac{2}{3}}\right) = 4 \cdot 6 + 9 \cdot 4 \cdot \frac{2}{3} = 48$$

$$f\left(-\sqrt{6}, -2\sqrt{\frac{2}{3}}\right) = 4 \cdot 6 + 9 \cdot 4 \cdot \frac{2}{3} = 48$$

On the constraint, $y = \frac{4}{x}$, thus $f(x, y) = f\left(x, \frac{4}{x}\right) = h(x) = 4x^2 + \frac{144}{x^2}$. Since $\lim\limits_{x\to\infty} h(x) = \lim_{x\to-\infty} h(x) = \infty$, h has a global minimum of 48 (but no maximum!) on $(-\infty, \infty)$.

7. $f(x, y) = xy, \quad 4x^2 + 9y^2 = 32$

SOLUTION We find the extreme values of $f(x, y) = xy$ under the constraint $g(x, y) = 4x^2 + 9y^2 - 32 = 0$.
Step 1. Write out the Lagrange Equation. The gradient vectors are $\nabla f = \langle y, x\rangle$ and $\nabla g = \langle 8x, 18y\rangle$, hence the Lagrange Condition is

$$\nabla f = \lambda \nabla g$$
$$\langle y, x\rangle = \lambda \langle 8x, 18y\rangle$$

We obtain the following equations:

$$y = \lambda(8x)$$
$$x = \lambda(18y)$$

Step 2. Solve for λ in terms of x and y. If $x = 0$, then the Lagrange equations also imply that $y = 0$ and vice versa. Since the point $(0, 0)$ does not satisfy the equation of the constraint, we may assume that $x \neq 0$ and $y \neq 0$. The two equations give

$$\lambda = \frac{y}{8x} \quad \text{and} \quad \lambda = \frac{x}{18y}$$

Step 3. Solve for x and y using the constraint. We equate the two expressions for λ to obtain

$$\frac{y}{8x} = \frac{x}{18y} \quad \Rightarrow \quad 18y^2 = 8x^2 \quad \Rightarrow \quad y = \pm\frac{2}{3}x$$

We now substitute $y = \pm\frac{2}{3}x$ in the equation of the constraint and solve for x and y:

$$4x^2 + 9 \cdot \left(\pm\frac{2}{3}x\right)^2 = 32$$

$$4x^2 + 9 \cdot \frac{4x^2}{9} = 32$$
$$8x^2 = 32 \quad \Rightarrow \quad x = -2, \quad x = 2$$

We find y by the relation $y = \pm\frac{2}{3}x$:

$$y = \frac{2}{3} \cdot (-2) = -\frac{4}{3}, \quad y = -\frac{2}{3} \cdot (-2) = \frac{4}{3}, \quad y = \frac{2}{3} \cdot 2 = \frac{4}{3}, \quad y = -\frac{2}{3} \cdot 2 = -\frac{4}{3}$$

We obtain the following critical points:

$$\left(-2, -\frac{4}{3}\right), \quad \left(-2, \frac{4}{3}\right), \quad \left(2, \frac{4}{3}\right), \quad \left(2, -\frac{4}{3}\right)$$

Extreme values can also occur at the point where $\nabla g = \langle 8x, 18y \rangle = \langle 0, 0 \rangle$, that is, at the point $(0, 0)$. However, the point does not lie on the constraint.

Step 4. Calculate f at the critical points. We evaluate $f(x, y) = xy$ at the critical points:

$$f\left(-2, -\frac{4}{3}\right) = f\left(2, \frac{4}{3}\right) = \frac{8}{3}$$
$$f\left(-2, \frac{4}{3}\right) = f\left(2, -\frac{4}{3}\right) = -\frac{8}{3}$$

Since f is continuous and the constraint is a closed and bounded set in R^2 (an ellipse), f attains global extrema on the constraint. We conclude that $\frac{8}{3}$ is the maximum value and $-\frac{8}{3}$ is the minimum value.

8. $f(x, y) = x^2y + x + y, \quad xy = 4$

SOLUTION Under the constraint $xy = 4$, then $f(x, y) = x(xy) + x + y = 4x + x + \frac{4}{x}$. Therefore, as $x \to 0+$, $f(x, y) \to +\infty$ on the constraint, and as $x \to 0-$, $f(x, y) \to -\infty$. Therefore there are no minimum and maximum values of $f(x, y)$ under the constraint.

9. $f(x, y) = x^2 + y^2, \qquad x^4 + y^4 = 1$

SOLUTION We find the extreme values of $f(x, y) = x^2 + y^2$ under the constraint $g(x, y) = x^4 + y^4 - 1 = 0$.

Step 1. Write out the Lagrange Equations. We have $\nabla f = \langle 2x, 2y \rangle$ and $\nabla g = \left\langle 4x^3, 4y^3 \right\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives

$$\langle 2x, 2y \rangle = \lambda \left\langle 4x^3, 4y^3 \right\rangle$$

or

$$\begin{aligned} 2x &= \lambda\left(4x^3\right) \\ 2y &= \lambda\left(4y^3\right) \end{aligned} \quad \Rightarrow \quad \begin{aligned} x &= 2\lambda x^3 \\ y &= 2\lambda y^3 \end{aligned} \tag{1}$$

Step 2. Solve for λ in terms of x and y. We first assume that $x \neq 0$ and $y \neq 0$. Then the Lagrange equations give

$$\lambda = \frac{1}{2x^2} \quad \text{and} \quad \lambda = \frac{1}{2y^2}$$

Step 3. Solve for x and y using the constraint. Equating the two expressions for λ gives

$$\frac{1}{2x^2} = \frac{1}{2y^2} \quad \Rightarrow \quad y^2 = x^2 \quad \Rightarrow \quad y = \pm x$$

We now substitute $y = \pm x$ in the equation of the constraint $x^4 + y^4 = 1$ and solve for x and y:

$$x^4 + (\pm x)^4 = 1$$
$$2x^4 = 1$$
$$x^4 = \frac{1}{2} \quad \Rightarrow \quad x = \frac{1}{2^{1/4}}, \quad x = -\frac{1}{2^{1/4}}$$

The corresponding values of y are obtained by the relation $y = \pm x$. The critical points are thus

$$\left(\frac{1}{2^{1/4}}, \frac{1}{2^{1/4}}\right), \quad \left(\frac{1}{2^{1/4}}, -\frac{1}{2^{1/4}}\right), \quad \left(-\frac{1}{2^{1/4}}, \frac{1}{2^{1/4}}\right), \quad \left(-\frac{1}{2^{1/4}}, -\frac{1}{2^{1/4}}\right) \tag{2}$$

We examine the case $x = 0$ or $y = 0$. Notice that the point $(0, 0)$ does not satisfy the equation of the constraint, hence either $x = 0$ or $y = 0$ can hold, but not both at the same time.

Case 1: $x = 0$. Substituting $x = 0$ in the constraint $x^4 + y^4 = 1$ gives $y = \pm 1$. We thus obtain the critical points

$$(0, -1), \quad (0, 1) \tag{3}$$

Case 2: $y = 0$. We may interchange x and y in the discussion in case 1, and obtain the critical points:

$$(-1, 0), \quad (1, 0) \tag{4}$$

Combining (2), (3), and (4) we conclude that the critical points are

$$A_1 = \left(\frac{1}{2^{1/4}}, \frac{1}{2^{1/4}}\right), \quad A_2 = \left(\frac{1}{2^{1/4}}, -\frac{1}{2^{1/4}}\right), \quad A_3 = \left(-\frac{1}{2^{1/4}}, \frac{1}{2^{1/4}}\right),$$
$$A_4 = \left(-\frac{1}{2^{1/4}}, -\frac{1}{2^{1/4}}\right), \quad A_5 = (0, -1), \quad A_6 = (0, 1), \quad A_7 = (-1, 0), \quad A_8 = (1, 0)$$

The point where $\nabla g = \left\langle 4x^3, 4y^3 \right\rangle = \langle 0, 0 \rangle$, that is, $(0, 0)$, does not lie on the constraint.

Step 4. Compute f at the critical points. We evaluate $f(x, y) = x^2 + y^2$ at the critical points:

$$f(A_1) = f(A_2) = f(A_3) = f(A_4) = \left(\frac{1}{2^{1/4}}\right)^2 + \left(\frac{1}{2^{1/4}}\right)^2 = \frac{2}{2^{1/2}} = \sqrt{2}$$
$$f(A_5) = f(A_6) = f(A_7) = f(A_8) = 1$$

The constraint $x^4 + y^4 = 1$ is a closed and bounded set in R^2 and f is continuous on this set, hence f has global extrema on the constraint. We conclude that $\sqrt{2}$ is the maximum value and 1 is the minimum value.

10. $f(x, y) = x^2 y^4, \quad x^2 + 2y^2 = 6$

SOLUTION We find the extreme values of $f(x, y) = x^2 y^4$ on the constraint $g(x, y) = x^2 + 2y^2 - 6 = 0$.

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \left\langle 2xy^4, 4y^3x^2 \right\rangle$ and $\nabla g = \langle 2x, 4y \rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives

$$\left\langle 2xy^4, 4y^3x^2 \right\rangle = \lambda \langle 2x, 4y \rangle$$

or

$$\begin{aligned} 2xy^4 &= \lambda(2x) \\ 4y^3x^2 &= \lambda(4y) \end{aligned} \quad \Rightarrow \quad \begin{aligned} xy^4 &= \lambda x \\ x^2y^3 &= \lambda y \end{aligned} \tag{1}$$

Step 2. Solve for λ in terms of x and y. Notice that if $x = 0$ or $y = 0$, then $f(x, y) = x^2 y^4$ has the value 0, which is the minimum value (since $f(x, y) \geq 0$). We thus assume that $x \neq 0$ and $y \neq 0$. The Lagrange equations (1) give

$$\lambda = \frac{xy^4}{x} = y^4, \quad \lambda = \frac{x^2y^3}{y} = x^2y^2$$

Step 3. Solve for x and y using the constraint. Equating the two expressions for λ gives

$$y^4 = x^2y^2 \quad \Rightarrow \quad y^2 = x^2 \quad \Rightarrow \quad y = \pm x$$

Substituting $y = \pm x$ in the equation of the constraint $x^2 + 2y^2 = 6$ and solving for x and y gives

$$\begin{aligned} x^2 + 2x^2 &= 6 \\ 3x^2 &= 6 \\ x^2 &= 2 \quad \Rightarrow \quad x = \sqrt{2}, \quad x = -\sqrt{2} \end{aligned}$$

The corresponding value of y is obtained by the relation $y = \pm x$. We obtain the following points:

$$\left(\sqrt{2}, -\sqrt{2}\right), \quad \left(\sqrt{2}, \sqrt{2}\right), \quad \left(-\sqrt{2}, -\sqrt{2}\right), \quad \left(-\sqrt{2}, \sqrt{2}\right)$$

Extreme values can occur also at the point where $\nabla g = \langle 2x, 4y \rangle = \langle 0, 0 \rangle$, that is, $(0, 0)$. However, this point does not lie on the constraint.

Step 4. Computing f at the critical points. We evaluate $f(x, y) = x^2y^4$ at the critical points:

$$f\left(\sqrt{2}, -\sqrt{2}\right) = f\left(\sqrt{2}, \sqrt{2}\right) = f\left(-\sqrt{2}, -\sqrt{2}\right) = f\left(-\sqrt{2}, \sqrt{2}\right) = \left(\sqrt{2}\right)^2\left(\sqrt{2}\right)^4 = \left(\sqrt{2}\right)^6 = 8$$

Recall that there are critical points with $x = 0$ or $y = 0$ at which the value of f is zero. Since f has global extrema on the ellipse $x^2 + 2y^2 = 6$, we conclude that the minimum value of f on the constraint is 0 and the maximum value is 8.

11. $f(x, y, z) = 3x + 2y + 4z, \quad x^2 + 2y^2 + 6z^2 = 1$

SOLUTION We find the extreme values of $f(x, y, z) = 3x + 2y + 4z$ under the constraint $g(x, y, z) = x^2 + 2y^2 + 6z^2 - 1 = 0$.

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \langle 3, 2, 4\rangle$ and $\nabla g = \langle 2x, 4y, 12z\rangle$, therefore the Lagrange Condition $\nabla f = \lambda\nabla g$ is:

$$\langle 3, 2, 4\rangle = \lambda \langle 2x, 4y, 12z\rangle$$

The Lagrange equations are, thus:

$$\begin{aligned} 3 &= \lambda(2x) & & \frac{3}{2} = \lambda x \\ 2 &= \lambda(4y) & \Rightarrow \quad & \frac{1}{2} = \lambda y \\ 4 &= \lambda(12z) & & \frac{1}{3} = \lambda z \end{aligned}$$

Step 2. Solve for λ in terms of x, y, and z. The Lagrange equations imply that $x \neq 0$, $y \neq 0$, and $z \neq 0$. Solving for λ we get

$$\lambda = \frac{3}{2x}, \quad \lambda = \frac{1}{2y}, \quad \lambda = \frac{1}{3z}$$

Step 3. Solve for x, y, and z using the constraint. Equating the expressions for λ gives

$$\frac{3}{2x} = \frac{1}{2y} = \frac{1}{3z} \quad \Rightarrow \quad x = \frac{9}{2}z, \quad y = \frac{3}{2}z$$

Substituting $x = \frac{9}{2}z$ and $y = \frac{3}{2}z$ in the equation of the constraint $x^2 + 2y^2 + 6z^2 = 1$ and solving for z we get

$$\begin{aligned} \left(\frac{9}{2}z\right)^2 + 2\left(\frac{3}{2}z\right)^2 + 6z^2 &= 1 \\ \frac{123}{4}z^2 &= 1 \quad \Rightarrow \quad z_1 = \frac{2}{\sqrt{123}}, z_2 = -\frac{2}{\sqrt{123}} \end{aligned}$$

Using the relations $x = \frac{9}{2}z$, $y = \frac{3}{2}z$ we get

$$\begin{aligned} x_1 &= \frac{9}{2}\cdot\frac{2}{\sqrt{123}} = \frac{9}{\sqrt{123}}, \quad y_1 = \frac{3}{2}\cdot\frac{2}{\sqrt{123}} = \frac{3}{\sqrt{123}}, \quad z_1 = \frac{2}{\sqrt{123}} \\ x_2 &= \frac{9}{2}\cdot\frac{-2}{\sqrt{123}} = -\frac{9}{\sqrt{123}}, \quad y_2 = \frac{3}{2}\cdot\frac{-2}{\sqrt{123}} = -\frac{3}{\sqrt{123}}, \quad z_2 = -\frac{2}{\sqrt{123}} \end{aligned}$$

We obtain the following critical points:

$$p_1 = \left(\frac{9}{\sqrt{123}}, \frac{3}{\sqrt{123}}, \frac{2}{\sqrt{123}}\right) \quad \text{and} \quad p_2 = \left(-\frac{9}{\sqrt{123}}, -\frac{3}{\sqrt{123}}, -\frac{2}{\sqrt{123}}\right)$$

Critical points are also the points on the constraint where $\nabla g = 0$. However, $\nabla g = \langle 2x, 4y, 12z\rangle = \langle 0, 0, 0\rangle$ only at the origin, and this point does not lie on the constraint.

Step 4. Computing f at the critical points. We evaluate $f(x, y, z) = 3x + 2y + 4z$ at the critical points:

$$\begin{aligned} f(p_1) &= \frac{27}{\sqrt{123}} + \frac{6}{\sqrt{123}} + \frac{8}{\sqrt{123}} = \frac{41}{\sqrt{123}} = \sqrt{\frac{41}{3}} \approx 3.7 \\ f(p_2) &= -\frac{27}{\sqrt{123}} - \frac{6}{\sqrt{123}} - \frac{8}{\sqrt{123}} = -\frac{41}{\sqrt{123}} = -\sqrt{\frac{41}{3}} \approx -3.7 \end{aligned}$$

Since f is continuous and the constraint is closed and bounded in R^3, f has global extrema under the constraint. We conclude that the minimum value of f under the constraint is about -3.7 and the maximum value is about 3.7.

12. $f(x, y, z) = x^2 - y - z, \quad x^2 - y^2 + z = 0$

SOLUTION We show that the function $f(x, y, z) = x^2 - y - z$ does not have minimum and maximum values subject to the constraint $x^2 - y^2 + z = 0$. Notice that the curve $(x, x, 0)$ lies on the constraint, since it satisfies the equation of the constraint. On this curve we have

$$f(x, y, z) = f(x, x, 0) = x^2 - x - 0 = x^2 - x$$

Since $\lim_{x\to\pm\infty}(x^2 - x) = \infty$, f does not have a maximum value subject to the constraint. Observe that the curve $\left(0, \sqrt{z}, z\right)$ also lies on the constraint, and we have

$$f(x, y, z) = f\left(0, \sqrt{z}, z\right) = 0^2 - \sqrt{z} - z = -\left(z + \sqrt{z}\right)$$

Since $\lim_{z\to\infty} -\left(z + \sqrt{z}\right) = -\infty$, f does not attain a minimum value on the constraint either.

13. $f(x, y, z) = xy + 3xz + 2yz, \quad 5x + 9y + z = 10$

SOLUTION We show that $f(x, y, z) = xy + 3xz + 2yz$ does not have minimum and maximum values subject to the constraint $g(x, y, z) = 5x + 9y + z - 10 = 0$. First notice that the curve $c_1 : (x, x, 10 - 14x)$ lies on the surface of the constraint since it satisfies the equation of the constraint. On c_1 we have,

$$f(x, y, z) = f(x, x, 10 - 14x) = x^2 + 3x(10 - 14x) + 2x(10 - 14x) = -69x^2 + 50x$$

Since $\lim_{x\to\infty}\left(-69x^2 + 50x\right) = -\infty$, f does not have minimum value on the constraint. Notice that the curve c_2 : $(x, -x, 10 + 4x)$ also lies on the surface of the constraint. The values of f on c_2 are

$$f(x, y, z) = f(x, -x, 10 + 4x) = -x^2 + 3x(10 + 4x) - 2x(10 + 4x) = 3x^2 + 10x$$

The limit $\lim_{x\to\infty}(3x^2 + 10x) = \infty$ implies that f does not have a maximum value subject to the constraint.

14. Let

$$f(x, y) = x^3 + xy + y^3, \qquad g(x, y) = x^3 - xy + y^3$$

(a) Show that there is a unique point $P = (a, b)$ on $g(x, y) = 1$ where $\nabla f_P = \lambda \nabla g_P$ for some scalar λ.

(b) Refer to Figure 12 to determine whether $f(P)$ is a local minimum or a local maximum of f subject to the constraint.

(c) Does Figure 12 suggest that $f(P)$ is a global extremum subject to the constraint?

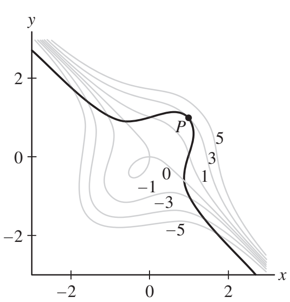

FIGURE 12 Contour map of $f(x, y) = x^3 + xy + y^3$ and graph of the constraint $g(x, y) = x^3 - xy + y^3 = 1$.

SOLUTION

(a) The gradients of f and g are $\nabla f = \left\langle 3x^2 + y, x + 3y^2\right\rangle$ and $\nabla g = \left\langle 3x^2 - y, -x + 3y^2\right\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ is

$$\left\langle 3x^2 + y, x + 3y^2\right\rangle = \lambda\left\langle 3x^2 - y, -x + 3y^2\right\rangle$$

or

$$\begin{aligned} 3x^2 + y &= \lambda(3x^2 - y) \\ x + 3y^2 &= \lambda(-x + 3y^2) \end{aligned} \tag{1}$$

Notice that if $3x^2 - y = 0$, the first equation implies that also $3x^2 + y = 0$, hence $y = 0$ and $x = 0$. Since the point $(0, 0)$ does not satisfy the equation of the constraint, we may assume that $3x^2 - y \neq 0$. Similarly, if $-x + 3y^2 = 0$, the second equation implies that also $x + 3y^2 = 0$, therefore $x = y = 0$. We thus may also assume that $-x + 3y^2 \neq 0$. Using these assumptions, we have by (1):

$$\lambda = \frac{3x^2 + y}{3x^2 - y}, \quad \lambda = \frac{x + 3y^2}{-x + 3y^2}$$

Equating the two expressions for λ we get

$$\frac{3x^2+y}{3x^2-y}=\frac{x+3y^2}{-x+3y^2}$$
$$\left(3x^2+y\right)\left(-x+3y^2\right)=\left(x+3y^2\right)\left(3x^2-y\right)$$
$$-3x^3+9x^2y^2-yx+3y^3=3x^3-xy+9x^2y^2-3y^3$$
$$x^3=y^3 \quad\Rightarrow\quad x=y$$

We now substitute $x=y$ in the constraint $x^3-xy+y^3=1$ and solve for y:

$$y^3-y^2+y^3=1$$
$$2y^3-y^2-1=0$$

We notice that $y=1$ is a root of $2y^3-y^2-1$, hence this polynomial is divisible by $y-1$. Long division yields

$$(y-1)(2y^2+y+1)=0$$

Since $2y^2+y+1>0$ for all y (the discriminant is negative), the only solution is $y=1$. Then, $x=y=1$ and the only critical point is $(1,1)$.

(b) Figure 12 suggests that the values of $f(x,y)$ are increasing as (x,y) approaches the critical point $(1,1)$ along the constraint. Therefore, f has a local maximum at P, subject to the constraint.

(c) Figure 12 shows the behavior of f and g only in the range $-3\le x\le 3$, so we cannot know whether P is a global maximum, but it is reasonable to guess that it is.

15. Find the point (a,b) on the graph of $y=e^x$ where the value ab is as small as possible.

SOLUTION We must find the point where $f(x,y)=xy$ has a minimum value subject to the constraint $g(x,y)=e^x-y=0$.

Step 1. Write out the Lagrange Equations. Since $\nabla f=\langle y,x\rangle$ and $\nabla g=\left\langle e^x,-1\right\rangle$, the Lagrange Condition $\nabla f=\lambda\nabla g$ is

$$\langle y,x\rangle=\lambda\left\langle e^x,-1\right\rangle$$

The Lagrange equations are thus

$$y=\lambda e^x$$
$$x=-\lambda$$

Step 2. Solve for λ in terms of x and y. The Lagrange equations imply that

$$\lambda=ye^{-x}\quad\text{and}\quad\lambda=-x$$

Step 3. Solve for x and y using the constraint. We equate the two expressions for λ to obtain

$$ye^{-x}=-x\quad\Rightarrow\quad y=-xe^x$$

We now substitute $y=-xe^x$ in the equation of the constraint and solve for x:

$$e^x-(-xe^x)=0$$
$$e^x(1+x)=0$$

Since $e^x\ne 0$ for all x, we have $x=-1$. The corresponding value of y is determined by the relation $y=-xe^x$. That is,

$$y=-(-1)e^{-1}=e^{-1}$$

We obtain the critical point

$$(-1,e^{-1})$$

Step 4. Calculate f at the critical point. We evaluate $f(x,y)=xy$ at the critical point.

$$f(-1,e^{-1})=(-1)\cdot e^{-1}=-e^{-1}$$

We conclude (see Remark) that the minimum value of xy on the graph of $y=e^x$ is $-e^{-1}$, and it is obtained for $x=-1$ and $y=e^{-1}$.

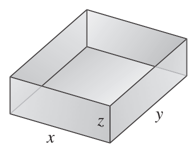
Remark: Since the constraint is not bounded, we need to justify the existence of a minimum value. The values $f(x, y) = xy$ on the constraint $y = e^x$ are $f(x, e^x) = h(x) = xe^x$. Since $h(x) > 0$ for $x > 0$, the minimum value (if it exists) occurs at a point $x < 0$. Since

$$\lim_{x\to-\infty} xe^x = \lim_{x\to-\infty} \frac{x}{e^{-x}} = \lim_{x\to-\infty} \frac{1}{-e^{-x}} = \lim_{x\to-\infty} -e^x = 0,$$

then for $x <$ some negative number $-R$, we have $|f(x) - 0| < 0.1$, say. Thus, on the bounded region $-R \le x \le 0$, f has a minimum value of $-e^{-1} \approx -0.37$, and this is thus a global minimum (for all x).

16. Find the rectangular box of maximum volume if the sum of the lengths of the edges is 300 cm.

SOLUTION We denote by x, y, and z the dimensions of the rectangular box.



Then the volume of the box is xyz. We must find the values of x, y and z that maximize the volume $f(x, y, z) = xyz$, subject to the constraint $g(x, y, z) = x + y + z = 300$, $x \ge 0$, $y \ge 0$, $z \ge 0$. (One could also argue that the sums of the lengths of the edges is $4x + 4y + 4z = 300$, but that would give a different answer, of course. Instead, we will choose to interpret the problem with the constraint $x + y + z = 300$).

Step 1. Write out the Lagrange Equations. The Lagrange Condition is

$$\nabla f = \lambda \nabla g$$
$$\langle yz, xz, xy\rangle = \lambda \langle 1, 1, 1\rangle$$

We obtain the following equations:

$$yz = \lambda$$
$$xz = \lambda$$
$$xy = \lambda$$

Step 2. Solve for λ in terms of x, y, and z. The Lagrange equations already give λ in terms of x, y, and z. Equating the expressions for λ we get $yz = xz = xy$.

Step 3. Solve for x, y, and z using the constraint. We have

$$\begin{matrix} yz = xz \\ xy = xz \end{matrix} \quad\Rightarrow\quad \begin{matrix} z(x-y) = 0 \\ x(z-y) = 0 \end{matrix}$$

If $x = 0$, $y = 0$, or $z = 0$, the volume has the minimum value 0. We thus may assume that $x \ne 0$, $y \ne 0$, and $z \ne 0$. The first equation implies that $x = y$ and the second equation gives $z = y$. We now substitute $x = y$ and $z = y$ in the constraint $x + y + z = 300$ and solve for y:

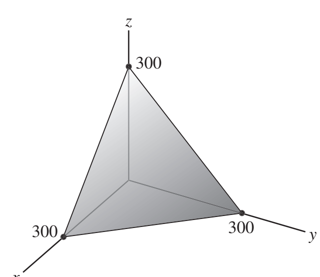
$$y + y + y = 300$$
$$3y = 300 \quad\Rightarrow\quad y = 100$$

Therefore, $x = 100$ and $z = 100$. The critical point is $(100, 100, 100)$.

Step 4. Conclusions. The value of $f(x, y, z) = xyz$ at the critical point is

$$f(100, 100, 100) = 100^3 = 10^6 \text{ cm}^3$$

The constraint $x + y + z = 300$, $x \ge 0$, $y \ge 0$, $z \ge 0$ is the part of the plane $x + y + z = 300$ that lies in the first octant. This is a bounded and closed set in R^3. Since f is continuous on this set, f has global extreme values on this set. The minimum value is zero (obtained if one of the variables is zero), hence the value 10^6 is the maximum value. We conclude that the box with maximum value is a cube of edge 100 cm.



17. The surface area of a right-circular cone of radius r and height h is $S = \pi r\sqrt{r^2+h^2}$, and its volume is $V = \frac{1}{3}\pi r^2 h$.
(a) Determine the ratio h/r for the cone with given surface area S and maximum volume V.
(b) What is the ratio h/r for a cone with given volume V and minimum surface area S?
(c) Does a cone with given volume V and maximum surface area exist?

SOLUTION

(a) Let S_0 denote a given surface area. We must find the ratio $\frac{h}{r}$ for which the function $V(r,h) = \frac{1}{3}\pi r^2 h$ has maximum value under the constraint $S(r,h) = \pi r\sqrt{r^2+h^2} = \pi\sqrt{r^4+h^2r^2} = S_0$.
Step 1. Write out the Lagrange Equation. We have

$$\nabla V = \pi\left\langle \frac{2rh}{3}, \frac{r^2}{3}\right\rangle \quad \text{and} \quad \nabla S = \pi\left\langle \frac{2r^3+h^2r}{\sqrt{r^4+h^2r^2}}, \frac{hr^2}{\sqrt{r^4+h^2r^2}}\right\rangle$$

The Lagrange Condition $\nabla V = \lambda\nabla S$ gives the following equations:

$$\frac{2rh}{3} = \frac{2r^3+h^2r}{\sqrt{r^4+h^2r^2}}\lambda \quad \Rightarrow \quad \frac{2h}{3} = \frac{2r^2+h^2}{\sqrt{r^4+h^2r^2}}\lambda$$
$$\frac{r^2}{3} = \frac{hr^2}{\sqrt{r^4+h^2r^2}}\lambda \quad \Rightarrow \quad \frac{1}{3} = \frac{h}{\sqrt{r^4+h^2r^2}}\lambda$$

Step 2. Solve for λ in terms of r and h. These equations yield two expressions for λ that must be equal:

$$\lambda = \frac{2h}{3}\frac{\sqrt{r^4+h^2r^2}}{2r^2+h^2} = \frac{1}{3h}\sqrt{r^4+h^2r^2}$$

Step 3. Solve for r and h using the constraint. We have

$$\frac{2h}{3}\frac{\sqrt{r^4+h^2r^2}}{2r^2+h^2} = \frac{1}{3h}\sqrt{r^4+h^2r^2}$$
$$2h\frac{1}{2r^2+h^2} = \frac{1}{h}$$
$$2h^2 = 2r^2+h^2 \quad \Rightarrow \quad h^2 = 2r^2 \quad \Rightarrow \quad \frac{h}{r} = \sqrt{2}$$

We substitute $h^2 = 2r^2$ in the constraint $\pi r\sqrt{r^2+h^2} = S_0$ and solve for r. This gives

$$\pi r\sqrt{r^2+2r^2} = S_0$$
$$\pi r\sqrt{3r^2} = S_0$$
$$\sqrt{3}\pi r^2 = S_0 \quad \Rightarrow \quad r^2 = \frac{S_0}{\sqrt{3}\pi}, \quad h^2 = 2r^2 = \frac{2S_0}{\sqrt{3}\pi}$$

Extreme values can occur also at points on the constraint where $\nabla S = \left\langle \frac{2r^2+h^2r}{\sqrt{r^4+h^2r^2}}, \frac{hr^2}{\sqrt{r^4+h^2r^2}}\right\rangle = \langle 0,0\rangle$, that is, at $(r,h) = (0,h)$, $h \neq 0$. However, since the radius of the cone is positive ($r > 0$), these points are irrelevant. We conclude that for the cone with surface area S_0 and maximum volume, the following holds:

$$\frac{h}{r} = \sqrt{2}, \quad h = \sqrt{\frac{2S_0}{\sqrt{3}\pi}}, \quad r = \sqrt{\frac{S_0}{\sqrt{3}\pi}}$$

For the surface area $S_0 = 1$ we get

$$h = \sqrt{\frac{2}{\sqrt{3}\pi}} \approx 0.6, \quad r = \sqrt{\frac{1}{\sqrt{3}\pi}} = 0.43$$

(b) We now must find the ratio $\frac{h}{r}$ that minimizes the function $S(r,h) = \pi r\sqrt{r^2+h^2}$ under the constraint

$$V(r,h) = \frac{1}{3}\pi r^2 h = V_0$$

Using the gradients computed in part (a), the Lagrange Condition $\nabla S = \lambda \nabla V$ gives the following equations:

$$\begin{aligned} \frac{2r^3 + h^2 r}{\sqrt{r^4 + h^2 r^2}} &= \lambda \frac{2rh}{3} \\ \frac{hr^2}{\sqrt{r^4 + h^2 r^2}} &= \lambda \frac{r^2}{3} \end{aligned} \quad \Rightarrow \quad \begin{aligned} \frac{2r^2 + h^2}{\sqrt{r^4 + h^2 r^2}} &= \lambda \frac{2h}{3} \\ \frac{h}{\sqrt{r^4 + h^2 r^2}} &= \frac{\lambda}{3} \end{aligned}$$

These equations give

$$\frac{\lambda}{3} = \frac{1}{2h} \frac{2r^2 + h^2}{\sqrt{r^4 + h^2 r^2}} = \frac{h}{\sqrt{r^4 + h^2 r^2}}$$

We simplify and solve for $\frac{h}{r}$:

$$\begin{aligned} \frac{2r^2 + h^2}{2h} &= h \\ 2r^2 + h^2 &= 2h^2 \\ 2r^2 &= h^2 \quad \Rightarrow \quad \frac{h}{r} = \sqrt{2} \end{aligned}$$

We conclude that the ratio $\frac{h}{r}$ for a cone with a given volume and minimal surface area is

$$\frac{h}{r} = \sqrt{2}$$

(c) The constant $V = 1$ gives $\frac{1}{3}\pi r^2 h = 1$ or $h = \frac{3}{\pi r^2}$. As $r \to \infty$, we have $h \to 0$, therefore

$$\lim_{\substack{r \to \infty \\ h \to 0}} S(r, h) = \lim_{\substack{r \to \infty \\ h \to 0}} \pi r \sqrt{r^2 + h^2} = \infty$$

That is, S does not have maximum value on the constraint, hence there is no cone of volume 1 and maximal surface area.

18. In Example 1, we found the maximum of $f(x, y) = 2x + 5y$ on the ellipse $(x/4)^2 + (y/3)^2 = 1$. Solve this problem again without using Lagrange multipliers. First, show that the ellipse is parametrized by $x = 4\cos t$, $y = 3\sin t$. Then find the maximum value of $f(4\cos t, 3\sin t)$ using single-variable calculus. Is one method easier than the other?

SOLUTION We want to find the maximum of $f(x, y) = 2x + 5y$ on the ellipse $(x/4)^2 + (y/3)^2 = 1$ without using Lagrange multipliers. We rewrite the equation of the ellipse in the form

$$\frac{x^2}{16} + \frac{y^2}{9} = 1$$

We now identify the following parametrization for the ellipse:

$$x = 4\cos t, \quad y = 3\sin t, \quad 0 \le t \le 2\pi$$

Substituting in the function $f(x, y) = 2x + 5y$ we obtain the following function of t:

$$g(t) = 8\cos t + 15\sin t$$

We now find the maximum value of the single variable function $g(t) = 8\cos t + 15\sin t$ in the interval $0 \le t \le 2\pi$. We first compute the critical points in the interval $0 < t < 2\pi$ by solving $g'(t) = 0$ in this interval. We obtain

$$\begin{aligned} g'(t) &= -8\sin t + 15\cos t = 0 \\ 15\cos t &= 8\sin t \\ \tan t &= \frac{15}{8} \quad \Rightarrow \quad t = \tan^{-1}(15/8) \approx 1.08 \end{aligned}$$

We evaluate $g(t) = 8\cos t + 15\sin t$ at the critical points and at the endpoints $t = 0$, $t = 2\pi$ of the interval:

$$\begin{aligned} g(\tan^{-1}(15/8)) &= 8\cos(\tan^{-1}(15/8)) + 15\sin(\tan^{-1}(15/8)) = 8 \cdot \frac{8}{17} + 15 \cdot \frac{15}{17} = \frac{289}{17} = 17 \\ g(0) &= 8\cos 0 + 15\sin 0 = 8 \\ g(2\pi) &= 8\cos 2\pi + 15\sin 2\pi = 8 \end{aligned}$$

The greatest value is $g(\tan^{-1}(15/8)) = 17$. We conclude that the maximum value of g in the interval $0 \le t \le 2\pi$ is $g(\tan^{-1}(15/8)) = 17$. Therefore, the maximum value of $f(x, y) = 2x + 5y$ on the ellipse $x^2/16 + y^2/9 = 1$ is 17, and it occurs at the point $\left(4\cos(\tan^{-1}(15/8)), 3\sin(\tan^{-1}(15/8))\right) = (4 \cdot 8/17, 3 \cdot 15/17) = (32/17, 45/17)$.

In this example the two methods do not demand much work, hence neither of them is much easier than the other.

19. Find the point on the ellipse

$$x^2 + 6y^2 + 3xy = 40$$

with largest x-coordinate (Figure 13).

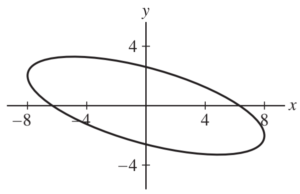


FIGURE 13 Graph of $x^2 + 6y^2 + 3xy = 40$

SOLUTION We need to maximize $f(x, y) = x$ subject to the constraint

$$g(x, y) = x^2 + 6y^2 + 3xy = 40$$

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \langle 1, 0\rangle$ and $\nabla g = \langle 2x + 3y, 12y + 3x\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives:

$$\langle 1, 0\rangle = \lambda \langle 2x + 3y, 12y + 3x\rangle$$

or

$$1 = \lambda(2x + 3y), \qquad 0 = \lambda(12y + 3x)$$

this yields

$$x = -4y$$

Step 2. Solve for x and y using the constraint.

$$x^2 + 6y^2 + 3xy = (-4y)^2 + 6y^2 + 3(-4y)y = (16 + 6 - 12)y^2 = 10y^2 = 40$$

so $y = \pm 2$. If $y = 2$ then $x = -8$ and if $y = -2$ then $x = 8$. The extreme points are $(-8, 2)$ and $(8, -2)$. We conclude that the point with largest x-coordinate is $P = (8, -2)$.

20. Find the maximum area of a rectangle inscribed in the ellipse (Figure 14):

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

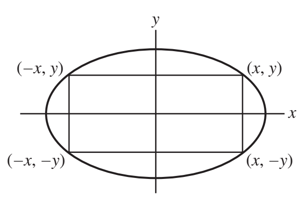

FIGURE 14 Rectangle inscribed in the ellipse $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1$.

SOLUTION Since (x, y) is in the first quadrant, $x > 0$ and $y > 0$. The area of the rectangle is $2x \cdot 2y = 4xy$. The vertices lie on the ellipse, hence their coordinates $(\pm x, \pm y)$ must satisfy the equation of the ellipse. Therefore, we must find the maximum value of the function $f(x, y) = 4xy$ under the constraint

$$g(x, y) = \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \quad x > 0, \quad y > 0.$$

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \langle 4y, 4x\rangle$ and $\nabla g = \left\langle \frac{2x}{a^2}, \frac{2y}{b^2}\right\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives

$$\langle 4y, 4x\rangle = \lambda \left\langle \frac{2x}{a^2}, \frac{2y}{b^2}\right\rangle$$

or

$$\begin{aligned} 4y &= \lambda\left(\frac{2x}{a^2}\right) \\ 4x &= \lambda\left(\frac{2y}{b^2}\right) \end{aligned} \quad \Rightarrow \quad \begin{aligned} 2y &= \lambda\frac{x}{a^2} \\ 2x &= \lambda\frac{y}{b^2} \end{aligned}$$

Step 2. Solve for λ in terms of x and y. The Lagrange equations give the following two expressions for λ:

$$\lambda = \frac{2ya^2}{x}, \quad \lambda = \frac{2xb^2}{y}$$

Equating the two equations we get

$$\frac{2ya^2}{x} = \frac{2xb^2}{y}$$

Step 3. Solve for x and y using the constraint. We solve the equation in step 2 for y in terms of x:

$$\begin{aligned} \frac{2ya^2}{x} &= \frac{2xb^2}{y} \\ 2y^2a^2 &= 2x^2b^2 \\ y^2 &= \frac{x^2b^2}{a^2} \quad \Rightarrow \quad y = \frac{b}{a}x \end{aligned}$$

We now substitute $y = \frac{b}{a}x$ in the equation of the constraint $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ and solve for x:

$$\begin{aligned} \frac{x^2}{a^2} + \frac{\left(\frac{b}{a}x\right)^2}{b^2} &= 1 \\ \frac{x^2}{a^2} + \frac{x^2}{a^2} &= 1 \\ \frac{2x^2}{a^2} &= 1 \\ x^2 = \frac{a^2}{2} \quad &\Rightarrow \quad x = \frac{a}{\sqrt{2}} \end{aligned}$$

The corresponding value of y is obtained by the relation $y = \frac{b}{a}x$:

$$y = \frac{b}{a} \cdot \frac{a}{\sqrt{2}} = \frac{b}{\sqrt{2}}$$

We obtain the critical point $\left(\frac{a}{\sqrt{2}}, \frac{b}{\sqrt{2}}\right)$. Extreme values can also occur at points on the constraint where $\nabla g = \left\langle \frac{2x}{a^2}, \frac{2y}{b^2} \right\rangle = \langle 0, 0 \rangle$. However, the point $(0, 0)$ is not on the constraint. We conclude that if $f(x, y) = 4xy$ has a maximum value on the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ with $x > 0$, $y > 0$, then it occurs at the point $\left(\frac{a}{\sqrt{2}}, \frac{b}{\sqrt{2}}\right)$ and the maximum value is

$$f\left(\frac{a}{\sqrt{2}}, \frac{b}{\sqrt{2}}\right) = 4 \cdot \frac{a}{\sqrt{2}} \cdot \frac{b}{\sqrt{2}} = 2ab$$

We now justify why the maximum value exists. We consider the problem of finding the extreme values of $f(x, y) = 4xy$ on the quarter ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ in the first quadrant. Since the constraint curve is bounded and $f(x, y)$ is continuous, f has a minimum and maximum values on the ellipse. The minimum volume occurs at the end points:

$$x = 0, \quad y = b \quad \Rightarrow \quad 4xy = 0 \qquad \text{or} \qquad x = a, \quad y = 0 \quad \Rightarrow \quad 4xy = 0$$

So the critical point $\left(\frac{a}{\sqrt{2}}, \frac{b}{\sqrt{2}}\right)$ must be a maximum.

21. Find the point (x_0, y_0) on the line $4x + 9y = 12$ that is closest to the origin.

SOLUTION Since we are minimizing distance, we can minimize the square of the distance function without loss of generality:

$$f(x, y) = (x - 0)^2 + (y - 0)^2 = x^2 + y^2$$

subject to the constraint $g(x, y) = 4x + 9y - 12$.

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \langle 2x, 2y\rangle$ and $\nabla g = \langle 4, 9\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives

$$\langle 2x, 2y\rangle = \lambda \langle 4, 9\rangle$$

or

$$2x = 4\lambda \quad \Rightarrow \quad x = 2\lambda, \quad 2y = 9\lambda$$

Step 2. Solve for λ in terms of x and y. The Lagrange equations give the following two expressions for λ:

$$\lambda = \frac{x}{2}, \quad \lambda = \frac{9}{2}y$$

Equating these two

$$\frac{x}{2} = \frac{9}{2}y \quad \Rightarrow \quad x = 9y$$

Step 3. Solve for x and y using the constraint. We are given $4x + 9y = 12$, therefore we can write:

$$4(9y) + 9y = 12 \quad \Rightarrow \quad 45y = 12 \quad \Rightarrow \quad y = \frac{12}{45} = \frac{4}{15}$$

Since $x = 9y$, then we conclude:

$$y = \frac{4}{15} \quad x = 9 \cdot \frac{4}{15} = \frac{12}{5}$$

Step 4. Conclusions. Therefore the point closest to the origin lying on the plane $4x + 9y = 12$ is the point $(12/5, 4/15)$.

22. Show that the point (x_0, y_0) closest to the origin on the line $ax + by = c$ has coordinates

$$x_0 = \frac{ac}{a^2 + b^2}, \qquad y_0 = \frac{bc}{a^2 + b^2}$$

SOLUTION We need to minimize the distance $d(x, y) = \sqrt{x^2 + y^2}$ subject to the constraint $g(x, y) = ax + by = c$. Notice that the distance $d(x, y)$ is at a minimum at the same points where the square of the distance $d^2(x, y)$ is at a minimum (since the function u^2 is increasing for $u \geq 0$). Therefore, we may find the minimum of $f(x, y) = x^2 + y^2$ subject to the constraint $ax + by = c$.

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \langle 2x, 2y\rangle$ and $\nabla g = \langle a, b\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ is

$$\langle 2x, 2y\rangle = \lambda \langle a, b\rangle$$

or

$$2x = \lambda a$$
$$2y = \lambda b$$

Step 2. Solve for λ in terms of x and y. The Lagrange equations give

$$\lambda = \frac{2x}{a} \quad \text{and} \quad \lambda = \frac{2y}{b}$$

Step 3. Solve for x and y using the constraint. We equate the two expressions for λ and solve for y in terms of x:

$$\frac{2x}{a} = \frac{2y}{b} \quad \Rightarrow \quad y = \frac{b}{a}x$$

We now substitute $y = \frac{bx}{a}$ in the equation of the constraint $ax + by = c$ and solve for x:

$$ax + b \cdot \frac{b}{a}x = c$$
$$\left(a + \frac{b^2}{a}\right)x = c$$
$$\frac{a^2 + b^2}{a}x = c \quad \Rightarrow \quad x = \frac{ac}{a^2 + b^2}$$

We find y using the relation $y = \frac{bx}{a}$:

$$y = \frac{b}{a} \cdot \frac{ac}{a^2 + b^2} = \frac{bc}{a^2 + b^2}$$

The critical point is thus

$$x_0 = \frac{ac}{a^2 + b^2}, \quad y_0 = \frac{bc}{a^2 + b^2} \tag{1}$$

Step 4. Conclusions. It is clear geometrically that the problem has a minimum value and it does not have a maximum value. Therefore the minimum occurs at the critical point. We conclude that the point closest to the origin on the line $ax + by = c$ is given by (1). To show that the vector $\langle x_0, y_0 \rangle$ is perpendicular to the line, we write the line in vector form as $\langle x - x_0, y - y_0 \rangle \cdot \langle a, b \rangle = 0$. Thus, $\langle a, b \rangle$ is perpendicular to the line. Since $\langle x_0, y_0 \rangle = \frac{c}{a^2+b^2} \langle a, b \rangle$, then $\langle x_0, y_0 \rangle$ is parallel to $\langle a, b \rangle$, and thus also perpendicular to the line.

23. Find the maximum value of $f(x, y) = x^a y^b$ for $x \geq 0$, $y \geq 0$ on the line $x + y = 1$, where $a, b > 0$ are constants.

SOLUTION

Step 1. Write the Lagrange Equations. We must find the maximum value of $f(x, y) = x^a y^b$ under the constraints $g(x, y) = x + y - 1$, $x > 0$, $y > 0$. The gradient vectors are $\nabla f = \left\langle ax^{a-1} y^b, bx^a y^{b-1} \right\rangle$ and $\nabla g = \lambda \langle 1, 1 \rangle$, hence the Lagrange Condition$\nabla f = \lambda \nabla g$ is

$$\left\langle ax^{a-1} y^b, bx^a y^{b-1} \right\rangle = \lambda \langle 1, 1 \rangle$$

We obtain the following equations:

$$\begin{aligned} ax^{a-1} y^b &= \lambda \\ bx^a y^{b-1} &= \lambda \end{aligned} \quad \Rightarrow \quad ax^{a-1} y^b = bx^a y^{b-1}$$

Step 2. Solve for x and y using the constraint. We solve the equation in step 1 for y in terms of x. This gives

$$\begin{aligned} ax^{a-1} y^b &= bx^a y^{b-1} \\ ay &= bx \quad \Rightarrow \quad y = \frac{b}{a} x \end{aligned}$$

We now substitute $y = \frac{b}{a} x$ in the constraint $x + y = 1$ and solve for x:

$$\begin{aligned} x + \frac{b}{a} x &= 1 \\ (a + b)x &= a \quad \Rightarrow \quad x = \frac{a}{a + b} \end{aligned}$$

We find y using the relation $y = \frac{b}{a} x$:

$$y = \frac{b}{a} \cdot \frac{a}{a + b} = \frac{b}{a + b}$$

The critical point is thus

$$\left(\frac{a}{a + b}, \frac{b}{a + b} \right) \tag{1}$$

Step 3. Conclusions. We compute $f(x, y) = x^a y^b$ at the critical point:

$$f\left(\frac{a}{a + b}, \frac{b}{a + b} \right) = \left(\frac{a}{a + b} \right)^a \left(\frac{b}{a + b} \right)^b = \frac{a^a b^b}{(a + b)^{a+b}}$$

Now, since f is continuous on the segment $x + y = 1$, $x \geq 0$, $y \geq 0$, which is a closed and bounded set in R^2, then f has minimum and maximum values on this segment. The minimum value is 0 (obtained at $(0, 1)$ and $(1, 0)$), therefore the critical point (1) corresponds to the maximum value. We conclude that the maximum value of $x^a y^b$ on $x + y = 1$, $x > 0$, $y > 0$ is

$$\frac{a^a b^b}{(a + b)^{a+b}}$$

24. Show that the maximum value of $f(x, y) = x^2y^3$ on the unit circle is $\frac{6}{25}\sqrt{\frac{3}{5}}$.

SOLUTION We must maximize $f(x, y) = x^2y^3$ subject to the constraint $x^2 + y^2 = 1$ (the equation of the unit circle). We will write the constraint equation as $g(x, y) = x^2 + y^2 - 1$.

Step 1. Write the Lagrange equations. The gradient vectors are $\nabla f = \left\langle 2xy^3, 3x^2y^2 \right\rangle$ and $\nabla g = \langle 2x, 2y \rangle$, hence the Lagrange condition, $\nabla f = \lambda \nabla g$ gives the following equations:

$$\left\langle 2xy^3, 3x^2y^2 \right\rangle = \lambda \langle 2x, 2y \rangle$$

or

$$2xy^3 = 2\lambda x \quad \Rightarrow \quad xy^3 = \lambda x, \quad 3x^2y^2 = 2\lambda y$$

Step 2. Solve for λ in terms of x and y. Using the first equation above, we can conclude:

$$xy^3 - \lambda x = 0 \quad \Rightarrow \quad x(y^3 - \lambda) = 0 \quad \Rightarrow \quad x = 0 \text{ or } \lambda = y^3$$

If $x = 0$, then using the constraint, $x^2 + y^2 = 1$ we get $y = \pm 1$.

If $\lambda = y^3$, using the second equation we have

$$3x^2y^2 - 2y^4 = 0 \quad \Rightarrow \quad y^2(3x^2 - 2y^2) = 0 \quad \Rightarrow \quad y = 0 \text{ or } x = \pm\sqrt{\frac{2}{3}}y$$

If $y = 0$, then using the constraint we get $x = \pm 1$.

Using the constraint, $x^2 + y^2 = 1$, for $x = \pm\sqrt{\frac{2}{3}}y$, then

$$\frac{2}{3}y^2 + y^2 = 1 \quad \Rightarrow \quad y^2 = \frac{3}{5} \quad \Rightarrow \quad y = \pm\sqrt{\frac{3}{5}}$$

Since $y = \pm\sqrt{\frac{3}{5}}$, then $x = \pm\sqrt{\frac{2}{5}}$.

Step 3. Now to examine the maximum value of the function $f(x, y) = x^2y^3$:

$$f(0, 1) = 0, \quad f(0, -1) = 0, \quad f(1, 0) = 1, \quad f(-1, 0) = 0$$

$$f\left(\sqrt{\frac{2}{5}}, \sqrt{\frac{3}{5}}\right) = \frac{6}{25}\sqrt{\frac{3}{5}}, \quad f\left(-\sqrt{\frac{2}{5}}, \sqrt{\frac{3}{5}}\right) = \frac{6}{25}\sqrt{\frac{3}{5}}$$

$$f\left(\sqrt{\frac{2}{5}}, -\sqrt{\frac{3}{5}}\right) = -\frac{6}{25}\sqrt{\frac{3}{5}}, \quad f\left(-\sqrt{\frac{2}{5}}, -\sqrt{\frac{3}{5}}\right) = -\frac{6}{25}\sqrt{\frac{3}{5}}$$

Step 4. Conclusions. From the analyzing above in Step 3, we see that the maximum value for $f(x, y) = x^2y^3$ on the unit circle is $\frac{6}{25}\sqrt{\frac{3}{5}}$.

25. Find the maximum value of $f(x, y) = x^a y^b$ for $x \geq 0$, $y \geq 0$ on the unit circle, where $a, b > 0$ are constants.

SOLUTION We must find the maximum value of $f(x, y) = x^a y^b$ $(a, b > 0)$ subject to the constraint $g(x, y) = x^2 + y^2 = 1$.

Step 1. Write out the Lagrange Equations. We have $\nabla f = \left\langle ax^{a-1}y^b, bx^a y^{b-1} \right\rangle$ and $\nabla g = \langle 2x, 2y \rangle$. Therefore the Lagrange Condition $\nabla f = \lambda \nabla g$ is

$$\left\langle ax^{a-1}y^b, bx^a y^{b-1} \right\rangle = \lambda \langle 2x, 2y \rangle$$

or

$$\begin{aligned} ax^{a-1}y^b &= 2\lambda x \\ bx^a y^{b-1} &= 2\lambda y \end{aligned} \tag{1}$$

Step 2. Solve for λ in terms of x and y. If $x = 0$ or $y = 0$, f has the minimum value 0. We thus may assume that $x > 0$ and $y > 0$. The equations (1) imply that

$$\lambda = \frac{ax^{a-2}y^b}{2}, \quad \lambda = \frac{bx^a y^{b-2}}{2}$$

Step 3. Solve for x and y using the constraint. Equating the two expressions for λ and solving for y in terms of x gives

$$\begin{aligned}\frac{ax^{a-2}y^b}{2} &= \frac{bx^ay^{b-2}}{2}\\ ax^{a-2}y^b &= bx^ay^{b-2}\\ ay^2 &= bx^2\\ y^2 &= \frac{b}{a}x^2 \quad\Rightarrow\quad y=\sqrt{\frac{b}{a}}x\end{aligned}$$

We now substitute $y=\sqrt{\frac{b}{a}}x$ in the constraint $x^2+y^2=1$ and solve for $x>0$. We obtain

$$\begin{aligned}x^2+\frac{b}{a}x^2 &= 1\\ (a+b)x^2 &= a\\ x^2 &= \frac{a}{a+b} \quad\Rightarrow\quad x=\sqrt{\frac{a}{a+b}}\end{aligned}$$

We find y using the relation $y=\sqrt{\frac{b}{a}}x$:

$$y=\sqrt{\frac{b}{a}}\sqrt{\frac{a}{a+b}}=\sqrt{\frac{ab}{a(a+b)}}=\sqrt{\frac{b}{a+b}}$$

We obtain the critical point:

$$\left(\sqrt{\frac{a}{a+b}},\sqrt{\frac{b}{a+b}}\right)$$

Extreme points can also occur where $\nabla g=\mathbf{0}$, that is, $\langle 2x,2y\rangle=\langle 0,0\rangle$ or $(x,y)=(0,0)$. However, this point is not on the constraint.

Step 4. Conclusions. We compute $f(x,y)=x^ay^b$ at the critical point:

$$f\left(\sqrt{\frac{a}{a+b}},\sqrt{\frac{b}{a+b}}\right)=\left(\frac{a}{a+b}\right)^{a/2}\left(\frac{b}{a+b}\right)^{b/2}=\frac{a^{a/2}b^{b/2}}{(a+b)^{(a+b)/2}}=\sqrt{\frac{a^ab^b}{(a+b)^{a+b}}}$$

The function $f(x,y)=x^ay^b$ is continuous on the set $x^2+y^2=1$, $x\ge 0$, $y\ge 0$, which is a closed and bounded set in R^2, hence f has minimum and maximum values on the set. The minimum value is 0 (obtained at $(0,1)$ and $(1,0)$), hence the critical point that we found corresponds to the maximum value. We conclude that the maximum value of x^ay^b on $x^2+y^2=1$, $x>0$, $y>0$ is

$$\sqrt{\frac{a^ab^b}{(a+b)^{a+b}}}.$$

26. Find the maximum value of $f(x,y,z)=x^ay^bz^c$ for $x,y,z\ge 0$ on the unit sphere, where $a,b,c>0$ are constants.

SOLUTION We must find the maximum value of $f(x,y,z)=x^ay^bz^c$ subject to the constraint $g(x,y,z)=x^2+y^2+z^2-1=0$, $x\ge 0$, $y\ge 0$, $z\ge 0$.

Step 1. Write the Lagrange Equations. The gradient vectors are $\nabla f=\left\langle ax^{a-1}y^bz^c, by^{b-1}x^az^c, cz^{c-1}x^ay^b\right\rangle$ and $\nabla g=\langle 2x,2y,2z\rangle$, hence the Lagrange Condition $\nabla f=\lambda\nabla g$ gives the following equations:

$$\begin{aligned}ax^{a-1}y^bz^c &= \lambda(2x)\\ by^{b-1}x^az^c &= \lambda(2y)\\ cz^{c-1}x^ay^b &= \lambda(2z)\end{aligned}\tag{1}$$

Step 2. Solve for λ in terms of x, y, and z. If $x=0$, $y=0$, or $z=0$, f attains the minimum value 0, therefore we may assume that $x\ne 0$, $y\ne 0$, and $z\ne 0$. The Lagrange equations (1) give

$$\lambda=\frac{ax^{a-2}y^bz^c}{2},\quad \lambda=\frac{by^{b-2}x^az^c}{2},\quad \lambda=\frac{cz^{c-2}x^ay^b}{2}$$

Step 3. Solve for x, y, and z using the constraint. Equating the expressions for λ, we obtain the following equations:

$$\begin{aligned} ax^{a-2}y^bz^c &= by^{b-2}x^az^c \\ ax^{a-2}y^bz^c &= cz^{c-2}x^ay^b \end{aligned} \tag{2}$$

We solve for x and y in terms of z. We first divide the first equation by the second equation to obtain

$$\begin{aligned} 1 &= \frac{by^{b-2}x^az^c}{cz^{c-2}x^ay^b} = \frac{b}{c}\frac{z^2}{y^2} \\ y^2 &= \frac{b}{c}z^2 \quad \Rightarrow \quad y = \sqrt{\frac{b}{c}}z \end{aligned} \tag{3}$$

Both equations (2) imply that

$$\begin{aligned} by^{b-2}x^az^c &= ax^{a-2}y^bz^c \\ by^{b-2}x^az^c &= cz^{c-2}x^ay^b \end{aligned}$$

Dividing the first equation by the second equation gives

$$\begin{aligned} 1 &= \frac{ax^{a-2}y^bz^c}{cz^{c-2}x^ay^b} = \frac{a}{c}\frac{z^2}{x^2} \\ x^2 &= \frac{a}{c}z^2 \quad \Rightarrow \quad x = \sqrt{\frac{a}{c}}z \end{aligned} \tag{4}$$

We now substitute x and y from (3) and (4) in the constraint $x^2 + y^2 + z^2 = 1$ and solve for z. This gives

$$\begin{aligned} \left(\sqrt{\frac{a}{c}}z\right)^2 + \left(\sqrt{\frac{b}{c}}z\right)^2 + z^2 &= 1 \\ \left(\frac{a}{c} + \frac{b}{c} + 1\right)z^2 &= 1 \\ \frac{a+b+c}{c}z^2 &= 1 \quad \Rightarrow \quad z = \sqrt{\frac{c}{a+b+c}} \end{aligned}$$

We find x and y using (4) and (3):

$$\begin{aligned} x &= \sqrt{\frac{a}{c}}\sqrt{\frac{c}{a+b+c}} = \sqrt{\frac{ac}{c(a+b+c)}} = \sqrt{\frac{a}{a+b+c}} \\ y &= \sqrt{\frac{b}{c}}\sqrt{\frac{c}{a+b+c}} = \sqrt{\frac{bc}{c(a+b+c)}} = \sqrt{\frac{b}{a+b+c}} \end{aligned}$$

We obtain the critical point:

$$P = \left(\sqrt{\frac{a}{a+b+c}}, \sqrt{\frac{b}{a+b+c}}, \sqrt{\frac{c}{a+b+c}}\right)$$

We examine the point where $\nabla g = \langle 2x, 2y, 2z\rangle = \langle 0, 0, 0\rangle$, that is, $(0, 0, 0)$: This point does not lie on the constraint, hence it is not a critical point.

Step 4. Conclusions. We compute $f(x, y, z) = x^ay^bz^c$ at the critical point:

$$f(P) = \left(\sqrt{\frac{a}{a+b+c}}\right)^a \left(\sqrt{\frac{b}{a+b+c}}\right)^b \left(\sqrt{\frac{c}{a+b+c}}\right)^c = \sqrt{\frac{a^ab^bc^c}{(a+b+c)^{a+b+c}}}$$

Now, $f(x, y, z) = x^ay^bz^c$ is continuous on the set $x^2 + y^2 + z^2 = 1$, $x \geq 0$, $y \geq 0$, $z \geq 0$, which is closed and bounded in R^3. The minimum value is 0 (obtained at the points with at least one zero coordinate), therefore the critical point that we found corresponds to the maximum value. We conclude that the maximum value of $x^ay^bz^c$ subject to the constraint $x^2 + y^2 + z^2 = 1$, $x \geq 0$, $y \geq 0$, $z \geq 0$ is

$$\sqrt{\frac{a^ab^bc^c}{(a+b+c)^{a+b+c}}}$$

27. Show that the minimum distance from the origin to a point on the plane $ax + by + cz = d$ is

$$\frac{|d|}{\sqrt{a^2 + b^2 + c^2}}$$

SOLUTION We want to minimize the distance $P = \sqrt{x^2 + y^2 + z^2}$ subject to $ax + by + cz = d$. Since the square function u^2 is increasing for $u \geq 0$, the square P^2 attains its minimum at the same point where the distance P attains its minimum. Thus, we may minimize the function $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraint $g(x, y, z) = ax + by + cz = d$.

Step 1. Write out the Lagrange Equations. We have $\nabla f = \langle 2x, 2y, 2z \rangle$ and $\nabla g = \langle a, b, c \rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives the following equations:

$$2x = \lambda a$$
$$2y = \lambda b$$
$$2z = \lambda c$$

Assume for now that $a \neq 0$, $b \neq 0$, $c \neq 0$.

Step 2. Solve for λ in terms of x, y, and z. The Lagrange Equations imply that

$$\lambda = \frac{2x}{a}, \quad \lambda = \frac{2y}{b}, \quad \lambda = \frac{2z}{c}$$

Step 3. Solve for x, y, and z using the constraint. Equating the expressions for λ give the following equations:

$$\begin{array}{c} \dfrac{2x}{a} = \dfrac{2z}{c} \\ \dfrac{2y}{b} = \dfrac{2z}{c} \end{array} \quad \Rightarrow \quad \begin{array}{c} x = \dfrac{a}{c} z \\ y = \dfrac{b}{c} z \end{array} \tag{1}$$

We now substitute $x = \frac{a}{c} z$ and $y = \frac{b}{c} z$ in the equation of the constraint $ax + by + cz = d$ and solve for z. This gives

$$a \left(\frac{a}{c} z \right) + b \left(\frac{b}{c} z \right) + cz = d$$
$$\frac{a^2}{c} z + \frac{b^2}{c} z + cz = d$$
$$\left(a^2 + b^2 + c^2 \right) z = dc$$

Since $a^2 + b^2 + c^2 \neq 0$, we get $z = \frac{dc}{a^2+b^2+c^2}$. We now use (1) to compute y and x:

$$x = \frac{a}{c} \cdot \frac{dc}{a^2 + b^2 + c^2} = \frac{ad}{a^2 + b^2 + c^2}, \quad y = \frac{b}{c} \cdot \frac{dc}{a^2 + b^2 + c^2} = \frac{bd}{a^2 + b^2 + c^2}$$

We obtain the critical point:

$$P = \left(\frac{ad}{a^2 + b^2 + c^2}, \frac{bd}{a^2 + b^2 + c^2}, \frac{dc}{a^2 + b^2 + c^2} \right) \tag{2}$$

Step 4. Conclusions. It is clear geometrically that f has a minimum value subject to the constraint, hence the minimum value occurs at the point P. We conclude that the point P is the point on the plane closest to the origin. We now consider the case where $a = 0$. We consider the planes $ax + by + cz = d$, where $a \neq 0$ and $a \to 0$. A continuous change in a causes a continuous change in the closest point P. Therefore, the point P closest to the origin in case of $a = 0$ can be obtained by computing the limit of P in (2) as $a \to 0$, that is, by substituting $a = 0$. Similar considerations hold for $b = 0$ or $c = 0$. We conclude that the closest point P in (2) holds also for the planes with $a = 0$, $b = 0$, or $c = 0$ (but not all of them 0). The distance P of that point to the origin is

$$P = \sqrt{\frac{(ad)^2 + (bd)^2 + (dc)^2}{\left(a^2 + b^2 + c^2\right)^2}} = |d| \sqrt{\frac{a^2 + b^2 + c^2}{\left(a^2 + b^2 + c^2\right)^2}} = \frac{|d|}{\sqrt{a^2 + b^2 + c^2}}$$

28. Antonio has \$5.00 to spend on a lunch consisting of hamburgers (\$1.50 each) and French fries (\$1.00 per order). Antonio's satisfaction from eating x_1 hamburgers and x_2 orders of French fries is measured by a function $U(x_1, x_2) = \sqrt{x_1 x_2}$. How much of each type of food should he purchase to maximize his satisfaction? (Assume that fractional amounts of each food can be purchased.)

SOLUTION Antonio has \$5.00 to spend on the lunch, hence the total cost $1.5x_1 + x_2$ must satisfy

$$1.5x_1 + x_2 = 5$$

We thus want to maximize the function $U(x_1, x_2) = \sqrt{x_1 x_2}$ subject to the constraint $g(x, y) = 1.5x_1 + x_2 = 5$ with $x_1 > 0, x_2 > 0$.

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla U = \frac{1}{2}\left\langle \sqrt{\frac{x_2}{x_1}}, \sqrt{\frac{x_1}{x_2}} \right\rangle$ and $\nabla g = \langle 1.5, 1 \rangle$, hence the Lagrange Condition $\nabla U = \lambda \nabla g$ gives the following equations:

$$\begin{aligned} \frac{1}{2}\sqrt{\frac{x_2}{x_1}} &= 1.5\lambda \\ \frac{1}{2}\sqrt{\frac{x_1}{x_2}} &= \lambda \end{aligned} \quad \Rightarrow \quad \begin{aligned} \frac{x_2}{x_1} &= 9\lambda^2 \\ \frac{x_1}{x_2} &= 4\lambda^2 \end{aligned}$$

Step 2. Solve for x_1 and x_2 using the constraint. The two equations in step 1 give

$$\lambda^2 = \frac{x_2}{9x_1} = \frac{x_1}{4x_2}$$

Therefore,

$$\begin{aligned} 4x_2^2 &= 9x_1^2 \\ x_2^2 &= \frac{9}{4}x_1^2 \quad \Rightarrow \quad x_2 = \frac{3}{2}x_1 \end{aligned}$$

We now substitute $x_2 = \frac{3}{2}x_1$ in the constraint $1.5x_1 + x_2 = 5$ and solve for x_1. We get

$$\begin{aligned} 1.5x_1 + \frac{3}{2}x_1 &= 5 \\ 3x_1 &= 5 \quad \Rightarrow \quad x_1 = \frac{5}{3} \end{aligned}$$

We find x_2 by the relation $x_2 = \frac{3}{2}x_1$:

$$x_2 = \frac{3}{2} \cdot \frac{5}{3} = \frac{5}{2}$$

We obtain the critical point:

$$\left(\frac{5}{3}, \frac{5}{2} \right)$$

Step 3. Conclusions. We conclude that Antonio should have $\frac{5}{3}$ hamburgers and $\frac{5}{2}$ orders of fries, to maximize his satisfaction. Notice that $U(x_1, x_2) = \sqrt{x_1 x_2}$ is continuous on the set $1.5x_1 + x_2 = 5$, $x_1 \geq 0$, $x_2 \geq 0$, which is closed and bounded in R^2 (it is a triangle in the first quadrant). f has minimum and maximum values on this set. The minimum value 0 is obtained for $x_1 = 0$ or $x_2 = 0$, hence the critical point that we found corresponds to the maximum value.

29. Let Q be the point on an ellipse closest to a given point P outside the ellipse. It was known to the Greek mathematician Apollonius (third century BCE) that $\overline{PQ}$ is perpendicular to the tangent to the ellipse at Q (Figure 15). Explain in words why this conclusion is a consequence of the method of Lagrange multipliers. *Hint:* The circles centered at P are level curves of the function to be minimized.

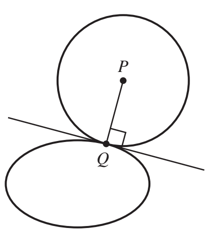

FIGURE 15

SOLUTION Let $P = (x_0, y_0)$. The distance d between the point P and a point $Q = (x, y)$ on the ellipse is minimum where the square d^2 is minimum (since the square function u^2 is increasing for $u \geq 0$). Therefore, we want to minimize the function

$$f(x, y, z) = (x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2$$

subject to the constraint

$$g(x, y) = \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

The method of Lagrange indicates that the solution Q is the point on the ellipse where $\nabla f = \lambda \nabla g$, that is, the point on the ellipse where the gradients ∇f and ∇g are parallel. Since the gradient is orthogonal to the level curves of the function, ∇g is orthogonal to the ellipse $g(x, y) = 1$, and ∇f is orthogonal to the level curve of f passing through Q. But this level curve is a circle through Q centered at P, hence the parallel vectors ∇g and ∇f are orthogonal to the ellipse and to the circle centered at P respectively. We conclude that the point Q is the point at which the tangent to the ellipse is also the tangent to the circle through Q centered at P. That is, the tangent to the ellipse at Q is perpendicular to the radius $\overline{PQ}$ of the circle.

30. In a contest, a runner starting at A must touch a point P along a river and then run to B in the shortest time possible (Figure 16). The runner should choose the point P that minimizes the total length of the path.

(a) Define a function

$$f(x, y) = AP + PB, \quad \text{where } P = (x, y)$$

Rephrase the runner's problem as a constrained optimization problem, assuming that the river is given by an equation $g(x, y) = 0$.

(b) Explain why the level curves of $f(x, y)$ are ellipses.

(c) Use Lagrange multipliers to justify the following statement: The ellipse through the point P minimizing the length of the path is tangent to the river.

(d) Identify the point on the river in Figure 16 for which the length is minimal.

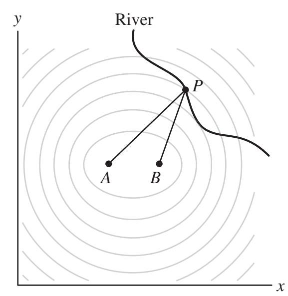

FIGURE 16

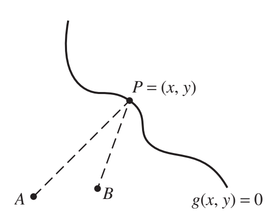
SOLUTION

(a) Let A and B be the points $A = (a, b)$ and $B = (c, d)$.



By the Length Formula we have

$$\overline{AP} = \sqrt{(x-a)^2 + (y-b)^2}$$

$$\overline{PB} = \sqrt{(x-c)^2 + (y-d)^2}$$

The distance traveled by the runner is

$$f(x, y) = \sqrt{(x-a)^2 + (y-b)^2} + \sqrt{(x-c)^2 + (y-d)^2}$$

We must minimize the function f subject to the constraint $g(x, y) = 0$ (since the point $P = (x, y)$ must satisfy the equation of the river).

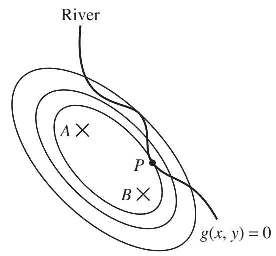
(b) The level curves of $f(x, y)$ are $f(x, y) = k$ for positive constants k. That is,

$$\sqrt{(x-a)^2 + (y-b)^2} + \sqrt{(x-c)^2 + (y-d)^2} = k$$

The level curve consists of all the points $P = (x, y)$ such that the sum of the distances to the two fixed points $A = (a, b)$ and $B = (c, d)$ is constant $k > 0$. Therefore the level curves are ellipses with foci at A and B.

(c) The point P that minimizes the length of the path must satisfy the Lagrange Condition $\nabla f_P = \lambda \nabla g_P$. That is, the gradients of f and g are parallel vectors. Since the gradient at P is orthogonal to the level curve of the function passing through P, the level curve of f through P (which is the ellipse through P) is tangent to the level curve of g through P, that is, it is tangent to the river.

(d) The path-minimizing point is the point closest to the line through A and B such that the ellipse through P is tangent to the river.



In Exercises 31 and 32, let V be the volume of a can of radius r and height h, and let S be its surface area (including the top and bottom).

31. Find r and h that minimize S subject to the constraint $V = 54\pi$.

SOLUTION We see that the surface area of the can is $S = 2\pi rh + 2\pi r^2$ subject to $V = 54\pi = \pi r^2 h$. Let us write the constraint as $V(r, h) = \pi r^2 h - 54\pi$ and use Lagrange Multipliers to solve.

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla S = \langle 2\pi h + 4\pi r, 2\pi r\rangle$ and $\nabla V = \left\langle 2\pi rh, \pi r^2\right\rangle$. Then using $\nabla S = \lambda \nabla V$, we see

$$\langle 2\pi h + 4\pi r, 2\pi r\rangle = \lambda \left\langle 2\pi rh, \pi r^2\right\rangle$$

or

$$2\pi h + 4\pi r = 2\pi\lambda rh, \quad 2\pi r = \lambda\pi r^2$$

Consider the second equation, rewriting we have:

$$2\pi r - \lambda\pi r^2 = 0 \quad \Rightarrow \quad \pi r(2 - \lambda r) = 0 \quad \Rightarrow \quad r = 0, \lambda = \frac{2}{r}$$

We can ignore when $r = 0$ since it does not correspond to any point on the constraint curve $54\pi = \pi r^2 h$.

Using the first equation, rewriting we have:

$$2\pi h + 4\pi r = 2\pi\lambda rh \quad \Rightarrow \quad \lambda = \frac{2\pi h + 4\pi r}{2\pi rh} = \frac{h + 2r}{rh}$$

Step 2. Solve for r, h using the constraint to determine the critical point.

Using the two derived equations for λ we have:

$$\frac{2}{r} = \frac{h + 2r}{rh} \quad \Rightarrow \quad 2rh = hr + 2r^2 \quad r(2h - h - 2r) = 0 \quad \Rightarrow \quad h = 2r$$

Then using the constraint, $54\pi = \pi r^2 h$ we see:

$$54\pi = \pi r^2(2r) \quad \Rightarrow \quad 54 = 2r^3 \quad \Rightarrow \quad r^3 = 27 \quad \Rightarrow \quad r = 3$$

Thus $r = 3$ and $h = 2(3) = 6$.

Step 3. Conclusions. The minimum surface area, given that the volume must be 54π is determined by a can having radius $r = 3$ and height $h = 6$. We know this is the minimum surface area because surface area is an increasing function of r and h.

32. Show that for both of the following two problems, $P = (r, h)$ is a Lagrange critical point if $h = 2r$:

- Minimize surface area S for fixed volume V.
- Maximize volume V for fixed surface area S.

Then use the contour plots in Figure 17 to explain why S has a minimum for fixed V but no maximum and, similarly, V has a maximum for fixed S but no minimum.

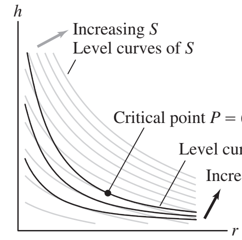


FIGURE 17

SOLUTION

- To minimize surface area $S = 2\pi rh + 2\pi r^2$ for a fixed volume (subject to the constraint $c(r, h) = \pi r^2 h - V$) we use the Lagrange equations. Then using $\nabla S = \lambda \nabla c$, we see

$$\langle 2\pi h + 4\pi r, 2\pi r\rangle = \lambda \left\langle 2\pi rh, \pi r^2 \right\rangle$$

or

$$2\pi h + 4\pi r = 2\pi \lambda rh, \quad 2\pi r = \lambda \pi r^2$$

Consider the second equation, rewriting we have:

$$2\pi r - \lambda \pi r^2 = 0 \quad \Rightarrow \quad \pi r(2 - \lambda r) = 0 \quad \Rightarrow \quad r = 0, \lambda = \frac{2}{r}$$

Since this is a question about surface area, we are not interested in the point when $r = 0$.

Using the first equation, rewriting we have:

$$2\pi h + 4\pi r = 2\pi \lambda rh \quad \Rightarrow \quad \lambda = \frac{2\pi h + 4\pi r}{2\pi rh} = \frac{h + 2r}{rh}$$

Now to solve for r, h using the constraint to determine the critical point. Using the two derived equations for λ we have:

$$\frac{2}{r} = \frac{h + 2r}{rh} \quad \Rightarrow \quad 2rh = hr + 2r^2 \quad r(2h - h - 2r) = 0 \quad \Rightarrow \quad h = 2r$$

Therefore, we see that the critical point is (r, h) where $h = 2r$.

- To maximize the volume $V = \pi r^2 h$ for a fixed surface area (subject to the constraint $c(r, h) = 2\pi rh + 2\pi r^2 - S$) we use the Lagrange equations. Then using $\nabla V = \lambda \nabla c$ we see

$$\left\langle 2\pi rh, \pi r^2 \right\rangle = \lambda \langle 2\pi h + 4\pi r, 2\pi r\rangle$$

or

$$\lambda(2\pi h + 4\pi r) = 2\pi rh, \quad \lambda(2\pi r) = \pi r^2$$

$$\lambda = \frac{rh}{h + 2r}, \quad \lambda = \frac{r}{2}$$

Using these two derived equations for λ, we have:

$$\frac{r}{2} = \frac{rh}{h + 2r} \quad \Rightarrow \quad h = 2r$$

Therefore, we see that the critical point is (r, h) where $h = 2r$.

Using the contour plots in the figure, we can see that S has a minimum for a fixed value of V, but no maximum because it increases without an upper bound, whereas has V has a maximum for a fixed value of S, but no minimum because it decreases without a lower bound.

33. A plane with equation $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ $(a, b, c > 0)$ together with the positive coordinate planes forms a tetrahedron of volume $V = \frac{1}{6}abc$ (Figure 18). Find the minimum value of V among all planes passing through the point $P = (1, 1, 1)$.

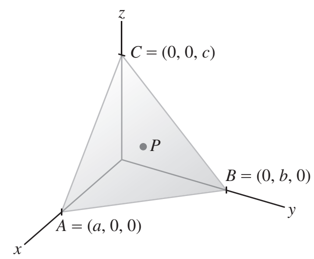

FIGURE 18

SOLUTION The plane is constrained to pass through the point $P = (1, 1, 1)$, hence this point must satisfy the equation of the plane. That is,

$$\frac{1}{a} + \frac{1}{b} + \frac{1}{c} = 1$$

We thus must minimize the function $V(a, b, c) = \frac{1}{6}abc$ subject to the constraint $g(a, b, c) = \frac{1}{a} + \frac{1}{b} + \frac{1}{c} = 1$, $a > 0$, $b > 0$, $c > 0$.

Step 1. Write out the Lagrange Equations. We have $\nabla V = \left\langle \frac{1}{6}bc, \frac{1}{6}ac, \frac{1}{6}ab \right\rangle$ and $\nabla g = \left\langle -\frac{1}{a^2}, -\frac{1}{b^2}, -\frac{1}{c^2} \right\rangle$, hence the Lagrange Condition $\nabla V = \lambda \nabla g$ yields the following equations:

$$\frac{1}{6}bc = -\frac{1}{a^2}\lambda$$
$$\frac{1}{6}ac = -\frac{1}{b^2}\lambda$$
$$\frac{1}{6}ab = -\frac{1}{c^2}\lambda$$

Step 2. Solve for λ in terms of a, b, and c. The Lagrange equations imply that

$$\lambda = -\frac{bca^2}{6}, \quad \lambda = -\frac{acb^2}{6}, \quad \lambda = -\frac{abc^2}{6}$$

Step 3. Solve for a, b, and c using the constraint. Equating the expressions for λ, we obtain the following equations:

$$\begin{aligned} bca^2 &= acb^2 \\ abc^2 &= acb^2 \end{aligned} \quad \Rightarrow \quad \begin{aligned} abc(a-b) &= 0 \\ abc(c-b) &= 0 \end{aligned}$$

Since a, b, c are positive numbers, we conclude that $a = b$ and $c = b$. We now substitute $a = b$ and $c = b$ in the equation of the constraint $\frac{1}{a} + \frac{1}{b} + \frac{1}{c} = 1$ and solve for b. This gives

$$\frac{1}{b} + \frac{1}{b} + \frac{1}{b} = 1$$
$$\frac{3}{b} = 1 \quad \Rightarrow \quad b = 3$$

Therefore also $a = b = 3$ and $c = b = 3$. We obtain the critical point $(3, 3, 3)$.

Step 4. Conclusions. If V has a minimum value subject to the constraint then it occurs at the point $(3, 3, 3)$. That is, the plane that minimizes V is

$$\frac{x}{3} + \frac{y}{3} + \frac{z}{3} = 1 \quad \text{or} \quad x + y + z = 3$$

Remark: Since the constraint is not bounded, we need to justify the existence of a minimum value of $V = \frac{1}{6}abc$ under the constraint $\frac{1}{a} + \frac{1}{b} + \frac{1}{c} = 1$. First notice that since a, b, c are nonnegative and the sum of their reciprocals is 1, none of them can tend to zero. In fact, none of a, b, c can be less than 1. Therefore, if $a \to \infty$, $b \to \infty$, or $c \to \infty$, then $V \to \infty$. This means that we can find a cube that includes the point $\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right)$ such that, on the part of the constraint that is outside the cube, it holds that $V > V\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right) = \frac{1}{162}$. On the part of the constraint inside the cube, V has a minimum value m, since it is a closed and bounded set. Clearly m is the minimum of V on the whole constraint.

34. With the same set-up as in the previous problem, find the plane that minimizes V if the plane is constrained to pass through a point $P = (\alpha, \beta, \gamma)$ with $\alpha, \beta, \gamma > 0$.

SOLUTION The plane $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ must pass through the point $P(\alpha, \beta, \gamma)$, hence

$$\frac{\alpha}{a} + \frac{\beta}{b} + \frac{\gamma}{c} = 1$$

We thus must minimize the function $V(a, b, c) = \frac{1}{6}abc$ subject to the constant $g(a, b, c) = \frac{\alpha}{a} + \frac{\beta}{b} + \frac{\gamma}{c} = 1$, $a > 0$, $b > 0$, $c > 0$.

Step 1. Write out the Lagrange Equations. We have $\nabla V = \left\langle \frac{1}{6}bc, \frac{1}{6}ac, \frac{1}{6}ab \right\rangle$ and $\nabla g = \left\langle -\frac{\alpha}{a^2}, -\frac{\beta}{b^2}, -\frac{\gamma}{c^2} \right\rangle$, hence the Lagrange Condition $\nabla V = \lambda \nabla g$ yields the following equations:

$$\begin{aligned} \frac{1}{6}bc &= -\frac{\alpha}{a^2}\lambda & & \lambda = -\frac{a^2bc}{6\alpha} \\ \frac{1}{6}ac &= -\frac{\beta}{b^2}\lambda & \Rightarrow \quad & \lambda = -\frac{b^2ac}{6\beta} \\ \frac{1}{6}ab &= -\frac{\gamma}{c^2}\lambda & & \lambda = -\frac{c^2ab}{6\gamma} \end{aligned}$$

Step 2. Solve for a, b, c using the constraint. The Lagrange equations imply the following equations:

$$\frac{a^2bc}{\alpha} = \frac{c^2ab}{\gamma}$$
$$\frac{b^2ac}{\beta} = \frac{c^2ab}{\gamma}$$

We simplify the two equations to obtain

$$abc(\gamma a - \alpha c) = 0$$
$$abc(\gamma b - \beta c) = 0$$

Since $abc \neq 0$, these equations imply that

$$\begin{aligned} \gamma a - \alpha c = 0 \quad &\Rightarrow \quad a = \frac{\alpha}{\gamma}c \\ \gamma b - \beta c = 0 \quad &\Rightarrow \quad b = \frac{\beta}{\gamma}c \end{aligned} \tag{1}$$

We now substitute in the constraint $\frac{\alpha}{a} + \frac{\beta}{b} + \frac{\gamma}{c} = 1$ and solve for c. This gives

$$\begin{aligned} \frac{\alpha}{\frac{\alpha}{\gamma}c} + \frac{\beta}{\frac{\beta}{\gamma}c} + \frac{\gamma}{c} &= 1 \\ \frac{\gamma}{c} + \frac{\gamma}{c} + \frac{\gamma}{c} &= 1 \\ \frac{3\gamma}{c} &= 1 \quad \Rightarrow \quad c = 3\gamma \end{aligned}$$

We find a and b using (1):

$$a = \frac{\alpha}{\gamma} \cdot 3\gamma = 3\alpha, \quad b = \frac{\beta}{\gamma} \cdot 3\gamma = 3\beta$$

We obtain the solution

$$P = (3\alpha, 3\beta, 3\gamma)$$

Step 3. Conclusions. Since V has a minimum value subject to the constraint, it occurs at the critical point. We substitute $a = 3\alpha$, $b = 3\beta$, and $c = 3\gamma$ in the equation of the plane $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ to obtain the following plane, which minimizes V:

$$\frac{x}{3\alpha} + \frac{y}{3\beta} + \frac{z}{3\gamma} = 1 \quad \text{or} \quad \frac{x}{\alpha} + \frac{y}{\beta} + \frac{z}{\gamma} = 3$$

35. Show that the Lagrange equations for $f(x, y) = x + y$ subject to the constraint $g(x, y) = x + 2y = 0$ have no solution. What can you conclude about the minimum and maximum values of f subject to $g = 0$? Show this directly.

SOLUTION Using the methods of Lagrange we can write $\nabla f = \lambda \nabla g$ and see

$$\langle 1, 1 \rangle = \lambda \langle 1, 2 \rangle$$

Which gives us the equations:

$$1 = \lambda, \quad 1 = 2\lambda$$

hence, $\lambda = 1$ or $\lambda = 1/2$. This is an inconsistent set of equations, thus the Lagrange method has no solution. What we can conclude from this is that the maximum and minimum values of f subject to $g = 0$ does not exist. This means that $f(x, y)$ increases without an upper bound and decreases without a lower bound.

To show this directly, we can write $y = -1/2x$ from the constraint equation and substitute it into $f(x, y) = f(x, -1/2x) = x - 1/2x = 1/2x$. We know that $y = 1/2x$ is a straight line having slope $1/2$, increasing, with no maximum nor minimum values.

36. Show that the Lagrange equations for $f(x, y) = 2x + y$ subject to the constraint $g(x, y) = x^2 - y^2 = 1$ have a solution but that f has no min or max on the constraint curve. Does this contradict Theorem 1?

SOLUTION Using the methods of Lagrange we can write $\nabla f = \lambda \nabla g$ and see

$$\langle 2, 1 \rangle = \lambda \langle 2x, -2y \rangle$$

or

$$2 = 2\lambda x, \quad 1 = -2\lambda y$$

and

$$\lambda x = 1, \quad 1 = -2\lambda y$$

hence

$$\lambda x = -2\lambda y \quad \Rightarrow \quad \lambda x + 2\lambda y = 0 \quad \Rightarrow \quad \lambda(x + 2y) = 0$$

Hence $\lambda = 0$ or $x = -2y$. But we see if $\lambda = 0$ above, we get an inconsistent equation, therefore $x = -2y$. Using the constraint equation we see

$$(-2y)^2 - y^2 = 1 \quad \Rightarrow \quad 4y^2 - y^2 = 1 \quad \Rightarrow \quad y = \pm\frac{1}{\sqrt{3}}, x = \mp\frac{2}{\sqrt{3}}$$

Evaluating at these points we see

$$f\left(\frac{2}{\sqrt{3}}, -\frac{1}{\sqrt{3}}\right) = \sqrt{3}, \quad f\left(-\frac{2}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right) = -\sqrt{3}$$

Now, to show that $f(x, y)$ has no min or max on the constraint curve.

The point $(x, y) = (x, \sqrt{x^2 - 1})$ lies on the constraint for all $x \ge 1$. Consider the following:

$$\lim_{x\to\infty} f(x, y) = \lim_{x\to\infty} f(x, \sqrt{x^2 - 1}) = \lim_{x\to\infty} 2x + \sqrt{x^2 + 1} \to \infty$$

However, the point $(-x, y) = (-x, -\sqrt{x^2 - 1})$ also lies on the constraint curve, and

$$\lim_{x\to\infty} f(x, y) = \lim_{x\to\infty} f(-x, -\sqrt{x^2 - 1}) = \lim_{x\to\infty} -2x - \sqrt{x^2 - 1} \to -\infty$$

Therefore, $f(x, y)$ has no min nor max on the constraint curve.

These calculations do not contradict the Lagrange theorem in the text because the theorem says only that the extrema (if they exist) must satisfy the Lagrange equations.

37. Let L be the minimum length of a ladder that can reach over a fence of height h to a wall located a distance b behind the wall.

(a) Use Lagrange multipliers to show that $L = (h^{2/3} + b^{2/3})^{3/2}$ (Figure 19). *Hint:* Show that the problem amounts to minimizing $f(x, y) = (x + b)^2 + (y + h)^2$ subject to $y/b = h/x$ or $xy = bh$.

(b) Show that the value of L is also equal to the radius of the circle with center $(-b, -h)$ that is tangent to the graph of $xy = bh$.

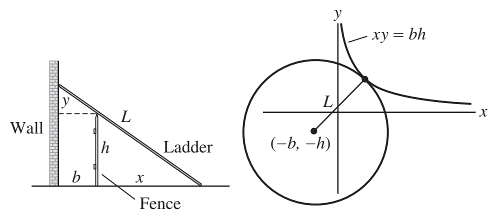

FIGURE 19

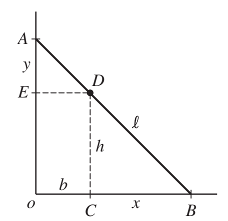
SOLUTION

(a) We denote by x and y the lengths shown in the figure, and express the length l of the ladder in terms of x and y.



Using the Pythagorean Theorem, we have

$$l = \sqrt{\overline{OA}^2 + \overline{OB}^2} = \sqrt{(y+h)^2 + (x+b)^2} \tag{1}$$

Since the function u^2 is increasing for $u \geq 0$, l and l^2 have their minimum values at the same point. Therefore, we may minimize the function $f(x, y) = l^2(x, y)$, which is

$$f(x, y) = (x+b)^2 + (y+h)^2$$

We now identify the constraint on the variables x and y. (Notice that h, b are constants while x and y are free to change). Using proportional lengths in the similar triangles ΔAED and ΔDCB, we have

$$\frac{\overline{AE}}{\overline{DC}} = \frac{\overline{ED}}{\overline{CB}}$$

That is,

$$\frac{y}{h} = \frac{b}{x} \quad \Rightarrow \quad xy = bh$$

We thus must minimize $f(x, y) = (x+b)^2 + (y+h)^2$ subject to the constraint $g(x, y) = xy = bh$, $x > 0$, $y > 0$.

Step 1. Write out the Lagrange Equations. We have $\nabla f = \langle 2(x+b), 2(y+h) \rangle$ and $\nabla g = \langle y, x \rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives the following equations:

$$2(x+b) = \lambda y$$
$$2(y+h) = \lambda x$$

Step 2. Solve for λ in terms of x and y. The equation of the constraint implies that $y \neq 0$ and $x \neq 0$. Therefore, the Lagrange equations yield

$$\lambda = \frac{2(x+b)}{y}, \quad \lambda = \frac{2(y+h)}{x}$$

Step 3. Solve for x and y using the constraint. Equating the two expressions for λ gives

$$\frac{2(x+b)}{y} = \frac{2(y+h)}{x}$$

We simplify:

$$x(x+b) = y(y+h)$$
$$x^2 + xb = y^2 + yh$$

The equation of the constraint implies that $y = \frac{bh}{x}$. We substitute and solve for $x > 0$. This gives

$$\begin{aligned} x^2 + xb &= \left(\frac{bh}{x}\right)^2 + \frac{bh}{x} \cdot h \\ x^2 + xb &= \frac{b^2h^2}{x^2} + \frac{bh^2}{x} \\ x^4 + x^3 b &= b^2h^2 + bh^2 x \\ x^4 + bx^3 - bh^2 x - b^2h^2 &= 0 \\ x^3(x+b) - bh^2(x+b) &= 0 \\ \left(x^3 - bh^2\right)(x+b) &= 0 \end{aligned}$$

Since $x > 0$ and $b > 0$, also $x + b > 0$ and the solution is

$$x^3 - bh^2 = 0 \quad \Rightarrow \quad x = (bh^2)^{1/3}$$

We compute y. Using the relation $y = \frac{bh}{x}$,

$$y = \frac{bh}{(bh^2)^{1/3}} = \frac{bh}{b^{1/3}h^{2/3}} = b^{2/3}h^{1/3} = (b^2h)^{1/3}$$

We obtain the solution

$$x = \left(bh^2\right)^{1/3}, \quad y = \left(b^2h\right)^{1/3} \tag{2}$$

Extreme values may also occur at the point on the constraint where $\nabla g = \mathbf{0}$. However, $\nabla g = \langle y, x\rangle = \langle 0, 0\rangle$ only at the point $(0, 0)$, which is not on the constraint.

Step 4. Conclusions. Notice that on the constraint $y = \frac{bh}{x}$ or $x = \frac{bh}{y}$, as $x \to 0+$ then $y \to \infty$, and as $x \to \infty$, then $y \to 0+$. Also, as $y \to 0+$, $x \to \infty$ and as $y \to \infty$, $x \to 0+$. In either case, $f(x, y)$ is increasing without bound. Using this property and the theorem on the existence of extreme values for a continuous function on a closed and bounded set (for a certain part of the constraint), one can show that f has a minimum value on the constraint. This minimum value occurs at the point (2). We substitute this point in (1) to obtain the following minimum length L:

$$\begin{aligned} L &= \sqrt{\left((b^2h)^{1/3} + h\right)^2 + \left((bh^2)^{1/3} + b\right)^2} \\ &= \sqrt{(b^2h)^{2/3} + 2h(b^2h)^{1/3} + h^2 + (bh^2)^{2/3} + 2b(bh^2)^{1/3} + b^2} \\ &= \sqrt{b^{\frac{4}{3}}h^{2/3} + 2h^{\frac{4}{3}}b^{2/3} + h^2 + b^{2/3}h^{\frac{4}{3}} + 2b^{\frac{4}{3}}h^{2/3} + b^2} \\ &= \sqrt{3b^{\frac{4}{3}}h^{2/3} + 3h^{\frac{4}{3}}b^{2/3} + h^2 + b^2} \\ &= \sqrt{\left(h^{2/3}\right)^3 + 3\left(h^{2/3}\right)^2 b^{2/3} + 3h^{2/3}\left(b^{2/3}\right)^2 + \left(b^{2/3}\right)^3} \end{aligned}$$

Using the identity $(\alpha + \beta)^3 = \alpha^3 + 3\alpha^2\beta + 3\alpha\beta^2 + \beta^3$, we conclude that

$$L = \sqrt{\left(h^{2/3} + b^{2/3}\right)^3} = \left(h^{2/3} + b^{2/3}\right)^{3/2}.$$

(b) The Lagrange Condition states that the gradient vectors ∇f_P and ∇g_P are parallel (where P is the minimizing point). The gradient ∇f_P is orthogonal to the level curve of f passing through P, which is a circle through P centered at $(-b, -h)$. ∇g_P is orthogonal to the level curve of g passing through P, which is the curve of the constraint $xy = bh$. We conclude that the circle and the curve $xy = bh$, both being perpendicular to parallel vectors, are tangent at P. The radius of the circle is the minimum value L, of $f(x, y)$.

38. Find the maximum value of $f(x, y, z) = xy + xz + yz - xyz$ subject to the constraint $x + y + z = 1$, for $x \geq 0$, $y \geq 0$, $z \geq 0$.

SOLUTION

Step 1. Write out the Lagrange Equations. We have $\nabla f = \langle y + z - 4yz, x + z - 4xz, x + y - 4xy\rangle$ and $\nabla g = \langle 1, 1, 1\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ yields the following equations:

$$\begin{aligned} y + z - 4yz &= \lambda \\ x + z - 4xz &= \lambda \\ x + y - 4xy &= \lambda \end{aligned}$$

Step 2. Solve for x, y, and z using the constraint. The Lagrange equations imply that

$$\begin{aligned} x+z-4xz &= y+z-4yz \\ x+y-4xy &= y+z-4yz \end{aligned} \quad \Rightarrow \quad \begin{aligned} x-4xz &= y-4yz \\ x-4xy &= z-4yz \end{aligned} \tag{1}$$

We solve for x and y in terms of z. The first equation gives

$$\begin{aligned} x-y+4yz-4xz &= 0 \\ x-y-4z(x-y) &= 0 \\ (x-y)(1-4z) &= 0 \quad \Rightarrow \quad x=y \quad \text{or} \quad z=\frac{1}{4} \end{aligned} \tag{2}$$

The second equation in (1) gives:

$$\begin{aligned} x-z+4yz-4xy &= 0 \\ x-z-4y(x-z) &= 0 \\ (x-z)(1-4y) &= 0 \quad \Rightarrow \quad x=z \quad \text{or} \quad y=\frac{1}{4} \end{aligned} \tag{3}$$

We examine the possible solutions.

(1) $x=y$, $x=z$. Substituting $x=y=z$ in the equation of the constraint $x+y+z=1$ gives $3z=1$ or $z=\frac{1}{3}$. We obtain the solution

$$\left(\frac{1}{3},\frac{1}{3},\frac{1}{3}\right)$$

(2) $x=y$, $y=\frac{1}{4}$. Substituting $x=y=\frac{1}{4}$ in the constraint $x+y+z=1$ gives

$$\frac{1}{4}+\frac{1}{4}+z=1 \quad \Rightarrow \quad z=\frac{1}{2}$$

We obtain the solution

$$\left(\frac{1}{4},\frac{1}{4},\frac{1}{2}\right)$$

(3) $z=\frac{1}{4}$, $x=z$. Substituting $z=\frac{1}{4}$, $x=\frac{1}{4}$ in the constraint gives

$$\frac{1}{4}+y+\frac{1}{4}=1 \quad \Rightarrow \quad y=\frac{1}{2}$$

We get the point

$$\left(\frac{1}{4},\frac{1}{2},\frac{1}{4}\right)$$

(4) $z=\frac{1}{4}$, $y=\frac{1}{4}$. Substituting in the constraint gives $x+\frac{1}{4}+\frac{1}{4}=1$ or $x=\frac{1}{2}$. We obtain the point

$$\left(\frac{1}{2},\frac{1}{4},\frac{1}{4}\right)$$

We conclude that the critical points are

$$\begin{aligned} P_1 &= \left(\frac{1}{3},\frac{1}{3},\frac{1}{3}\right), \quad P_2=\left(\frac{1}{4},\frac{1}{4},\frac{1}{2}\right) \\ P_3 &= \left(\frac{1}{4},\frac{1}{2},\frac{1}{4}\right), \quad P_4=\left(\frac{1}{2},\frac{1}{4},\frac{1}{4}\right) \end{aligned} \tag{4}$$

Step 3. Conclusions. The constraint $x+y+z=1$, $x\ge 0$, $y\ge 0$, $z\ge 0$ is the part of the plane $x+y+z=1$ in the first octant. This is a closed and bounded set in R^3, hence f (which is a continuous function) has minimum and maximum value subject to the constraint. The extreme values occur at points from (4). We evaluate $f(x,y,z)=xy+xz+yz-4xyz$ at these points:

$$\begin{aligned} f(P_1) &= \frac{1}{3}\cdot\frac{1}{3}+\frac{1}{3}\cdot\frac{1}{3}+\frac{1}{3}\cdot\frac{1}{3}-4\cdot\frac{1}{3}\cdot\frac{1}{3}\cdot\frac{1}{3}=\frac{3}{9}-\frac{4}{27}=\frac{5}{27} \\ f(P_2)=f(P_3)=f(P_4) &= \frac{1}{4}\cdot\frac{1}{4}+\frac{1}{4}\cdot\frac{1}{2}+\frac{1}{4}\cdot\frac{1}{2}-4\cdot\frac{1}{4}\cdot\frac{1}{4}\cdot\frac{1}{2}=\frac{3}{16} \end{aligned}$$

We conclude that the maximum value of f subject to the constraint is

$$f(P_2) = f(P_3) = f(P_4) = \frac{3}{16}.$$

39. Find the point lying on the intersection of the plane $x + \frac{1}{2}y + \frac{1}{4}z = 0$ and the sphere $x^2 + y^2 + z^2 = 9$ with the largest z-coordinate.

SOLUTION We will use the method of Lagrange Multipliers with two constraints here. We want to maximize $f(x, y, z) = z$ subject to the two surfaces. Set the first constraint as $g(x, y, z) = x + \frac{1}{2}y + \frac{1}{4}z = 0$ and the second as $h(x, y, z) = x^2 + y^2 + z^2 - 9 = 0$.

Write out the Lagrange equations. We have $\nabla f = \langle 0, 0, 1\rangle$, $\nabla g = \left\langle 1, \frac{1}{2}, \frac{1}{4}\right\rangle$ and $\nabla g = \langle 2x, 2y, 2z\rangle$, hence the Lagrange condition, $\nabla f = \lambda\nabla g + \mu\nabla h$ yields the following equations:

$$\langle 0, 0, 1\rangle = \lambda\left\langle 1, \frac{1}{2}, \frac{1}{4}\right\rangle + \mu\,\langle 2x, 2y, 2z\rangle$$

and

$$0 = \lambda + 2\mu x, \quad 0 = \frac{1}{2}\lambda + 2\mu y, \quad 1 = \frac{1}{4}\lambda + 2\mu z$$

Hence, from the first two equations we see

$$\lambda = -2\mu x, \quad \lambda = -4\mu y$$

Therefore

$$-2\mu x = -4\mu y \quad \Rightarrow \quad x = 2y$$

since $\mu \neq 0$. Using the first constraint equation $x + \frac{1}{2}y + \frac{1}{4}z = 0$ we have

$$2y + \frac{1}{2}y + \frac{1}{4}z = 0 \quad \Rightarrow \quad \frac{5}{2}y + \frac{1}{4}z = 0 \quad \Rightarrow \quad y = -\frac{1}{10}z$$

Finally, we can substitute $y = -1/10z$ and $x = 2y = -1/5z$ into the second constraint equation $x^2 + y^2 + z^2 = 9$ to see

$$\left(-\frac{1}{5}z\right)^2 + \left(-\frac{1}{10}z\right)^2 + z^2 = 9 \quad \Rightarrow \quad \frac{1}{25}z^2 + \frac{1}{100}z^2 + z^2 = 9 \quad \Rightarrow \quad 4z^2 + z^2 + 100z^2 = 900$$

Hence

$$105z^2 = 900 \quad \Rightarrow \quad z^2 = \frac{900}{105} = \frac{60}{7}$$

Therefore $z = \pm\sqrt{\frac{60}{7}} = \pm 2\sqrt{\frac{15}{7}}$. The two critical points are:

$$P\left(-\frac{2}{5}\sqrt{\frac{15}{7}}, -\frac{1}{5}\sqrt{\frac{15}{7}}, 2\sqrt{\frac{15}{7}}\right), \quad Q\left(\frac{2}{5}\sqrt{\frac{15}{7}}, \frac{1}{5}\sqrt{\frac{15}{7}}, -2\sqrt{\frac{15}{7}}\right)$$

The critical point with the largest z-coordinate (the maximum of $f(x, y, z)$) is P with z-coordinate $2\sqrt{\frac{15}{7}} \approx 2.928$.

40. Find the maximum of $f(x, y, z) = x + y + z$ subject to the two constraints $x^2 + y^2 + z^2 = 9$ and $\frac{1}{4}x^2 + \frac{1}{4}y^2 + 4z^2 = 9$.

SOLUTION We will use the method of Lagrange Multipliers with two constraints here. We want to maximize $f(x, y, z) = x + y + z$ subject to the two constraints. The first constraint is $g(x, y, z) = x^2 + y^2 + z^2 - 9$ and the second, $h(x, y, z) = \frac{1}{4}x^2 + \frac{1}{4}y^2 + 4z^2 - 9$.

Write out the Lagrange equations. We have $\nabla f = \langle 1, 1, 1\rangle$, $\nabla g = \langle 2x, 2y, 2z\rangle$, and $\nabla h = \left\langle \frac{1}{2}x, \frac{1}{2}y, 8z\right\rangle$. Therefore the Lagrange condition $\nabla f = \lambda\nabla g + \mu\nabla h$ yields the following equation:

$$\langle 1, 1, 1\rangle = \lambda\,\langle 2x, 2y, 2z\rangle + \mu\left\langle \frac{1}{2}x, \frac{1}{2}y, 8z\right\rangle$$

and

$$1 = 2\lambda x + \frac{1}{2}\mu x, \quad 1 = 2\lambda y + \frac{1}{2}\mu y, \quad 1 = 2\lambda z + 8\mu z$$

Using the first two equations and solving for λ we see:

$$\lambda = \frac{1 - \frac{1}{2}\mu x}{2x}, \quad \lambda = \frac{1 - \frac{1}{2}\mu y}{2y}$$

Setting these equal and solving for x and y we see

$$x = y$$

Now using the first constraint equation we have

$$x^2 + y^2 + z^2 = 9 \quad \Rightarrow \quad 2y^2 + z^2 = 9 \quad \Rightarrow \quad z^2 = 9 - 2y^2$$

Next, using the second constraint equation we have

$$\frac{1}{4}x^2 + \frac{1}{4}y^2 + 4z^2 = 9 \quad \Rightarrow \quad \frac{1}{4}y^2 + \frac{1}{4}y^2 + 4(9 - 2y^2) = 9 \quad \Rightarrow \quad \frac{15}{2}y^2 = 27 \quad \Rightarrow \quad y^2 = \frac{18}{5}$$

Therefore we can conclude $y = \pm 3\sqrt{\frac{2}{5}}$ and, since $x = y$, then $x = \pm 3\sqrt{\frac{2}{5}}$. Then also,

$$x^2 + y^2 + z^2 = 9 \quad \Rightarrow \quad \frac{18}{5} + \frac{18}{5} + z^2 = 9 \quad \Rightarrow \quad z^2 = \frac{11}{5}$$

Hence $z = \pm\frac{3}{\sqrt{5}}$. Our critical points are

$$\left(3\sqrt{\frac{2}{5}}, 3\sqrt{\frac{2}{5}}, \frac{3}{\sqrt{5}}\right), \quad \left(3\sqrt{\frac{2}{5}}, 3\sqrt{\frac{2}{5}}, -\frac{3}{\sqrt{5}}\right)$$

$$\left(-3\sqrt{\frac{2}{5}}, -3\sqrt{\frac{2}{5}}, \frac{3}{\sqrt{5}}\right), \quad \left(-3\sqrt{\frac{2}{5}}, -3\sqrt{\frac{2}{5}}, -\frac{3}{\sqrt{5}}\right)$$

We must evaluate $f(x, y, z) = x + y + z$ at the four critical points to determine the maximum value. But note since we are interested in the sum of the coordinates, the maximum value is obtained when they are all positive:

$$f\left(3\sqrt{\frac{2}{5}}, 3\sqrt{\frac{2}{5}}, \frac{3}{\sqrt{5}}\right) \approx 5.136$$

41. The cylinder $x^2 + y^2 = 1$ intersects the plane $x + z = 1$ in an ellipse. Find the point on that ellipse that is farthest from the origin.

SOLUTION We need to use Lagrange Multipliers with two constraints here. We want to maximize the square of the distance from the origin $f(x, y, z) = x^2 + y^2 + z^2$ subject to $g(x, y, z) = x^2 + y^2 - 1$ and $h(x, y, z) = x + z - 1$. Taking the gradients we have $\nabla f = \langle 2x, 2y, 2z\rangle$, $\nabla g = \langle 2x, 2y, 0\rangle$, and $\nabla h = \langle 1, 0, 1\rangle$. Writing the Lagrange condition $\nabla f = \lambda \nabla g + \mu \nabla h$ we have

$$\langle 2x, 2y, 2z\rangle = \lambda \langle 2x, 2y, 0\rangle + \mu \langle 1, 0, 1\rangle$$

and

$$2x = 2\lambda x + \mu, \quad 2y = 2\lambda y, \quad 2z = \mu$$

Using the second equation we see:

$$2y - 2\lambda y = 0 \quad \Rightarrow \quad 2y(\lambda - 1) = 0$$

Therefore, either $\lambda = 1$ or $y = 0$.

If $\lambda = 1$ then this implies $\mu = 0$ and $z = 0$. Using the constraint $x + z = 1$ then $x = 1$, and using the constraint $x^2 + y^2 = 1$, then $y = 0$. This gives the critical point

$$(1, 0, 0)$$

If $y = 0$, using the constraint $x^2 + y^2 = 1$, then $x = \pm 1$. If $x = 1$, then $z = 0$, if $x = -1$ then $z = 2$. This gives the critical points

$$(1, 0, 0), \quad (-1, 0, 2)$$

Now we examine $f(x, y, z) = x^2 + y^2 + z^2$ at the two critical points for the maximum value:

$$f(1, 0, 0) = 1, \quad f(-1, 0, 2) = 5$$

Thus, the point farthest from the origin on this ellipse is the point $(-1, 0, 2)$ (at $\sqrt{5}$ units away).

42. Find the minimum and maximum of $f(x, y, z) = y + 2z$ subject to two constraints, $2x + z = 4$ and $x^2 + y^2 = 1$.

SOLUTION The constraint equations are:

$$g(x, y) = 2x + z - 4 = 0, \quad h(x, y) = x^2 + y^2 - 1 = 0$$

We now write out the Lagrange Equations. We have, $\nabla f = \langle 0, 1, 2\rangle$, $\nabla g = \langle 2, 0, 1\rangle$, and $\nabla h = \langle 2x, 2y, 0\rangle$, so the Lagrange Condition is

$$\nabla f = \lambda \nabla g + \mu \nabla h$$
$$\langle 0, 1, 2\rangle = \lambda \langle 2, 0, 1\rangle + \mu \langle 2x, 2y, 0\rangle = \langle 2\lambda + 2\mu x, 2\mu y, \lambda\rangle$$

From the third coordinate we get that $\lambda = 2$, which then gives us the following from the first two coordinates:

$$0 = 4 + 2\mu x$$
$$1 = 2\mu y$$

From the second equation, we see that neither μ nor y can be zero, so we can write $\mu = 1/2y$ and substitute it into the first equation, resulting in $0 = 4 + 2(1/2y)x = 4 + x/y$, or in other words, $x = -4y$. Plugging this into the second constraint, we find that $16y^2 + y^2 = 1$, so $y = \pm 1/\sqrt{17}$. Thus, our two points of interest are

$$\left(\frac{-4}{\sqrt{17}}, \frac{1}{\sqrt{17}}, 4 + \frac{8}{\sqrt{17}}\right) \quad \text{and} \quad \left(\frac{4}{\sqrt{17}}, \frac{-1}{\sqrt{17}}, 4 - \frac{8}{\sqrt{17}}\right)$$

The function f at the first point is $17/\sqrt{17}$, and at the second point is $-17/\sqrt{17}$, so these must be our maximum and minimum values, respectively.

43. Find the minimum value of $f(x, y, z) = x^2 + y^2 + z^2$ subject to two constraints, $x + 2y + z = 3$ and $x - y = 4$.

SOLUTION The constraint equations are

$$g(x, y, z) = x + 2y + z - 3 = 0, \quad h(x, y) = x - y - 4 = 0$$

Step 1. Write out the Lagrange Equations. We have $\nabla f = \langle 2x, 2y, 2z\rangle$, $\nabla g = \langle 1, 2, 1\rangle$, and $\nabla h = \langle 1, -1, 0\rangle$, hence the Lagrange Condition is

$$\nabla f = \lambda \nabla g + \mu \nabla h$$
$$\langle 2x, 2y, 2z\rangle = \lambda \langle 1, 2, 1\rangle + \mu \langle 1, -1, 0\rangle$$
$$= \langle \lambda + \mu, 2\lambda - \mu, \lambda\rangle$$

We obtain the following equations:

$$2x = \lambda + \mu$$
$$2y = 2\lambda - \mu$$
$$2z = \lambda$$

Step 2. Solve for λ and μ. The first equation gives $\lambda = 2x - \mu$. Combining with the third equation we get

$$2z = 2x - \mu \tag{1}$$

The second equation gives $\mu = 2\lambda - 2y$, combining with the third equation we get $\mu = 4z - 2y$. Substituting in (1) we obtain

$$2z = 2x - (4z - 2y) = 2x - 4z + 2y$$
$$6z = 2x + 2y \quad \Rightarrow \quad z = \frac{x + y}{3} \tag{2}$$

Step 3. Solve for x, y, and z using the constraints. The constraints give x and y as functions of z:

$$x - y = 4 \quad \Rightarrow \quad y = x - 4$$
$$x + 2y + z = 3 \quad \Rightarrow \quad y = \frac{3 - x - z}{2}$$

Combining the two equations we get

$$x - 4 = \frac{3 - x - z}{2}$$

$$2x - 8 = 3 - x - z$$
$$3x = 11 - z \quad \Rightarrow \quad x = \frac{11 - z}{3}$$

We find y using $y = x - 4$:

$$y = \frac{11 - z}{3} - 4 = \frac{-1 - z}{3}$$

We substitute x and y in (2) and solve for z:

$$z = \frac{\frac{11-z}{3} + \frac{-1-z}{3}}{3} = \frac{11 - z - 1 - z}{9} = \frac{10 - 2z}{9}$$
$$9z = 10 - 2z$$
$$11z = 10 \quad \Rightarrow \quad z = \frac{10}{11}$$

We find x and y:

$$y = \frac{-1 - z}{3} = \frac{-1 - \frac{10}{11}}{3} = -\frac{21}{33} = -\frac{7}{11}$$
$$x = \frac{11 - z}{3} = \frac{11 - \frac{10}{11}}{3} = \frac{111}{33} = \frac{37}{11}$$

We obtain the solution

$$P = \left(\frac{37}{11}, -\frac{7}{11}, \frac{10}{11}\right)$$

Step 4. Calculate the critical values. We compute $f(x, y, z) = z^2 + y^2 + z^2$ at the critical point:

$$f(P) = \left(\frac{37}{11}\right)^2 + \left(-\frac{7}{11}\right)^2 + \left(\frac{10}{11}\right)^2 = \frac{1518}{121} = \frac{138}{11} \approx 12.545$$

As x tends to infinity, so also does $f(x, y, z)$ tend to ∞. Therefore f has no maximum value and the given critical point P must produce a minimum. We conclude that the minimum value of f subject to the two constraints is $f(P) = \frac{138}{11} \approx 12.545$.

Further Insights and Challenges

44. Suppose that both $f(x, y)$ and the constraint function $g(x, y)$ are linear. Use contour maps to explain why $f(x, y)$ does not have a maximum subject to $g(x, y) = 0$ unless $g = af + b$ for some constants a, b.

SOLUTION We denote the linear functions by

$$f(x, y) = Ax + By + C, \quad g(x, y) = Dx + Ey + F$$

If f has a maximum value at a point P subject to g, then at this point $\nabla f_P \parallel \nabla g_P$. Since the gradient is normal to the level curve of the function passing through P, the tangents to the level curves of f and g at P coincide. In our case, the level curves of f (and of g) consist of parallel lines, hence since their tangents coincide, then these parallel contour lines coincide. That is, the contour line $f(x, y) = K$ is also the contour line $g(x, y) = L$ for some K, L, or in other words,

$$Ax + By + C = K, \quad Dx + Ey + F = L$$

Therefore,

$$D = aA, \quad E = aB, \quad F - L = a(C - K)$$

The function g is thus

$$g(x, y) = Dx + Ey + F = aAx + aBy + aC - aK + L$$
$$= a(Ax + By + C) + L - aK = af(x, y) + L - aK$$

Therefore, for $b = L - aK$ we have

$$g(x, y) = af(x, y) + b \tag{1}$$

By Theorem 1 we conclude that if g is not in the form (1), f does not have a maximum subject to $g(x, y) = 0$.

45. Assumptions Matter Consider the problem of minimizing $f(x, y) = x$ subject to $g(x, y) = (x-1)^3 - y^2 = 0$.
(a) Show, without using calculus, that the minimum occurs at $P = (1, 0)$.
(b) Show that the Lagrange condition $\nabla f_P = \lambda \nabla g_P$ is not satisfied for any value of λ.
(c) Does this contradict Theorem 1?

SOLUTION
(a) The equation of the constraint can be rewritten as

$$(x-1)^3 = y^2 \quad \text{or} \quad x = y^{2/3} + 1$$

Therefore, at the points under the constraint, $x \geq 1$, hence $f(x, y) \geq 1$. Also at the point $P = (1, 0)$ we have $f(1, 0) = 1$, hence $f(1, 0) = 1$ is the minimum value of f under the constraint.
(b) We have $\nabla f = \langle 1, 0 \rangle$ and $\nabla g = \left\langle 3(x-1)^2, -2y \right\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ yields the following equations:

$$1 = \lambda \cdot 3(x-1)^2$$
$$0 = -2\lambda y$$

The first equation implies that $\lambda \neq 0$ and $x - 1 = \pm \frac{1}{\sqrt{3\lambda}}$. The second equation gives $y = 0$. Substituting in the equation of the constraint gives

$$(x-1)^3 - y^2 = \left(\frac{\pm 1}{\sqrt{3\lambda}} \right)^3 - 0^2 = \frac{\pm 1}{(3\lambda)^{3/2}} \neq 0$$

We conclude that the Lagrange Condition is not satisfied by any point under the constraint.
(c) Theorem 1 is not violated since at the point $P = (1, 0)$, $\nabla g = \mathbf{0}$, whereas the Theorem is valid for points where $\nabla g_P \neq \mathbf{0}$.

46. Marginal Utility Goods 1 and 2 are available at dollar prices of p_1 per unit of good 1 and p_2 per unit of good 2. A utility function $U(x_1, x_2)$ is a function representing the **utility** or benefit of consuming x_j units of good j. The **marginal utility** of the jth good is $\partial U / \partial x_j$, the rate of increase in utility per unit increase in the jth good. Prove the following law of economics: Given a budget of L dollars, utility is maximized at the consumption level (a, b) where the ratio of marginal utility is equal to the ratio of prices:

$$\frac{\text{Marginal utility of good 1}}{\text{Marginal utility of good 2}} = \frac{U_{x_1}(a, b)}{U_{x_2}(a, b)} = \frac{p_1}{p_2}$$

SOLUTION We must maximize the utility $U(x_1, x_2)$ subject to the constraint $p_1 x_1 + p_2 x_2 = L$ or $g(x_1, x_2) = p_1 x_1 + p_2 x_2 - L = 0$, $x_1 \geq 0$, $x_2 \geq 0$. We have $\nabla U = \left\langle U_{x_1}, U_{x_2} \right\rangle$ and $\nabla g = \langle p_1, p_2 \rangle$, hence the Lagrange Condition $\nabla U = \lambda \nabla g$ gives the following equations:

$$\begin{aligned} U_{x_1} &= \lambda p_1 \\ U_{x_2} &= \lambda p_2 \end{aligned} \quad \Rightarrow \quad \begin{aligned} \frac{U_{x_1}}{p_1} &= \lambda \\ \frac{U_{x_2}}{p_2} &= \lambda \end{aligned}$$

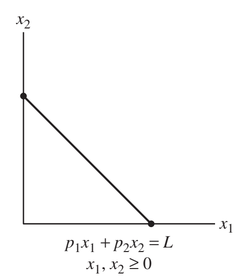
(we assume $p_1, p_2 > 0$). Equating the two expressions for λ we get

$$\frac{U_{x_1}}{p_1} = \frac{U_{x_2}}{p_2} \quad \Rightarrow \quad \frac{U_{x_1}}{U_{x_2}} = \frac{p_1}{p_2}$$

That is, $U(x_1, x_2)$ is maximized at the consumption level (a, b), where the following holds:

$$\frac{\text{marginal utility of good 1}}{\text{marginal utility of good 2}} = \frac{U_{x_1}(a, b)}{U_{x_2}(a, b)} = \frac{p_1}{p_2}$$

Notice that the constraint is a segment in the x_1x_2-plane (if $p_1 > 0$ and $p_2 > 0$), which is a closed and bounded set in this plane. Hence, if U is continuous, it assumes extreme values on this segment.



47. Consider the utility function $U(x_1, x_2) = x_1 x_2$ with budget constraint $p_1 x_1 + p_2 x_2 = c$.

(a) Show that the maximum of $U(x_1, x_2)$ subject to the budget constraint is equal to $c^2/(4p_1 p_2)$.

(b) Calculate the value of the Lagrange multiplier λ occurring in (a).

(c) Prove the following interpretation: λ is the rate of increase in utility per unit increase in total budget c.

SOLUTION

(a) By the earlier exercise, the utility is maximized at a point where the following equality holds:

$$\frac{U_{x_1}}{U_{x_2}} = \frac{p_1}{p_2}$$

Since $U_{x_1} = x_2$ and $U_{x_2} = x_1$, we get

$$\frac{x_2}{x_1} = \frac{p_1}{p_2} \quad \Rightarrow \quad x_2 = \frac{p_1}{p_2} x_1$$

We now substitute x_2 in terms of x_1 in the constraint $p_1 x_1 + p_2 x_2 = c$ and solve for x_1. This gives

$$p_1 x_1 + p_2 \cdot \frac{p_1}{p_2} x_1 = c$$

$$2p_1 x_1 = c \quad \Rightarrow \quad x_1 = \frac{c}{2p_1}$$

The corresponding value of x_2 is computed by $x_2 = \frac{p_1}{p_2} x_1$:

$$x_2 = \frac{p_1}{p_2} \cdot \frac{c}{2p_1} = \frac{c}{2p_2}$$

That is, $U(x_1, x_2)$ is maximized at the consumption level $x_1 = \frac{c}{2p_1}$, $x_2 = \frac{c}{2p_2}$. The maximum value is

$$U\left(\frac{c}{2p_1}, \frac{c}{2p_2}\right) = \frac{c}{2p_1} \cdot \frac{c}{2p_2} = \frac{c^2}{4p_1 p_2}$$

(b) The Lagrange condition $\nabla U = \lambda \nabla g$ for $U(x_1, x_2) = x_1 x_2$ and $g(x_1, x_2) = p_1 x_1 + p_2 x_2 - c = 0$ is

$$\langle x_2, x_1 \rangle = \lambda \langle p_1, p_2 \rangle \tag{1}$$

or

$$\begin{aligned} x_2 &= \lambda p_1 \\ x_1 &= \lambda p_2 \end{aligned} \quad \Rightarrow \quad \lambda = \frac{x_2}{p_1} = \frac{x_1}{p_2}$$

In part (a) we showed that at the maximizing point $x_1 = \frac{c}{2p_1}$, therefore the value of λ is

$$\lambda = \frac{x_1}{p_2} = \frac{c}{2p_1 p_2}$$

(c) We compute $\frac{dU}{dc}$ using the Chain Rule:

$$\frac{dU}{dc} = \frac{\partial U}{\partial x_1} x_1'(c) + \frac{\partial U}{\partial x_2} x_2'(c) = x_2 x_1'(c) + x_1 x_2'(c) = \langle x_2, x_1 \rangle \cdot \langle x_1'(c), x_2'(c) \rangle$$

Substituting in (1) we get

$$\frac{dU}{dc} = \lambda \langle p_1, p_2 \rangle \cdot \langle x_1'(c), x_2'(c) \rangle = \lambda \left(p_1 x_1'(c) + p_2 x_2'(c) \right) \tag{2}$$

We now use the Chain Rule to differentiate the equation of the constraint $p_1 x_1 + p_2 x_2 = c$ with respect to c:

$$p_1 x_1'(c) + p_2 x_2'(c) = 1$$

Substituting in (2), we get

$$\frac{dU}{dc} = \lambda \cdot 1 = \lambda$$

Using the approximation $\Delta U \approx \frac{dU}{dc} \Delta c$, we conclude that λ is the rate of increase in utility per unit increase of total budget L.

48. This exercise shows that the multiplier λ may be interpreted as a rate of change in general. Assume that the maximum of $f(x, y)$ subject to $g(x, y) = c$ occurs at a point P. Then P depends on the value of c, so we may write $P = (x(c), y(c))$ and we have $g(x(c), y(c)) = c$.

(a) Show that

$$\nabla g(x(c), y(c)) \cdot \langle x'(c), y'(c) \rangle = 1$$

Hint: Differentiate the equation $g(x(c), y(c)) = c$ with respect to c using the Chain Rule.

(b) Use the Chain Rule and the Lagrange condition $\nabla f_P = \lambda \nabla g_P$ to show that

$$\frac{d}{dc} f(x(c), y(c)) = \lambda$$

(c) Conclude that λ is the rate of increase in f per unit increase in the "budget level" c.

SOLUTION

(a) We differentiate the equation $g(x(c), y(c)) = c$ with respect to c, using the Chain Rule. This gives

$$\frac{\partial g}{\partial x} x'(c) + \frac{\partial g}{\partial y} y'(c) = 1$$

We rewrite this equality using the dot product and the definition of the gradient:

$$\left\langle \frac{\partial g}{\partial x}, \frac{\partial g}{\partial y} \right\rangle \cdot \langle x'(c), y'(c) \rangle = 1$$
$$\nabla g(x(c), y(c)) \cdot \langle x'(c), y'(c) \rangle = 1$$

(b) We now differentiate $f(x(c), y(c))$ with respect to c, using the Chain Rule. We obtain

$$\frac{d}{dc} f(x(c), y(c)) = \frac{\partial f}{\partial x} x'(c) + \frac{\partial f}{\partial y} y'(c) = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle \cdot \langle x'(c), y'(c) \rangle = \nabla f \cdot \langle x'(c), y'(c) \rangle$$

We use the Lagrange Condition $\nabla f = \lambda \nabla g$ and the result in part (a) to write

$$\frac{d}{dc} f(x(c), y(c)) = \lambda \cdot \nabla g \cdot \langle x'(c), y'(c) \rangle = \lambda \cdot 1 = \lambda$$

(c) The equality obtained in part (b) implies that λ is the rate of change in the maximum value of $f(x, y)$, subject to the constraint $g(x, y) = c$, with respect to c.

49. Let $B > 0$. Show that the maximum of

$$f(x_1, \dots, x_n) = x_1 x_2 \cdots x_n$$

subject to the constraints $x_1 + \cdots + x_n = B$ and $x_j \geq 0$ for $j = 1, \dots, n$ occurs for $x_1 = \cdots = x_n = B/n$. Use this to conclude that

$$(a_1 a_2 \cdots a_n)^{1/n} \leq \frac{a_1 + \cdots + a_n}{n}$$

for all positive numbers $a_1, \dots, a_n$.

SOLUTION We first notice that the constraints $x_1 + \cdots + x_n = B$ and $x_j \geq 0$ for $j = 1, \dots, n$ define a closed and bounded set in the nth dimensional space, hence f (continuous, as a polynomial) has extreme values on this set. The minimum value zero occurs where one of the coordinates is zero (for example, for $n = 2$ the constraint $x_1 + x_2 = B$, $x_1 \geq 0, x_2 \geq 0$ is a triangle in the first quadrant). We need to maximize the function $f(x_1, \dots, x_n) = x_1 x_2 \cdots x_n$ subject to the constraints $g(x_1, \dots, x_n) = x_1 + \cdots + x_n - B = 0$, $x_j \geq 0$, $j = 1, \dots, n$.

Step 1. Write out the Lagrange Equations. The gradient vectors are

$$\nabla f = \langle x_2 x_3 \cdots x_n, x_1 x_3 \cdots x_n, \dots, x_1 x_2 \cdots x_{n-1} \rangle$$
$$\nabla g = \langle 1, 1, \dots, 1 \rangle$$

The Lagrange Condition $\nabla f = \lambda \nabla g$ yields the following equations:

$$x_2 x_3 \cdots x_n = \lambda$$
$$x_1 x_3 \cdots x_n = \lambda$$
$$x_1 x_2 \cdots x_{n-1} = \lambda$$

Step 2. Solving for $x_1, x_2, \ldots, x_n$ using the constraint. The Lagrange equations imply the following equations:

$$\begin{aligned} x_2x_3\cdots x_n &= x_1x_2\cdots x_{n-1} \\ x_1x_3\cdots x_n &= x_1x_2\cdots x_{n-1} \\ x_1x_2x_4\cdots x_n &= x_1x_2\cdots x_{n-1} \\ &\vdots \\ x_1x_2\cdots x_{n-2}x_n &= x_1x_2\cdots x_{n-1} \end{aligned}$$

We may assume that $x_j \neq 0$ for $j = 1, \ldots, n$, since if one of the coordinates is zero, f has the minimum value zero. We divide each equation by its right-hand side to obtain

$$\begin{aligned} \frac{x_n}{x_1} &= 1 \\ \frac{x_n}{x_2} &= 1 \\ \frac{x_n}{x_3} &= 1 \\ &\vdots \\ \frac{x_n}{x_{n-1}} &= 1 \end{aligned} \quad \Rightarrow \quad \begin{aligned} x_1 &= x_n \\ x_2 &= x_n \\ x_3 &= x_n \\ &\vdots \\ x_{n-1} &= x_n \end{aligned}$$

Substituting in the constraint $x_1 + \cdots + x_n = B$ and solving for x_n gives

$$\underbrace{x_n + x_n + \cdots + x_n}_{n} = B$$

$$nx_n = B \quad \Rightarrow \quad x_n = \frac{B}{n}$$

Hence $x_1 = \cdots = x_n = \frac{B}{n}$.

Step 3. Conclusions. The maximum value of $f(x_1, \ldots, x_n) = x_1x_2\cdots x_n$ on the constraint $x_1 + \cdots + x_n = B$, $x_j \geq 0$, $j = 1, \ldots, n$ occurs at the point at which all coordinates are equal to $\frac{B}{n}$. The value of f at this point is

$$f\left(\frac{B}{n}, \frac{B}{n}, \ldots, \frac{B}{n}\right) = \left(\frac{B}{n}\right)^n$$

It follows that for any point $(x_1, \ldots, x_n)$ on the constraint, that is, for any point satisfying $x_1 + \cdots + x_n = B$ with x_j positive, the following holds:

$$f(x_1, \ldots, x_n) \leq \left(\frac{B}{n}\right)^n$$

That is,

$$x_1\cdots x_n \leq \left(\frac{x_1 + \cdots + x_n}{n}\right)^n$$

or

$$(x_1\cdots x_n)^{1/n} \leq \frac{x_1 + \cdots + x_n}{n}.$$

50. Let $B > 0$. Show that the maximum of $f(x_1, \ldots, x_n) = x_1 + \cdots + x_n$ subject to $x_1^2 + \cdots + x_n^2 = B^2$ is $\sqrt{n}B$. Conclude that

$$|a_1| + \cdots + |a_n| \leq \sqrt{n}(a_1^2 + \cdots + a_n^2)^{1/2}$$

for all numbers $a_1, \ldots, a_n$.

SOLUTION First notice that the function is continuous and the constraint is a sphere centered at the origin in the nth-dimensional space, hence f has extreme values on this set. (For $n = 2$, the constraint defines the circle $x^2 + y^2 = B^2$). We must maximize $f(x_1, \ldots, x_n) = x_1 + \cdots + x_n$ subject to the constraint $g(x_1, \ldots, x_n) = x_1^2 + \cdots + x_n^2 - B^2 = 0$.

Step 1. Write out the Lagrange Equations. The gradient vectors are

$$\nabla f = \langle 1, 1, \ldots, 1\rangle \quad \text{and} \quad \nabla g = \langle 2x_1, 2x_2, \ldots, 2x_n\rangle$$

Hence, the Lagrange Condition $\nabla f = \lambda \nabla g$ gives the following equations:

$$\begin{aligned} 1 &= \lambda(2x_1) \\ 1 &= \lambda(2x_2) \\ &\vdots \\ 1 &= \lambda(2x_n) \end{aligned}$$

Step 2. Solve for λ in terms of $x_1, \ldots, x_n$. The Lagrange equations imply that $x_j \neq 0$ for $j = 1, \ldots, n$. Therefore we may divide by x_j to obtain

$$\begin{aligned} \lambda &= \frac{1}{2x_1} \\ \lambda &= \frac{1}{2x_2} \\ &\vdots \\ \lambda &= \frac{1}{2x_n} \end{aligned}$$

Step 3. Solving for $x_1, \ldots, x_n$ using the constraint. Equating the expressions for λ gives the following equations:

$$\begin{aligned} \frac{1}{2x_1} &= \frac{1}{2x_n} \\ \frac{1}{2x_2} &= \frac{1}{2x_n} \\ &\vdots \\ \frac{1}{2x_{n-1}} &= \frac{1}{2x_n} \end{aligned} \quad \Rightarrow \quad \begin{aligned} x_1 &= x_n \\ x_2 &= x_n \\ &\vdots \\ x_{n-1} &= x_n \end{aligned}$$

Substituting $x_1, \ldots, x_{n-1}$ in terms of x_n in the equation of the constraint $x_1^2 + \cdots + x_n^2 = B^2$ and solving for x_n, gives

$$\begin{aligned} \underbrace{x_n^2 + x_n^2 + \cdots + x_n^2}_{n} &= B^2 \\ nx_n^2 &= B^2 \\ x_n^2 &= \frac{B^2}{n} \quad \Rightarrow \quad |x_n| = \frac{B}{\sqrt{n}} \end{aligned}$$

We conclude that $|x_1| = |x_2| = \cdots = |x_n| = \frac{B}{\sqrt{n}}$. Since $x_j = x_n$ for all j, the maximum value occurs when x_n is positive, and the minimum value corresponds to the negative value of x_n. We conclude that the maximizing point is

$$x_1 = x_2 = \cdots = x_n = \frac{B}{\sqrt{n}}$$

Notice that the point where $\nabla g = \langle 2x_1, 2x_2, \ldots, 2x_n \rangle = \mathbf{0}$ is the point at the origin, and this point does not lie on the constraint.

Step 4. Conclusions. The maximum value of $f(x_1, \ldots, x_n) = x_1 + \cdots + x_n$ under the constraint is

$$f\left(\frac{B}{\sqrt{n}}, \ldots, \frac{B}{\sqrt{n}}\right) = n\frac{B}{\sqrt{n}} = \sqrt{n}B$$

This means that for any point under the constraint, that is, for any $(x_1, \ldots, x_n)$ such that $x_1^2 + \cdots + x_n^2 = B^2$, we have

$$f(x_1, \ldots, x_n) \leq \sqrt{n}B$$

That is,

$$x_1 + \cdots + x_n \leq \sqrt{n}\sqrt{x_1^2 + \cdots + x_n^2} \tag{1}$$

Notice that if $(x_1, \ldots, x_n)$ is under the constraint, then $(|x|_1, \ldots, |x|_n)$ is also under the constraint, and the right-hand side in (1) has the same value at these two points. Therefore, we also have

$$|x_1| + \cdots + |x_n| \leq \sqrt{n}\left(x_1^2 + \cdots + x_n^2\right)^{1/2}.$$

51. Given constants E, E_1, E_2, E_3, consider the maximum of

$$S(x_1, x_2, x_3) = x_1 \ln x_1 + x_2 \ln x_2 + x_3 \ln x_3$$

subject to two constraints:

$$x_1 + x_2 + x_3 = N, \qquad E_1 x_1 + E_2 x_2 + E_3 x_3 = E$$

Show that there is a constant μ such that $x_i = A^{-1} e^{\mu E_i}$ for $i = 1, 2, 3$, where $A = N^{-1}(e^{\mu E_1} + e^{\mu E_2} + e^{\mu E_3})$.

SOLUTION The constraints equations are

$$g(x_1, x_2, x_3) = x_1 + x_2 + x_3 - N = 0$$
$$h(x_1, x_2, x_3) = E_1 x_1 + E_2 x_2 + E_3 x_3 - E = 0$$

We first find the Lagrange equations. The gradient vectors are

$$\nabla S = \left\langle \ln x_1 + x_1 \cdot \frac{1}{x_1}, \ln x_2 + x_2 \cdot \frac{1}{x_2}, \ln x_3 + x_3 \cdot \frac{1}{x_3} \right\rangle = \langle 1 + \ln x_1, 1 + \ln x_2, 1 + \ln x_3 \rangle$$
$$\nabla g = \langle 1, 1, 1 \rangle, \quad \nabla h = \langle E_1, E_2, E_3 \rangle$$

The Lagrange Condition $\nabla f = \lambda \nabla g + \mu \nabla h$ gives the following equation:

$$\langle 1 + \ln x_1, 1 + \ln x_2, 1 + \ln x_3 \rangle = \lambda \langle 1, 1, 1 \rangle + \mu \langle E_1, E_2, E_3 \rangle = \langle \lambda + \mu E_1, \lambda + \mu E_2, \lambda + \mu E_3 \rangle$$

We obtain the Lagrange equations:

$$1 + \ln x_1 = \lambda + \mu E_1$$
$$1 + \ln x_2 = \lambda + \mu E_2$$
$$1 + \ln x_3 = \lambda + \mu E_3$$

We subtract the third equation from the other equations to obtain

$$\ln x_1 - \ln x_3 = \mu (E_1 - E_3)$$
$$\ln x_2 - \ln x_3 = \mu (E_2 - E_3)$$

or

$$\begin{aligned} \ln \frac{x_1}{x_3} &= \mu (E_1 - E_3) \\ \ln \frac{x_2}{x_3} &= \mu (E_2 - E_3) \end{aligned} \quad \Rightarrow \quad \begin{aligned} x_1 &= x_3 e^{\mu(E_1 - E_3)} \\ x_2 &= x_3 e^{\mu(E_2 - E_3)} \end{aligned} \tag{1}$$

Substituting x_1 and x_2 in the equation of the constraint $g(x_1, x_2, x_3) = 0$ and solving for x_3 gives

$$x_3 e^{\mu(E_1 - E_3)} + x_3 e^{\mu(E_2 - E_3)} + x_3 = N$$

We multiply by $e^{\mu E_3}$:

$$x_3 \left(e^{\mu E_1} + e^{\mu E_2} + e^{\mu E_3}\right) = N e^{\mu E_3}$$
$$x_3 = \frac{N e^{\mu E_3}}{e^{\mu E_1} + e^{\mu E_2} + e^{\mu E_3}}$$

Substituting in (1) we get

$$x_1 = \frac{N e^{\mu E_3}}{e^{\mu E_1} + e^{\mu E_2} + e^{\mu E_3}} \cdot e^{\mu(E_1 - E_3)} = \frac{N e^{\mu E_1}}{e^{\mu E_1} + e^{\mu E_2} + e^{\mu E_3}}$$
$$x_2 = \frac{N e^{\mu E_3}}{e^{\mu E_1} + e^{\mu E_2} + e^{\mu E_3}} \cdot e^{\mu(E_2 - E_3)} = \frac{N e^{\mu E_2}}{e^{\mu E_1} + e^{\mu E_2} + e^{\mu E_3}}$$

Letting $A = \frac{e^{\mu E_1} + e^{\mu E_2} + e^{\mu E_3}}{N}$, we obtain

$$x_1 = A^{-1} e^{\mu E_1}, \quad x_2 = A^{-1} e^{\mu E_2}, \quad x_3 = A^{-1} e^{\mu E_3}$$

The value of μ is determined by the second constraint $h(x_1, x_2, x_3) = 0$.

52. Boltzmann Distribution Generalize Exercise 51 to n variables: Show that there is a constant μ such that the maximum of

$$S = x_1 \ln x_1 + \cdots + x_n \ln x_n$$

subject to the constraints

$$x_1 + \cdots + x_n = N, \qquad E_1 x_1 + \cdots + E_n x_n = E$$

occurs for $x_i = A^{-1} e^{\mu E_i}$, where

$$A = N^{-1}(e^{\mu E_1} + \cdots + e^{\mu E_n})$$

This result lies at the heart of statistical mechanics. It is used to determine the distribution of velocities of gas molecules at temperature T; x_i is the number of molecules with kinetic energy E_i; $\mu = -(kT)^{-1}$, where k is Boltzmann's constant. The quantity S is called the **entropy**.

SOLUTION The constraints equations are

$$g(x_1, \dots, x_n) = x_1 + \cdots + x_n - N$$
$$h(x_1, \dots, x_n) = E_1 x_1 + \cdots + E_n x_n - E$$

We find the Lagrange Equations. The gradient vectors are

$$\nabla S = \left\langle \ln x_1 + x_1 \cdot \frac{1}{x_1}, \dots, \ln x_n + x_n \cdot \frac{1}{x_n} \right\rangle = \langle 1 + \ln x_1, \dots, 1 + \ln x_n \rangle$$
$$\nabla g = \langle 1, \dots, 1 \rangle, \nabla h = \langle E_1, \dots, E_n \rangle$$

We write the Lagrange Condition $\nabla S = \lambda \nabla g + \mu \nabla h$:

$$\langle 1 + \ln x_1, \dots, 1 + \ln x_n \rangle = \lambda \langle 1, \dots, 1 \rangle + \mu \langle E_1, \dots, E_n \rangle = \langle \lambda + \mu E_1, \dots, \lambda + \mu E_n \rangle$$

yielding the following Lagrange equations:

$$\begin{aligned} 1 + \ln x_1 &= \lambda + \mu E_1 \\ 1 + \ln x_2 &= \lambda + \mu E_2 \\ &\vdots \\ 1 + \ln x_n &= \lambda + \mu E_n \end{aligned}$$

Subtracting the ith equation from the jth equation, we

$$\ln x_i - \ln x_j = \ln \frac{x_i}{x_j} = \mu(E_i - E_j)$$

or

$$\ln \frac{x_i}{x_j} = \mu \left(E_i - E_j\right) \quad \Rightarrow \quad x_i e^{-\mu E_i} = x_j e^{-\mu E_j} \tag{1}$$

Let A be the common value of $x_i^{-1} e^{\mu E_i}$. Then

$$x_i = A^{-1} e^{\mu E_i}$$

The constraint $x_1 + \cdots + x_n = N$ gives

$$A^{-1}\left(e^{\mu E_1} + e^{\mu E_2} + \cdots + e^{\mu E_n}\right) = N$$

Therefore

$$A = \frac{e^{\mu E_1} + e^{\mu E_2} + \cdots + e^{\mu E_n}}{N}$$

The value of μ is determined by the second constraint $h(x_1, \dots, x_n) = 0$, although it would be very difficult to calculate.

CHAPTER REVIEW EXERCISES

1. Given $f(x, y) = \dfrac{\sqrt{x^2 - y^2}}{x + 3}$:

(a) Sketch the domain of f.

(b) Calculate $f(3, 1)$ and $f(-5, -3)$.

(c) Find a point satisfying $f(x, y) = 1$.

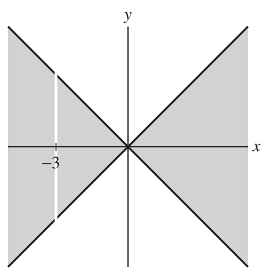
SOLUTION

(a) f is defined where $x^2 - y^2 \geq 0$ and $x + 3 \neq 0$. We solve these two inequalities:

$$x^2 - y^2 \geq 0 \quad \Rightarrow \quad x^2 \geq y^2 \quad \Rightarrow \quad |x| \geq |y|$$
$$x + 3 \neq 0 \quad \Rightarrow \quad x \neq -3$$

Therefore, the domain of f is the following set:

$$D = \{(x, y) : |x| \geq |y|, x \neq -3\}$$



(b) To find $f(3, 1)$ we substitute $x = 3$, $y = 1$ in $f(x, y)$. We get

$$f(3, 1) = \frac{\sqrt{3^2 - 1^2}}{3 + 3} = \frac{\sqrt{8}}{6} = \frac{\sqrt{2}}{3}$$

Similarly, setting $x = -5$, $y = -3$, we get

$$f(-5, -3) = \frac{\sqrt{(-5)^2 - (-3)^2}}{-5 + 3} = \frac{\sqrt{16}}{-2} = -2.$$

(c) We must find a point (x, y) such that

$$f(x, y) = \frac{\sqrt{x^2 - y^2}}{x + 3} = 1$$

We choose, for instance, $y = 1$, substitute and solve for x. This gives

$$\frac{\sqrt{x^2 - 1^2}}{x + 3} = 1$$
$$\sqrt{x^2 - 1} = x + 3$$
$$x^2 - 1 = (x + 3)^2 = x^2 + 6x + 9$$
$$6x = -10 \quad \Rightarrow \quad x = -\frac{5}{3}$$

Thus, the point $\left(-\frac{5}{3}, 1\right)$ satisfies $f\left(-\frac{5}{3}, 1\right) = 1$.

2. Find the domain and range of:

(a) $f(x, y, z) = \sqrt{x - y} + \sqrt{y - z}$

(b) $f(x, y) = \ln(4x^2 - y)$

SOLUTION

(a) $f(x, y, z)$ is defined where the differences under the root signs are nonnegative. That is, $x - y \geq 0$ and $y - z \geq 0$. We solve the inequalities

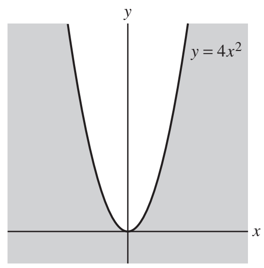
$$\left.\begin{array}{l} x - y \geq 0 \quad \Rightarrow \quad y \leq x \\ y - z \geq 0 \quad \Rightarrow \quad y \geq z \end{array}\right. \quad \Rightarrow \quad z \leq y \leq x$$

The domain of f is the following set:

$$D = \{(x, y, z) | z \le y \le x\}$$

The range is the set of all nonnegative numbers.

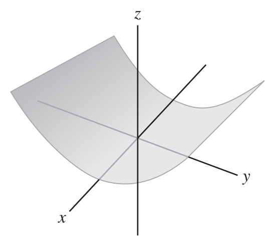
(b) f is defined when $4x^2 - y > 0$ or $y < 4x^2$. The domain $D = \left\{(x, y) : y < 4x^2\right\}$ is shown in the figure.



Since the logarithm function takes on all real values, the range of f is all real values.

3. Sketch the graph $f(x, y) = x^2 - y + 1$ and describe its vertical and horizontal traces.

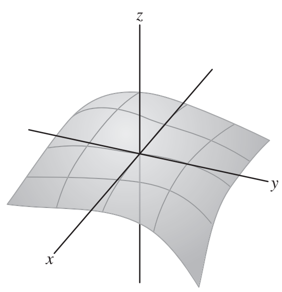
SOLUTION The graph is shown in the following figure.

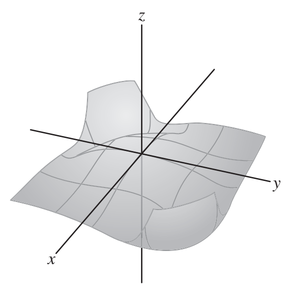


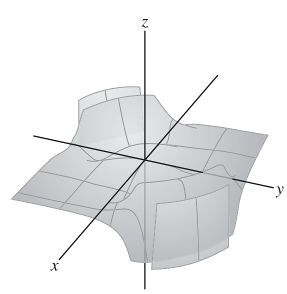
The trace obtained by setting $x = c$ is the line $z = c^2 - y + 1$ or $z = (c^2 + 1) - y$ in the plane $x = c$. The trace obtained by setting $y = c$ is the parabola $z = x^2 - c + 1$ in the plane $y = c$. The trace obtained by setting $z = c$ is the parabola $y = x^2 + 1 - c$ in the plane $z = c$.

4. CAS Use a graphing utility to draw the graph of the function $\cos(x^2 + y^2)e^{1-xy}$ in the domains $[-1, 1] \times [-1, 1]$, $[-2, 2] \times [-2, 2]$, and $[-3, 3] \times [-3, 3]$, and explain its behavior.

SOLUTION The graphs of the function $f(x, y) = \cos(x^2 + y^2)e^{1-xy}$ in the given domains are shown in the following figures.







The graph in the domain $[-1, 1] \times [-1, 1]$ shows a saddle point and two local maxima. In the domain $[-2, 2] \times [-2, 2]$ we see two additional local minima and two maxima and in the last graph two additional maxima and two additional minima appear. We can see that when $|xy| \to 0$, $\cos(x^2 + y^2)$ is the dominant part of the function, and as xy grows, e^{1-xy} gains more effect. When $xy \to -\infty$, the function oscillates between ∞ and $-\infty$, while for $xy \to +\infty$, $f(x, y) \to 0$.

5. Match the functions (a)–(d) with their graphs in Figure 1.

(a) $f(x, y) = x^2 + y$

(b) $f(x, y) = x^2 + 4y^2$

(c) $f(x, y) = \sin(4xy)e^{-x^2-y^2}$

(d) $f(x, y) = \sin(4x)e^{-x^2-y^2}$

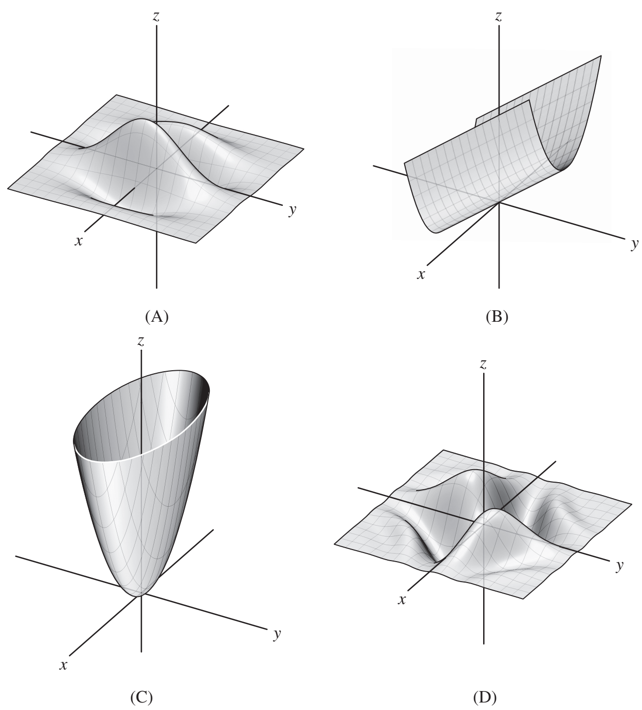


FIGURE 1

SOLUTION The function $f = x^2 + y$ matches picture (b), as can be seen by taking the $x = 0$ slice. The function $f = x^2 + 4y^2$ matches picture (c), as can be seen by taking $z = c$ slices (giving ellipses). Since $\sin(4xy)e^{-x^2-y^2}$ is symmetric with respect to x and y, and so also is picture (d), we match $\sin(4xy)e^{-x^2-y^2}$ with (d). That leaves the third function, $\sin(4x)e^{-x^2-y^2}$, to match with picture (a).

6. Referring to the contour map in Figure 2:

(a) Estimate the average rate of change of elevation from A to B and from A to D.

(b) Estimate the directional derivative at A in the direction of $\mathbf{v}$.

(c) What are the signs of f_x and f_y at D?

(d) At which of the labeled points are both f_x and f_y negative?

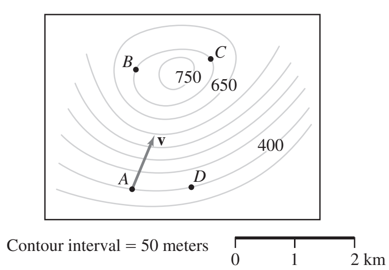

FIGURE 2

SOLUTION

(a) From A to B: The segment $\overline{AB}$ spans 6 level curves and the contour interval is $m = 50$ m, so the change of altitude is $6 \cdot 50 = 300$ m. From the horizontal scale of contour map we see that the horizontal distance from A to B is 2 km or 2000 m. Therefore,

$$\text{Average ROC from } A \text{ to } B = \frac{\Delta\text{altitude}}{\Delta\text{horizontal distance}} = \frac{300}{2000} = 0.15$$

From A to D: A and D lie on the same level curve, hence there is no change in altitude from A to D. Therefore,

$$\text{Average ROC from} A \text{ to } D = \frac{0}{\Delta\text{horizontal distance}} = 0.$$

(b) We first estimate the gradient at A. We get

$$\left.\frac{\partial f}{\partial x}\right|_A \approx \frac{\Delta f}{\Delta x} = \frac{0}{\Delta x} = 0 \qquad \left.\frac{\partial f}{\partial y}\right|_A \approx \frac{\Delta f}{\Delta y} \approx \frac{50}{200} \approx 0.25 \quad \Rightarrow \quad \left.\nabla f\right|_A \approx \langle 0, 0.22\rangle$$

We estimate $\mathbf{v}$, by $\mathbf{v} \approx \left\langle \frac{4}{9}, 1\right\rangle \approx \langle 0.44, 1\rangle$, hence the cosine of the angle between $\mathbf{v}$ and the gradient at A is

$$\cos\theta = \frac{\langle 0, 0.25\rangle \cdot \langle 0.44, 1\rangle}{0.25 \cdot \sqrt{0.44^2 + 1}} = \frac{0.25}{0.25 \cdot 1.093} = 0.915$$

Hence,

$$D_{\mathbf{v}} f(A) = \|\nabla f_A\| \cos\theta = 0.25 \cdot 0.915 \approx 0.229.$$

(Another method is to note that in the direction of $\mathbf{v}$, we cross four contour lines in about 1000 meters; thus, the change of f in that direction is about $4 \cdot 50/10000 = 0.2$.)

(c) At the point D we see that $f_x < 0$ since the elevation is decreasing in the x direction, while $f_y > 0$ since the elevation is increasing in the y direction.

(d) At the point C we see that $f_x < 0$ and $f_y < 0$, the elevation is decreasing in both the x and y direction at the point C.

7. Describe the level curves of:

(a) $f(x, y) = e^{4x-y}$ **(b)** $f(x, y) = \ln(4x - y)$

(c) $f(x, y) = 3x^2 - 4y^2$ **(d)** $f(x, y) = x + y^2$

SOLUTION

(a) The level curves of $f(x, y) = e^{4x-y}$ are the curves $e^{4x-y} = c$ in the xy-plane, where $c > 0$. Taking ln from both sides we get $4x - y = \ln c$. Therefore, the level curves are the parallel lines of slope 4, $4x - y = \ln c$, $c > 0$, in the xy-plane.

(b) The level curves of $f(x, y) = \ln(4x - y)$ are the curves $\ln(4x - y) = c$ in the xy-plane. We rewrite it as $4x - y = e^c$ to obtain the parallel lines of slope 4, with negative y-intercepts.

(c) The level curves of $f(x, y) = 3x^2 - 4y^2$ are the hyperbolas $3x^2 - 4y^2 = c$ in the xy plane.

(d) The level curves of $f(x, y) = x + y^2$ are the curves $x + y^2 = c$ or $x = c - y^2$ in the xy-plane. These are parabolas whose axis is the x-axis.

8. Match each function (a)–(c) with its contour graph (i)–(iii) in Figure 3:

(a) $f(x, y) = xy$

(b) $f(x, y) = e^{xy}$

(c) $f(x, y) = \sin(xy)$

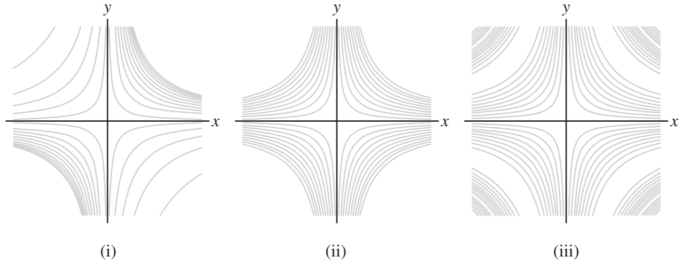

FIGURE 3

SOLUTION We find the level curves of the three functions:

(a) The level curves of $f(x, y) = xy$ are the curves $xy = c$ in the xy-plane, where c is any real value.

(b) The level curves of $f(x, y) = e^{xy}$ are $e^{xy} = c$ or $xy = \ln c$ where $c > 0$.

(c) The level curves of $f(x, y) = \sin xy$ are $\sin xy = c$ for $|c| \le 1$, or $xy = \sin^{-1} c + 2\pi k$.

The contour graphs corresponding to these functions are thus

(a) → (ii)
(b) → (i)
(c) → (iii)

Notice that the curves $xy = \ln c$ become closer and closer when c increases, while the curves $xy = c$ are equidistant for a certain contour interval. The contour map of (b) is in the first and third quadrants for $c > 1$, since then $\ln c > 0$.

In Exercises 9–14, evaluate the limit or state that it does not exist.

9. $\displaystyle\lim_{(x,y)\to(1,-3)} (xy + y^2)$

SOLUTION The function $f(x, y) = xy + y^2$ is continuous everywhere because it is a polynomial, therefore we evaluate the limit using substitution:

$$\lim_{(x,y)\to(1,-3)} \left(xy + y^2\right) = 1 \cdot (-3) + (-3)^2 = 6$$

10. $\displaystyle\lim_{(x,y)\to(1,-3)} \ln(3x + y)$

SOLUTION Approaching $(1, -3)$ along the ray $y = -3$, $x > 1$ gives

$$\lim_{x\to 1+} \ln(3x - 3) = -\infty$$

Therefore f takes on arbitrary small values at the intersection of every disk around the point $(1, -3)$ with the domain of the function. This shows that $\displaystyle\lim_{(x,y)\to(1,-3)} \ln(3x + y)$ does not exist.

11. $\displaystyle\lim_{(x,y)\to(0,0)} \frac{xy + xy^2}{x^2 + y^2}$

SOLUTION We evaluate the limits as (x, y) approaches the origin along the lines $y = x$ and $y = 2x$:

$$\lim_{\substack{(x,y)\to(0,0)\\ \text{along } y=x}} \frac{xy + xy^2}{x^2 + y^2} = \lim_{x\to 0} \frac{x \cdot x + x \cdot x^2}{x^2 + x^2} = \lim_{x\to 0} \frac{x^2 + x^3}{2x^2} = \lim_{x\to 0} \frac{1 + x}{2} = \frac{1}{2}$$

$$\lim_{\substack{x\to(0,0)\\ \text{along } y=2x}} \frac{xy + xy^2}{x^2 + y^2} = \lim_{x\to 0} \frac{x \cdot 2x + x \cdot (2x)^2}{x^2 + (2x)^2} = \lim_{x\to 0} \frac{2x^2 + 4x^3}{5x^2} = \lim_{x\to 0} \frac{2 + 4x}{5} = \frac{2}{5}$$

Since the two limits are different, $f(x, y)$ does not approach one limit as $(x, y) \to (0, 0)$, therefore the limit does not exist.

12. $\displaystyle\lim_{(x,y)\to(0,0)} \frac{x^3y^2 + x^2y^3}{x^4 + y^4}$

SOLUTION We use polar coordinates $x = r\cos\theta$, $y = r\sin\theta$. Then $(x, y) \to (0, 0)$ if and only if $r = \sqrt{x^2 + y^2} \to 0+$. Therefore,

$$\begin{aligned}
\lim_{(x,y)\to(0,0)} \frac{x^3y^2 + x^2y^3}{x^4 + y^4} &= \lim_{r\to 0+} \frac{r^3\cos^3\theta \cdot r^2\sin^2\theta + r^2\cos^2\theta \cdot r^3\sin^3\theta}{r^4\cos^4\theta + r^4\sin^4\theta} \\
&= \lim_{r\to 0+} \frac{r^5\left(\cos^3\theta\sin^2\theta + \cos^2\theta\sin^3\theta\right)}{r^4\left(\cos^4\theta + \sin^4\theta\right)} \\
&= \lim_{r\to 0+} \frac{r\left(\cos^3\theta\sin^2\theta + \cos^2\theta\sin^3\theta\right)}{\cos^4\theta + \sin^4\theta} \\
&= \lim_{r\to 0+} r \cdot \frac{\cos^3\theta\sin^2\theta + \cos^2\theta\sin^3\theta}{\cos^4\theta + \left(1 - \cos^2\theta\right)^2} \\
&= \lim_{r\to 0+} r \cdot \frac{\cos^2\theta\sin^2\theta(\cos\theta + \sin\theta)}{2\cos^4\theta - 2\cos^2\theta + 1}
\end{aligned}$$

The minimum value of the function $s = 2t^4 - 2t^2 + 1$ is $\frac{1}{2}$. Therefore, since $|\cos\theta| \le 1$ and $|\sin\theta| \le 1$, we find that

$$\left|\frac{\cos^2\theta\sin^2\theta(\cos\theta + \sin\theta)}{2\cos^4\theta - 2\cos^2\theta + 1}\right| \le \left|\frac{\cos^2\theta\sin^2\theta(\cos\theta + \sin\theta)}{\frac{1}{2}}\right| \le 2|\cos\theta + \sin\theta| \le 4$$

Hence,

$$0 \le \left| r \frac{\cos^2\theta \sin^2\theta(\cos\theta + \sin\theta)}{2\cos^4\theta - 2\cos^2\theta + 1} \right| \le 4r$$

We now use the Squeeze Theorem to conclude that the limit as $r \to 0+$ is zero, hence also the given limit is zero.

13. $\lim\limits_{(x,y)\to(1,-3)} (2x+y)e^{-x+y}$

SOLUTION The function $f(x,y) = (2x+y)e^{-x+y}$ is continuous, hence we evaluate the limit using substitution:

$$\lim_{(x,y)\to(1,-3)} (2x+y)e^{-x+y} = (2\cdot 1 - 3)e^{-1-3} = -e^{-4}$$

14. $\lim\limits_{(x,y)\to(0,2)} \dfrac{(e^x-1)(e^y-1)}{x}$

SOLUTION We have

$$\lim_{(x,y)\to(0,2)} \frac{\left(e^x-1\right)\left(e^y-1\right)}{x} = \lim_{x\to 0}\frac{e^x-1}{x}\lim_{y\to 2}\left(e^y-1\right) = \left(e^2-1\right)\lim_{x\to 0}\frac{e^x-1}{x} \tag{1}$$

By L'Hôpital's Rules,

$$\lim_{x\to 0}\frac{e^x-1}{x} = \lim_{x\to 0}\frac{\frac{d}{dx}(e^x-1)}{\frac{d}{dx}(x)} = \lim_{x\to 0}\frac{e^x}{1} = 1 \tag{2}$$

Combining (1) and (2) we conclude that

$$\lim_{(x,y)\to(0,2)} \frac{(e^x-1)(e^y-1)}{x} = (e^2-1)\cdot 1 = e^2-1.$$

15. Let

$$f(x,y) = \begin{cases} \dfrac{(xy)^p}{x^4+y^4} & (x,y)\ne(0,0) \\ 0 & (x,y)=(0,0) \end{cases}$$

Use polar coordinates to show that $f(x,y)$ is continuous at all (x,y) if $p>2$ but is discontinuous at $(0,0)$ if $p\le 2$.

SOLUTION We show using the polar coordinates $x = r\cos\theta$, $y = r\sin\theta$, that the limit of $f(x,y)$ as $(x,y)\to(0,0)$ is zero for $p>2$. This will prove that f is continuous at the origin. Since f is a rational function with nonzero denominator for $(x,y)\ne(0,0)$, f is continuous there. We have

$$\lim_{(x,y)\to(0,0)} f(x,y) = \lim_{r\to 0+}\frac{(r\cos\theta)^p(r\sin\theta)^p}{(r\cos\theta)^4+(r\sin\theta)^4} = \lim_{r\to 0+}\frac{r^{2p}(\cos\theta\sin\theta)^p}{r^4\left(\cos^4\theta+\sin^4\theta\right)} \tag{1}$$

$$= \lim_{r\to 0+}\frac{r^{2(p-2)}(\cos\theta\sin\theta)^p}{\cos^4\theta+\sin^4\theta}$$

We use the following inequalities:

$$\left|\cos^4\theta\sin^4\theta\right| \le 1$$

$$\begin{aligned}\cos^4\theta+\sin^4\theta &= \left(\cos^2\theta+\sin^2\theta\right)^2 - 2\cos^2\theta\sin^2\theta = 1 - \frac{1}{2}\cdot(2\cos\theta\sin\theta)^2 \\ &= 1 - \frac{1}{2}\sin^2 2\theta \ge 1 - \frac{1}{2} = \frac{1}{2}\end{aligned}$$

Therefore,

$$0 \le \left|\frac{r^{2(p-2)}(\cos\theta\sin\theta)^p}{\cos^4\theta+\sin^4\theta}\right| \le \frac{r^{2(p-2)}\cdot 1}{\frac{1}{2}} = 2r^{2(p-2)}$$

Since $p-2>0$, $\lim\limits_{r\to 0+} 2r^{2(p-2)} = 0$, hence by the Squeeze Theorem the limit in (1) is also zero. We conclude that f is continuous for $p>2$.

We now show that for $p < 2$ the limit of $f(x, y)$ as $(x, y) \to (0, 0)$ does not exist. We compute the limit as (x, y) approaches the origin along the line $y = x$.

$$\lim_{\substack{(x,y)\to(0,0)\\ \text{along } y=x}} f(x, y) = \lim_{x\to 0} \frac{(x^2)^p}{x^4 + x^4} = \lim_{x\to 0} \frac{x^{2p}}{2x^4} = \lim_{x\to 0} \frac{x^{2(p-2)}}{2} = \infty$$

Therefore the limit of $f(x, y)$ as $(x, y) \to (0, 0)$ does not exist for $p < 2$. We now show that the limit $\lim_{(x,y)\to(0,0)} \frac{x^2y^2}{x^4+y^4}$ does not exist for $p = 2$ as well. We compute the limits along the line $y = 0$ and $y = x$:

$$\lim_{\substack{(x,y)\to(0,0)\\ \text{along } y=0}} \frac{x^2y^2}{x^4 + y^4} = \lim_{x\to 0} \frac{x^2 \cdot 0^2}{x^4 + 0^4} = \lim_{x\to 0} \frac{0}{x^4} = 0$$

$$\lim_{\substack{(x,y)\to(0,0)\\ \text{along } y=x}} \frac{x^2y^2}{x^4 + y^4} = \lim_{x\to 0} \frac{x^2 \cdot x^2}{x^4 + x^4} = \lim_{x\to 0} \frac{x^4}{2x^4} = \frac{1}{2}$$

Since the limits along two paths are different, $f(x, y)$ does not approach one limit as $(x, y) \to (0, 0)$. We thus showed that if $p \le 2$, the limit $\lim_{(x,y)\to(0,0)} f(x, y)$ does not exist, and f is not continuous at the origin for $p \le 2$.

16. Calculate $f_x(1, 3)$ and $f_y(1, 3)$ for $f(x, y) = \sqrt{7x + y^2}$.

SOLUTION To calculate $f_x(x, y)$ we treat y as a constant and use the Chain Rule. This gives

$$f_x(x, y) = \frac{\partial}{\partial x}\sqrt{7x + y^2} = \frac{1}{2\sqrt{7x + y^2}} \frac{\partial}{\partial x}\left(7x + y^2\right) = \frac{7}{2\sqrt{7x + y^2}}$$

We compute $f_y(x, y)$ similarly, treating x as a constant:

$$f_y(x, y) = \frac{\partial}{\partial y}\sqrt{7x + y^2} = \frac{1}{2\sqrt{7x + y^2}} \frac{\partial}{\partial y}\left(7x + y^2\right) = \frac{2y}{2\sqrt{7x + y^2}} = \frac{y}{\sqrt{7x + y^2}}$$

At the point $(1, 3)$ we have

$$f_x(1, 3) = \frac{7}{2\sqrt{7 \cdot 1 + 3^2}} = \frac{7}{2 \cdot 4} = \frac{7}{8}$$

$$f_y(1, 3) = \frac{3}{\sqrt{7 \cdot 1 + 3^2}} = \frac{3}{4}$$

In Exercises 17–20, compute f_x and f_y.

17. $f(x, y) = 2x + y^2$

SOLUTION To find f_x we treat y as a constant, and to find f_y we treat x as a constant. We get

$$f_x = \frac{\partial}{\partial x}\left(2x + y^2\right) = \frac{\partial}{\partial x}(2x) + \frac{\partial}{\partial x}\left(y^2\right) = 2 + 0 = 2$$

$$f_y = \frac{\partial}{\partial y}\left(2x + y^2\right) = \frac{\partial}{\partial y}(2x) + \frac{\partial}{\partial y}\left(y^2\right) = 0 + 2y = 2y$$

18. $f(x, y) = 4xy^3$

SOLUTION We compute f_x, treating y as a constant:

$$f_x = \frac{\partial}{\partial x}(4xy^3) = 4y^3 \frac{\partial}{\partial x}(x) = 4y^3 \cdot 1 = 4y^3$$

We compute f_y treating x as a constant:

$$f_y = \frac{\partial}{\partial y}(4xy^3) = 4x \frac{\partial}{\partial y}(y^3) = 4x \cdot 3y^2 = 12xy^2.$$

19. $f(x, y) = \sin(xy)e^{-x-y}$

SOLUTION We compute f_x, treating y as a constant and using the Product Rule and the Chain Rule. We get

$$\begin{aligned} f_x &= \frac{\partial}{\partial x}\left(\sin(xy)e^{-x-y}\right) = \frac{\partial}{\partial x}\left(\sin(xy)\right)e^{-x-y} + \sin(xy)\frac{\partial}{\partial x}e^{-x-y} \\ &= \cos(xy)\cdot ye^{-x-y} + \sin(xy)\cdot(-1)e^{-x-y} = e^{-x-y}\left(y\cos(xy) - \sin(xy)\right) \end{aligned}$$

We compute f_y similarly, treating x as a constant. Notice that since $f(y, x) = f(x, y)$, the partial derivative f_y can be obtained from f_x by interchanging x and y. That is,

$$f_y = e^{-x-y}\left(x\cos(yx) - \sin(yx)\right).$$

20. $f(x, y) = \ln(x^2 + xy^2)$

SOLUTION Using the Chain Rule we obtain

$$\begin{aligned} f_x &= \frac{\partial}{\partial x}\ln\left(x^2 + xy^2\right) = \frac{1}{x^2 + xy^2}\frac{\partial}{\partial x}\left(x^2 + xy^2\right) = \frac{1}{x^2 + xy^2}\cdot\left(2x + y^2\right) = \frac{2x + y^2}{x^2 + xy^2} \\ f_y &= \frac{\partial}{\partial y}\ln\left(x^2 + xy^2\right) = \frac{1}{x^2 + xy^2}\frac{\partial}{\partial y}\left(x^2 + xy^2\right) = \frac{1}{x^2 + xy^2}\cdot(2xy) = \frac{2xy}{x^2 + xy^2} \end{aligned}$$

21. Calculate f_{xxyz} for $f(x, y, z) = y\sin(x + z)$.

SOLUTION We differentiate f twice with respect to x, once with respect to y, and finally with respect to z. This gives

$$\begin{aligned} f_x &= \frac{\partial}{\partial x}\left(y\sin(x + z)\right) = y\cos(x + z) \\ f_{xx} &= \frac{\partial}{\partial x}\left(y\cos(x + z)\right) = -y\sin(x + z) \\ f_{xxy} &= \frac{\partial}{\partial y}\left(-y\sin(x + z)\right) = -\sin(x + z) \\ f_{xxyz} &= \frac{\partial}{\partial z}\left(-\sin(x + z)\right) = -\cos(x + z) \end{aligned}$$

22. Fix $c > 0$. Show that for any constants α, β, the function $u(t, x) = \sin(\alpha ct + \beta)\sin(\alpha x)$ satisfies the wave equation

$$\frac{\partial^2 u}{\partial t^2} = c^2\frac{\partial^2 u}{\partial x^2}$$

SOLUTION We compute the partial derivatives u_t and u_x using the Chain Rule:

$$\begin{aligned} u_t &= \frac{\partial}{\partial t}\left(\sin(\alpha ct + \beta)\sin(\alpha x)\right) = \sin(\alpha x)\frac{\partial}{\partial t}\sin(\alpha ct + \beta) = \sin(\alpha x)\cos(\alpha ct + \beta)\cdot\alpha c \\ u_x &= \frac{\partial}{\partial x}\left(\sin(\alpha ct + \beta)\sin(\alpha x)\right) = \sin(\alpha ct + \beta)\frac{\partial}{\partial x}\sin(\alpha x) = \sin(\alpha ct + \beta)\cos(\alpha x)\cdot\alpha \end{aligned}$$

We find u_{tt} and u_{xx}, differentiating u_t and u_x with respect to t and x respectively, we get

$$\begin{aligned} u_{tt} &= \alpha c\sin(\alpha x)\frac{\partial}{\partial t}\cos(\alpha ct + \beta) = -\alpha^2 c^2\sin(\alpha x)\sin(\alpha ct + \beta) \\ u_{xx} &= \alpha\sin(\alpha ct + \beta)\frac{\partial}{\partial x}\cos(\alpha x) = -\alpha^2\sin(\alpha ct + \beta)\sin(\alpha x) \end{aligned}$$

We see that $u_{tt} = c^2 u_{xx}$.

23. Find an equation of the tangent plane to the graph of $f(x, y) = xy^2 - xy + 3x^3 y$ at $P = (1, 3)$.

SOLUTION The tangent plane has the equation

$$z = f(1, 3) + f_x(1, 3)(x - 1) + f_y(1, 3)(y - 3) \tag{1}$$

We compute the partial derivatives of $f(x, y) = xy^2 - xy + 3x^3 y$:

$$\left.\begin{aligned} f_x(x, y) &= y^2 - y + 9x^2 y \\ f_y(x, y) &= 2xy - x + 3x^3 \end{aligned}\right. \quad\Rightarrow\quad \begin{aligned} f_x(1, 3) &= 3^2 - 3 + 9\cdot 1^2\cdot 3 = 33 \\ f_y(1, 3) &= 2\cdot 1\cdot 3 - 1 + 3\cdot 1^3 = 8 \end{aligned}$$

Also, $f(1,3) = 1 \cdot 3^2 - 1 \cdot 3 + 3 \cdot 1^3 \cdot 3 = 15$. Substituting these values in (1), we obtain the following equation:

$$z = 15 + 33(x-1) + 8(y-3)$$

or

$$z = 33x + 8y - 42$$

24. Suppose that $f(4,4) = 3$ and $f_x(4,4) = f_y(4,4) = -1$. Use the linear approximation to estimate $f(4.1, 4)$ and $f(3.88, 4.03)$.

SOLUTION The linear approximation is

$$f(a+h, b+k) \approx f(a,b) + f_x(a,b)h + f_y(a,b)k$$

We use the linear approximation at the point $(4, 4)$. Therefore, estimating $f(3.88, 4.03)$,

$$\begin{aligned} h &= 3.88 - 4 = -0.12 \\ k &= 4.03 - 4 = 0.03 \\ f(3.88, 4.03) &\approx f(4,4) + f_x(4,4)\cdot(-0.12) + f_y(4,4)\cdot 0.03 \\ f(3.88, 4.03) &\approx 3 - 1\cdot(-0.12) - 1\cdot 0.03 = 3.09 \end{aligned}$$

Estimating $f(4.1, 4)$,

$$\begin{aligned} h &= 4.1 - 4 = 0.1 \\ k &= 4 - 4 = 0 \\ f(4.1, 4) &\approx f(4,4) + f_x(4,4)(0.1) + f_y(4,4)\cdot 0 \\ f(4.1, 4) &\approx 3 - 1\cdot(0.1) - 1\cdot 0 = 2.9 \end{aligned}$$

We obtain the estimations $f(3.88, 4.03) \approx 3.09$ and $f(4.1, 4) \approx 2.9$.

25. Use a linear approximation of $f(x,y,z) = \sqrt{x^2 + y^2 + z}$ to estimate $\sqrt{7.1^2 + 4.9^2 + 69.5}$. Compare with a calculator value.

SOLUTION The function whose value we want to approximate is

$$f(x,y,z) = \sqrt{x^2 + y^2 + z}$$

We will use the linear approximation at the point $(7, 5, 70)$. Recall that the linear approximation to a surface will be:

$$L(x,y,z) = f(7,5,70) + f_x(7,5,70)(x-7) + f_y(7,5,70)(y-5) + f_z(7,5,70)(z-70)$$

We compute the partial derivatives of f:

$$\begin{aligned} f_x(x,y,z) &= \frac{2x}{2\sqrt{x^2+y^2+z}} = \frac{x}{\sqrt{x^2+y^2+z}} &\Rightarrow\quad f_x(7,5,70) &= \frac{7}{\sqrt{7^2+5^2+70}} = \frac{7}{12} \\ f_y(x,y,z) &= \frac{2y}{2\sqrt{x^2+y^2+z}} = \frac{y}{\sqrt{x^2+y^2+z}} &\Rightarrow\quad f_y(7,5,70) &= \frac{5}{\sqrt{7^2+5^2+70}} = \frac{5}{12} \\ f_z(x,y,z) &= \frac{1}{2\sqrt{x^2+y^2+z}} &\Rightarrow\quad f_z(7,5,70) &= \frac{1}{2\sqrt{7^2+5^2+70}} = \frac{1}{24} \end{aligned}$$

Also, $f(7,5,70) = \sqrt{7^2+5^2+70} = 12$. Substituting the values in the linear approximation equation we obtain the following approximation:

$$L(x,y,z) = 12 + \frac{7}{12}(x-7) + \frac{5}{12}(y-5) + \frac{1}{24}(z-70)$$

Now we are ready to approximate $\sqrt{7.1^2 + 4.9^2 + 69.5}$. That is, using the linear approximation,

$$\begin{aligned} L(7.1, 4.9, 69.5) &= 12 + \frac{7}{12}(7.1-7) + \frac{5}{12}(4.9-5) + \frac{1}{24}(69.5-70) \\ &= 12 + \frac{7}{12}\cdot\frac{1}{10} + \frac{5}{12}\cdot -\frac{1}{10} + \frac{1}{24}\cdot -\frac{1}{2} \\ &= 12 + \frac{7}{120} - \frac{5}{120} - \frac{1}{48} \\ &= \frac{2879}{240} = 11.9958333 \end{aligned}$$

The value obtained using a calculator is 11.996667.

26. The plane $z = 2x - y - 1$ is tangent to the graph of $z = f(x, y)$ at $P = (5, 3)$.
(a) Determine $f(5, 3)$, $f_x(5, 3)$, and $f_y(5, 3)$.
(b) Approximate $f(5.2, 2.9)$.

SOLUTION
(a)

$$f_x(x, y) = 2 \quad \Rightarrow \quad f_x(5, 3) = 2 \tag{1}$$
$$f_y(x, y) = -1 \quad \Rightarrow \quad f_y(5, 3) = -1 \tag{2}$$

and

$$f(5, 3) = 2 \cdot 5 - 3 - 1 = 6$$

(b) Now using the linear approximation:

$$L(x, y) = f(5, 3) + f_x(5, 3)(x - 5) + f_y(5, 3)(y - 3)$$

and therefore

$$L(5.2, 2.9) = 6 + 2(5.2 - 5) - (2.9 - 3) = 6 + 2 \cdot \frac{2}{10} + \frac{1}{10} = 6.5$$

27. Figure 4 shows the contour map of a function $f(x, y)$ together with a path $c(t)$ in the counterclockwise direction. The points $c(1)$, $c(2)$, and $c(3)$ are indicated on the path. Let $g(t) = f(c(t))$. Which of statements (i)–(iv) are true? Explain.
(i) $g'(1) > 0$.
(ii) $g(t)$ has a local minimum for some $1 \le t \le 2$.
(iii) $g'(2) = 0$.
(iv) $g'(3) = 0$.

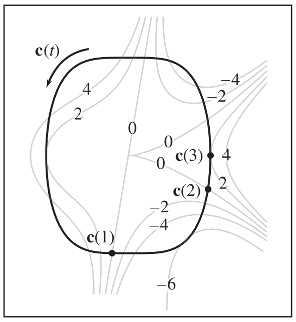

FIGURE 4

SOLUTION (ii) and (iv) are true

28. Jason earns $S(h, c) = 20h\left(1 + \frac{c}{100}\right)^{1.5}$ dollars per month at a used car lot, where h is the number of hours worked and c is the number of cars sold. He has already worked 160 hours and sold 69 cars. Right now Jason wants to go home but wonders how much more he might earn if he stays another 10 minutes with a customer who is considering buying a car. Use the linear approximation to estimate how much extra money Jason will earn if he sells his 70th car during these 10 minutes.

SOLUTION We estimate the money earned in staying for $\frac{1}{6}$ hour more and selling one more car, using the linear approximation

$$\Delta S \approx S_h(a, b)\Delta h + S_c(a, b)\Delta c \tag{1}$$

By the given information, $a = 160$, $b = 69$, $\Delta h = \frac{1}{6}$, and $\Delta c = 1$. We compute the partial derivative of the function:

$$S(h, c) = 20h\left(1 + \frac{c}{100}\right)^{1.5}$$
$$S_h(h, c) = 20\left(1 + \frac{c}{100}\right)^{1.5} \quad \Rightarrow \quad S_h(160, 69) = 43.94$$
$$S_c(h, c) = 20h \cdot 1.5\left(1 + \frac{c}{100}\right)^{0.5} \cdot \frac{1}{100} = 0.3h\left(1 + \frac{c}{100}\right)^{0.5} \quad \Rightarrow \quad S_c(160, 69) = 62.4$$

Substituting the values in (1), we get the following approximation:

$$\Delta S = S_h(160, 69) \cdot \frac{1}{6} + S_c(160, 69) \cdot 1 = 43.94 \cdot \frac{1}{6} + 62.4 \approx \$69.72$$

We see that John will make approximately \$69.72 more if he sells his 70th car during 10 min.

In Exercises 29–32, compute $\frac{d}{dt} f(\mathbf{c}(t))$ *at the given value of* t.

29. $f(x, y) = x + e^y$, $\quad \mathbf{c}(t) = (3t - 1, t^2)$ at $t = 2$

SOLUTION By the Chain Rule for Paths we have

$$\frac{d}{dt} f(\mathbf{c}(t)) = \nabla f \cdot \mathbf{c}'(t) \tag{1}$$

We evaluate the gradient ∇f and $\mathbf{c}'(t)$:

$$\mathbf{c}'(t) = \langle 3, 2t \rangle$$
$$\nabla f = \left\langle f_x, f_y \right\rangle = \left\langle 1, e^y \right\rangle \quad \Rightarrow \quad \nabla f_{\mathbf{c}(t)} = \left\langle 1, e^{t^2} \right\rangle$$

Substituting in (1) we get

$$\frac{d}{dt} f(\mathbf{c}(t)) = \left\langle 1, e^{t^2} \right\rangle \cdot \langle 3, 2t \rangle = 3 + 2te^{t^2}$$

At $t = 2$ we have

$$\frac{d}{dt} f(\mathbf{c}(t)) \bigg|_{t=2} = 3 + 2 \cdot 2 \cdot e^{2^2} = 3 + 4e^4 \approx 221.4.$$

30. $f(x, y, z) = xz - y^2$, $\quad \mathbf{c}(t) = (t, t^3, 1 - t)$ at $t = -2$

SOLUTION We use the Chain Rule for Paths:

$$\frac{d}{dt} f(\mathbf{c}(t)) = \nabla f_{\mathbf{c}(t)} \cdot \mathbf{c}'(t) \tag{1}$$

We compute the gradient of f:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \langle z, -2y, x \rangle$$

On the path, $x = t$, $y = t^3$, and $z = 1 - t$. Therefore,

$$\nabla f_{\mathbf{c}(t)} = \left\langle 1 - t, -2t^3, t \right\rangle$$

Also, $\mathbf{c}'(t) = \left\langle 1, 3t^2, -1 \right\rangle$, hence by (1) we obtain

$$\frac{d}{dt} f(\mathbf{c}(t)) = \left\langle 1 - t, -2t^3, t \right\rangle \cdot \left\langle 1, 3t^2, -1 \right\rangle = 1 - t + 3t^2 \left(-2t^3 \right) - t = -6t^5 - 2t + 1$$

Hence,

$$\frac{d}{dt} f(\mathbf{c}(2) = -6(2)^5 - 2(2) + 1 = -6(32) - 4 + 1 = -195$$

31. $f(x, y) = xe^{3y} - ye^{3x}$, $\quad \mathbf{c}(t) = (e^t, \ln t)$ at $t = 1$

SOLUTION We use the Chain Rule for Paths:

$$\frac{d}{dt} f(\mathbf{c}(t)) = \nabla f_{\mathbf{c}(t)} \cdot \mathbf{c}'(t) \tag{1}$$

We find the ∇f at the point $\mathbf{c}(1)$ and compute $\mathbf{c}'(1)$. We get

$$\nabla f = \left\langle f_x, f_y \right\rangle = \left\langle e^{3y} - 3ye^{3x}, 3xe^{3y} - e^{3x} \right\rangle$$
$$\mathbf{c}(1) = \left\langle e^1, \ln 1 \right\rangle = \langle e, 0 \rangle$$
$$\nabla f_{\mathbf{c}(1)} = \left\langle e^{3 \cdot 0} - 3 \cdot 0 e^{3e}, 3ee^{3 \cdot 0} - e^{3e} \right\rangle = \left\langle 1, 3e - e^{3e} \right\rangle \tag{2}$$
$$\mathbf{c}'(t) = \frac{d}{dt} \left\langle e^t, \ln t \right\rangle = \left\langle e^t, t^{-1} \right\rangle \quad \Rightarrow \quad \mathbf{c}'(1) = \langle e, 1 \rangle \tag{3}$$

Substituting (2) and (3) in (1) gives

$$\frac{d}{dt} f(\mathbf{c}(t)) \bigg|_{t=1} = \nabla f_{c(1)} \cdot \mathbf{c}'(1) = \left\langle 1, 3e - e^{3e} \right\rangle \cdot \langle e, 1 \rangle = e + 3e - e^{3e} = 4e - e^{3e}$$

32. $f(x,y)=\tan^{-1}\frac{y}{x}$, $\mathbf{c}(t)=(\cos t,\sin t)$, $t=\frac{\pi}{3}$

SOLUTION We use the Chain Rule for Paths. We have

$$\nabla f=\left\langle\frac{\partial f}{\partial x},\frac{\partial f}{\partial y}\right\rangle=\left\langle\frac{-\frac{y}{x^2}}{1+\left(\frac{y}{x}\right)^2},\frac{\frac{1}{x}}{1+\left(\frac{y}{x}\right)^2}\right\rangle=\left\langle\frac{-y}{x^2+y^2},\frac{x}{x^2+y^2}\right\rangle$$

On the path, $x=\cos t$ and $y=\sin t$. Therefore,

$$\nabla f_{\mathbf{c}(t)}=\left\langle-\frac{\sin t}{\cos^2 t+\sin^2 t},\frac{\cos t}{\cos^2 t+\sin^2 t}\right\rangle=\langle-\sin t,\cos t\rangle$$
$$\mathbf{c}'(t)=\langle-\sin t,\cos t\rangle$$

At the point $t=\frac{\pi}{3}$ we have

$$\nabla f_{\mathbf{c}\left(\frac{\pi}{3}\right)}=\left\langle-\sin\frac{\pi}{3},\cos\frac{\pi}{3}\right\rangle=\left\langle-\frac{\sqrt{3}}{2},\frac{1}{2}\right\rangle\quad\text{and}\quad\mathbf{c}'\left(\frac{\pi}{3}\right)=\left(-\sin\frac{\pi}{3},\cos\frac{\pi}{3}\right)=\left\langle-\frac{\sqrt{3}}{2},\frac{1}{2}\right\rangle$$

Therefore,

$$\left.\frac{d}{dt}f(\mathbf{c}(t))\right|_{t=\frac{\pi}{3}}=\nabla f_{\mathbf{c}\left(\frac{\pi}{3}\right)}\cdot\mathbf{c}'\left(\frac{\pi}{3}\right)=\left\langle-\frac{\sqrt{3}}{2},\frac{1}{2}\right\rangle\cdot\left\langle-\frac{\sqrt{3}}{2},\frac{1}{2}\right\rangle=\frac{3}{4}+\frac{1}{4}=1$$

In Exercises 33–36, compute the directional derivative at P in the direction of $\mathbf{v}$.

33. $f(x,y)=x^3y^4$, $P=(3,-1)$, $\mathbf{v}=2\mathbf{i}+\mathbf{j}$

SOLUTION We first normalize $\mathbf{v}$ to find a unit vector $\mathbf{u}$ in the direction of $\mathbf{v}$:

$$\mathbf{u}=\frac{\mathbf{v}}{\|\mathbf{v}\|}=\frac{2\mathbf{i}+\mathbf{j}}{\sqrt{2^2+1^2}}=\frac{2}{\sqrt{5}}\mathbf{i}+\frac{1}{\sqrt{5}}\mathbf{j}$$

We compute the directional derivative using the following equality:

$$D_{\mathbf{u}}f(3,-1)=\nabla f_{(3,-1)}\cdot\mathbf{u}$$

The gradient vector at the given point is the following vector:

$$\nabla f=\langle f_x,f_y\rangle=\left\langle 3x^2y^4,4x^3y^3\right\rangle\quad\Rightarrow\quad\nabla f_{(3,-1)}=\langle 27,-108\rangle$$

Hence,

$$D_{\mathbf{u}}f(3,-1)=\langle 27,-108\rangle\cdot\left\langle\frac{2}{\sqrt{5}},\frac{1}{\sqrt{5}}\right\rangle=\frac{54}{\sqrt{5}}-\frac{108}{\sqrt{5}}=-\frac{54}{\sqrt{5}}$$

34. $f(x,y,z)=zx-xy^2$, $P=(1,1,1)$, $\mathbf{v}=\langle 2,-1,2\rangle$

SOLUTION We first normalize $\mathbf{v}$ to obtain a unit vector $\mathbf{u}$ in the direction of $\mathbf{v}$:

$$\mathbf{u}=\frac{\langle 2,-1,2\rangle}{\sqrt{2^2+(-1)^2+2^2}}=\left\langle\frac{2}{3},-\frac{1}{3},\frac{2}{3}\right\rangle$$

We compute the directional derivative using the following equality:

$$D_{\mathbf{u}}f(1,1,1)=\nabla f_{(1,1,1)}\cdot\mathbf{u}$$

The gradient vector at the point $(1,1,1)$ is the following vector:

$$\nabla f=\langle f_x,f_y,f_z\rangle=\left\langle z-y^2,-2xy,x\right\rangle\quad\Rightarrow\quad\nabla f_{(1,1,1)}=\langle 0,-2,1\rangle$$

Hence,

$$D_{\mathbf{u}}f(1,1,1)=\langle 0,-2,1\rangle\cdot\left\langle\frac{2}{3},-\frac{1}{3},\frac{2}{3}\right\rangle=0+\frac{2}{3}+\frac{2}{3}=\frac{4}{3}$$

35. $f(x,y)=e^{x^2+y^2}$, $P=\left(\frac{\sqrt{2}}{2},\frac{\sqrt{2}}{2}\right)$, $\mathbf{v}=\langle 3,-4\rangle$

SOLUTION We normalize $\mathbf{v}$ to obtain a vector $\mathbf{u}$ in the direction of $\mathbf{v}$:

$$\mathbf{u}=\frac{\langle 3,-4\rangle}{\sqrt{3^2+(-4)^2}}=\left\langle\frac{3}{5},-\frac{4}{5}\right\rangle$$

We use the following theorem:

$$D_{\mathbf{u}} f(P) = \nabla f_P \cdot \mathbf{u} \tag{1}$$

We find the gradient of f at the given point:

$$\nabla f = \langle f_x, f_y \rangle = \left\langle 2xe^{x^2+y^2}, 2ye^{x^2+y^2} \right\rangle = 2e^{x^2+y^2} \langle x, y \rangle$$

Hence,

$$\nabla f_P = 2e^{\left(\frac{\sqrt{2}}{2}\right)^2+\left(\frac{\sqrt{2}}{2}\right)^2} \left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle = e\sqrt{2} \langle 1, 1 \rangle$$

Substituting in (1) we get

$$D_{\mathbf{u}} f(P) = \sqrt{2}e \langle 1, 1 \rangle \cdot \left\langle \frac{3}{5}, -\frac{4}{5} \right\rangle = \sqrt{2}e \left(\frac{3}{5} - \frac{4}{5} \right) = -\frac{\sqrt{2}e}{5}$$

36. $f(x, y, z) = \sin(xy + z), \quad P = (0, 0, 0), \quad \mathbf{v} = \mathbf{j} + \mathbf{k}$

SOLUTION We normalize $\mathbf{v}$ to obtain a vector $\mathbf{u}$ in the direction of $\mathbf{v}$:

$$\mathbf{u} = \frac{1}{\sqrt{0^2 + 1^2 + 1^2}} \cdot \langle 0, 1, 1 \rangle = \frac{1}{\sqrt{2}} \langle 0, 1, 1 \rangle$$

By the Theorem on Evaluating Directional Derivatives,

$$D_{\mathbf{v}} f(P) = \nabla f_P \cdot \mathbf{u} \tag{1}$$

We compute the gradient vector:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \langle y\cos(xy + z), x\cos(xy + z), \cos(xy + z) \rangle$$

Hence,

$$\nabla f_P = \langle 0, 0, 1 \rangle .$$

By (1) we conclude that

$$D_{\mathbf{v}} f(P) = \nabla f_P \cdot \mathbf{u} = \langle 0, 0, 1 \rangle \cdot \frac{1}{\sqrt{2}} \langle 0, 1, 1 \rangle = \frac{1}{\sqrt{2}}.$$

37. Find the unit vector $\mathbf{e}$ at $P = (0, 0, 1)$ pointing in the direction along which $f(x, y, z) = xz + e^{-x^2+y}$ increases most rapidly.

SOLUTION The gradient vector ∇f_P points in the direction of maximum rate of increase of f. Therefore we need to find a unit vector in the direction of ∇f_P. We first find the gradient of $f(x, y, z) = xz + e^{-x^2+y}$:

$$\nabla f = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle = \left\langle z - 2xe^{-x^2+y}, e^{-x^2+y}, x \right\rangle$$

At the point $P = (0, 0, 1)$ we have

$$\nabla f_P = \langle 1, 1, 0 \rangle .$$

We normalize ∇f_P to obtain the unit vector $\mathbf{e}$ at P pointing in the direction of maximum increase of f:

$$\mathbf{e} = \frac{\nabla f_P}{\|\nabla f_P\|} = \left\langle \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 0 \right\rangle.$$

38. Find an equation of the tangent plane at $P = (0, 3, -1)$ to the surface with equation

$$ze^x + e^{z+1} = xy + y - 3$$

SOLUTION The surface is defined implicitly by the equation

$$F(x, y, z) = ze^x + e^{z+1} - xy - y + 3$$

The tangent plane to the surface at the point $(0, 3, -1)$ has the following equation:

$$0 = F_x(0, 3, -1)x + F_y(0, 3, -1)(y - 3) + F_z(0, 3, -1)(z + 1) \tag{1}$$

We compute the partial derivatives at the given point:

$$\begin{aligned} F_x(x, y, z) &= ze^x - y && \Rightarrow && F_x(0, 3, -1) = -1e^0 - 3 = -4 \\ F_y(x, y, z) &= -x - 1 && \Rightarrow && F_y(0, 3, -1) = -0 - 1 = -1 \\ F_z(x, y, z) &= e^x + e^{z+1} && \Rightarrow && F_z(0, 3, -1) = e^0 + e^{-1+1} = 2 \end{aligned}$$

Substituting in (1) we obtain the following equation:

$$\begin{aligned} -4x - (y - 3) + 2(z + 1) &= 0 \\ -4x - y + 2z + 5 &= 0 \\ 2z = 4x + y - 5 \quad &\Rightarrow \quad z = 2x + 0.5y - 2.5 \end{aligned}$$

39. Let $n \neq 0$ be an integer and r an arbitrary constant. Show that the tangent plane to the surface $x^n + y^n + z^n = r$ at $P = (a, b, c)$ has equation

$$a^{n-1}x + b^{n-1}y + c^{n-1}z = r$$

SOLUTION The tangent plane to the surface, defined implicitly by $F(x, y, z) = r$ at a point (a, b, c) on the surface, has the following equation:

$$0 = F_x(a, b, c)(x - a) + F_y(a, b, c)(y - b) + F_z(a, b, c)(z - c) \tag{1}$$

The given surface is defined by the function $F(x, y, z) = x^n + y^n + z^n$. We find the partial derivative of F at a point $P = (a, b, c)$ on the surface:

$$\begin{aligned} F_x(x, y, z) &= nx^{n-1} & & F_x(a, b, c) = na^{n-1} \\ F_y(x, y, z) &= ny^{n-1} & \Rightarrow \quad & F_y(a, b, c) = nb^{n-1} \\ F_z(x, y, z) &= nz^{n-1} & & F_z(a, b, c) = nc^{n-1} \end{aligned}$$

Substituting in (1) we get

$$na^{n-1}(x - a) + nb^{n-1}(y - b) + nc^{n-1}(z - c) = 0$$

We divide by n and simplify:

$$\begin{aligned} a^{n-1}x - a^n + b^{n-1}y - b^n + c^{n-1}z - c^n &= 0 \\ a^{n-1}x + b^{n-1}y + c^{n-1}z &= a^n + b^n + c^n \end{aligned} \tag{2}$$

The point $P = (a, b, c)$ lies on the surface, hence it satisfies the equation of the surface. That is,

$$a^n + b^n + c^n = r$$

Substituting in (2) we obtain the following equation of the tangent plane:

$$a^{n-1}x + b^{n-1}y + c^{n-1}z = r$$

40. Let $f(x, y) = (x - y)e^x$. Use the Chain Rule to calculate $\partial f/\partial u$ and $\partial f/\partial v$ (in terms of u and v), where $x = u - v$ and $y = u + v$.

SOLUTION First we calculate the Primary Derivatives:

$$\frac{\partial f}{\partial x} = e^x(x - y) + e^x = e^x(x - y + 1), \quad \frac{\partial f}{\partial y} = -e^x$$

Since $\frac{\partial x}{\partial u} = 1$, $\frac{\partial y}{\partial u} = 1$, $\frac{\partial x}{\partial v} = -1$, and $\frac{\partial y}{\partial v} = 1$, the Chain Rule gives

$$\begin{aligned} \frac{\partial f}{\partial u} &= \frac{\partial f}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial u} = e^x(x - y + 1) \cdot 1 - e^x \cdot 1 = e^x(x - y + 1 - 1) = e^x(x - y) \\ \frac{\partial f}{\partial v} &= \frac{\partial f}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial v} = e^x(x - y + 1) \cdot (-1) - e^x \cdot 1 = e^x(y - x - 2) \end{aligned}$$

We now substitute $x = u - v$ and $y = u + v$ to express the partial derivatives in terms of u and v. We get

$$\frac{\partial f}{\partial u} = e^{u-v}(u - v - u - v) = -2ve^{u-v}$$

$$\frac{\partial f}{\partial v} = e^{u-v}(u + v - u + v - 2) = 2e^{u-v}(v - 1)$$

41. Let $f(x, y, z) = x^2y + y^2z$. Use the Chain Rule to calculate $\partial f/\partial s$ and $\partial f/\partial t$ (in terms of s and t), where

$$x = s + t, \quad y = st, \quad z = 2s - t$$

SOLUTION We compute the Primary Derivatives:

$$\frac{\partial f}{\partial x} = 2xy, \quad \frac{\partial f}{\partial y} = x^2 + 2yz, \quad \frac{\partial f}{\partial z} = y^2$$

Since $\frac{\partial x}{\partial s} = 1$, $\frac{\partial y}{\partial s} = t$, $\frac{\partial z}{\partial s} = 2$, $\frac{\partial x}{\partial t} = 1$, $\frac{\partial y}{\partial t} = s$, and $\frac{\partial z}{\partial t} = -1$, the Chain Rule gives

$$\begin{aligned}
\frac{\partial f}{\partial s} &= \frac{\partial f}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial s} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial s} = 2xy \cdot 1 + \left(x^2 + 2yz\right)t + y^2 \cdot 2 \\
&= 2xy + \left(x^2 + 2yz\right)t + 2y^2 \\
\frac{\partial f}{\partial t} &= \frac{\partial f}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial t} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial t} = 2xy \cdot 1 + \left(x^2 + 2yz\right)s + y^2 \cdot (-1) \\
&= 2xy + \left(x^2 + 2yz\right)s - y^2
\end{aligned}$$

We now substitute $x = s + t$, $y = st$, and $z = 2s - t$ to express the answer in terms of the independent variables s, t. We get

$$\begin{aligned}
\frac{\partial f}{\partial s} &= 2(s+t)st + \left((s+t)^2 + 2st(2s-t)\right)t + 2s^2t^2 \\
&= 2s^2t + 2st^2 + \left(s^2 + 2st + t^2 + 4s^2t - 2st^2\right)t + 2s^2t^2 \\
&= 3s^2t + 4st^2 + t^3 - 2st^3 + 6s^2t^2 \\
\frac{\partial f}{\partial t} &= 2(s+t)st + \left((s+t)^2 + 2st(2s-t)\right)s - s^2t^2 \\
&= 2s^2t + 2st^2 + \left(s^2 + 2st + t^2 + 4s^2t - 2st^2\right)s - s^2t^2 \\
&= 4s^2t + 3st^2 + s^3 + 4s^3t - 3s^2t^2
\end{aligned}$$

42. Let P have spherical coordinates $(\rho, \theta, \phi) = \left(2, \frac{\pi}{4}, \frac{\pi}{4}\right)$. Calculate $\left.\frac{\partial f}{\partial \phi}\right|_P$ assuming that

$$f_x(P) = 4, \quad f_y(P) = -3, \quad f_z(P) = 8$$

Recall that $x = \rho\cos\theta\sin\phi,\ y = \rho\sin\theta\sin\phi,\ z = \rho\cos\phi$.

SOLUTION Recall the Chain Rule:

$$\frac{\partial f}{\partial \phi} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial \phi} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial \phi} + \frac{\partial f}{\partial z}\frac{\partial z}{\partial \phi}$$

Taking partial derivatives (with respect to ϕ) and evaluating:

$$\begin{aligned}
\frac{\partial x}{\partial \phi} &= \rho\cos\theta\cos\phi \quad \Rightarrow \quad \left.\frac{\partial x}{\partial \phi}\right|_{(2,\pi/4,\pi/4)} = 1 \\
\frac{\partial y}{\partial \phi} &= \rho\sin\theta\cos\phi \quad \Rightarrow \quad \left.\frac{\partial y}{\partial \phi}\right|_{(2,\pi/4,\pi/4)} = 1 \\
\frac{\partial z}{\partial \phi} &= -\rho\sin\phi \quad \Rightarrow \quad \left.\frac{\partial z}{\partial \phi}\right|_{(2,\pi/4,\pi/4)} = -\sqrt{2}
\end{aligned}$$

Hence,

$$\left.\frac{\partial f}{\partial \phi}\right|_P = 4 \cdot 1 - 3 \cdot 1 - 8\sqrt{2} = 1 - 8\sqrt{2}$$

43. Let $g(u, v) = f(u^3 - v^3, v^3 - u^3)$. Prove that

$$v^2 \frac{\partial g}{\partial u} - u^2 \frac{\partial g}{\partial v} = 0$$

SOLUTION We are given the function $f(x, y)$, where $x = u^3 - v^3$ and $y = v^3 - u^3$. Using the Chain Rule we have the following derivatives:

$$\frac{\partial g}{\partial u} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial u}$$
$$\frac{\partial g}{\partial v} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial v} \qquad (1)$$

We compute the following partial derivatives:

$$\frac{\partial x}{\partial u} = 3u^2, \quad \frac{\partial y}{\partial u} = -3u^2$$
$$\frac{\partial x}{\partial v} = -3v^2, \quad \frac{\partial y}{\partial v} = 3v^2$$

Substituting in (1) we obtain

$$\frac{\partial g}{\partial u} = \frac{\partial f}{\partial x} \cdot 3u^2 + \frac{\partial f}{\partial y}\left(-3u^2\right) = 3u^2\left(\frac{\partial f}{\partial x} - \frac{\partial f}{\partial y}\right)$$
$$\frac{\partial g}{\partial v} = \frac{\partial f}{\partial x}\left(-3v^2\right) + \frac{\partial f}{\partial y}\left(3v^2\right) = -3v^2\left(\frac{\partial f}{\partial x} - \frac{\partial f}{\partial y}\right)$$

Therefore,

$$v^2 \frac{\partial g}{\partial u} + u^2 \frac{\partial g}{\partial v} = 3u^2v^2\left(\frac{\partial f}{\partial x} - \frac{\partial f}{\partial y}\right) - 3u^2v^2\left(\frac{\partial f}{\partial x} - \frac{\partial f}{\partial y}\right) = 0$$

44. Let $f(x, y) = g(u)$, where $u = x^2 + y^2$ and $g(u)$ is differentiable. Prove that

$$\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2 = 4u\left(\frac{dg}{du}\right)^2$$

SOLUTION We use the Chain Rule and the partial derivatives $\frac{\partial u}{\partial x} = 2x$, $\frac{\partial u}{\partial y} = 2y$, to differentiate the equation $f(x, y, z) = g(u)$ with respect to x and to y. We get

$$\frac{\partial f}{\partial x} = g'(u) \cdot \frac{\partial u}{\partial x} = g'(u) \cdot 2x$$
$$\frac{\partial f}{\partial y} = g'(u) \cdot \frac{\partial u}{\partial y} = g'(u) \cdot 2y$$

Therefore,

$$\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2 = \left(g'(u) \cdot 2x\right)^2 + \left(g'(u) \cdot 2y\right)^2 = 4x^2 g'(u)^2 + 4y^2 g'(u)^2$$
$$= 4\left(x^2 + y^2\right) g'(u)^2 = 4ug'(u)^2$$

Since $\frac{\partial f}{\partial u} = g'(u)$, we find that

$$\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2 = 4u\left(\frac{\partial f}{\partial u}\right)^2$$

45. Calculate $\partial z/\partial x$, where $xe^z + ze^y = x + y$.

SOLUTION The function $F(x, y, z) = xe^z + ze^y - x - y = 0$ defines z implicitly as a function of x and y. Using implicit differentiation, the partial derivative of z with respect to x is

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} \qquad (1)$$

We compute the partial derivatives F_x and F_z:

$$F_x = e^z - 1$$
$$F_z = xe^z + e^y$$

Substituting in (1) gives

$$\frac{\partial z}{\partial x} = -\frac{e^z - 1}{xe^z + e^y}.$$

46. Let $f(x, y) = x^4 - 2x^2 + y^2 - 6y$.

(a) Find the critical points of f and use the Second Derivative Test to determine whether they are a local minima or a local maxima.

(b) Find the minimum value of f without calculus by completing the square.

SOLUTION

(a) To find the critical points of the function $f(x, y) = x^4 - 2x^2 + y^2 - 6y$ we set the partial derivatives equal to zero and solve. This gives

$$\left.\begin{aligned} f_x(x, y) &= 4x^3 - 4x = 4x\left(x^2 - 1\right) = 0 \\ f_y(x, y) &= 2y - 6 = 2(y - 3) = 0 \end{aligned}\right. \quad \Rightarrow \quad x = 0, \quad x = -1, \quad x = 1, \quad y = 3$$

The critical points are $(0, 3)$, $(-1, 3)$, $(1, 3)$. We now apply the Second Derivative Test to examine the critical points. We compute the second-order partials:

$$f_{xx}(x, y) = 12x^2 - 4, \quad f_{yy} = 2, \quad f_{xy} = 0$$

The discriminant is

$$D = f_{xx} f_{yy} - f_{xy}^2 = 2\left(12x^2 - 4\right) = 8\left(3x^2 - 1\right)$$

Substituting the critical points gives

$$\begin{aligned} D(0, 3) &= -8 < 0 \quad \Rightarrow \quad (0, 3) \text{ is a saddle point} \\ D(-1, 3) &= 16 > 0, \quad f_{xx}(-1, 3) = 8 > 0 \quad \Rightarrow \quad f(-1, 3) \text{ is a local minimum} \\ D(1, 3) &= 16 > 0, \quad f_{xx}(1, 3) = 8 > 0 \quad \Rightarrow \quad f(1, 3) \text{ is a local minimum} \end{aligned}$$

(b) Computing the square in x and y, we obtain

$$\begin{aligned} x^4 - 2x^2 + y^2 - 6y &= \left(x^2 - 1\right)^2 - 1 + (y - 3)^2 - 9 \\ &= \left(x^2 - 1\right)^2 + (y - 3)^2 - 10 \end{aligned}$$

This function has a minimum when $x^2 - 1 = 0$ and $y - 3 = 0$, that is, $x = \pm 1$ and $y = 3$. Therefore, the minimum value is -10 obtained at the points $(1, 3)$ and $(-1, 3)$.

In Exercises 47–50, find the critical points of the function and analyze them using the Second Derivative Test.

47. $f(x, y) = x^4 - 4xy + 2y^2$

SOLUTION To find the critical points, we need the first-order partial derivatives and set them equal to zero to solve for x and y:

$$f_x(x, y) = 4x^3 - 4y = 0, \quad f_y(x, y) = -4x + 4y = 0$$

Looking at the second equation we see $x = y$. Using this in the first equation, then

$$4x^3 - 4x = 0 \quad \Rightarrow \quad 4x(x^2 - 1) = 0 \quad \Rightarrow \quad x = 0, \pm 1$$

Therefore, our critical points are:

$$(0, 0), (1, 1), (-1, -1)$$

Now to find the discriminant, D, we need the second-order partial derivatives:

$$f_{xx}(x, y) = 12x^2, \quad f_{yy}(x, y) = 4, \quad f_{xy}(x, y) = -4$$

Hence,

$$D(x, y) = f_{xx} f_{yy} - f{xy}^2 = 48x^2 - 16 = 16(3x^2 - 1)$$

Analyzing our three critical points we see:

$$D(0,0) = -16 < 0, \quad D(1,1) = 32 > 0, \quad D(-1,-1) = 32 > 0$$

Since the discriminant for (0, 0) is negative, (0, 0) is a saddle point.

Looking at $f_{xx}(1,1) = 12 > 0$ and $f_{xx}(-1,-1) = 12 > 0$ hence, the points (1, 1) and (−1, −1) are both local minima.

48. $f(x, y) = x^3 + 2y^3 - xy$

SOLUTION We set the partial derivatives of $f(x, y) = x^3 + 2y^3 - xy$ equal to zero and solve to find the critical points. We get

$$f_x(x, y) = 3x^2 - y = 0$$
$$f_y(x, y) = 6y^2 - x = 0$$

The first equation gives $y = 3x^2$. Substituting in the second equation we get

$$6 \cdot \left(3x^2\right)^2 - x = 0$$
$$54x^4 - x = x \cdot \left(54x^3 - 1\right) = 0$$
$$54x^3 - 1 = 0 \quad \Rightarrow \quad x_1 = 0, \quad x_2 = 0.26$$

The corresponding y-coordinates are obtained from $y = 3x^2$. That is,

$$y_1 = 0, \quad y_2 = 3 \cdot 0.26^2 = 0.2$$

There are two critical points, (0, 0) and (0.26, 0.2). We next use the Second Derivative Test to examine the critical points. We compute the second-order partials at these points:

$$\begin{array}{lclll} f_{xx}(x,y) = 6x & & f_{xx}(0,0) = 0 & f_{xx}(0.26, 0.2) = 1.56 \\ f_{yy}(x,y) = 12y & \Rightarrow & f_{yy}(0,0) = 0 & f_{yy}(0.26, 0.2) = 2.4 \\ f_{xy}(x,y) = -1 & & f_{xy}(0,0) = -1 & f_{xy}(0.26, 0.2) = -1 \end{array}$$

We compute the discriminant at the critical points:

$$D(0,0) = f_{xx} \cdot f_{yy} - f_{xy}^2 = -1 < 0$$
$$D(0.26, 0.2) = f_{xx} \cdot f_{yy} - f_{xy}^2 = 1.56 \cdot 2.4 - 1 > 0, \quad f_{xx}(0.26, 0.2) > 0$$

We conclude that (0, 0) is a saddle point, whereas at (0.26, 0.2) the function has a local minimum.

49. $f(x, y) = e^{x+y} - xe^{2y}$

SOLUTION We find the critical point by setting the partial derivatives of $f(x, y) = e^{x+y} - xe^{2y}$ equal to zero and solve. This gives

$$f_x(x, y) = e^{x+y} - e^{2y} = 0$$
$$f_y(x, y) = e^{x+y} - 2xe^{2y} = 0$$

The first equation gives $e^{x+y} = e^{2y}$ and the second equation gives $e^{x+y} = 2xe^{2y}$. Equating the two expressions, dividing by the nonzero function e^{2y}, and solving for x, we obtain

$$e^{2y} = 2xe^{2y} \quad \Rightarrow \quad 1 = 2x \quad \Rightarrow \quad x = \frac{1}{2}$$

We now substitute $x = \frac{1}{2}$ in the first equation and solve for y, to obtain

$$e^{\frac{1}{2}+y} - e^{2y} = 0 \quad \Rightarrow \quad e^{\frac{1}{2}+y} = e^{2y} \quad \Rightarrow \quad \frac{1}{2} + y = 2y \quad \Rightarrow \quad y = \frac{1}{2}$$

There is one critical point, $\left(\frac{1}{2}, \frac{1}{2}\right)$. We examine the critical point using the Second Derivative Test. We compute the second derivatives at this point:

$$f_{xx}(x, y) = e^{x+y} \quad \Rightarrow \quad f_{xx}\left(\frac{1}{2}, \frac{1}{2}\right) = e^{\frac{1}{2}+\frac{1}{2}} = e$$

$$f_{yy}(x, y) = e^{x+y} - 4xe^{2y} \quad \Rightarrow \quad f_{yy}\left(\frac{1}{2}, \frac{1}{2}\right) = e^{\frac{1}{2}+\frac{1}{2}} - 4 \cdot \frac{1}{2}e^{2\cdot\frac{1}{2}} = -e$$

$$f_{xy}(x, y) = e^{x+y} - 2e^{2y} \quad \Rightarrow \quad f_{xy}\left(\frac{1}{2}, \frac{1}{2}\right) = e^{\frac{1}{2}+\frac{1}{2}} - 2e^{2\cdot\frac{1}{2}} = -e$$

Therefore the discriminant at the critical point is

$$D\left(\frac{1}{2},\frac{1}{2}\right) = f_{xx}f_{yy} - f_{xy}^2 = e\cdot(-e) - (-e)^2 = -2e^2 < 0$$

We conclude that $\left(\frac{1}{2},\frac{1}{2}\right)$ is a saddle point.

50. $f(x,y) = \sin(x+y) - \dfrac{1}{2}(x+y^2)$

SOLUTION We find the critical points by setting the partial derivatives of $f(x,y) = \sin(x+y) - 0.5\left(x+y^2\right)$ equal to zero and solve. We get

$$f_x(x,y) = \cos(x+y) - \frac{1}{2} = 0$$
$$f_y(x,y) = \cos(x+y) - y = 0$$

By the second equation $y = \cos(x+y)$. Substituting in the first equation gives $y - \frac{1}{2} = 0$ or $y = \frac{1}{2}$. We set $y = \frac{1}{2}$ in the first equation and solve for x, to obtain

$$\cos\left(x+\frac{1}{2}\right) - \frac{1}{2} = 0$$
$$\cos\left(x+\frac{1}{2}\right) = \frac{1}{2}$$

The general solution is

$$x + \frac{1}{2} = \pm\frac{\pi}{3} + 2\pi k \quad \Rightarrow \quad x = -\frac{1}{2} \pm \frac{\pi}{3} + 2\pi k$$

The critical points are thus

$$P_k = \left(-\frac{1}{2} + \frac{\pi}{3} + 2\pi k, \frac{1}{2}\right), \quad Q_k = \left(-\frac{1}{2} - \frac{\pi}{3} + 2\pi k, \frac{1}{2}\right)$$

We examine the critical points using the Second Derivative Test. We first compute the second-order partials at the critical points:

$$f_{xx}(x,y) = -\sin(x+y) \quad \Rightarrow \quad f_{xx}(P_k) = -\sin\left(\frac{\pi}{3} + 2\pi k\right) = -\frac{\sqrt{3}}{2}$$
$$f_{xx}(Q_k) = -\sin\left(-\frac{\pi}{3} + 2\pi k\right) = \frac{\sqrt{3}}{2}$$
$$f_{yy}(x,y) = -\sin(x+y) - 1 \quad \Rightarrow \quad f_{yy}(P_k) = -\frac{\sqrt{3}}{2} - 1$$
$$f_{yy}(Q_k) = \frac{\sqrt{3}}{2} - 1$$
$$f_{xy}(x,y) = -\sin(x+y) \quad \Rightarrow \quad f_{xy}(P_k) = -\frac{\sqrt{3}}{2}$$
$$f_{xy}(Q_k) = \frac{\sqrt{3}}{2}$$

We compute the discriminant $D = f_{xx}f_{yy} - f_{xy}^2$ at the critical points:

$$D(P_k) = \left(-\frac{\sqrt{3}}{2}\right)\cdot\left(-\frac{\sqrt{3}}{2} - 1\right) - \left(-\frac{\sqrt{3}}{2}\right)^2 = \frac{\sqrt{3}}{2} > 0, \quad f_{xx}(P_k) = -\frac{\sqrt{3}}{2} < 0$$
$$D(Q_k) = \frac{\sqrt{3}}{2}\left(\frac{\sqrt{3}}{2} - 1\right) - \left(\frac{\sqrt{3}}{2}\right)^2 = -\frac{\sqrt{3}}{2} < 0$$

We conclude that $Q_k = \left(-\frac{1}{2} - \frac{\pi}{3} + 2\pi k, \frac{1}{2}\right)$ are saddle points, and at the points $P_k = \left(-\frac{1}{2} + \frac{\pi}{3} + 2\pi k, \frac{1}{2}\right)$ the function has local maxima.

51. Prove that $f(x, y) = (x + 2y)e^{xy}$ has no critical points.

SOLUTION We find the critical points by setting the partial derivatives of $f(x, y) = (x + 2y)e^{xy}$ equal to zero and solving. We get

$$f_x(x, y) = e^{xy} + (x + 2y)ye^{xy} = e^{xy}\left(1 + xy + 2y^2\right) = 0$$

$$f_y(x, y) = 2e^{xy} + (x + 2y)xe^{xy} = e^{xy}\left(2 + x^2 + 2xy\right) = 0$$

We divide the two equations by the nonzero expression e^{xy} to obtain the following equations:

$$1 + xy + 2y^2 = 0$$
$$2 + 2xy + x^2 = 0$$

The first equation implies that $xy = -1 - 2y^2$. Substituting in the second equation gives

$$\begin{aligned} 2 + 2\left(-1 - 2y^2\right) + x^2 &= 0 \\ 2 - 2 - 4y^2 + x^2 &= 0 \\ x^2 = 4y^2 \quad &\Rightarrow \quad x = 2y \quad \text{or} \quad x = -2y \end{aligned}$$

We substitute in the first equation and solve for y:

$$\begin{array}{cc} x = 2y & x = -2y \\ \hline 1 + 2y^2 + 2y^2 = 0 & 1 - 2y^2 + 2y^2 = 0 \\ 1 + 4y^2 = 0 & 1 = 0 \\ y^2 = -\frac{1}{4} & \end{array}$$

In both cases there is no solution. We conclude that there are no solutions for $f_x = 0$ and $f_y = 0$, that is, there are no critical points.

52. Find the global extrema of $f(x, y) = x^3 - xy - y^2 + y$ on the square $[0, 1] \times [0, 1]$.

SOLUTION

Step 1. Examine the critical points. We set the partial derivatives of $f(x, y) = x^3 - xy - y^2 + y$ equal to zero and solve to find the critical points in the interior of the square.

$$f_x(x, y) = 3x^2 - y = 0$$
$$f_y(x, y) = -x - 2y + 1 = 0$$

The first equation gives $y = 3x^2$. We substitute in the second equation and solve for x.

$$\begin{aligned} &-x - 2 \cdot 3x^2 + 1 = 0 \\ &6x^2 + x - 1 = 0 \\ &x_{1,2} = \frac{-1 \pm \sqrt{1 + 24}}{12} = \frac{-1 \pm 5}{12} \quad \Rightarrow \quad x_1 = -\frac{1}{2}, \quad x_2 = \frac{1}{3} \end{aligned}$$

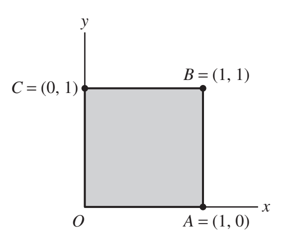
The corresponding y-coordinates are determined by $y = 3x^2$. That is,

$$y_1 = 3 \cdot \left(-\frac{1}{2}\right)^2 = \frac{3}{4}, \quad y_2 = 3 \cdot \left(\frac{1}{3}\right)^2 = \frac{1}{3}$$

Therefore, the critical points are

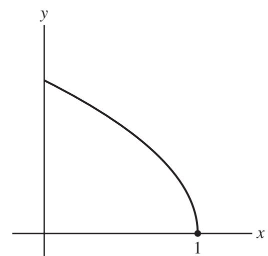
$$\left(-\frac{1}{2}, \frac{3}{4}\right), \quad \left(\frac{1}{3}, \frac{1}{3}\right)$$

Step 2. Find the global extrema on the boundary.



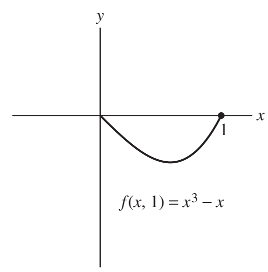
We consider each part of the boundary separately.

The segment $\overline{OA}$: On this segment $y = 0$, $0 \le x \le 1$, hence $f(x, 0) = x^3$. The maximum value occurs at $x = 1$ and the minimum value occurs at $x = 0$. The corresponding points are $(0, 0)$ and $(1, 0)$.
The segment $\overline{AB}$: On this segment $x = 1$, $0 \le y \le 1$, hence $f(1, y) = 1 - y - y^2 + y = 1 - y^2$.



$f(1, y) = 1 - y^2$

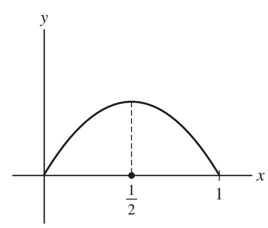
The maximum value in the interval $0 \le y \le 1$ occurs at $y = 0$, and the minimum value occurs at $y = 1$. The corresponding points on the boundary of the square are $(1, 0)$ and $(1, 1)$.
The segment $\overline{BC}$: On this segment $y = 1$, $0 \le x \le 1$, hence $f(x, 1) = x^3 - x - 1 + 1 = x^3 - x$.



Using calculus of one variable and referring to the graph of $f(x, 1)$, we see that the maximum value occurs at $x = 0$ and $x = 1$ and the minimum value occurs at $x = \frac{1}{\sqrt{3}}$. The corresponding points on the segment $\overline{BC}$ are

$$\left(\frac{1}{\sqrt{3}}, 1\right), \quad (0, 1), \quad \text{and} \quad (1, 1)$$

The segment $\overline{OC}$: On this segment $x = 0$, $0 \le y \le 1$, hence $f(0, y) = -y^2 + y$.



$f(0, y) = -y^2 + y$

The maximum value occurs at $y = \frac{1}{2}$ and the minimum value occurs at $y = 0$ and $y = 1$. The corresponding points on the segment $\overline{OC}$ are

$$\left(0, \frac{1}{2}\right), \quad (0, 0), \quad (0, 1)$$

Step 3. Conclusions. Since the global extrema occur either at critical points in the interior of the region or on the boundary of the region, the candidates for global extrema are the following points:

$$\left(-\frac{1}{2}, \frac{3}{4}\right), \quad \left(\frac{1}{3}, \frac{1}{3}\right), \quad (0, 0), \quad (1, 0), \quad (1, 1), \quad (0, 1), \quad \left(0, \frac{1}{2}\right), \quad \left(\frac{1}{\sqrt{3}}, 1\right)$$

We compute $f(x, y) = x^3 - xy - y^2 + y$ at these points:

$$f\left(-\frac{1}{2}, \frac{3}{4}\right) = \left(-\frac{1}{2}\right)^3 + \frac{1}{2} \cdot \frac{3}{4} - \left(\frac{3}{4}\right)^2 + \frac{3}{4} = \frac{7}{16} \approx 0.437$$

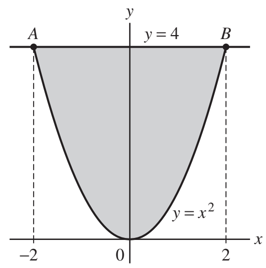
$$f\left(\frac{1}{3}, \frac{1}{3}\right) = \left(\frac{1}{3}\right)^3 - \frac{1}{3} \cdot \frac{1}{3} - \left(\frac{1}{3}\right)^2 + \frac{1}{3} = \frac{4}{27} \approx 0.148$$

$$f(0,0)=0$$
$$f(1,0)=1$$
$$f(1,1)=1-1-1+1=0$$
$$f(0,1)=-1^2+1=0$$
$$f\left(0,\frac{1}{2}\right)=-\left(\frac{1}{2}\right)^2+\frac{1}{2}=\frac{1}{4}$$
$$f\left(\frac{1}{\sqrt{3}},1\right)=\left(\frac{1}{\sqrt{3}}\right)^3-\frac{1}{\sqrt{3}}-1+1=-\frac{2\sqrt{3}}{9}=-0.38$$

We conclude that the maximum value of f on the square is $f(1,0)=1$ and the minimum value is $f\left(\frac{1}{\sqrt{3}},1\right)=-0.38$.

53. Find the global extrema of $f(x,y)=2xy-x-y$ on the domain $\{y\le 4, y\ge x^2\}$.

SOLUTION The region is shown in the figure.



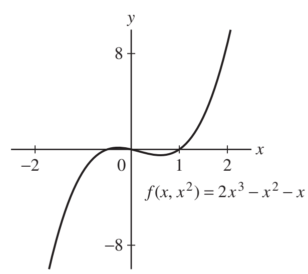
Step 1. Finding the critical points. We find the critical points in the interior of the domain by setting the partial derivatives equal to zero and solving. We get

$$f_x=2y-1=0$$
$$f_y=2x-1=0 \quad\Rightarrow\quad x=\frac{1}{2},\quad y=\frac{1}{2}$$

The critical point is $\left(\frac{1}{2},\frac{1}{2}\right)$. (It lies in the interior of the domain since $\frac{1}{2}<4$ and $\frac{1}{2}>\left(\frac{1}{2}\right)^2$).

Step 2. Finding the global extrema on the boundary. We consider the two parts of the boundary separately.

The parabola $y=x^2$, $-2\le x\le 2$:



On this curve, $f(x,x^2)=2\cdot x\cdot x^2-x-x^2=2x^3-x^2-x$. Using calculus in one variable or the graph of the function, we see that the minimum of $f(x,x^2)$ on the interval occurs at $x=-2$ and the maximum at $x=2$. The corresponding points are $(-2,4)$ and $(2,4)$.

The segment $\overline{AB}$: On this segment $y=4$, $-2\le x\le 2$, hence $f(x,4)=2\cdot x\cdot 4-x-4=7x-4$. The maximum value occurs at $x=2$ and the minimum value at $x=-2$. The corresponding points on the segment $\overline{AB}$ are $(-2,4)$ and $(2,4)$

Step 3. Conclusions. Since the global extrema occur either at critical points in the interior of the domain or on the boundary of the domain, the candidates for global extrema are the following points:

$$\left(\frac{1}{2},\frac{1}{2}\right),\quad (-2,4),\quad (2,4)$$

We compute the values of $f=2xy-x-y$ at these points:

$$f\left(\frac{1}{2},\frac{1}{2}\right)=2\cdot\frac{1}{2}\cdot\frac{1}{2}-\frac{1}{2}-\frac{1}{2}=-\frac{1}{2}$$

$$f(-2,4) = 2 \cdot (-2) \cdot 4 + 2 - 4 = -18$$
$$f(2,4) = 2 \cdot 2 \cdot 4 - 2 - 4 = 10$$

We conclude that the global maximum is $f(2,4) = 10$ and the global minimum is $f(-2,4) = -18$.

54. Find the maximum of $f(x,y,z) = xyz$ subject to the constraint $g(x,y,z) = 2x + y + 4z = 1$.

SOLUTION

Step 1. Write out the Lagrange Equations. We have $\nabla f = \langle yz, xz, xy \rangle$ and $\nabla g = \langle 2, 1, 4 \rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ is

$$\langle yz, xz, xy \rangle = \lambda \langle 2, 1, 4 \rangle$$

or

$$yz = 2\lambda, \quad xz = \lambda, \quad xy = 4\lambda$$

Step 2. Solve for λ in terms of x, y, and z. The Lagrange equations imply that

$$\lambda = \frac{yz}{2}, \quad \lambda = xz, \quad \lambda = \frac{xy}{4}$$

Step 3. Solve for x, y, and z using the constraint. Equating the expressions for λ gives the following equations:

$$\begin{aligned} \frac{yz}{2} &= xz \\ \frac{xy}{4} &= xz \end{aligned} \quad \Rightarrow \quad \begin{aligned} z(2x - y) &= 0 \\ x(4z - y) &= 0 \end{aligned}$$

The first equation implies that $z = 0$ or $y = 2x$. The second equation implies that $x = 0$ or $y = 4z$. We examine all possible solutions.

(1) $z = 0$ and $x = 0$: Then substituting in the constraint $2x + y + 4z = 1$ gives $2 \cdot 0 + y + 4 \cdot 0 = 1$ or $y = 1$. We obtain the point $(0, 1, 0)$.

(2) $z = 0$ and $y = 4z$: Then $y = 4 \cdot 0 = 0$. Substituting $z = 0$ and $y = 0$ in the constraint $2x + y + 4z = 1$ gives $2x + 0 + 4 \cdot 0 = 1$ or $x = \frac{1}{2}$. We obtain the point $\left(\frac{1}{2}, 0, 0\right)$.

(3) $y = 2x$ and $x = 0$: Then $y = 2 \cdot 0 = 0$. Substituting $x = y = 0$ in the constraint $2x + y + 4z = 1$ gives $2 \cdot 0 + 0 + 4z = 1$ or $z = \frac{1}{4}$. The corresponding point is $\left(0, 0, \frac{1}{4}\right)$.

(4) $y = 2x$, $y = 4z$: Then $x = \frac{y}{2}$ and $z = \frac{y}{4}$. We substitute in the constraint $2x + y + 4z = 1$ and solve for y:

$$2 \cdot \frac{y}{2} + y + 4 \cdot \frac{y}{4} = 1$$
$$3y = 1 \quad \Rightarrow \quad y = \frac{1}{3}$$

Hence, $x = \frac{y}{2} = \frac{1}{6}$, $z = \frac{y}{4} = \frac{1}{12}$. We obtain the point $\left(\frac{1}{6}, \frac{1}{3}, \frac{1}{12}\right)$.

Step 4. Conclusions. We evaluate $f(x,y,z) = xyz$ at the critical points:

$$f(0,1,0) = 0 \cdot 1 \cdot 0 = 0$$
$$f\left(\frac{1}{2}, 0, 0\right) = \frac{1}{2} \cdot 0 \cdot 0 = 0$$
$$f\left(\frac{1}{6}, \frac{1}{3}, \frac{1}{12}\right) = \frac{1}{6} \cdot \frac{1}{3} \cdot \frac{1}{12} = \frac{1}{216}$$
$$f\left(0, 0, \frac{1}{4}\right) = 0 \cdot 0 \cdot \frac{1}{4} = 0$$

We conclude that the local maximum of f subject to the constraint is

$$f\left(\frac{1}{6}, \frac{1}{3}, \frac{1}{12}\right) = \frac{1}{216}.$$

Notice that f does not have a global maximum on the plane $2x + y + 4z = 1$ since, for all t, the point $\left(-t^2, 1 + 6t^2, -t^2\right)$ is on the plane and we have

$$\lim_{t\to\infty} f\left(-t^2, 1 + 6t^2, -t^2\right) = \lim_{t\to\infty} t^4 \left(1 + 6t^2\right) = \infty$$

55. Use Lagrange multipliers to find the minimum and maximum values of $f(x, y) = 3x - 2y$ on the circle $x^2 + y^2 = 4$.

SOLUTION

Step 1. Write out the Lagrange Equations. The constraint curve is $g(x, y) = x^2 + y^2 - 4 = 0$, hence $\nabla g = \langle 2x, 2y\rangle$ and $\nabla f = \langle 3, -2\rangle$. The Lagrange Condition $\nabla f = \lambda \nabla g$ is thus $\langle 3, -2\rangle = \lambda \langle 2x, 2y\rangle$. That is,

$$3 = \lambda \cdot 2x$$
$$-2 = \lambda \cdot 2y$$

Note that $\lambda \neq 0$.

Step 2. Solve for x and y using the constraint. The Lagrange equations gives

$$\begin{aligned} 3 &= \lambda \cdot 2x \\ -2 &= \lambda \cdot 2y \end{aligned} \quad \Rightarrow \quad \begin{aligned} x &= \frac{3}{2\lambda} \\ y &= -\frac{1}{\lambda} \end{aligned} \tag{1}$$

We substitute x and y in the equation of the constraint and solve for λ. We get

$$\left(\frac{3}{2\lambda}\right)^2 + \left(-\frac{1}{\lambda}\right)^2 = 4$$
$$\frac{9}{4\lambda^2} + \frac{1}{\lambda^2} = 4$$
$$\frac{1}{\lambda^2} \cdot \frac{13}{4} = 4 \quad \Rightarrow \quad \lambda = \frac{\sqrt{13}}{4} \quad \text{or} \quad \lambda = -\frac{\sqrt{13}}{4}$$

Substituting in (1), we obtain the points

$$x = \frac{6}{\sqrt{13}}, \quad y = -\frac{4}{\sqrt{13}}$$
$$x = -\frac{6}{\sqrt{13}}, \quad y = \frac{4}{\sqrt{13}}$$

The critical points are thus

$$P_1 = \left(\frac{6}{\sqrt{13}}, -\frac{4}{\sqrt{13}}\right)$$
$$P_2 = \left(-\frac{6}{\sqrt{13}}, \frac{4}{\sqrt{13}}\right)$$

Step 3. Calculate the value at the critical points. We find the value of $f(x, y) = 3x - 2y$ at the critical points:

$$f(P_1) = 3 \cdot \frac{6}{\sqrt{13}} - 2 \cdot \frac{-4}{\sqrt{13}} = \frac{26}{\sqrt{13}}$$
$$f(P_2) = 3 \cdot \frac{-6}{\sqrt{13}} - 2 \cdot \frac{4}{\sqrt{13}} = \frac{-26}{\sqrt{13}}$$

Thus, the maximum value of f on the circle is $\frac{26}{\sqrt{13}}$, and the minimum is $-\frac{26}{\sqrt{13}}$.

56. Find the minimum value of $f(x, y) = xy$ subject to the constraint $5x - y = 4$ in two ways: using Lagrange multipliers and setting $y = 5x - 4$ in $f(x, y)$.

SOLUTION We find the minimum value of $f(x, y) = xy$ subject to the constraint $g(x, y) = 5x - y - 4 = 0$ using the Lagrange multipliers.

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \langle y, x\rangle$ and $\nabla g = \langle 5, -1\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ is

$$\langle y, x\rangle = \lambda \langle 5, -1\rangle$$
$$\langle y, x\rangle = \langle 5\lambda, -\lambda\rangle$$

The Lagrange Equations are thus

$$\begin{aligned} y &= 5\lambda \\ x &= -\lambda \end{aligned} \quad \Rightarrow \quad \lambda = \frac{y}{5}, \quad \lambda = -x$$

Step 2. Solve for x and y using the constraint. Equating the two expressions for λ gives

$$\frac{y}{5} = -x \quad \Rightarrow \quad y = -5x$$

We substitute $y = -5x$ in the equation of the constraint $5x - y = 4$ and solve for x. This gives

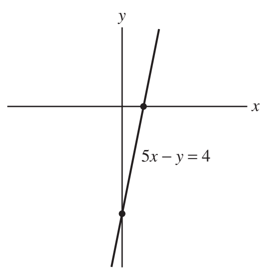
$$\begin{aligned} 5x - (-5x) &= 4 \\ 10x &= 4 \end{aligned} \quad \Rightarrow \quad x = \frac{2}{5}$$

The y-coordinate is $y = -5 \cdot \frac{2}{5} = -2$. We obtain the critical point $\left(\frac{2}{5}, -2\right)$.

Step 3. Calculate the value at the critical point. The value of $f(x, y) = xy$ at the critical point is

$$f\left(\frac{2}{5}, -2\right) = \frac{2}{5} \cdot (-2) = -\frac{4}{5} \tag{1}$$

This value is the minimum value of f subject to the constraint:



Note that since $f(x, y) = xy$ is positive in the first and third quadrant, the minimum value of f subject to the constraint's part in the fourth quadrant is also the minimum value subject to the entire constraint. The part of the constraint in the fourth quadrant is a closed and bounded segment, hence the minimum value of f on this segment exists, and is given in (1).

We now find the minimum value of $f(x, y) = xy$ subject to the constraint $5x - y = 4$ using the second way. On the constraint $5x - y = 4$, we have $y = 5x - 4$. We substitute in the function $f(x, y) = xy$ and then find the minimum of the resulting one-variable function. We get

$$g(x) = f(x, 5x - 4) = x(5x - 4) = 5x^2 - 4x$$

We now find the minimum value of $g(x) = 5x^2 - 4x$ in the interval $-\infty < x < \infty$. We find the critical points:

$$g'(x) = 10x - 4 = 0 \quad \Rightarrow \quad x = \frac{2}{5}$$

The limits

$$\lim_{x\to\infty} g(x) = \lim_{x\to\infty} \left(5x^2 - 4x\right) = \infty \quad \text{and} \quad \lim_{x\to-\infty} g(x) = \lim_{x\to-\infty} \left(5x^2 - 4x\right) = \infty$$

imply that g has a minimum value for $-\infty < x < \infty$, and it occurs at the critical point. Therefore, the minimum value of g occurs at $x = \frac{2}{5}$. The corresponding y-coordinate is $y = 5 \cdot \frac{2}{5} - 4 = -2$, therefore the minimum value of $f(x, y) = xy$ is

$$f\left(\frac{2}{5}, -2\right) = \frac{2}{5} \cdot (-2) = -\frac{4}{5}$$

57. Find the minimum and maximum values of $f(x, y) = x^2y$ on the ellipse $4x^2 + 9y^2 = 36$.

SOLUTION We must find the minimum and maximum values of $f(x, y) = x^2y$ subject to the constraint $g(x, y) = 4x^2 + 9y^2 - 36 = 0$.

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \left\langle 2xy, x^2 \right\rangle$ and $\nabla g = \langle 8x, 18y\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives

$$\left\langle 2xy, x^2 \right\rangle = \lambda \langle 8x, 18y\rangle = \langle 8\lambda x, 18\lambda y\rangle$$

We obtain the following Lagrange Equations:

$$\begin{aligned} 2xy &= 8\lambda x \\ x^2 &= 18\lambda y \end{aligned}$$

Step 2. Solve for λ in terms of x and y. If $x = 0$, the equation of the constraint implies that $y = \pm 2$. The points $(0, 2)$ and $(0, -2)$ satisfy the Lagrange Equations for $\lambda = 0$. If $x \neq 0$, the second Lagrange Equation implies that $y \neq 0$. Therefore the Lagrange Equations give

$$2xy = 8\lambda x \quad \Rightarrow \quad \lambda = \frac{y}{4}$$
$$x^2 = 18\lambda y \quad \Rightarrow \quad \lambda = \frac{x^2}{18y}$$

Step 3. Solve for x and y using the constraint. We equate the two expressions for λ to obtain

$$\frac{y}{4} = \frac{x^2}{18y}$$
$$18y^2 = 4x^2$$

We now substitute $4x^2 = 18y^2$ in the equation of the constraint $4x^2 + 9y^2 = 36$ and solve for y. This gives

$$\begin{aligned} 18y^2 + 9y^2 &= 36 \\ 27y^2 &= 36 \end{aligned} \quad \Rightarrow \quad y^2 = \frac{36}{27} \quad \Rightarrow \quad y_1 = \frac{2}{\sqrt{3}}, \quad y_2 = -\frac{2}{\sqrt{3}}$$

We find the x-coordinates using $x^2 = \frac{9y^2}{2}$:

$$x^2 = \frac{9y^2}{2}$$
$$x^2 = \frac{9}{2} \cdot \frac{4}{3} = 6 \quad \Rightarrow \quad x_1 = \sqrt{6}, \quad x_2 = -\sqrt{6}$$

We obtain the following critical points:

$$P_1 = (0, 2), \quad P_2 = (0, -2), \quad P_3 = \left(\sqrt{6}, \frac{2}{\sqrt{3}}\right)$$
$$P_4 = \left(\sqrt{6}, -\frac{2}{\sqrt{3}}\right), \quad P_5 = \left(-\sqrt{6}, \frac{2}{\sqrt{3}}\right), \quad P_6 = \left(-\sqrt{6}, -\frac{2}{\sqrt{3}}\right)$$

Step 4. Conclusions. We evaluate the function $f(x, y) = x^2 y$ at the critical points:

$$f(P_1) = 0^2 \cdot 2 = 0$$
$$f(P_2) = 0^2 \cdot (-2) = 0$$
$$f(P_3) = f(P_5) = 6 \cdot \frac{2}{\sqrt{3}} = \frac{12}{\sqrt{3}}$$
$$f(P_4) = f(P_5) = 6 \cdot \left(-\frac{2}{\sqrt{3}}\right) = -\frac{12}{\sqrt{3}}$$

Since the min and max of f occur on the ellipse, it must occur at critical points. Thus, we conclude that the maximum and minimum of f subject to the constraint are $\frac{12}{\sqrt{3}}$ and $-\frac{12}{\sqrt{3}}$ respectively.

58. Find the point in the first quadrant on the curve $y = x + x^{-1}$ closest to the origin.

SOLUTION We need to minimize the distance $d = \sqrt{x^2 + y^2}$ subject to the constraint $g(x, y) = x + \frac{1}{x} - y = 0$. Since the function u^2 is increasing for $u \geq 0$, the distance d is minimal where the square d^2 is minimal. Therefore, we minimize the function $f(x, y) = d^2 = x^2 + y^2$ subject to the constraint.

Step 1. Write out the Lagrange Equations. The gradient vectors are $\nabla f = \langle 2x, 2y \rangle$ and $\nabla g = \left\langle 1 - \frac{1}{x^2}, -1 \right\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives

$$\langle 2x, 2y \rangle = \lambda \left\langle 1 - \frac{1}{x^2}, -1 \right\rangle = \left\langle \lambda \left(1 - \frac{1}{x^2}\right), -\lambda \right\rangle$$

The Lagrange Equations are

$$2x = \lambda \left(1 - \frac{1}{x^2}\right)$$
$$2y = -\lambda$$

Step 2. Solve for λ in terms of x and y. The second Lagrange equation gives $\lambda = -2y$, and the first equation gives

$$2x = \lambda \frac{x^2 - 1}{x^2} \quad \Rightarrow \quad \lambda = \frac{2x^3}{x^2 - 1}$$

Step 3. Solve for x and y using the constraint. Equating the two expressions for λ, we get

$$-2y = \frac{2x^3}{x^2 - 1} \quad \Rightarrow \quad y = \frac{x^3}{1 - x^2}$$

We now substitute y as a function of x in the equation of the constraint and solve for x. This gives

$$\frac{x^3}{1 - x^2} = x + \frac{1}{x} = \frac{x^2 + 1}{x}$$

$$x^4 = \left(1 - x^2\right)\left(1 + x^2\right) = 1 - x^4$$

$$2x^4 = 1 \quad \Rightarrow \quad x = 2^{-1/4}, \quad x = -2^{-1/4}$$

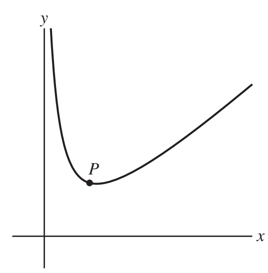
The solution in the first quadrant is $x = 2^{-1/4} = \frac{1}{\sqrt[4]{2}}$. We find the y-coordinate using $y = \frac{x^3}{1-x^2}$:

$$y = \frac{2^{-3/4}}{1 - 2^{-1/2}} = \frac{2^{-1/4}}{2^{1/2} - 1} = 2^{-1/4}\left(2^{1/2} + 1\right) = 2^{1/4} + 2^{-1/4} = \sqrt[4]{2} + \frac{1}{\sqrt[4]{2}}$$

We obtain the critical point:

$$P = \left(\frac{1}{\sqrt[4]{2}}, \sqrt[4]{2} + \frac{1}{\sqrt[4]{2}}\right)$$

Step 4. Conclusion.



Graph of $y = x + \frac{1}{x}$, $x > 0$, $y > 0$

It is clear from the graph of $y = x + \frac{1}{x}$ that the critical point is a minimum. Therefore, the point P is the closest to the origin on the curve $y = x + \frac{1}{x}$ in the first quadrant.

59. Find the extreme values of $f(x, y, z) = x + 2y + 3z$ subject to the two constraints $x + y + z = 1$ and $x^2 + y^2 + z^2 = 1$.

SOLUTION We must find the extreme values of $f(x, y, z) = x + 2y + 3z$ subject to the constraints $g(x, y, z) = x + y + z - 1 = 0$ and $h(x, y, z) = x^2 + y^2 + z^2 - 1 = 0$.

Step 1. Write out the Lagrange Equations. We have $\nabla f = < 1, 2, 3 >$, $\nabla g = < 1, 1, 1 >$, $\nabla h = < 2x, 2y, 2z >$, hence the Lagrange condition $\nabla f = \lambda \nabla g + \mu \nabla h$ gives

$$< 1, 2, 3 > = \lambda < 1, 1, 1 > + \mu < 2x, 2y, 2z > = < \lambda + 2\mu x, \lambda + 2\mu y, \lambda + 2\mu z >$$

or

$$1 = \lambda + 2\mu x$$
$$2 = \lambda + 2\mu y$$
$$3 = \lambda + 2\mu z$$

Step 2. Solve for λ and μ. The Lagrange Equations give

$$\begin{aligned} 1 &= \lambda + 2\mu x & & \lambda = 1 - 2\mu x \\ 2 &= \lambda + 2\mu y & \Rightarrow \quad & \lambda = 2 - 2\mu y \\ 3 &= \lambda + 2\mu z & & \lambda = 3 - 2\mu z \end{aligned}$$

Equating the three expressions for λ, we get the following equations:

$$\begin{aligned} 1-2\mu x &= 2-2\mu y \\ 1-2\mu x &= 3-2\mu z \end{aligned} \quad\Rightarrow\quad \begin{aligned} 2\mu(y-x) &= 1 \\ \mu(z-x) &= 2 \end{aligned}$$

The first equation implies that $\mu = \frac{1}{2(y-x)}$, and the second implies that $\mu = \frac{2}{z-x}$. Equating the two expressions for μ, we get

$$\frac{1}{2(y-x)} = \frac{2}{z-x}$$
$$z-x = 4y-4x \quad\Rightarrow\quad z = 4y-3x$$

Step 3. Solve for x, y, and z using the constraints. We substitute $z = 4y-3x$ in the equations of the constraints and solve to find x and y. This gives

$$\begin{aligned} x+y+(4y-3x) &= 1 \\ x^2+y^2+(4y-3x)^2 &= 1 \end{aligned} \quad\Rightarrow\quad \begin{aligned} y &= \frac{1+2x}{5} \\ 10x^2+17y^2-24xy &= 1 \end{aligned}$$

Substituting in the second equation and solving for x, we get

$$y = \frac{1+2x}{5}$$
$$10x^2+17\left(\frac{1+2x}{5}\right)^2 - 24x\cdot\frac{1+2x}{5} = 1$$
$$250x^2+17(1+2x)^2-120x\,(1+2x) = 25$$
$$39x^2-26x-4 = 0$$
$$x_{1,2} = \frac{26\pm\sqrt{1300}}{78}$$
$$\Rightarrow\quad x_1 = \frac{1}{3}+\frac{5\sqrt{13}}{39} \approx 0.8, \quad x_2 = \frac{1}{3}-\frac{5\sqrt{13}}{39} \approx -0.13$$

We find the y-coordinates using $y = \frac{1+2x}{5}$.

$$y_1 = \frac{1+2\cdot 0.8}{5} = 0.52, \quad y_2 = \frac{1-2\cdot 0.13}{5} = 0.15$$

Finally, we find the z-coordinate using $z = 4y-3x$:

$$z_1 = 4\cdot 0.52 - 3\cdot 0.8 = -0.32, \quad z_2 = 4\cdot 0.15 + 3\cdot 0.13 = 0.99$$

We obtain the critical points:

$$P_1 = (0.8, 0.52, -0.32), \quad P_2 = (-0.13, 0.15, 0.99)$$

.

Step 4. Conclusions. We evaluate the function $f(x,y,z) = x+2y+3z$ at the critical points:

$$f(P_1) = 0.8 + 2\cdot 0.52 - 3\cdot 0.32 = 0.88$$
$$f(P_2) = -0.13 + 2\cdot 0.15 + 3\cdot 0.99 = 3.14 \qquad (1)$$

The two constraints determine the common points of the unit sphere $x^2+y^2+z^2 = 1$ and the plane $x+y+z = 1$. This set is a circle that is a closed and bounded set in R^3. Therefore, f has a minimum and maximum values on this set. These extrema are given in (1).

60. Find the minimum and maximum values of $f(x,y,z) = x-z$ on the intersection of the cylinders $x^2+y^2 = 1$ and $x^2+z^2 = 1$ (Figure 5).

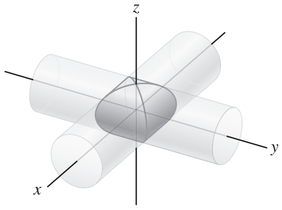


FIGURE 5

SOLUTION Let us use the Lagrange Multipliers method with two constraints for $f(x, y, z) = x - z$ subject to $g(x, y, z) = x^2 + y^2 - 1 = 0$ and $h(x, y, z) = x^2 + z^2 - 1 = 0$. The Lagrange condition would be $\nabla f = \lambda \nabla g + \mu \nabla h$. Noting here that we have $\nabla f = \langle 1, 0, -1 \rangle$, $\nabla g = \langle 2x, 2y, 0 \rangle$, and $\nabla h = \langle 2x, 0, 2z \rangle$. Therefore we have

$$\langle 1, 0, -1 \rangle = \lambda \langle 2x, 2y, 0 \rangle + \mu \langle 2x, 0, 2z \rangle$$

yielding the equations:

$$1 = 2\lambda x + 2\mu x, \quad 0 = 2\lambda y, \quad -1 = 2\mu z$$

Next, using the second equation, we find either $\lambda = 0$ or $y = 0$.

If $y = 0$, then using the first constraint equation, $x = \pm 1$ and using the second constraint equation we find $z = 0$. The derived critical points are then:

$$(1, 0, 0), \quad (-1, 0, 0)$$

If $\lambda = 0$, then using the first equation above we see $1 = 2\mu x$ which implies

$$\mu = \frac{1}{2x}$$

Using the last equation above we have:

$$-1 = 2 \cdot \frac{1}{2x} z \quad \Rightarrow \quad -x = z$$

Then using the second constraint equation, we have

$$2x^2 = 1 \quad \Rightarrow \quad x = \pm \frac{1}{\sqrt{2}}, z = \mp \frac{1}{\sqrt{2}}$$

Using the first constraint equation, we have

$$x^2 + y^2 = 1 \quad \Rightarrow \quad y^2 = \frac{1}{2} \quad \Rightarrow \quad y = \pm \frac{1}{\sqrt{2}}$$

We have four derived critical points here:

$$\left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right), \quad \left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right), \quad \left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right), \quad \left(-\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)$$

Now to analyze $f(x, y, z) = x - z$ for maximum and minimum values:

$$f(1, 0, 0) = 1, \quad f(-1, 0, 0) = -1$$

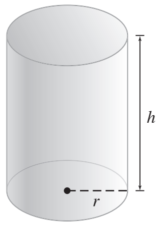
$$f\left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right) = \sqrt{2}, \quad f\left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right) = \sqrt{2}$$

$$f\left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right) = -\sqrt{2}, \quad f\left(-\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right) = -\sqrt{2}$$

Hence the maximum value of $f(x, y, z) = x - z$ subject to the two constraints is $\sqrt{2}$, while the minimum value is $-\sqrt{2}$.

61. Use Lagrange multipliers to find the dimensions of a cylindrical can with a bottom but no top, of fixed volume V with minimum surface area.

SOLUTION We denote the radius of the cylinder by r and the height by h.



The volume of the cylinder is $g = \pi r^2 h$ and the surface area is

$$f = 2\pi r h + 2\pi r^2$$

We need to minimize $f(r, h) = 2\pi r h + 2\pi r^2$ subject to the constraint $g(r, h) = \pi r^2 h - V = 0$.

Step 1. Write out the Lagrange Equations. We have $\nabla f = \langle 2\pi h + 4\pi r, 2\pi r\rangle = 2\pi \langle h + 2r, r\rangle$ and $\nabla g = \left\langle 2\pi hr, \pi r^2\right\rangle = \pi \left\langle 2hr, r^2\right\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ is

$$2\pi \langle h + 2r, r\rangle = \pi\lambda \left\langle 2hr, r^2\right\rangle$$

or

$$2 \langle h + 2r, r\rangle = \lambda \left\langle 2hr, r^2\right\rangle$$

We obtain the following equations:

$$\begin{aligned} 2(h+2r) &= 2hr\lambda \\ 2r &= \lambda r^2 \end{aligned} \quad \Rightarrow \quad \begin{aligned} h+2r &= hr\lambda \\ 2r &= \lambda r^2 \end{aligned}$$

Step 2. Solve for λ in terms of r and h. The equation of the constraint implies that $r \neq 0$ and $h \neq 0$ (we assume that $V > 0$). Therefore, the Lagrange equations give

$$\lambda = \frac{h+2r}{hr} = \frac{1}{r} + \frac{2}{h}, \quad \lambda = \frac{2}{r}$$

Step 3. Solve for r and h using the constraint. Equating the two expressions for λ gives

$$\begin{aligned} \frac{1}{r} + \frac{2}{h} &= \frac{2}{r} \\ \frac{2}{h} &= \frac{1}{r} \quad \Rightarrow \quad h = 2r \end{aligned}$$

We substitute $h = 2r$ in the equation of the constraint $\pi r^2 h = V$ and solve for r. We obtain

$$\begin{aligned} \pi r^2 \cdot 2r &= V \\ 2\pi r^3 &= V \quad \Rightarrow \quad r = \left(\frac{V}{2\pi}\right)^{1/3} \end{aligned}$$

We find h using the relation $h = 2r$:

$$h = 2\left(\frac{V}{2\pi}\right)^{1/3}$$

The critical point is $h = 2\left(\frac{V}{2\pi}\right)^{1/3}$, $r = \left(\frac{V}{2\pi}\right)^{1/3}$.

Step 4. Conclusions. On the constraint $\pi r^2 h = V$ we have $h = \frac{V}{\pi r^2}$ and $r = \sqrt{\frac{V}{\pi h}}$, hence

$$\begin{aligned} f\left(r, \frac{V}{\pi r^2}\right) &= 2\pi r \cdot \frac{V}{\pi r^2} + 2\pi r^2 = \frac{2V}{r} + 2\pi r^2 \\ f\left(\sqrt{\frac{V}{\pi h}}, h\right) &= 2\pi \sqrt{\frac{V}{\pi h}} h + 2\pi \cdot \frac{V}{\pi h} = 2\sqrt{\pi V}\sqrt{h} + \frac{2V}{h} \end{aligned}$$

We see that as $h \to 0+$ or $h \to \infty$, we have $f(r, h) \to \infty$, and as $r \to 0+$ or $r \to \infty$, we have $f(r, h) \to \infty$. Therefore, f has a minimum value on the constraint, which occurs at the critical point. We evaluate $f(r, h) = 2\pi rh + 2\pi r^2 = 2\pi(rh + r^2)$ at the critical point P:

$$f(P) = 2\pi\left(\left(\frac{V}{2\pi}\right)^{1/3} \cdot 2\left(\frac{V}{2\pi}\right)^{1/3} + \left(\frac{V}{2\pi}\right)^{2/3}\right) = 2\pi\left(2\left(\frac{V}{2\pi}\right)^{2/3} + \left(\frac{V}{2\pi}\right)^{2/3}\right) = 6\pi\left(\frac{V}{2\pi}\right)^{2/3}$$

We conclude that the minimum surface area is $6\pi\left(\frac{V}{2\pi}\right)^{2/3}$, and the dimensions of the corresponding cylinder are $r = \left(\frac{V}{2\pi}\right)^{1/3}$, $h = 2\left(\frac{V}{2\pi}\right)^{1/3}$.

62. Find the dimensions of the box of maximum volume with its sides parallel to the coordinate planes that can be inscribed in the ellipsoid (Figure 6)

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 = 1$$

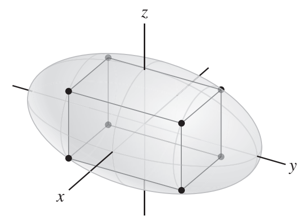


FIGURE 6

SOLUTION We denote the vertices of the box by $(\pm x, \pm y, \pm z)$, where $x \ge 0$, $y \ge 0$, $z \ge 0$. The volume of the box is

$$V(x, y, z) = 8xyz$$

The vertices of the box must satisfy the equation of the ellipsoid, hence,

$$g(x, y, z) = \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} - 1 = 0, \quad x \ge 0, \quad y \ge 0, \quad z \ge 0.$$

We need to maximize V due to the constraint: $g(x, y, z) = 0$, $x \ge 0$, $y \ge 0$, $z \ge 0$.

Step 1. Write out the Lagrange Equations. We have $\nabla V = 8\langle yz, xz, xy\rangle$ and $\nabla g = \left\langle \frac{2x}{a^2}, \frac{2y}{b^2}, \frac{2z}{c^2}\right\rangle$, hence the Lagrange Condition $\nabla V = \lambda \nabla g$ gives the following equations:

$$yz = \lambda \frac{2x}{a^2}$$
$$xz = \lambda \frac{2y}{b^2}$$
$$xy = \lambda \frac{2z}{c^2}$$

Step 2. Solve for λ in terms of x, y, and z. If $x = 0$, $y = 0$, or $z = 0$, the volume of the box has the minimum value zero. We thus may assume that $x \ne 0$, $y \ne 0$, and $z \ne 0$. The Lagrange equations give

$$\lambda = \frac{a^2 yz}{2x}, \quad \lambda = \frac{b^2 xz}{2y}, \quad \lambda = \frac{c^2 xy}{2z}$$

Step 3. Solve for x, y, and z using the constraint. Equating the three expressions for λ yields the following equations:

$$\begin{array}{c} \frac{a^2}{2}\frac{yz}{x} = \frac{c^2}{2}\frac{xy}{z} \\ \frac{b^2}{2}\frac{xz}{y} = \frac{c^2}{2}\frac{xy}{z} \end{array} \quad \Rightarrow \quad \begin{array}{c} y\left(c^2x^2 - a^2z^2\right) = 0 \\ x\left(c^2y^2 - b^2z^2\right) = 0 \end{array}$$

Since $x > 0$ and $y > 0$, these equations imply that

$$\begin{array}{c} c^2x^2 - a^2z^2 = 0 \\ c^2y^2 - b^2z^2 = 0 \end{array} \quad \Rightarrow \quad \begin{array}{c} x = \frac{az}{c} \\ y = \frac{bz}{c} \end{array} \tag{1}$$

We now substitute x and y in the equation of the constraint and solve for z. This gives

$$\frac{\left(\frac{az}{c}\right)^2}{a^2} + \frac{\left(\frac{bz}{c}\right)^2}{b^2} + \frac{z^2}{c^2} = 1$$
$$\frac{z^2}{c^2} + \frac{z^2}{c^2} + \frac{z^2}{c^2} = 1$$
$$\frac{3z^2}{c^2} = 1 \quad \Rightarrow \quad z = \frac{c}{\sqrt{3}}$$

We find x and y using (1):

$$x = \frac{a}{c}\frac{c}{\sqrt{3}} = \frac{a}{\sqrt{3}}, \quad y = \frac{b}{c}\frac{c}{\sqrt{3}} = \frac{b}{\sqrt{3}}$$

We obtain the critical point:

$$P = \left(\frac{a}{\sqrt{3}}, \frac{b}{\sqrt{3}}, \frac{c}{\sqrt{3}}\right)$$

Step 4. Conclusions. The function $V = 8xyz$ is a polynomial, hence it is continuous. The constraint defines a closed and compact set in R^3, hence f has extreme values on the constraint. The maximum value is obtained at the critical point P. We find it:

$$V(P) = 8\frac{a}{\sqrt{3}} \cdot \frac{b}{\sqrt{3}} \cdot \frac{c}{\sqrt{3}} = 8\frac{abc}{3\sqrt{3}}$$

We conclude that the dimensions of the box of maximum volume with sides parallel to the coordinate planes, which can be inscribed in the ellipsoid, are

$$x = \frac{a}{\sqrt{3}}, \quad y = \frac{b}{\sqrt{3}}, \quad z = \frac{c}{\sqrt{3}}.$$

63. Given n nonzero numbers $\sigma_1, \dots, \sigma_n$, show that the minimum value of

$$f(x_1, \dots, x_n) = x_1^2\sigma_1^2 + \cdots + x_n^2\sigma_n^2$$

subject to $x_1 + \cdots + x_n = 1$ is c, where $c = \left(\sum_{j=1}^{n} \sigma_j^{-2}\right)^{-1}$.

SOLUTION We must minimize the function $f(x_1, \dots, x_n) = x_1^2\sigma_1^2 + \cdots + x_n^2\sigma_n^2$ subject to the constraint $g(x_1, \dots, x_n) = x_1 + \cdots + x_n - 1 = 0$.

Step 1. Write out the Lagrange Equations. We have $\nabla f = \left\langle 2\sigma_1^2 x_1, \dots, 2\sigma_n^2 x_n \right\rangle$ and $\nabla g = \langle 1, \dots, 1\rangle$, hence the Lagrange Condition $\nabla f = \lambda \nabla g$ gives the following equations:

$$2\sigma_i^2 x_i = \lambda, \quad i = 1, \dots, n$$

Step 2. Solve for $x_1, \dots, x_n$ using the constraint. The Lagrange equations imply the following equations:

$$2\sigma_i^2 x_i = 2\sigma_n^2 x_n, \quad x_i = \frac{\sigma_n^2}{\sigma_i^2} x_n; \quad i = 1, \dots, n-1$$

We substitute these values in the equation of the constraint $x_1 + \cdots + x_n = 1$ and solve for x_n. This gives

$$\frac{\sigma_n^2}{\sigma_1^2} x_n + \frac{\sigma_n^2}{\sigma_2^2} x_n + \cdots + \frac{\sigma_n^2}{\sigma_{n-1}^2} x_n + x_n = 1$$

$$\sigma_n^2 \left(\frac{1}{\sigma_1^2} + \frac{1}{\sigma_2^2} + \cdots + \frac{1}{\sigma_{n-1}^2} + \frac{1}{\sigma_n^2} \right) x_n = 1$$

$$\sigma_n^2 \left(\sum_{j=1}^{n} \sigma_j^{-2} \right) x_n = 1$$

Denoting $c = \left(\sum_{j=1}^{n} \sigma_j^{-2}\right)^{-1}$, we get $x_n = \frac{c}{\sigma_n^2}$. Using $x_i = \frac{\sigma_n^2}{\sigma_i^2} x_n$ we get

$$x_i = \frac{\sigma_n^2}{\sigma_i^2} \cdot \frac{c}{\sigma_n^2} = \frac{c}{\sigma_i^2}$$

We obtain the following point:

$$P = \left(\frac{c}{\sigma_1^2}, \frac{c}{\sigma_2^2}, \dots, \frac{c}{\sigma_n^2} \right)$$

Step 3. Conclusions. As $x_i \to \infty$ or $x_i \to -\infty$, for one or more i's the function $f(x_1, \dots, x_n)$ tends to ∞. f is continuous since it is a polynomial, hence f has a minimum value on the constraint. This minimum occurs at the critical point. We find it:

$$f(P) = \sum_{j=1}^{n} \sigma_j^2 \left(\frac{c}{\sigma_j^2} \right)^2 = \sum_{j=1}^{n} \frac{\sigma_j^2 c^2}{\sigma_j^4} = c^2 \sum_{j=1}^{n} \sigma_j^{-2} = c^2 \cdot c^{-1} = c$$

15 MULTIPLE INTEGRATION

15.1 Integration in Two Variables (LT Section 16.1)

Preliminary Questions

1. If $S_{8,4}$ is a Riemann sum for a double integral over $\mathcal{R} = [1, 5] \times [2, 10]$ using a regular partition, what is the area of each subrectangle? How many subrectangles are there?

SOLUTION Since the partition is regular, all subrectangles have sides of length

$$\Delta x = \frac{5-1}{8} = \frac{1}{2}, \quad \Delta y = \frac{10-2}{4} = 2$$

Therefore the area of each subrectangle is $\Delta A = \Delta x \Delta y = \frac{1}{2} \cdot 2 = 1$, and the number of subrectangles is $8 \cdot 4 = 32$.

2. Estimate the double integral of a continuous function f over the small rectangle $\mathcal{R} = [0.9, 1.1] \times [1.9, 2.1]$ if $f(1, 2) = 4$.

SOLUTION Since we are given the value of f at one point in $\mathcal{R}$ only, we can only use the approximation S_{11} for the integral of f over $\mathcal{R}$. For S_{11} we have one rectangle wi th sides

$$\Delta x = 1.1 - 0.9 = 0.2, \quad \Delta y = 2.1 - 1.9 = 0.2$$

Hence, the area of the rectangle is $\Delta A = \Delta x \Delta y = 0.2 \cdot 0.2 = 0.04$. We obtain the following approximation:

$$\iint_{\mathcal{R}} f\, dA \approx S_{1,1} = f(1, 2)\Delta A = 4 \cdot 0.04 = 0.16$$

3. What is the integral of the constant function $f(x, y) = 5$ over the rectangle $[-2, 3] \times [2, 4]$?

SOLUTION The integral of f over the unit square $\mathcal{R} = [-2, 3] \times [2, 4]$ is the volume of the box of base $\mathcal{R}$ and height 5. That is,

$$\iint_{\mathcal{R}} 5\, dA = 5 \cdot \text{Area}(\mathcal{R}) = 5 \cdot 5 \cdot 2 = 50$$

4. What is the interpretation of $\iint_{\mathcal{R}} f(x, y)\, dA$ if $f(x, y)$ takes on both positive and negative values on $\mathcal{R}$?

SOLUTION The double integral $\iint_{\mathcal{R}} f(x, y)\, dA$ is the signed volume between the graph $z = f(x, y)$ for $(x, y) \in \mathcal{R}$, and the xy-plane. The region below the xy-plane is treated as negative volume.

5. Which of (a) or (b) is equal to $\int_1^2 \int_4^5 f(x, y)\, dy\, dx$?

(a) $\int_1^2 \int_4^5 f(x, y)\, dx\, dy$

(b) $\int_4^5 \int_1^2 f(x, y)\, dx\, dy$

SOLUTION The integral $\int_1^2 \int_4^5 f(x, y)\, dy\, dx$ is written with dy preceding dx, therefore the integration is first with respect to y over the interval $4 \le y \le 5$, and then with respect to x over the interval $1 \le x \le 2$. By Fubini's Theorem, we may replace the order of integration over the corresponding intervals. Therefore the given integral is equal to (b) rather than to (a).

6. For which of the following functions is the double integral over the rectangle in Figure 15 equal to zero? Explain your reasoning.

(a) $f(x, y) = x^2 y$

(b) $f(x, y) = xy^2$

(c) $f(x, y) = \sin x$

(d) $f(x, y) = e^x$

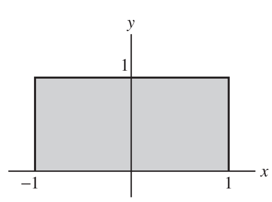

FIGURE 15

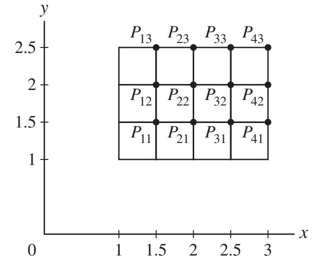
SOLUTION The double integral is the signed volume of the region between the graph of $f(x, y)$ and the xy-plane over $\mathcal{R}$. In (b) and (c) the function satisfies $f(-x, y) = -f(x, y)$, hence the region below the xy-plane, where $-1 \le x \le 0$ cancels with the region above the xy-plane, where $0 \le x \le 1$. Therefore, the double integral is zero. In (a) and (d), the function $f(x, y)$ is always positive on the rectangle, so the double integral is greater than zero.

Exercises

1. Compute the Riemann sum $S_{4,3}$ to estimate the double integral of $f(x, y) = xy$ over $\mathcal{R} = [1, 3] \times [1, 2.5]$. Use the regular partition and upper-right vertices of the subrectangles as sample points.

SOLUTION The rectangle $\mathcal{R}$ and the subrectangles are shown in the following figure:



The subrectangles have sides of length

$$\Delta x = \frac{3-1}{4} = 0.5, \quad \Delta y = \frac{2.5-1}{3} = 0.5 \quad \Rightarrow \quad \Delta A = 0.5 \cdot 0.5 = 0.25$$

The upper right vertices are the following points:

$$\begin{array}{llll} P_{11} = (1.5, 1.5) & P_{21} = (2, 1.5) & P_{31} = (2.5, 1.5) & P_{41} = (3, 1.5) \\ P_{12} = (1.5, 2) & P_{22} = (2, 2) & P_{32} = (2.5, 2) & P_{42} = (3, 2) \\ P_{13} = (1.5, 2.5) & P_{23} = (2, 2.5) & P_{33} = (2.5, 2.5) & P_{43} = (3, 2.5) \end{array}$$

We compute $f(x, y) = xy$ at these points:

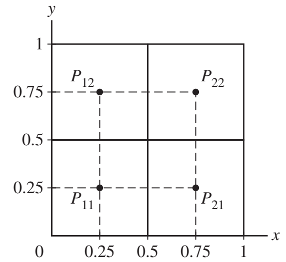
$$\begin{array}{lll} f(P_{11}) = 1.5 \cdot 1.5 = 2.25 & f(P_{12}) = 1.5 \cdot 2 = 3 & f(P_{13}) = 3.75 \\ f(P_{21}) = 2 \cdot 1.5 = 3 & f(P_{22}) = 2 \cdot 2 = 4 & f(P_{23}) = 5 \\ f(P_{31}) = 2.5 \cdot 1.5 = 3.75 & f(P_{32}) = 2.5 \cdot 2 = 5 & f(P_{33}) = 6.25 \\ f(P_{41}) = 3 \cdot 1.5 = 4.5 & f(P_{42}) = 3 \cdot 2 = 6 & f(P_{43}) = 7.5 \end{array}$$

Hence, $S_{4,3}$ is the following sum:

$$S_{4,3} = \sum_{i=1}^{4} \sum_{j=1}^{3} f(P_{ij}) \Delta A = 0.25(2.25 + 3 + 3.75 + 4.5 + 3 + 4 + 5 + 6 + 3.75 + 5 + 6.25 + 7.5) = 13.5$$

2. Compute the Riemann sum with $N = M = 2$ to estimate the integral of $\sqrt{x+y}$ over $\mathcal{R} = [0, 1] \times [0, 1]$. Use the regular partition and midpoints of the subrectangles as sample points.

SOLUTION The rectangle $\mathcal{R}$ and the subintervals are shown in the following figure:



The subrectangles have sides of length $\Delta x = \frac{1}{2} = 0.5$ and $\Delta y = \frac{1}{2} = 0.5$ and area $\Delta A = 0.5 \cdot 0.5 = 0.25$. The midpoints of the subrectangles are:

$$P_{11} = (0.25, 0.25), \quad P_{21} = (0.75, 0.25),$$
$$P_{12} = (0.25, 0.75), \quad P_{22} = (0.75, 0.75)$$

We compute the values of $f(x, y) = \sqrt{x + y}$ at the sample points:

$$f(P_{11}) = \sqrt{0.25 + 0.25} = 0.707$$
$$f(P_{21}) = \sqrt{0.75 + 0.25} = 1$$
$$f(P_{12}) = \sqrt{0.25 + 0.75} = 1$$
$$f(P_{22}) = \sqrt{0.75 + 0.75} = 1.225$$

Hence, S_{22} is the following sum:

$$S_{22} = \sum_{i=1}^{2} \sum_{j=1}^{2} f\left(P_{ij}\right) \Delta A = 0.25(0.707 + 1 + 1 + 1.225) = 0.983$$

In Exercises 3–6, compute the Riemann sums for the double integral $\iint_{\mathcal{R}} f(x, y)\, dA$, *where* $\mathcal{R} = [1, 4] \times [1, 3]$, *for the grid and two choices of sample points shown in Figure 16.*

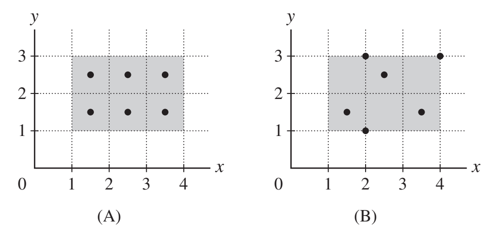


FIGURE 16

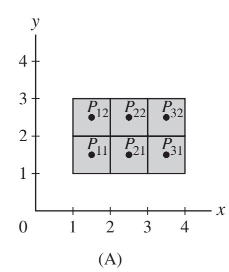
3. $f(x, y) = 2x + y$

SOLUTION The subrectangles have sides of length $\Delta x = \frac{4-1}{3} = 1$ and $\Delta y = \frac{3-1}{2} = 1$, and area $\Delta A = \Delta x \Delta y = 1$. We find the sample points in (A) and (B):

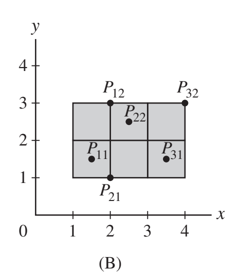
(A)

$$P_{11} = (1.5, 1.5) \quad P_{21} = (2.5, 1.5) \quad P_{31} = (3.5, 1.5)$$
$$P_{12} = (1.5, 2.5) \quad P_{22} = (2.5, 2.5) \quad P_{32} = (3.5, 2.5)$$



(B)

$$P_{11} = (1.5, 1.5) \quad P_{21} = (2, 1) \quad P_{31} = (3.5, 1.5)$$
$$P_{21} = (2, 3) \quad P_{22} = (2.5, 2.5) \quad P_{23} = (4, 3)$$



The Riemann Sum S_{32} is the following estimation of the double integral:

$$\iint_{\mathcal{R}} f(x, y)\, dA \approx S_{32} = \sum_{i=1}^{3} \sum_{j=1}^{2} f\left(P_{ij}\right) \Delta A = \sum_{i=1}^{3} \sum_{j=1}^{2} f\left(P_{ij}\right)$$

We compute S_{32} for the two choices of sample points (A) and (B), and the following function:

$$f(x, y) = 2x + y$$

We compute $f\left(P_{ij}\right)$ for the sample points computed above:

(A)

$$\begin{aligned}
f\left(P_{11}\right) &= f(1.5, 1.5) = 2 \cdot 1.5 + 1.5 = 4.5 \\
f\left(P_{21}\right) &= f(2.5, 1.5) = 2 \cdot 2.5 + 1.5 = 6.5 \\
f\left(P_{31}\right) &= f(3.5, 1.5) = 2 \cdot 3.5 + 1.5 = 8.5 \\
f\left(P_{12}\right) &= f(1.5, 2.5) = 2 \cdot 1.5 + 2.5 = 5.5 \\
f\left(P_{22}\right) &= f(2.5, 2.5) = 2 \cdot 2.5 + 2.5 = 7.5 \\
f\left(P_{32}\right) &= f(3.5, 2.5) = 2 \cdot 3.5 + 2.5 = 9.5
\end{aligned}$$

Hence,

$$S_{32} = \sum_{i=1}^{3} \sum_{j=1}^{2} f\left(P_{ij}\right) \Delta A = 4.5 + 6.5 + 8.5 + 5.5 + 7.5 + 9.5 = 42$$

(B)

$$\begin{aligned}
f\left(P_{11}\right) &= f(1.5, 1.5) = 2 \cdot 1.5 + 1.5 = 4.5 \\
f\left(P_{21}\right) &= f(2, 1) = 2 \cdot 2 + 1 = 5 \\
f\left(P_{31}\right) &= f(3.5, 1.5) = 2 \cdot 3.5 + 1.5 = 8.5 \\
f\left(P_{21}\right) &= f(2, 3) = 2 \cdot 2 + 3 = 7 \\
f\left(P_{22}\right) &= f(2.5, 2.5) = 2 \cdot 2.5 + 2.5 = 7.5 \\
f\left(P_{23}\right) &= f(4, 3) = 2 \cdot 4 + 3 = 11
\end{aligned}$$

Hence,

$$S_{32} = \sum_{i=1}^{3} \sum_{j=1}^{2} f\left(P_{ij}\right) \Delta A = 4.5 + 5 + 8.5 + 7 + 7.5 + 11 = 43.5$$

4. $f(x, y) = 7$

SOLUTION In this case $f\left(P_{ij}\right) = 7$ for all i and j hence for the sample points in (A) and in (B) we have the same Riemann sum, that is,

$$S_{32} = \sum_{i=1}^{3} \sum_{j=1}^{2} f\left(P_{ij}\right) \Delta A = 6 \cdot 7 = 42$$

5. $f(x, y) = 4x$

SOLUTION We compute the values of f at the sample points:

(A)

$$\begin{aligned}
f\left(P_{11}\right) &= f(1.5, 1.5) = 4 \cdot 1.5 = 6 \\
f\left(P_{21}\right) &= f(2.5, 1.5) = 4 \cdot 2.5 = 10 \\
f\left(P_{31}\right) &= f(3.5, 1.5) = 4 \cdot 3.5 = 14 \\
f\left(P_{12}\right) &= f(1.5, 2.5) = 4 \cdot 1.5 = 6 \\
f\left(P_{22}\right) &= f(2.5, 2.5) = 4 \cdot 2.5 = 10 \\
f\left(P_{32}\right) &= f(3.5, 2.5) = 4 \cdot 3.5 = 14 \\
\Delta x = \frac{4-1}{3} &= 1, \quad \Delta y = \frac{3-1}{2} = 1
\end{aligned}$$

Hence $\Delta A = \Delta x \cdot \Delta y = 1$ and we get

$$S_{32} = \sum_{i=1}^{3} \sum_{j=1}^{2} f\left(P_{ij}\right) \Delta A = 6 + 10 + 14 + 6 + 10 + 14 = 60$$

(B)

$$f(P_{11}) = f(1.5, 1.5) = 4 \cdot 1.5 = 6$$
$$f(P_{21}) = f(2, 1) = 4 \cdot 2 = 8$$
$$f(P_{31}) = f(3.5, 1.5) = 4 \cdot 3.5 = 14$$
$$f(P_{12}) = f(2, 3) = 4 \cdot 2 = 8$$
$$f(P_{22}) = f(2.5, 2.5) = 4 \cdot 2.5 = 10$$
$$f(P_{32}) = f(4, 3) = 4 \cdot 4 = 16$$

$\Delta A = 1$. Hence,

$$S_{32} = \sum_{i=1}^{3}\sum_{j=1}^{2} f\left(P_{ij}\right)\Delta A = 6 + 8 + 14 + 8 + 10 + 16 = 62$$

6. $f(x, y) = x - 2y$

SOLUTION We compute the values of f at the sample points:

(A)

$$f(P_{11}) = f(1.5, 1.5) = 1.5 - 2 \cdot 1.5 = -1.5$$
$$f(P_{21}) = f(2.5, 1.5) = 2.5 - 2 \cdot 1.5 = -0.5$$
$$f(P_{31}) = f(3.5, 1.5) = 3.5 - 2 \cdot 1.5 = 0.5$$
$$f(P_{12}) = f(1.5, 2.5) = 1.5 - 2 \cdot 2.5 = -3.5$$
$$f(P_{22}) = f(2.5, 2.5) = 2.5 - 2 \cdot 2.5 = -2.5$$
$$f(P_{32}) = f(3.5, 2.5) = 3.5 - 2 \cdot 2.5 = -1.5$$
$$\Delta x = \frac{4-1}{3} = 1, \quad \Delta y = \frac{3-1}{2} = 1$$

Hence $\Delta A = \Delta x \cdot \Delta y = 1$ and we get

$$S_{32} = \sum_{i=1}^{3}\sum_{j=1}^{2} f\left(P_{ij}\right)\Delta A = -1.5 - 0.5 + 0.5 - 3.5 - 2.5 - 1.5 = -9$$

(B)

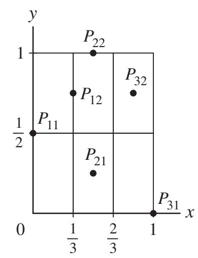
$$f(P_{11}) = f(1.5, 1.5) = 1.5 - 2 \cdot 1.5 = -1.5$$
$$f(P_{21}) = f(2, 1) = 2 - 2 \cdot 1 = 0$$
$$f(P_{31}) = f(3.5, 1.5) = 3.5 - 2 \cdot 1.5 = 0.5$$
$$f(P_{12}) = f(2, 3) = 2 - 2 \cdot 3 = -4$$
$$f(P_{22}) = f(2.5, 2.5) = 2.5 - 2 \cdot 2.5 = -2.5$$
$$f(P_{32}) = f(4, 3) = 4 - 2 \cdot 3 = -2$$

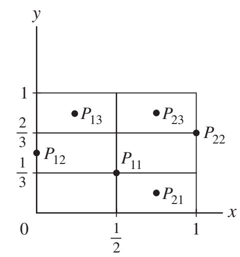
$\Delta A = 1$, hence

$$S_{32} = \sum_{i=1}^{3}\sum_{j=1}^{2} f\left(P_{ij}\right)\Delta A = -1.5 + 0 + 0.5 - 4 - 2.5 - 2 = -9.5$$

7. Let $\mathcal{R} = [0, 1] \times [0, 1]$. Estimate $\iint_{\mathcal{R}} (x + y)\, dA$ by computing two different Riemann sums, each with at least six rectangles.

SOLUTION We define the following subrectangles and sample points:





The sample points defined in the two figures are:

(A)

$$P_{11}=\left(0,\tfrac{1}{2}\right)\quad P_{21}=\left(\tfrac{1}{2},\tfrac{1}{4}\right)\quad P_{31}=(1,0)$$
$$P_{12}=\left(\tfrac{1}{3},\tfrac{3}{4}\right)\quad P_{22}=\left(\tfrac{1}{2},1\right)\quad P_{32}=\left(\tfrac{5}{6},\tfrac{3}{4}\right)$$

(B)

$$P_{11}=\left(\tfrac{1}{2},\tfrac{1}{3}\right)\quad P_{21}=\left(\tfrac{3}{4},\tfrac{1}{6}\right)\quad P_{12}=\left(0,\tfrac{1}{2}\right)$$
$$P_{22}=\left(1,\tfrac{2}{3}\right)\quad P_{13}=\left(\tfrac{1}{4},\tfrac{5}{6}\right)\quad P_{23}=\left(\tfrac{3}{4},\tfrac{5}{6}\right)$$

We compute the values of $f(x,y)=x+y$ at the sample points:

(A)

$$f(P_{11})=f\left(0,\frac{1}{2}\right)=0+\frac{1}{2}=\frac{1}{2}$$
$$f(P_{21})=f\left(\frac{1}{2},\frac{1}{4}\right)=\frac{1}{2}+\frac{1}{4}=\frac{3}{4}$$
$$f(P_{31})=f(1,0)=1+0=1$$
$$f(P_{12})=f\left(\frac{1}{3},\frac{3}{4}\right)=\frac{1}{3}+\frac{3}{4}=\frac{13}{12}$$
$$f(P_{22})=f\left(\frac{1}{2},1\right)=\frac{1}{2}+1=\frac{3}{2}$$
$$f(P_{32})=f\left(\frac{5}{6},\frac{3}{4}\right)=\frac{5}{6}+\frac{3}{4}=\frac{19}{12}$$

Each subrectangle has sides of length $\Delta x=\frac{1}{3}$, $\Delta y=\frac{1}{2}$ and area $\Delta A=\Delta x\Delta y=\frac{1}{3}\cdot\frac{1}{2}=\frac{1}{6}$. We obtain the following Riemann sum:

$$S_{32}=\sum_{i=1}^{3}\sum_{j=1}^{2}f\left(P_{ij}\right)\Delta A=\frac{1}{6}\left(\frac{1}{2}+\frac{3}{4}+1+\frac{13}{12}+\frac{3}{2}+\frac{19}{12}\right)=\frac{77}{72}\approx 1.069$$

(B)

$$f(P_{11})=f\left(\frac{1}{2},\frac{1}{3}\right)=\frac{1}{2}+\frac{1}{3}=\frac{5}{6}$$
$$f(P_{21})=f\left(\frac{3}{4},\frac{1}{6}\right)=\frac{3}{4}+\frac{1}{6}=\frac{11}{12}$$
$$f(P_{12})=f\left(0,\frac{1}{2}\right)=0+\frac{1}{2}=\frac{1}{2}$$
$$f(P_{22})=f\left(1,\frac{2}{3}\right)=1+\frac{2}{3}=\frac{5}{3}$$
$$f(P_{13})=f\left(\frac{1}{4},\frac{5}{6}\right)=\frac{1}{4}+\frac{5}{6}=\frac{13}{12}$$
$$f(P_{23})=f\left(\frac{3}{4},\frac{5}{6}\right)=\frac{3}{4}+\frac{5}{6}=\frac{19}{12}$$

Each subrectangle has sides of length $\Delta x=\frac{1}{2}$, $\Delta y=\frac{1}{3}$ and area $\Delta A=\Delta x\Delta y=\frac{1}{2}\cdot\frac{1}{3}=\frac{1}{6}$. We obtain the following Riemann sum:

$$S_{23}=\sum_{i=1}^{3}\sum_{j=1}^{2}f\left(P_{ij}\right)\Delta A=\frac{1}{6}\left(\frac{5}{6}+\frac{11}{12}+\frac{1}{2}+\frac{5}{3}+\frac{13}{12}+\frac{19}{12}\right)=\frac{79}{72}\approx 1.097$$

8. Evaluate $\iint_{\mathcal{R}} 4\,dA$, where $\mathcal{R}=[2,5]\times[4,7]$.

SOLUTION The double integral is the volume of the box of base $\mathcal{R}$ and height 4. That is,

$$\iint_{\mathcal{R}} 4\,dA=4\cdot\text{Area}(R) \tag{1}$$

The rectangle $\mathcal{R}$ has sides of length $5 - 2 = 3$ and $7 - 4 = 3$, therefore its area is $3 \cdot 3 = 9$. Hence, by (1) we get

$$\iint_{\mathcal{R}} 4\,dA = 4 \cdot 9 = 36$$

9. Evaluate $\iint_{\mathcal{R}} (15 - 3x)\,dA$, where $\mathcal{R} = [0, 5] \times [0, 3]$, and sketch the corresponding solid region (see Example 2).

SOLUTION This double integral is the volume V of the solid wedge underneath the graph of $f(x, y) = 15 - 3x$. The triangular face of the wedge has area

$$A = \frac{1}{2} \cdot 5 \cdot 15 = \frac{75}{2}$$

The volume of the wedge is equal to the area A times the length $\ell = 3$; that is

$$V = \ell A = 3\left(\frac{75}{2}\right) = \frac{225}{2}$$

10. Evaluate $\iint_{\mathcal{R}} (-5)\,dA$, where $\mathcal{R} = [2, 5] \times [4, 7]$.

SOLUTION The double integral is the signed volume of the box of base $\mathcal{R}$ and height -5. That is,

$$\iint_{\mathcal{R}} (-5)\,dA = -5 \cdot \text{Area}(\mathcal{R}) = -5 \cdot (5-2) \cdot (7-4) = -5 \cdot 9 = -45$$

11. The following table gives the approximate height at quarter-meter intervals of a mound of gravel. Estimate the volume of the mound by computing the average of the two Riemann sums $S_{4,3}$ with lower-left and upper-right vertices of the subrectangles as sample points.

0.75	0.1	0.2	0.2	0.15	0.1
0.5	0.2	0.3	0.5	0.4	0.2
0.25	0.15	0.2	0.4	0.3	0.2
0	0.1	0.15	0.2	0.15	0.1
$y \backslash x$	0	0.25	0.5	0.75	1

SOLUTION Each subrectangle is a square of side 0.25, hence the area of each subrectangle is $\Delta A = 0.25^2 = 0.0625$. By the given data, the lower-left vertex sample points are:

$$\begin{array}{lll}
f(P_{11}) = f(0,0) & f(P_{12}) = f(0,0.25) & f(P_{13}) = f(0,0.50) \\
f(P_{21}) = f(0.25,0) & f(P_{22}) = f(0.25,0.25) & f(P_{23}) = f(0.25,0.50) \\
f(P_{31}) = f(0.50,0) & f(P_{32}) = f(0.50,0.25) & f(P_{33}) = f(0.50,0.50) \\
f(P_{41}) = f(0.75,0) & f(P_{42}) = f(0.75,0.25) & f(P_{43}) = f(0.75,0.50)
\end{array}$$

The Riemann sum $S_{4,3}$ that corresponds to these lower-left vertex sample points is the following sum:

$$\begin{aligned}
S_{4,3} &= \sum_{i=1}^{4}\sum_{j=1}^{3} f\left(P_{ij}\right)\Delta A \\
&= 0.0625(0.1 + 0.15 + 0.2 + 0.15 + 0.2 + 0.3 + 0.2 + 0.4 + 0.5 + 0.15 + 0.3 + 0.4) \approx 0.190625
\end{aligned}$$

Now by the given data, the upper-right vertex sample points are:

$$\begin{array}{lll}
f(P_{11}) = f(0.25,0.25) & f(P_{12}) = f(0.25,0.50) & f(P_{13}) = f(0.25,0.75) \\
f(P_{21}) = f(0.50,0.25) & f(P_{22}) = f(0.50,0.50) & f(P_{23}) = f(0.50,0.75) \\
f(P_{31}) = f(0.75,0.25) & f(P_{32}) = f(0.75,0.50) & f(P_{33}) = f(0.75,0.75) \\
f(P_{41}) = f(1,0.25) & f(P_{42}) = f(1,0.50) & f(P_{43}) = f(1,0.75)
\end{array}$$

The Riemann sum S'_{43} that corresponds to these upper-right vertex sample points is the following sum:

$$\begin{aligned}
S'_{4,3} &= \sum_{i=1}^{4}\sum_{j=1}^{3} f\left(P_{ij}\right)\Delta A \\
&= 0.0625(0.2 + 0.3 + 0.2 + 0.4 + 0.5 + 0.2 + 0.3 + 0.4 + 0.15 + 0.2 + 0.2 + 0.1) \approx 0.196875
\end{aligned}$$

Taking the average of the two Riemann sums we have:

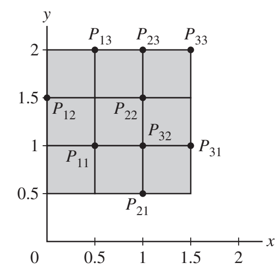
$$\text{volume} \approx \frac{S_{4,3} + S'_{4,3}}{2} = \frac{0.190625 + 0.196875}{2} = 0.19375$$

12. Use the following table to compute a Riemann sum $S_{3,3}$ for $f(x, y)$ on the square $\mathcal{R} = [0, 1.5] \times [0.5, 2]$. Use the regular partition and sample points of your choosing.

Values of $f(x, y)$

y \ x	0	0.5	1	1.5	2
2	2.6	2.17	1.86	1.62	1.44
1.5	2.2	1.83	1.57	1.37	1.22
1	1.8	1.5	1.29	1.12	1
0.5	1.4	1.17	1	0.87	0.78
0	1	0.83	0.71	0.62	0.56

SOLUTION The subrectangles and our choice of sample points are shown in the figure:



Each subrectangle is a square of side 0.5, hence the area of each subrectangle is $\Delta A = 0.5^2 = 0.25$. By the given data, the sample points are:

$$\begin{array}{lll} f(P_{11}) = f(0.5, 1) & f(P_{12}) = f(0, 1.5) & f(P_{13}) = f(0.5, 2) \\ f(P_{21}) = f(1, 0.5) & f(P_{22}) = f(1, 1.5) & f(P_{23}) = f(1, 2) \\ f(P_{31}) = f(1.5, 1) & f(P_{32}) = f(1, 1) & f(P_{33}) = f(1.5, 2) \end{array}$$

The Riemann sum S_{33} that corresponds to these sample points is the following sum:

$$S_{33} = \sum_{i=1}^{3} \sum_{j=1}^{3} f\left(P_{ij}\right) \Delta A = 0.25(1.5 + 1 + 1.12 + 2.2 + 1.57 + 1.29 + 2.17 + 1.86 + 1.62) \approx 3.58$$

13. CAS Let $S_{N,N}$ be the Riemann sum for $\int_0^1 \int_0^1 e^{x^3 - y^3} \, dy \, dx$ using the regular partition and the lower left-hand vertex of each subrectangle as sample points. Use a computer algebra system to calculate $S_{N,N}$ for $N = 25, 50, 100$.

SOLUTION Using a computer algebra system, we compute $S_{N,N}$ to be 1.0731, 1.0783, and 1.0809.

14. CAS Let $S_{N,M}$ be the Riemann sum for

$$\int_0^4 \int_0^2 \ln(1 + x^2 + y^2) \, dy \, dx$$

using the regular partition and the upper right-hand vertex of each subrectangle as sample points. Use a computer algebra system to calculate $S_{2N,N}$ for $N = 25, 50, 100$.

SOLUTION Using a computer algebra system, we compute $S_{2N,N}$ to be 14.632, 14.486, and 14.413.

In Exercises 15–18, use symmetry to evaluate the double integral.

15. $\iint_{\mathcal{R}} x^3 \, dA, \quad \mathcal{R} = [-4, 4] \times [0, 5]$

SOLUTION The double integral is the signed volume of the region between the graph of $f(x, y) = x^3$ and the xy-plane. However, $f(x, y)$ takes opposite values at (x, y) and $(-x, y)$:

$$f(-x, y) = (-x)^3 = -x^3 = -f(x, y)$$

Because of symmetry, the (negative) signed volume of the region below the xy-plane where $-4 \le x \le 0$ cancels with the (positive) signed volume of the region above the xy-plane where $0 \le x \le 4$. The net result is

$$\iint_{\mathcal{R}} x^3 \, dA = 0$$

16. $\displaystyle\iint_{\mathcal{R}} 1 \, dA, \quad \mathcal{R} = [2,4] \times [-7,7]$

SOLUTION This double integral is the signed volume of the region below the graph of $f(x,y) = 1$ (which is a plane at height 1). We can view this integral as the volume of the rectangular box having height 1 over the rectangle $\mathcal{R} = [2,4] \times [-7,7]$. The area of this rectangle is

$$A = (4-2)(7-(-7)) = 2 \cdot 14 = 28$$

Therefore, the volume of the rectangular box is

$$\iint_{\mathcal{R}} 1 \, dA = 1(28) = 28$$

17. $\displaystyle\iint_{\mathcal{R}} \sin x \, dA, \quad \mathcal{R} = [0, 2\pi] \times [0, 2\pi]$

SOLUTION Since $\sin(\pi + x) = -\sin x$, the region between the graph and the xy-plane where $\pi \le x \le 2\pi$, is below the xy-plane, and it cancels with the region above the xy-plane where $0 \le x \le \pi$. Hence,

$$\iint_{\mathcal{R}} \sin x \, dA = 0$$

18. $\displaystyle\iint_{\mathcal{R}} (2 + x^2 y) \, dA, \quad \mathcal{R} = [0,1] \times [-1,1]$

SOLUTION By additivity of the Double Integral, we have

$$\iint_{\mathcal{R}} \left(2 + x^2 y\right) dA = \iint_{\mathcal{R}} 2 \, dA + \iint_{\mathcal{R}} x^2 y \, dA \tag{1}$$

We consider each of the two integrals on the right-hand side:

$$\iint_{\mathcal{R}} 2 \, dA = \iint_{\mathcal{R}} 2 \cdot \text{Area}(\mathcal{R}) = 2 \cdot 1 \cdot 2 = 4 \tag{2}$$

The function $f(x,y) = x^2 y$ satisfies $f(x,-y) = -f(x,y)$. Since the double integral is the signed volume of the region between the graph and the xy-plane, the region below the xy-plane (where $-1 \le y \le 0$) cancels with the region above the xy-plane (where $0 \le y \le 1$). Thus,

$$\iint_{\mathcal{R}} x^2 y \, dA = 0 \tag{3}$$

Combining (1), (2), and (3), we obtain

$$\iint_{\mathcal{R}} \left(2 + x^2 y\right) dA = 4 + 0 = 4$$

In Exercises 19–36, evaluate the iterated integral.

19. $\displaystyle\int_1^3 \int_0^2 x^3 y \, dy \, dx$

SOLUTION We first compute the inner integral, treating x as a constant, then integrate the result with respect to x:

$$\int_1^3 \int_0^2 x^3 y \, dy \, dx = \int_1^3 x^3 \frac{y^2}{2}\bigg|_{y=0}^{2} dx = \int_1^3 x^3 \left(\frac{2^2}{2} - 0\right) dx = \int_1^3 2x^3 \, dx = \frac{x^4}{2}\bigg|_1^3 = 40$$

20. $\int_0^2 \int_1^3 x^3 y \, dx \, dy$

SOLUTION

$$\int_0^2 \int_1^3 x^3 y \, dx dy = \int_0^2 x^3 \left(\int_1^3 y \, dy \right) dx$$

$$= \int_0^2 x^3 \left(\frac{y^2}{2} \bigg|_1^3 \right) dy$$

$$= 4 \int_0^2 x^3 \, dx$$

$$= 4 \cdot \frac{x^4}{4} \bigg|_0^2$$

$$= 16$$

21. $\int_4^9 \int_{-3}^8 1 \, dx \, dy$

SOLUTION

$$\int_4^9 \int_{-3}^8 1 \, dx dy = \int_4^9 1 \left(\int_{-3}^8 1 \, dy \right) dx$$

$$= \int_4^9 1 \left(y \bigg|_{-3}^8 \right) dx$$

$$= \int_4^9 11 \, dx$$

$$= 11x \bigg|_4^9$$

$$= 99 - 44 = 55$$

22. $\int_{-4}^{-1} \int_4^8 (-5) \, dx \, dy$

SOLUTION

$$\int_{-4}^{-1} \int_4^8 (-5) \, dx \, dy = \int_{-4}^{1} \left(\int_4^8 (-5) \, dx \right) dy$$

$$= \int_{-4}^{-1} \left(-5x \bigg|_4^8 \right) dy$$

$$= \int_{-4}^{-1} (-40 + 20) \, dy$$

$$= \int_{-4}^{-1} (-20) \, dy$$

$$= -20y \bigg|_{-4}^{-1}$$

$$= 20 - (80) = -60$$

23. $\int_{-1}^1 \int_0^\pi x^2 \sin y \, dy \, dx$

SOLUTION We first evaluate the inner integral, treating x as a constant, then integrate the result with respect to x. This gives

$$\int_{-1}^1 \int_0^\pi x^2 \sin y \, dy \, dx = \int_{-1}^1 x^2 (-\cos y) \bigg|_{y=0}^{\pi} dx = \int_{-1}^1 x^2 (-\cos \pi + \cos 0) \, dx$$

$$= \int_{-1}^1 x^2 (1+1) \, dx = \int_{-1}^1 2x^2 \, dx = \frac{2}{3} x^3 \bigg|_{-1}^1 = \frac{2}{3} \left(1^3 - (-1)^3 \right) = \frac{4}{3}$$

24. $\int_{-1}^{1}\int_{0}^{\pi} x^2 \sin y\,dx\,dy$

SOLUTION

$$\begin{aligned}\int_{-1}^{1}\int_{0}^{\pi} x^2 \sin y\,dx\,dy &= \int_{-1}^{1} \sin y \left(\int_0^{\pi} x^2\,dx\right)\,dy \\ &= \int_{-1}^{1} \sin y \left(\frac{x^3}{3}\bigg|_0^{\pi}\right)\,dy \\ &= \frac{\pi^3}{3}\int_{-1}^{1}\sin y\,dy \\ &= \frac{\pi^3}{3}\left(-\cos y\bigg|_{-1}^{1}\right) \\ &= \frac{\pi^3}{3}(-\cos(1)+\cos(-1)) = 0\end{aligned}$$

25. $\int_{2}^{6}\int_{1}^{4} x^2\,dx\,dy$

SOLUTION We use Iterated Integral of a Product Function to compute the integral as follows:

$$\begin{aligned}\int_2^6\int_1^4 x^2\,dx\,dy = \int_2^6\int_1^4 x^2\cdot 1\,dx\,dy = \left(\int_1^4 x^2\,dx\right)\left(\int_2^6 1\,dy\right) = \left(\frac{x^3}{3}\bigg|_1^4\right)\left(y\bigg|_2^6\right) \\ = \left(\frac{4^3}{3}-\frac{1^3}{3}\right)(6-2) = 21\cdot 4 = 84\end{aligned}$$

26. $\int_{2}^{6}\int_{1}^{4} y^2\,dx\,dy$

SOLUTION Since the integrand is a product $f(x,y)=y^2\cdot 1$ we can compute the double integral as a product of integrals. That is,

$$\int_2^6\int_1^4 y^2\,dx\,dy = \left(\int_2^6 y^2\,dy\right)\left(\int_1^4 1\,dx\right) = \left(\frac{y^3}{3}\bigg|_2^6\right)\left(x\bigg|_1^4\right) = \left(\frac{6^3}{3}-\frac{2^3}{3}\right)(4-1) = \frac{208}{3}\cdot 3 = 208$$

27. $\int_{0}^{1}\int_{0}^{2}(x+4y^3)\,dx\,dy$

SOLUTION We use additivity of the double integral to write

$$\int_0^1\int_0^2 \left(x+4y^3\right)\,dx\,dy = \int_0^1\int_0^2 x\,dx\,dy + \int_0^1\int_0^2 4y^3\,dx\,dy \tag{1}$$

We now compute each of the double integrals using product of iterated integrals:

$$\begin{aligned}\int_0^1\int_0^2 x\,dx\,dy &= \left(\int_0^2 x\,dx\right)\left(\int_0^1 1\,dy\right) = \left(\frac{1}{2}x^2\bigg|_0^2\right)\left(y\bigg|_0^1\right) = 2\cdot 1 = 2 \\ \int_0^1\int_0^2 4y^3\,dx\,dy &= \left(\int_0^1 4y^3\,dy\right)\left(\int_0^2 1\,dx\right) = \left(y^4\bigg|_0^1\right)\left(x\bigg|_0^2\right) = 1\cdot 2 = 2\end{aligned}$$

Substituting in (1) gives

$$\int_0^1\int_0^2 (x+4y^3)\,dx\,dy = 2+2 = 4.$$

28. $\int_0^2 \int_0^2 (x^2 - y^2)\, dy\, dx$

SOLUTION We first use additivity of the double integral to rewrite the integral as the sum of two double integrals. Then we compute each of the resulting integrals as product of iterated integral. We obtain

$$\begin{aligned}\int_0^2 \int_0^2 \left(x^2 - y^2\right) dy\, dx &= \int_0^2 \int_0^2 x^2\, dy\, dx - \int_0^2 \int_0^2 y^2\, dy\, dx \\ &= \left(\int_0^2 x^2\, dx\right)\left(\int_0^2 1\, dy\right) - \left(\int_0^2 y^2\, dy\right)\left(\int_0^2 1\, dx\right) = 0\end{aligned}$$

29. $\int_0^4 \int_0^9 \sqrt{x + 4y}\, dx\, dy$

SOLUTION We compute the inner integral, treating y as a constant. Then we evaluate the resulting integral with respect to y:

$$\begin{aligned}\int_0^4 \int_0^9 \sqrt{x+4y}\, dx\, dy &= \int_0^4 \frac{2}{3}(x+4y)^{3/2}\Big|_{x=0}^{9} dy = \int_0^4 \frac{2}{3}\left((9+4y)^{3/2} - (4y)^{3/2}\right) dy \\ &= \frac{2}{3}\left(\frac{2}{5\cdot 4}(9+4y)^{5/2} - \frac{2}{5\cdot 4}(4y)^{5/2}\right)\Big|_0^4 \\ &= \frac{1}{15}(5^5 - 4^5) - \frac{1}{15}(3^5 - 0) \approx 123.8667\end{aligned}$$

30. $\int_0^{\pi/4} \int_{\pi/4}^{\pi/2} \cos(2x + y)\, dy\, dx$

SOLUTION

$$\begin{aligned}\int_0^{\pi/4} \int_{\pi/4}^{\pi/2} \cos(2x+y)\, dy\, dx &= \int_0^{\pi/4} \left(\sin(2x+y)\Big|_{\pi/4}^{\pi/2}\right) dx \\ &= \int_0^{\pi/4} \sin\left(2x + \frac{\pi}{2}\right) - \sin\left(2x + \frac{\pi}{4}\right) dx \\ &= \frac{1}{2}\left(-\cos\left(2x + \frac{\pi}{2}\right) + \cos\left(2x + \frac{\pi}{4}\right)\right)\Big|_0^{\pi/4} \\ &= \frac{1}{2}\left(-\cos\pi + \cos\frac{3\pi}{4} + \cos\frac{\pi}{2} - \cos\frac{\pi}{4}\right) \\ &= \frac{1}{2}\left(1 - \frac{1}{\sqrt{2}} + 0 - \frac{1}{\sqrt{2}}\right) = \frac{1}{2} - \frac{1}{\sqrt{2}}\end{aligned}$$

31. $\int_1^2 \int_0^4 \frac{dy\, dx}{x + y}$

SOLUTION The inner integral is an iterated integral with respect to y. We evaluate it first and then compute the resulting integral with respect to x. This gives

$$\int_1^2 \int_0^4 \frac{dy\, dx}{x+y} = \int_1^2 \left(\int_0^4 \frac{dy}{x+y}\right) dx = \int_1^2 \ln(x+y)\Big|_{y=0}^{4} dx = \int_1^2 (\ln(x+4) - \ln x)\, dx$$

We use the integral formula:

$$\int \ln(x+a)\, dx = (x+a)\left(\ln(x+a) - 1\right) + C$$

We get

$$\begin{aligned}\int_1^2 \int_0^4 \frac{dy\, dx}{x+y} &= (x+4)\left(\ln(x+4) - 1\right) - x(\ln x - 1)\Big|_1^2 \\ &= 6(\ln 6 - 1) - 2(\ln 2 - 1) - (5(\ln 5 - 1) - (\ln 1 - 1)) \\ &= 6\ln 6 - 2\ln 2 - 5\ln 5 \approx 1.31\end{aligned}$$

32. $\int_1^2 \int_2^4 e^{3x-y}\,dy\,dx$

SOLUTION

$$\begin{aligned}
\int_1^2 \int_2^4 e^{3x-y}\,dy\,dx &= \int_1^2 \int_2^4 e^{3x} \cdot e^{-y}\,dy\,dx \\
&= \int_1^2 e^{3x}\,dx \cdot \int_2^4 e^{-y}\,dy \\
&= \left(\frac{1}{3}e^{3x}\bigg|_1^2\right) \cdot \left(-e^{-y}\bigg|_2^4\right) \\
&= \frac{e^6 - e^3}{3} \cdot (e^{-2} - e^{-4}) \approx 14.953
\end{aligned}$$

33. $\int_0^4 \int_0^5 \frac{dy\,dx}{\sqrt{x+y}}$

SOLUTION

$$\begin{aligned}
\int_0^4 \int_0^5 \frac{dy\,dx}{\sqrt{x+y}} &= \int_0^4 \left(\int_0^5 \frac{dy}{\sqrt{x+y}}\right) dx \\
&= \int_0^4 \left(2\sqrt{x+y}\bigg|_{y=0}^5\right) dx \\
&= 2\int_0^4 (\sqrt{x+5} - \sqrt{x})\,dx \\
&= 2\left(\frac{2}{3}(x+5)^{3/2} - \frac{2}{3}x^{3/2}\right)\bigg|_0^4 \\
&= 2\left(\frac{2}{3}\cdot 27 - \frac{2}{3}\cdot 8\right) - 2\left(\frac{2}{3}\cdot 5^{3/2} - 0\right) \\
&= 36 - \frac{32}{3} - \frac{20}{3}\sqrt{5} = \frac{76}{3} - \frac{20}{3}\sqrt{5} \approx 10.426
\end{aligned}$$

34. $\int_0^8 \int_1^2 \frac{x\,dx\,dy}{\sqrt{x^2+y}}$

SOLUTION

$$\begin{aligned}
\int_0^8 \int_1^2 \frac{x\,dx\,dy}{\sqrt{x^2+y}} &= \int_0^8 y \int_1^2 \left(\frac{x\,dx}{\sqrt{x^2+y}}\right) dy \\
&= \int_0^8 \left(\sqrt{x^2+y}\bigg|_1^2\right) dy \\
&= \int_0^8 (\sqrt{4+y} - \sqrt{1+y})\,dy \\
&= \frac{2}{3}(4+y)^{3/2} - \frac{2}{3}(1+y)^{3/2}\bigg|_0^8 \\
&= \frac{2}{3}(12^{3/2} - 27) - \frac{2}{3}(8-1) \\
&= -\frac{68}{3} + 16\sqrt{3} \approx 5.047
\end{aligned}$$

35. $\int_1^2 \int_1^3 \frac{\ln(xy)\,dy\,dx}{y}$

SOLUTION

$$\int_1^2 \int_1^3 \frac{\ln(xy)\,dy\,dx}{y} = \int_1^2 \left(\frac{1}{2}[\ln(xy)]^2\bigg|_1^3\right) dx$$

$$= \frac{1}{2}\int_1^2 [\ln(3x)]^2 - [\ln(x)]^2\,dx$$
$$= \frac{1}{2}\int_1^2 [\ln(3x)]^2\,dx - \frac{1}{2}\int_1^2 [\ln(x)]^2\,dx$$
$$= \frac{1}{2}\left[x(\ln 3x)^2\Big|_1^2 - 2\int_1^2 \ln(3x)\,dx\right] - \frac{1}{2}\left[x(\ln x)^2\Big|_1^2 - 2\int_1^2 \ln x\,dx\right]$$
$$= \frac{1}{2}\left[2(\ln 6)^2 - (\ln 3)^2\right] - \int_1^2 \ln(3x)\,dx - \frac{1}{2}\left[2(\ln 2)^2 - 0\right] + \int_1^2 \ln x\,dx$$
$$= (\ln 6)^2 - \frac{1}{2}(\ln 3)^2 - \left[x\ln(3x) - x\Big|_1^2\right] - (\ln 2)^2 + \left[x\ln x - x\Big|_1^2\right]$$
$$= (\ln 6)^2 - \frac{1}{2}(\ln 3)^2 - (\ln 2)^2 - (2\ln 6 - 2 - \ln 3 + 1) + (2\ln 2 - 2 - 0 + 1)$$
$$= (\ln 6)^2 - \frac{1}{2}(\ln 3)^2 - (\ln 2)^2 - 2\ln 6 + \ln 3 + 1 + 2\ln 2 - 2 + 1$$
$$= (\ln 6)^2 - \frac{1}{2}(\ln 3)^2 - (\ln 2)^2 - 2\ln 6 + \ln 3 + 2\ln 2 \approx 1.028$$

36. $\displaystyle\int_0^1\int_2^3 \frac{1}{(x+4y)^3}\,dx\,dy$

SOLUTION We calculate the inner integral with respect to x, then we compute the resulting integral with respect to y. This gives

$$\int_0^1\int_2^3 \frac{1}{(x+4y)^3}\,dx\,dy = \int_0^1\left(\int_2^3 (x+4y)^{-3}\,dx\right)dy = \int_0^1 -\frac{1}{2}(x+4y)^{-2}\Big|_{x=2}^3\,dy$$
$$= -\frac{1}{2}\int_0^1\left((3+4y)^{-2} - (2+4y)^{-2}\right)dy = -\frac{1}{2\cdot 4}\left(-(3+4y)^{-1} + (2+4y)^{-1}\right)\Big|_0^1$$
$$= -\frac{1}{8}\left(\frac{1}{2+4y} - \frac{1}{3+4y}\right)\Big|_0^1 = -\frac{1}{8}\left(\left(\frac{1}{6}-\frac{1}{7}\right) - \left(\frac{1}{2}-\frac{1}{3}\right)\right)$$
$$= \frac{1}{8}\left(\frac{1}{7} - \frac{1}{6} + \frac{1}{2} - \frac{1}{3}\right) = \frac{1}{56}$$

In Exercises 37–42, use Eq. (1) to evaluate the integral.

37. $\displaystyle\iint_{\mathcal{R}} \frac{x}{y}\,dA, \quad \mathcal{R} = [-2,4]\times[1,3]$

SOLUTION We compute the double integral as the product of two single integrals:

$$\iint_{\mathcal{R}} \frac{x}{y}\,dA = \int_{-2}^4\int_1^3 \frac{x}{y}\,dy\,dx = \int_{-2}^4 x\,dx \cdot \int_1^3 \frac{1}{y}\,dy$$
$$= \left(\frac{1}{2}x^2\Big|_{-2}^4\right)\left(\ln y\Big|_1^3\right) = \frac{1}{2}(16-4)\cdot(\ln 3 - \ln 1)$$
$$= 6\ln 3$$

38. $\displaystyle\iint_{\mathcal{R}} x^2y\,dA, \quad \mathcal{R} = [-1,1]\times[0,2]$

SOLUTION We compute the double integral as the product of two single integrals:

$$\iint_{\mathcal{R}} x^2y\,dA = \int_0^2\int_{-1}^1 x^2y\,dx\,dy = \left(\int_{-1}^1 x^2\,dx\right)\left(\int_0^2 y\,dy\right) = \left(\frac{1}{3}x^3\Big|_{-1}^1\right)\left(\frac{1}{2}y^2\Big|_0^2\right) = \frac{2}{3}\cdot\frac{1}{2}\cdot 4 = \frac{4}{3}$$

39. $\iint_{\mathcal{R}} \cos x \sin 2y\, dA, \quad \mathcal{R} = \left[0, \frac{\pi}{2}\right] \times \left[0, \frac{\pi}{2}\right]$

SOLUTION Since the integrand has the form $f(x, y) = g(x)h(y)$, we may compute the double integral as the product of two single integrals. That is,

$$\iint_{\mathcal{R}} \cos x \sin 2y\, dA = \int_0^{\pi/2} \int_0^{\pi/2} \cos x \sin 2y\, dx\, dy = \left(\int_0^{\pi/2} \cos x\, dx\right)\left(\int_0^{\pi/2} \sin 2y\, dy\right)$$

$$= \left(\sin x \Big|_0^{\pi/2}\right)\left(-\frac{1}{2}\cos 2y \Big|_0^{\pi/2}\right) = \left(\sin\frac{\pi}{2} - \sin 0\right)\left(-\frac{1}{2}\cos\pi + \frac{1}{2}\cos 0\right)$$

$$= (1 - 0)\left(\frac{1}{2} + \frac{1}{2}\right) = 1$$

40. $\iint_{\mathcal{R}} \frac{y}{x+1}\, dA, \quad \mathcal{R} = [0, 2] \times [0, 4]$

SOLUTION We evaluate the integral as the product of two single integrals. This can be done since the function has the form $f(x, y) = g(x)h(y)$.

$$\iint_{\mathcal{R}} \frac{y}{x+1}\, dA = \int_0^4 \int_0^2 \frac{y}{x+1}\, dx\, dy = \left(\int_0^2 \frac{dx}{x+1}\right)\left(\int_0^4 y\, dy\right)$$

$$= \left(\ln(x+1)\Big|_0^2\right)\left(\frac{y^2}{2}\Big|_0^4\right) = (\ln 3 - \ln 1)\left(\frac{4^2}{2} - \frac{0^2}{2}\right) = 8\ln 3 \approx 8.79$$

41. $\iint_{\mathcal{R}} e^x \sin y\, dA, \quad \mathcal{R} = [0, 2] \times \left[0, \frac{\pi}{4}\right]$

SOLUTION We compute the double integral as the product of two single integrals. This can be done since the integrand has the form $f(x, y) = g(x)h(y)$. We get

$$\iint_{\mathcal{R}} e^x \sin y\, dA = \int_0^{\pi/4} \int_0^2 e^x \sin y\, dx\, dy = \left(\int_0^2 e^x\, dx\right)\left(\int_0^{\pi/4} \sin y\, dy\right)$$

$$= \left(e^x\Big|_0^2\right)\left(-\cos y\Big|_0^{\pi/4}\right) = \left(e^2 - e^0\right)\left(-\cos\frac{\pi}{4} + \cos 0\right) = \left(e^2 - 1\right)\left(1 - \frac{\sqrt{2}}{2}\right) \approx 1.87$$

42. $\iint_{\mathcal{R}} e^{3x+4y}\, dA, \quad \mathcal{R} = [0, 1] \times [1, 2]$

SOLUTION We can compute this double integral as the product of two single integrals:

$$\iint_{\mathcal{R}} e^{3x+4y}\, dA = \int_0^1 \int_1^2 e^{3x+4y}\, dy\, dx = \int_0^1 \int_1^2 e^{3x} e^{4y}\, dy\, dx$$

$$= \int_0^1 e^{3x}\, dx \cdot \int_1^2 e^{4y}\, dy = \left(\frac{1}{3}e^{3x}\Big|_0^1\right)\left(\frac{1}{4}e^{4y}\Big|_1^2\right)$$

$$= \frac{1}{3}(e^3 - 1) \cdot \frac{1}{4}(e^8 - e^1) = \frac{1}{12}(e^3 - 1)(e^8 - e)$$

43. Let $f(x, y) = mxy^2$, where m is a constant. Find a value of m such that $\iint_{\mathcal{R}} f(x, y)\, dA = 1$, where $\mathcal{R} = [0, 1] \times [0, 2]$.

SOLUTION Since $f(x, y) = mxy^2$ is a product of a function of x and a function of y, we may compute the double integral as the product of two single integrals. That is,

$$\int_0^2 \int_0^1 mxy^2\, dx\, dy = m\left(\int_0^1 x\, dx\right)\left(\int_0^2 y^2\, dy\right) \tag{1}$$

We compute each integral:

$$\int_0^1 x\, dx = \frac{1}{2}x^2\Big|_0^1 = \frac{1}{2}\left(1^2 - 0^2\right) = \frac{1}{2}$$

$$\int_0^2 y^2\, dy = \frac{1}{3}y^3\Big|_0^2 = \frac{1}{3}\left(2^3 - 0^3\right) = \frac{8}{3}$$

We substitute in (1), equate to 1 and solve the resulting equation for m. This gives

$$m \cdot \frac{1}{2} \cdot \frac{8}{3} = 1 \quad \Rightarrow \quad m = \frac{3}{4}$$

44. Evaluate $I = \int_1^3 \int_0^1 ye^{xy}\,dy\,dx$. You will need Integration by Parts and the formula

$$\int e^x (x^{-1} - x^{-2})\,dx = x^{-1}e^x + C$$

Then evaluate I again using Fubini's Theorem to change the order of integration (that is, integrate first with respect to x). Which method is easier?

SOLUTION We evaluate the inner integral with respect to y. Using integration by parts with $dv = e^{xy}\,dy$, $u = y$ we obtain

$$\int ye^{xy}\,dy = \frac{y}{x}e^{xy} - \int \frac{1}{x}e^{xy}\,dy = \frac{y}{x}e^{xy} - \frac{1}{x} \cdot \frac{1}{x}e^{xy} + C = \frac{e^{xy}}{x}\left(y - \frac{1}{x}\right) + C$$

Hence,

$$\int_0^1 ye^{xy}\,dy = \frac{e^{xy}}{x}\left(y - \frac{1}{x}\right)\Big|_{y=0}^{1} = \frac{e^x}{x}\left(1 - \frac{1}{x}\right) - \frac{1}{x}\left(0 - \frac{1}{x}\right) = e^x\left(x^{-1} - x^{-2}\right) + x^{-2}$$

We now integrate the result with respect to x, using the given integration formula:

$$\begin{aligned}\int_1^3 \left(e^x\left(x^{-1} - x^{-2}\right) + x^{-2}\right)dx &= \int_1^3 e^x\left(x^{-1} - x^{-2}\right)dx + \int_1^3 x^{-2}\,dx = x^{-1}e^x\Big|_1^3 - x^{-1}\Big|_1^3 \\ &= \frac{e^3}{3} - e - \left(\frac{1}{3} - 1\right) = \frac{e^3}{3} - e + \frac{2}{3} \approx 4.644\end{aligned}$$

The double integral is thus

$$\int_1^3 \int_0^1 ye^{xy}\,dy\,dx = \int_1^3 \left(\int_0^1 ye^{xy}\,dy\right)dx \approx 4.644$$

Using Fubini's Theorem, we now evaluate the double integral first with respect to x and then with respect to y (keeping the corresponding limits of integration). We obtain

$$\begin{aligned}\int_1^3 \int_0^1 ye^{xy}\,dy\,dx &= \int_0^1 \int_1^3 ye^{xy}\,dx\,dy = \int_0^1 \left(\int_1^3 ye^{xy}\,dx\right)dy = \int_0^1 \left(\frac{y}{y}e^{xy}\Big|_{x=1}^{3}\right)dy \\ &= \int_0^1 \left(e^{3y} - e^y\right)dy = \frac{1}{3}e^{3y} - e^y\Big|_0^1 = \left(\frac{1}{3}e^3 - e\right) - \left(\frac{1}{3}e^0 - e^0\right) \\ &= \frac{1}{3}e^3 - e - \left(\frac{1}{3} - 1\right) = \frac{1}{3}e^3 - e + \frac{2}{3} \approx 4.644\end{aligned}$$

Obviously, integrating first with respect to x and then with respect to y makes the computation much easier than using the reversed order.

45. Evaluate $\int_0^1 \int_0^1 \frac{y}{1+xy}\,dy\,dx$. *Hint:* Change the order of integration.

SOLUTION Using Fubini's Theorem we change the order of integration, integrating first with respect to x and then with respect to y. This gives

$$\begin{aligned}\int_0^1 \int_0^1 \frac{y}{1+xy}\,dy\,dx &= \int_0^1 \left(\int_0^1 \frac{y}{1+xy}\,dx\right)dy = \int_0^1 \left(y\int_0^1 \frac{dx}{1+xy}\right)dy = \int_0^1 y \cdot \frac{1}{y}\ln(1+xy)\Big|_{x=0}^{1} dy \\ &= \int_0^1 (\ln(1+y) - \ln 1)\,dy = \int_0^1 \ln(1+y)\,dy = (1+y)\left(\ln(1+y) - 1\right)\Big|_{y=0}^{1} \\ &= 2(\ln 2 - 1) - (\ln 1 - 1) = 2\ln 2 - 1 \approx 0.386\end{aligned}$$

46. Calculate a Riemann sum $S_{3,3}$ on the square $\mathcal{R} = [0, 3] \times [0, 3]$ for the function $f(x, y)$ whose contour plot is shown in Figure 17. Choose sample points and use the plot to find the values of $f(x, y)$ at these points.

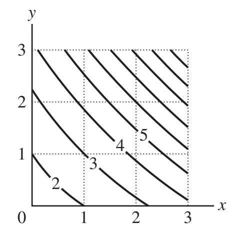


FIGURE 17 Contour plot of $f(x, y)$.

SOLUTION Each subrectangle is a square of side length 1, hence its area is $\Delta A = 1^2 = 1$. We choose the sample points shown in the figure. The contour plot shows the following values of f at the sample points:

$$\begin{array}{lll} f(P_{11}) = 2 & f(P_{21}) = 3 & f(P_{31}) = 4 \\ f(P_{12}) = 3 & f(P_{22}) = 4 & f(P_{32}) = 7 \\ f(P_{13}) = 5 & f(P_{23}) = 6 & f(P_{33}) = 10 \end{array}$$

The Riemann sum S_{33} is thus

$$S_{33} = \sum_{i=1}^{3}\sum_{j=1}^{3} f\left(P_{ij}\right)\Delta A = \sum_{i=1}^{3}\sum_{j=1}^{3} f\left(P_{ij}\right)\cdot 1 = 2+3+4+3+4+7+5+6+10 = 44$$

47. Using Fubini's Theorem, argue that the solid in Figure 18 has volume AL, where A is the area of the front face of the solid.

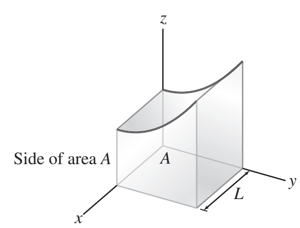

FIGURE 18

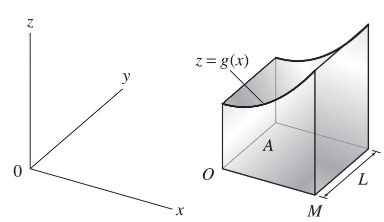
SOLUTION We denote by M the length of the other side of the rectangle in the basis of the solid. The volume of the solid is the double integral of the function $f(x, y) = g(x)$ over the rectangle

$$\mathcal{R} = [0, M] \times [0, L]$$

$$V = \iint_{\mathcal{R}} g(x)\, dA.$$



We use Fubini's Theorem to write the double integral as iterated integral, and then compute the resulting integral as the product of two single integrals. This gives

$$V = \iint_{\mathcal{R}} g(x)\, dA = \int_0^L \int_0^M g(x)\, dx\, dy = \left(\int_0^M g(x)\, dx\right)\left(\int_0^L 1\, dy\right) = \left(\int_0^M g(x)\, dx\right)\cdot L \qquad (1)$$

The integral $\int_0^M g(x)dx$ is the area A of the region under the graph of $z = g(x)$ over the interval $0 \le x \le M$. Substituting in (1) gives the following volume of the solid:

$$V = \left(\int_0^M g(x)dx\right)\cdot L = AL$$

Further Insights and Challenges

48. Prove the following extension of the Fundamental Theorem of Calculus to two variables: If $\dfrac{\partial^2 F}{\partial x\,\partial y} = f(x, y)$, then

$$\iint_{\mathcal{R}} f(x, y)\,dA = F(b, d) - F(a, d) - F(b, c) + F(a, c)$$

where $\mathcal{R} = [a, b] \times [c, d]$.

SOLUTION By Fubini's Theorem we get

$$\iint_{\mathcal{R}} f(x, y)\,dx = \int_c^d \int_a^b \frac{\partial^2 F}{\partial x\,\partial y}\,dx\,dy = \int_c^d \left(\int_a^b \frac{\partial}{\partial x}\left(\frac{\partial F}{\partial y}\right)dx\right)dy \tag{1}$$

In the inner integral, y is considered as constant. Therefore, by the Fundamental Theorem of calculus (part I) for the variable x, we have

$$\int_a^b \frac{\partial}{\partial x}\left(\frac{\partial F}{\partial y}\right)dx = \frac{\partial F}{\partial y}\bigg|_{x=b} - \frac{\partial F}{\partial y}\bigg|_{x=a} = \frac{\partial F}{\partial y}(b, y) - \frac{\partial F}{\partial y}(a, y)$$

We substitute in (1), use additivity of the single integral and use again the Fundamental Theorem, this time for the variable y. This gives

$$\begin{aligned}
\iint_{\mathcal{R}} f(x, y)\,dx &= \int_c^d \left(\frac{\partial F}{\partial y}(b, y) - \frac{\partial F}{\partial y}(a, y)\right)dy = \int_c^d \frac{\partial F}{\partial y}(b, y)\,dy - \int_c^d \frac{\partial F}{\partial y}(a, y)\,dy \\
&= \left(F(b, y)\bigg|_{y=d} - F(b, y)\bigg|_{y=c}\right) - \left(F(a, y)\bigg|_{y=d} - F(a, y)\bigg|_{y=c}\right) \\
&= F(b, d) - F(b, c) - F(a, d) + F(a, c)
\end{aligned}$$

49. Let $F(x, y) = x^{-1}e^{xy}$. Show that $\dfrac{\partial^2 F}{\partial x\,\partial y} = ye^{xy}$ and use the result of Exercise 48 to evaluate $\iint_{\mathcal{R}} ye^{xy}\,dA$ for the rectangle $\mathcal{R} = [1, 3] \times [0, 1]$.

SOLUTION Differentiating $F(x, y) = x^{-1}e^{xy}$ with respect to y gives

$$\frac{\partial F}{\partial y} = \frac{\partial}{\partial y}\left(x^{-1}e^{xy}\right) = x^{-1}xe^{xy} = e^{xy}$$

We now differentiate $\frac{\partial F}{\partial y}$ with respect to x:

$$\frac{\partial^2 F}{\partial x\,\partial y} = \frac{\partial}{\partial x}\left(e^{xy}\right) = ye^{xy}$$

In Exercise 48 we showed that

$$\int_c^d \int_a^b \frac{\partial^2 F}{\partial x\,\partial y}\,dx\,dy = F(b, d) - F(b, c) - F(a, d) + F(a, c)$$

Therefore, for $F(x, y) = x^{-1}e^{xy} = \frac{e^{xy}}{x}$ we obtain

$$\begin{aligned}
\iint_{\mathcal{R}} ye^{xy}\,dA &= \int_0^1 \int_1^3 ye^{xy}\,dx\,dy = F(3, 1) - F(3, 0) - F(1, 1) + F(1, 0) \\
&= \frac{e^3}{3} - \frac{e^0}{3} - \frac{e^1}{1} + \frac{e^0}{1} = \frac{e^3}{3} - \frac{1}{3} - e + 1 = 4.644
\end{aligned}$$

50. Find a function $F(x, y)$ satisfying $\dfrac{\partial^2 F}{\partial x\,\partial y} = 6x^2y$ and use the result of Exercise 48 to evaluate $\iint_{\mathcal{R}} 6x^2y\,dA$ for the rectangle $\mathcal{R} = [0, 1] \times [0, 4]$.

SOLUTION We integrate $\frac{\partial^2 F}{\partial x \partial y}$ with respect to x, taking zero as the constant of integration. We get $\frac{\partial F}{\partial y} = 6y\frac{x^3}{3} = 2yx^3$. We now integrate with respect to y, obtaining

$$F(x, y) = 2 \cdot \frac{y^2}{2}x^3 = y^2x^3$$

In Exercise 48 we showed that

$$\int_c^d \int_a^b \frac{\partial^2 F}{\partial x\, \partial y}\, dx\, dy = F(b,d) - F(b,c) - F(a,d) + F(a,c)$$

For $F(x, y) = y^2 x^3$ we get

$$\iint_{\mathcal{R}} 6x^2 y\, dA = \int_0^4 \int_0^1 6x^2 y\, dx\, dy = F(1,4) - F(1,0) - F(0,4) + F(0,0) = 4^2 \cdot 1^3 - 0 - 0 + 0 = 16$$

51. In this exercise, we use double integration to evaluate the following improper integral for $a > 0$ a positive constant:

$$I(a) = \int_0^\infty \frac{e^{-x} - e^{-ax}}{x}\, dx$$

(a) Use L'Hôpital's Rule to show that $f(x) = \dfrac{e^{-x} - e^{-ax}}{x}$, though not defined at $x = 0$, can be made continuous by assigning the value $f(0) = a - 1$.

(b) Prove that $|f(x)| \le e^{-x} + e^{-ax}$ for $x > 1$ (use the triangle inequality), and apply the Comparison Theorem to show that $I(a)$ converges.

(c) Show that $I(a) = \displaystyle\int_0^\infty \int_1^a e^{-xy}\, dy\, dx$.

(d) Prove, by interchanging the order of integration, that

$$I(a) = \ln a - \lim_{T \to \infty} \int_1^a \frac{e^{-Ty}}{y}\, dy \qquad \boxed{2}$$

(e) Use the Comparison Theorem to show that the limit in Eq. (2) is zero. *Hint:* If $a \ge 1$, show that $e^{-Ty}/y \le e^{-T}$ for $y \ge 1$, and if $a < 1$, show that $e^{-Ty}/y \le e^{-aT}/a$ for $a \le y \le 1$. Conclude that $I(a) = \ln a$ (Figure 19).

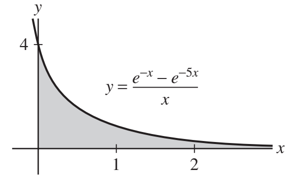


FIGURE 19 The shaded region has area ln 5.

SOLUTION

(a) The function $f(x) = \frac{e^{-x} - e^{-ax}}{x}$, $f(0) = a - 1$ is continuous if $\lim_{x \to 0} f(x) = f(0) = a - 1$. We verify this limit using L'Hôpital's Rule:

$$\lim_{x \to 0} \frac{e^{-x} - e^{-ax}}{x} = \lim_{x \to 0} \frac{-e^{-x} + ae^{-ax}}{1} = -1 + a = a - 1$$

Therefore, f is continuous.

(b) We now show that the following integral converges:

$$I(a) = \int_0^\infty \frac{e^{-x} - e^{-ax}}{x}\, dx \qquad (a > 0)$$

Since $e^{-x} - e^{-ax} < e^{-x} + e^{-ax}$ then also $\frac{e^{-x} - e^{-ax}}{x} < \frac{e^{-x} + e^{-ax}}{x}$ for $x > 0$. Therefore, if $x > 1$ we have

$$\frac{e^{-x} - e^{-ax}}{x} < \frac{e^{-x} + e^{-ax}}{x} < e^{-x} + e^{-ax}$$

That is, for $x > 1$,

$$f(x) < e^{-x} + e^{-ax} \qquad (1)$$

Also, since $e^{-ax} - e^{-x} < e^{-ax} + e^{-x}$ we have for $x > 1$,

$$\frac{e^{-ax} - e^{-x}}{x} < \frac{e^{-ax} + e^{-x}}{x} < e^{-ax} + e^{-x}$$

Thus, we get

$$-f(x) < e^{-x} + e^{-ax} \qquad (2)$$

Together with (1) we have

$$0 \le |f(x)| < e^{-x} + e^{-ax} \tag{3}$$

We now show that the integral of the right hand-side converges:

$$\begin{aligned}
\int_0^{\infty} \left(e^{-x} + e^{-ax}\right) dx &= \lim_{\mathcal{R}\to\infty} \int_0^{\mathcal{R}} \left(e^{-x} + e^{-ax}\right) dx \\
&= \lim_{\mathcal{R}\to\infty} \left(-e^{-x} - \frac{e^{-ax}}{a} \Big|_{x=0}^{\mathcal{R}} \right) \\
&= \lim_{R\to\infty} \left(-e^{-\mathcal{R}} - \frac{e^{-aR}}{a} + e^0 + \frac{e^0}{a} \right) \\
&= \lim_{\mathcal{R}\to\infty} \left(-e^{-\mathcal{R}} - \frac{e^{-a\mathcal{R}}}{a} + 1 + \frac{1}{a} \right) \\
&= 1 + \frac{1}{a}
\end{aligned}$$

Since the integral converges, we conclude by (3) and the Comparison Test for Improper Integrals that

$$\int_0^{\infty} \frac{e^{-x} - e^{-ax}}{x}\, dx$$

also converges for $a > 0$.

(c) We compute the inner integral with respect to y:

$$\int_1^a e^{-xy}\, dy = -\frac{1}{x} e^{-xy} \Big|_{y=1}^{a} = -\frac{1}{x}\left(e^{-xa} - e^{-x\cdot 1}\right) = \frac{e^{-x} - e^{-xa}}{x}$$

Therefore,

$$\int_0^{\infty} \int_1^a e^{-xy}\, dy\, dx = \int_0^{\infty} \left(\int_1^a e^{-xy}\, dy \right) dx = \int_0^{\infty} \frac{e^{-x} - e^{-xa}}{x}\, dx = I(a)$$

(d) By the definition of the improper integral,

$$I(a) = \lim_{T\to\infty} \int_0^T \int_1^a e^{-xy}\, dy\, dx \tag{4}$$

We compute the double integral. Using Fubini's Theorem we may compute the iterated integral using reversed order of integration. That is,

$$\begin{aligned}
\int_0^T \int_1^a e^{-xy}\, dy\, dx &= \int_1^a \int_0^T e^{-xy}\, dx\, dy = \int_1^a \left(\int_0^T e^{-xy}\, dx \right) dy = \int_1^a \left(-\frac{1}{y} e^{-xy} \Big|_{x=0}^{T} \right) dy \\
&= \int_1^a \left(-\frac{1}{y}\left(e^{-Ty} - e^{-0\cdot y}\right)\right) dy = \int_1^a \frac{1 - e^{-Ty}}{y}\, dy = \int_1^a \frac{dy}{y} - \int_1^a \frac{e^{-Ty}}{y}\, dy \\
&= \ln y \Big|_1^a - \int_1^a \frac{e^{-Ty}}{y}\, dy = \ln a - \ln 1 - \int_1^a \frac{e^{-Ty}}{y}\, dy = \ln a - \int_1^a \frac{e^{-Ty}}{y}\, dy
\end{aligned}$$

Combining with (4) we get

$$I(a) = \ln a - \lim_{T\to\infty} \int_1^a \frac{e^{-Ty}}{y}\, dy \tag{5}$$

(e) We now show, using the Comparison Theorem, that

$$\lim_{T\to\infty} \int_1^a \frac{e^{-Ty}}{y}\, dy = 0$$

We consider the following possible cases:

Case 1: $a \ge 1$. Then in the interval of integration $y \ge 1$. Also since $T \to \infty$, we may assume that $T > 0$. Thus,

$$\frac{e^{-Ty}}{y} \le \frac{e^{-T\cdot 1}}{1} = e^{-T}$$

Hence,

$$0 \le \int_1^a \frac{e^{-Ty}}{y}\,dy \le \int_1^a e^{-T}\,dy = e^{-T}(a-1)$$

By the limit $\lim_{T\to\infty} e^{-T}(a-1) = 0$ and the Squeeze Theorem we conclude that,

$$\lim_{T\to\infty}\int_1^a \frac{e^{-Ty}}{y}\,dy = 0$$

Case 2: $0 < a < 1$. Then,

$$\int_1^a \frac{e^{-Ty}}{y}\,dy = -\int_a^1 \frac{e^{-Ty}}{y}\,dy$$

and in the interval of integration $a \le y \le 1$, therefore

$$\frac{e^{-Ty}}{y} \le \frac{e^{-Ta}}{a}$$

(the function $\frac{e^{-Ty}}{y}$ is decreasing). Hence,

$$0 \le \int_a^1 \frac{e^{-Ty}}{y}\,dy \le \int_a^1 \frac{e^{-Ta}}{a}\,dy = \frac{(1-a)}{a}e^{-Ta}$$

By the limit $\lim_{T\to\infty} \frac{1-a}{a}e^{-Ta} = 0$ and the Squeeze Theorem we conclude also that

$$\lim_{T\to\infty}\int_1^a \frac{e^{-Ty}}{y} = -\lim_{T\to\infty}\int_a^1 \frac{e^{-Ty}}{y} = 0$$

We thus showed that for all $a > 0$, $\lim_{T\to\infty}\int_1^a \frac{e^{-Ty}}{y} = 0$. Combining with Eq. (5) obtained in part (c), we find that $I(a) = \ln a$.

15.2 Double Integrals over More General Regions (LT Section 16.2)

Preliminary Questions

1. .Which of the following expressions do not make sense?

(a) $\int_0^1 \int_1^x f(x,y)\,dy\,dx$

(b) $\int_0^1 \int_1^y f(x,y)\,dy\,dx$

(c) $\int_0^1 \int_x^y f(x,y)\,dy\,dx$

(d) $\int_0^1 \int_x^1 f(x,y)\,dy\,dx$

SOLUTION

(a) This integral is the following iterated integral:

$$\int_0^1 \int_1^x f(x,y)\,dy\,dx = \int_0^1 \left(\int_1^x f(x,y)\,dy\right)dx$$

The inner integral is a function of x and it is integrated with respect to x over the interval $0 \le x \le 1$. The result is a number. This integral makes sense.

(b) This integral is the same as

$$\int_0^1 \int_1^y f(x,y)\,dy\,dx = \int_0^1 \left(\int_1^y f(x,y)\,dy\right)dx$$

The inner integral is an integral with respect to y, over the interval $[1, y]$. This does not make sense.

(c) This integral is the following iterated integral:

$$\int_0^1 \left(\int_x^y f(x,y)\right)dy\,dx$$

The inner integral is a function of x and y and it is integrated with respect to y over the interval $x \le y \le y$. This does not make sense.

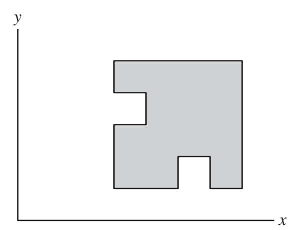
(d) This integral is the following iterated integral:

$$\int_0^1 \left(\int_x^1 f(x, y)\, dy \right) dx$$

The inner integral is a function of x and it is integrated with respect to x. This makes sense.

2. Draw a domain in the plane that is neither vertically nor horizontally simple.

SOLUTION The following region cannot be described in the form $\{a \le x \le b, \alpha(x) \le y \le \beta(x)\}$ nor in the form $\{c \le y \le d, \alpha(y) \le x \le \beta(y)\}$, hence it is neither vertically nor horizontally simple.



3. Which of the four regions in Figure 18 is the domain of integration for $\int_{-\sqrt{2}/2}^{0} \int_{-x}^{\sqrt{1-x^2}} f(x, y)\, dy\, dx$?

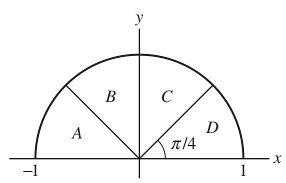


FIGURE 18

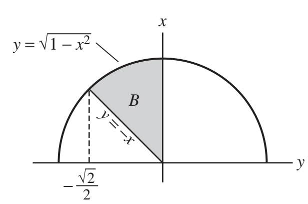
SOLUTION The region B is defined by the inequalities

$$-x \le y \le \sqrt{1 - x^2}, \qquad -\frac{\sqrt{2}}{2} \le x \le 0$$

To compute $\int_{-\sqrt{2}/2}^{0} \int_{-x}^{\sqrt{1-x^2}} f(x, y)\, dy\, dx$, we first integrate with respect to y over the interval $-x \le y \le \sqrt{1 - x^2}$, and then with respect to x over $-\frac{\sqrt{2}}{2} \le x \le 0$. That is, the domain of integration is B.



4. Let $\mathcal{D}$ be the unit disk. If the maximum value of $f(x, y)$ on $\mathcal{D}$ is 4, then the largest possible value of $\iint_{\mathcal{D}} f(x, y)\, dA$ is (choose the correct answer):

(a) 4 **(b)** 4π **(c)** $\frac{4}{\pi}$

SOLUTION The area of the unit disk is π and the maximum value of $f(x, y)$ on this region is $M = 4$, therefore we have,

$$\iint_{\mathcal{D}} f(x, y)\, dx\, dy \le 4\pi$$

The correct answer is (b).

Exercises

1. Calculate the Riemann sum for $f(x, y) = x - y$ and the shaded domain $\mathcal{D}$ in Figure 19 with two choices of sample points, $\bullet$ and $\circ$. Which do you think is a better approximation to the integral of f over $\mathcal{D}$? Why?

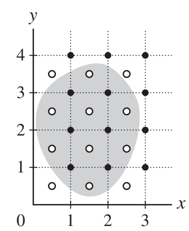


FIGURE 19

SOLUTION The subrectangles in Figure 17 have sides of length $\Delta x = \Delta y = 1$ and area $\Delta A = 1 \cdot 1 = 1$.

(a) Sample points $\bullet$. There are six sample points that lie in the domain $\mathcal{D}$. We compute the values of $f(x, y) = x - y$ at these points:

$$f(1,1) = 0, \qquad f(1,2) = -1, \qquad f(1,3) = -2,$$
$$f(2,1) = 1, \qquad f(2,2) = 0, \qquad f(2,3) = -1$$

The Riemann sum is

$$S_{3,4} = (0 - 1 - 2 + 1 + 0 - 1) \cdot 1 = -3$$

(b) Sample points $\circ$. We compute the values of $f(x, y) = x - y$ at the eight sample points that lie in $\mathcal{D}$:

$$\begin{array}{lll} & f(0.5, 1.5) = -1, & f(0.5, 2.5) = -2, \\ f(1.5, 0.5) = 1, & f(1.5, 1.5) = 0, & f(1.5, 2.5) = -1, \\ f(1.5, 3.5) = -2, & f(2.5, 1.5) = 1, & f(2.5, 2.5) = 0. \end{array}$$

The corresponding Riemann sum is thus

$$S_{34} = (1 - 1 - 2 + 0 - 1 - 2 + 1 + 0) \cdot 1 = -4.$$

2. Approximate values of $f(x, y)$ at sample points on a grid are given in Figure 20. Estimate $\iint_{\mathcal{D}} f(x, y)\,dx\,dy$ for the shaded domain by computing the Riemann sum with the given sample points.

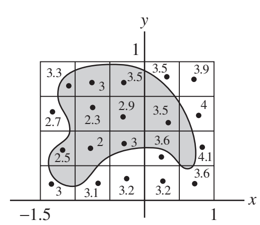

FIGURE 20

SOLUTION The subrectangles have sides of length $\Delta x = 0.5$ and $\Delta y = 0.25$, so the area is $\Delta A = 0.5 \cdot 0.25 = 0.125$. Only nine of the sample points lie in $\mathcal{D}$, hence the corresponding Riemann sum is

$$S_{5,4} = (2.5 + 3.3 + 2 + 2.3 + 3 + 3 + 2.9 + 3.5 + 3.5) \cdot 0.125 = 3.25$$

3. Express the domain $\mathcal{D}$ in Figure 21 as both a vertically simple region and a horizontally simple region, and evaluate the integral of $f(x, y) = xy$ over $\mathcal{D}$ as an iterated integral in two ways.

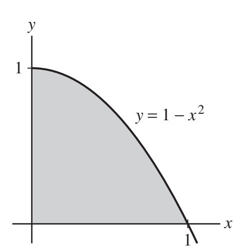

FIGURE 21

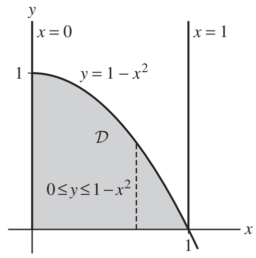
SOLUTION The domain $\mathcal{D}$ can be described as a vertically simple region as follows:

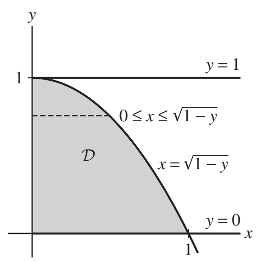
$$0 \le x \le 1, \quad 0 \le y \le 1 - x^2 \tag{1}$$



Vertically simple region

The domain $\mathcal{D}$ can also be described as a horizontally simple region. To do this, we must express x in terms of y, for nonnegative values of x. This gives

$$y = 1 - x^2 \quad \Rightarrow \quad x^2 = 1 - y \quad \Rightarrow \quad x = \sqrt{1-y}$$



Horizontally simple region

Therefore, we can describe $\mathcal{D}$ by the following inequalities:

$$0 \le y \le 1, \quad 0 \le x \le \sqrt{1-y} \tag{2}$$

We now compute the integral of $f(x, y) = xy$ over $\mathcal{D}$ first using definition (1) and then using definition (2). We obtain

$$\iint_{\mathcal{D}} xy\, dA = \int_0^1 \int_0^{1-x^2} xy\, dy\, dx = \int_0^1 \frac{xy^2}{2}\bigg|_{y=0}^{1-x^2} dx = \int_0^1 \frac{x}{2}\left((1-x^2)^2 - 0^2\right) dx = \int_0^1 \frac{x(1-x^2)^2}{2}\, dx$$

$$= \frac{1}{2}\int_0^1 (x - 2x^3 + x^5)\, dx = \frac{1}{2}\left(\frac{x^2}{2} - \frac{x^4}{2} + \frac{x^6}{6}\right)\bigg|_0^1 = \frac{1}{2}\left(\frac{1}{2} - \frac{1}{2} + \frac{1}{6}\right) = \frac{1}{12}$$

Using definition (2) gives

$$\iint_{\mathcal{D}} xy\, dA = \int_0^1 \int_0^{\sqrt{1-y}} xy\, dx\, dy = \int_0^1 \frac{yx^2}{2}\bigg|_{x=0}^{\sqrt{1-y}} dy = \int_0^1 \frac{y}{2}\left(\left(\sqrt{1-y}\right)^2 - 0^2\right) dy$$

$$= \int_0^1 \frac{y}{2}(1-y)\, dy = \int_0^1 \left(\frac{y}{2} - \frac{y^2}{2}\right) dy = \frac{y^2}{4} - \frac{y^3}{6}\bigg|_0^1 = \frac{1}{4} - \frac{1}{6} = \frac{1}{12}$$

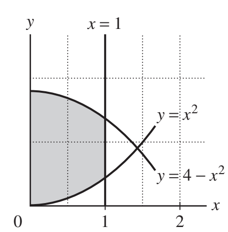
The answers agree as expected.

4. Sketch the domain

$$\mathcal{D} : 0 \le x \le 1, \quad x^2 \le y \le 4 - x^2$$

and evaluate $\iint_{\mathcal{D}} y\, dA$ as an iterated integral.

SOLUTION The domain $\mathcal{D}$ is shown in the following figure:



$\mathcal{D}$ is a vertically simple region and the limits of integration are

$$\underbrace{0 \le x \le 1}_{\text{limits of outer integral}} \qquad \underbrace{x^2 \le y \le 4 - x^2}_{\text{limits of inner integral}}$$

We follow three steps.

Step 1. Set up the iterated integral. The iterated integral is

$$\iint_{\mathcal{D}} y\, dA = \int_0^1 \int_{x^2}^{4-x^2} y\, dy\, dx.$$

Step 2. Evaluate the inner integral. We evaluate the inner integral with respect to y:

$$\int_{x^2}^{4-x^2} y\, dy = \frac{y^2}{2}\bigg|_{y=x^2}^{y=4-x^2} = \frac{1}{2}\left((4-x^2)^2 - (x^2)^2\right) = \frac{1}{2}(16 - 8x^2 + x^4 - x^4) = 8 - 4x^2$$

Step 3. Complete the computation. We integrate the resulting function with respect to x:

$$\iint_{\mathcal{D}} y\, dy = \int_0^1 (8 - 4x^2)\, dx = 8x - \frac{4}{3}x^3\bigg|_0^1 = 8 - \frac{4}{3} = \frac{20}{3} \approx 6.67$$

In Exercises 5–7, compute the double integral of $f(x, y) = x^2 y$ over the given shaded domain in Figure 22.

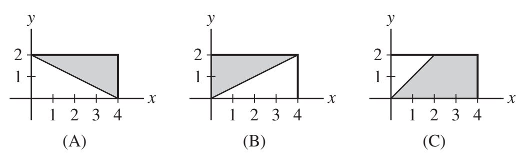


FIGURE 22

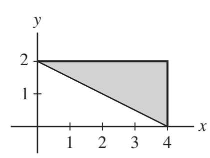
5. (A)

SOLUTION



We describe the domain $\mathcal{D}$ as a vertically simple region. We find the equation of the line connecting the points (0, 2) and (4, 0).

$$y - 0 = \frac{2-0}{0-4}(x-4) \quad \Rightarrow \quad y = -\frac{1}{2}x + 2$$

Therefore the domain is described as a vertically simple region by the inequalities

$$0 \le x \le 4, \quad -\frac{1}{2}x + 2 \le y \le 2$$

We use Theorem 2 to evaluate the double integral:

$$\iint_{\mathcal{D}} x^2 y\, dA = \int_0^4 \int_{-\frac{x}{2}+2}^{2} x^2 y\, dy\, dx = \int_0^4 \frac{x^2 y^2}{2}\bigg|_{y=-\frac{x}{2}+2}^{2} dx = \int_0^4 \frac{x^2}{2}\left(2^2 - \left(-\frac{x}{2}+2\right)^2\right) dx$$

$$= \int_0^4 \left(x^3 - \frac{x^4}{8}\right) dx = \frac{x^4}{4} - \frac{x^5}{40}\bigg|_0^4 = \frac{4^4}{4} - \frac{4^5}{40} = \frac{192}{5} = 38.4$$

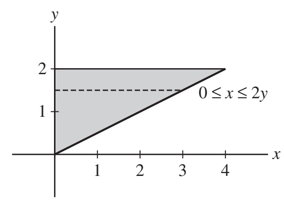
6. (B)

SOLUTION We describe the domain $\mathcal{D}$ as a horizontally simple region. We first find the equation of the line connecting the points (0, 0) and (4, 2).

$$y = \frac{1}{2}x \quad \Rightarrow \quad x = 2y$$

Therefore, the domain of integration is described by the following inequalities:

$$0 \le y \le 2, \quad 0 \le x \le 2y$$



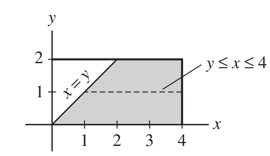
We use Theorem 2 to evaluate the double integral as follows:

$$\iint_{\mathcal{D}} x^2 y\, dA = \int_0^2 \int_0^{2y} x^2 y\, dx\, dy = \int_0^2 \left.\frac{x^3 y}{3}\right|_{x=0}^{2y} dy = \int_0^2 \frac{y}{3}\left((2y)^3 - 0^3\right) dy = \int_0^2 \frac{y}{3}\cdot 8y^3\, dy$$
$$= \int_0^2 \frac{8y^4}{3}\, dy = \left.\frac{8}{15}y^5\right|_0^2 = \frac{256}{15} \approx 17.07$$

7. (C)

SOLUTION The domain in (C) is a horizontally simple region, described by the inequalities

$$0 \le y \le 2, \quad y \le x \le 4$$

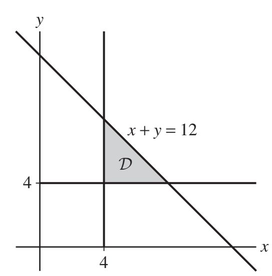


Using Theorem 2 we obtain the following integral:

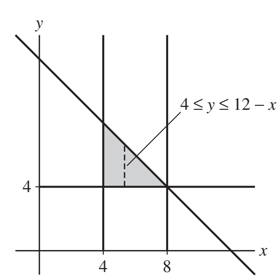
$$\iint_{\mathcal{D}} x^2 y\, dA = \int_0^2 \int_y^4 x^2 y\, dx\, dy = \int_0^2 \left.\frac{x^3 y}{3}\right|_{x=y}^{x=4} dy = \int_0^2 \frac{y}{3}\left(4^3 - y^3\right) dy = \int_0^2 \left(\frac{64y}{3} - \frac{y^4}{3}\right) dy$$
$$= \left.\frac{32}{3}y^2 - \frac{y^5}{15}\right|_0^2 = \frac{32\cdot 2^2}{3} - \frac{2^5}{15} = \frac{608}{15} \approx 40.53$$

8. Sketch the domain $\mathcal{D}$ defined by $x + y \le 12$, $x \ge 4$, $y \ge 4$ and compute $\iint_{\mathcal{D}} e^{x+y}\, dA$.

SOLUTION The domain $\mathcal{D} = \{(x, y) : x + y \le 12, x \ge 4, y \ge 4\}$ is shown in the following figure:



To compute the integral we described $\mathcal{D}$ as a vertically simple region by the following inequalities (see figure):



$$4 \le x \le 8, \quad 4 \le y \le 12 - x$$

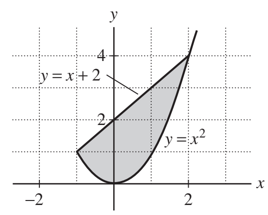
Using Theorem 2, we obtain the following integral:

$$\iint_{\mathcal{D}} e^{x+y}\,dA = \int_4^8 \int_4^{12-x} e^{x+y}\,dy\,dx = \int_4^8 e^{x+y}\Big|_{y=4}^{12-x}\,dx = \int_4^8 \left(e^{x+(12-x)} - e^{x+4}\right)dx$$

$$= \int_4^8 \left(e^{12} - e^{x+4}\right)dx = e^{12}x - e^{x+4}\Big|_4^8 = 8e^{12} - e^{12} - \left(4e^{12} - e^8\right) = 3e^{12} + e^8 \approx 491245.3$$

9. Integrate $f(x, y) = x$ over the region bounded by $y = x^2$ and $y = x + 2$.

SOLUTION The domain of integration is shown in the following figure:

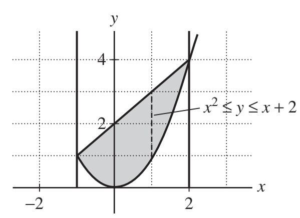


To find the inequalities defining the domain as a vertically simple region we first must find the x-coordinates of the two points where the line $y = x + 2$ and the parabola $y = x^2$ intersect. That is,

$$x + 2 = x^2 \quad\Rightarrow\quad x^2 - x - 2 = (x-2)(x+1) = 0$$
$$\Rightarrow\quad x_1 = -1, \quad x_2 = 2$$

We describe the domain by the following inequalities:

$$-1 \le x \le 2, \quad x^2 \le y \le x + 2$$



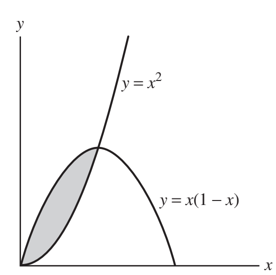
We now evaluate the integral of $f(x, y) = x$ over the vertically simple region $\mathcal{D}$:

$$\iint_{\mathcal{D}} x\,dA = \int_{-1}^2 \int_{x^2}^{x+2} x\,dy\,dx = \int_{-1}^2 xy\Big|_{y=x^2}^{x+2}\,dx = \int_{-1}^2 x\left(x + 2 - x^2\right)dx$$

$$= \int_{-1}^2 \left(x^2 + 2x - x^3\right)dx = \frac{x^3}{3} + x^2 - \frac{x^4}{4}\Big|_{-1}^2 = \left(\frac{8}{3} + 4 - 4\right) - \left(-\frac{1}{3} + 1 - \frac{1}{4}\right) = 2\frac{1}{4}$$

10. Sketch the region $\mathcal{D}$ between $y = x^2$ and $y = x(1 - x)$. Express $\mathcal{D}$ as a simple region and calculate the integral of $f(x, y) = 2y$ over $\mathcal{D}$.

SOLUTION The region $\mathcal{D}$ between $y = x^2$ and $y = x(1 - x)$ is shown in the following figure:

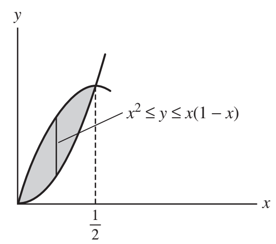


To find the inequalities for the vertically simple region $\mathcal{D}$, we first compute the x-coordinate of the point where the curves $y = x^2$ and $y = x(1-x)$ intersect.

$$x^2 = x(1-x) \quad \Rightarrow \quad x^2 = x - x^2$$
$$\Rightarrow \quad 2x^2 - x = x(2x-1) = 0$$
$$\Rightarrow \quad x_1 = 0, \quad x_2 = \frac{1}{2}$$

The region $\mathcal{D}$ is defined by the following inequalities:

$$0 \le x \le \frac{1}{2}, \quad x^2 \le y \le x(1-x)$$



The double integral of f over $\mathcal{D}$ is computed using Theorem 2. That is,

$$\iint_{\mathcal{D}} 2y\,dA = \int_0^{1/2} \int_{x^2}^{x(1-x)} 2y\,dy\,dx = \int_0^{1/2} y^2 \Big|_{y=x^2}^{y=x(1-x)} dx = \int_0^{1/2} x^2(1-x)^2 - x^4\,dx$$
$$= \int_0^{1/2} x^2 - 2x^3 + x^4 - x^4\,dx = \int_0^{1/2} x^2 - 2x^3\,dx = \frac{1}{96} \approx 0.010$$

11. Evaluate $\iint_{\mathcal{D}} \frac{y}{x}\,dA$, where $\mathcal{D}$ is the shaded part of the semicircle of radius 2 in Figure 23.

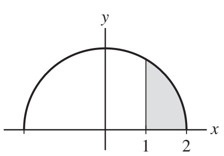


FIGURE 23 $y = \sqrt{4-x^2}$

SOLUTION The region is defined by the following inequalities:

$$1 \le x \le 2, \quad 0 \le y \le \sqrt{4-x^2}$$

Therefore, the double integral of f over $\mathcal{D}$ is:

$$\iint_{\mathcal{D}} \frac{y}{x}\,dA = \int_1^2 \int_0^{\sqrt{4-x^2}} \frac{y}{x}\,dy\,dx$$
$$= \int_1^2 \frac{1}{x}\left(\frac{1}{2}y^2\Big|_0^{\sqrt{4-x^2}}\right) dx$$
$$= \frac{1}{2}\int_1^2 \frac{1}{x}(4-x^2)\,dx$$
$$= \frac{1}{2}\int_1^2 \frac{4}{x} - x\,dx$$
$$= \frac{1}{2}\left(4\ln|x| - \frac{1}{2}x^2\right)\Big|_1^2$$
$$= \frac{1}{2}(4\ln 2 - 2) - \frac{1}{2}\left(0 - \frac{1}{2}\right)$$
$$= 2\ln 2 - 1 + \frac{1}{4} = 2\ln 2 - \frac{3}{4} \approx 0.636$$

12. Calculate the double integral of $f(x, y) = y^2$ over the rhombus $\mathcal{R}$ in Figure 24.

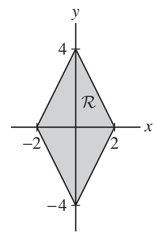

FIGURE 24 $|x| + \frac{1}{2}|y| \le 1$

SOLUTION Since $f(x, -y) = f(x, y)$ and since the rhombus is symmetric with respect to the x-axis, the double integral equals twice the integral over the upper half of the rhombus. Moreover, since $f(-x, y) = f(x, y)$ and $\mathcal{R}$ is symmetric with respect to the y-axis, the double integral over $\mathcal{R}$ equals twice the integral over the right half of the rhombus. Therefore, denoting by $\mathcal{D}$ the part of the rhombus in the first quadrant, we have

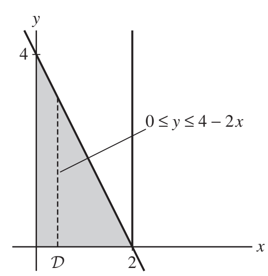
$$\iint_{\mathcal{R}} y^2\,dA = 4\iint_{\mathcal{D}} y^2\,dA \tag{1}$$

We now compute the double integral over $\mathcal{D}$. We express $\mathcal{D}$ as a vertically simple region. The line connecting the point $(0, 4)$ and $(2, 0)$ has the equation

$$y - 4 = \frac{4-0}{0-2}(x-0) \quad \Rightarrow \quad y - 4 = -2x \quad \Rightarrow \quad y = 4 - 2x$$

Thus, $\mathcal{D}$ is defined by the following inequalities:

$$0 \le x \le 2, \quad 0 \le y \le 4 - 2x$$



We now compute the integral over $\mathcal{D}$ using Theorem 2:

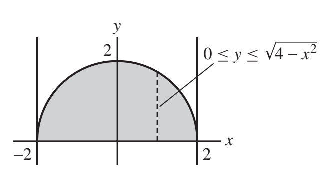
$$\iint_{\mathcal{D}} y^2\,dA = \int_0^2 \int_0^{4-2x} y^2\,dy\,dx = \int_0^2 \frac{y^3}{3}\bigg|_{y=0}^{4-2x} dx = \int_0^2 \frac{(4-2x)^3}{3}\,dx = \frac{(4-2x)^4}{12\cdot(-2)}\bigg|_0^2 = 0 + \frac{4^4}{24} = \frac{32}{3}$$

Combining with (1) we get

$$\iint_{\mathcal{R}} y^2\,dA = 4\cdot\frac{32}{3} \approx 42.67$$

13. Calculate the double integral of $f(x, y) = x + y$ over the domain $\mathcal{D} = \{(x, y) : x^2 + y^2 \le 4,\ y \ge 0\}$.

SOLUTION



The domain $\mathcal{D}$

The semicircle can be described as a vertically simple region, by the following inequalities:

$$-2 \le x \le 2, \quad 0 \le y \le \sqrt{4 - x^2}$$

We evaluate the double integral by the following iterated integral:

$$\iint_{\mathcal{D}} (x+y)\,dA = \int_{-2}^{2}\int_{0}^{\sqrt{4-x^2}} (x+y)\,dy\,dx = \int_{-2}^{2} xy + \frac{1}{2}y^2\Big|_{y=0}^{\sqrt{4-x^2}} dx = \int_{-2}^{2}\left(x\sqrt{4-x^2} + \frac{1}{2}\left(\sqrt{4-x^2}\right)^2\right) dx$$

$$= \int_{-2}^{2} x\sqrt{4-x^2}\,dx + \frac{1}{2}\int_{-2}^{2}(4-x^2)\,dx = \int_{-2}^{2} x\sqrt{4-x^2}\,dx + 2x - \frac{x^3}{6}\Big|_{x=-2}^{2}$$

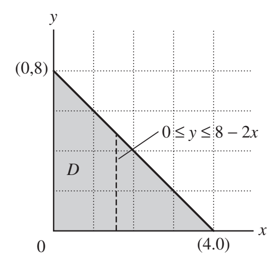
$$= \int_{-2}^{2} x\sqrt{4-x^2}\,dx + 4 - \frac{8}{6} - \left(-4 - \frac{-8}{6}\right) = \int_{-2}^{2} x\sqrt{4-x^2}\,dx + \frac{16}{3}$$

The integral of an odd function over an interval that is symmetric with respect to the origin is zero. Hence $\int_{-2}^{2} x\sqrt{4-x^2}\,dx = 0$, so we get

$$\iint_{\mathcal{D}} (x+y)\,dA = 0 + \frac{16}{3} = \frac{16}{3} \approx 5.33$$

14. Integrate $f(x,y) = (x+y+1)^{-2}$ over the triangle with vertices $(0,0)$, $(4,0)$, and $(0,8)$.

SOLUTION



We describe the region $\mathcal{D}$ as a vertically simple region, but first we need to find the equation of the line joining the points $(4,0)$ and $(0,8)$:

$$y - 8 = \frac{8-0}{0-4}(x-0) \quad \Rightarrow \quad y - 8 = -2x$$
$$\Rightarrow \quad y = 8 - 2x$$

We obtain the following inequalities for $\mathcal{D}$:

$$0 \le x \le 4, \quad 0 \le y \le 8 - 2x$$

We now evaluate the double integral of $f(x,y) = (x+y+1)^{-2}$ over the triangle $\mathcal{D}$, by the following iterated integral:

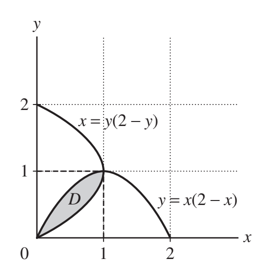
$$\iint_{\mathcal{D}} f(x,y)\,dA = \int_{0}^{4}\int_{0}^{8-2x} (x+y+1)^{-2}\,dy\,dx = \int_{0}^{4} -(x+y+1)^{-1}\Big|_{y=0}^{8-2x} dx$$

$$= \int_{0}^{4}\left(-(x+8-2x+1)^{-1} + (x+0+1)^{-1}\right) dx = \int_{0}^{4}\left(\frac{1}{x+1} - \frac{1}{9-x}\right) dx$$

$$= \ln(x+1) + \ln(9-x)\Big|_{0}^{4} = \ln 5 + \ln 5 - (\ln 1 + \ln 9) = 2\ln 5 - \ln 9 = \ln\frac{25}{9} \approx 1.02$$

15. Calculate the integral of $f(x,y) = x$ over the region $\mathcal{D}$ bounded above by $y = x(2-x)$ and below by $x = y(2-y)$. *Hint:* Apply the quadratic formula to the lower boundary curve to solve for y as a function of x.

SOLUTION The two graphs are symmetric with respect to the line $y = x$, thus their point of intersection is $(1,1)$. The region $\mathcal{D}$ is shown in the following figure:

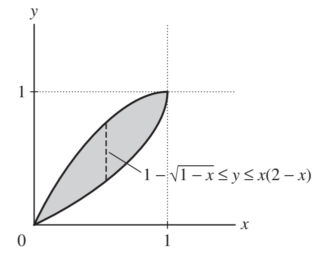


To find the inequalities defining the region $\mathcal{D}$ as a vertically simple region, we first must solve the lower boundary curve for y in terms of x. We get

$$x = y(2-y) = 2y - y^2$$
$$y^2 - 2y + x = 0$$

We solve the quadratic equation in y:

$$y = 1 \pm \sqrt{1-x}$$



The domain $\mathcal{D}$ lies below the line $y = 1$, hence the appropriate solution is $y = 1 - \sqrt{1-x}$. We obtain the following inequalities for $\mathcal{D}$:

$$0 \le x \le 1, \quad 1 - \sqrt{1-x} \le y \le x(2-x)$$

We now evaluate the double integral of $f(x,y) = x$ over $\mathcal{D}$:

$$\iint_{\mathcal{D}} x\,dA = \int_0^1 \int_{1-\sqrt{1-x}}^{x(2-x)} x\,dy\,dx = \int_0^1 xy\Big|_{y=1-\sqrt{1-x}}^{x(2-x)} dx = \int_0^1 \left(x^2(2-x) - \left(x - x\sqrt{1-x}\right)\right) dx$$
$$= \int_0^1 \left(2x^2 - x^3 - x + x\sqrt{1-x}\right) dx = \frac{2x^3}{3} - \frac{x^4}{4} - \frac{x^2}{2}\Big|_0^1 + \int_0^1 x\sqrt{1-x}\,dx$$
$$= -\frac{1}{12} + \int_0^1 x\sqrt{1-x}\,dx$$

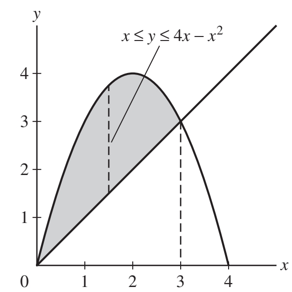
Using the substitution $u = \sqrt{1-x}$ it can be shown that $\int_0^1 x\sqrt{1-x}\,dx = \frac{4}{15}$. Therefore we get

$$\iint_{\mathcal{D}} x\,dA = -\frac{1}{12} + \frac{4}{15} = \frac{11}{60}$$

16. Integrate $f(x,y) = x$ over the region bounded by $y = x$, $y = 4x - x^2$, and $y = 0$ in two ways: as a vertically simple region and as a horizontally simple region.

SOLUTION

(a) The region $\mathcal{D}$ between $y = x$ and $y = 4x - x^2$ is a vertically simple region.



To find the inequalities for this region, we first compute the x-coordinates of the points of intersection of the two curves, by solving the following equation:

$$x = 4x - x^2 \quad \Rightarrow \quad x^2 - 3x = x(x-3) = 0 \quad \Rightarrow \quad x_1 = 0, \quad x_2 = 3$$

The region $\mathcal{D}$ is defined by the following inequalities:

$$0 \le x \le 3, \quad x \le y \le 4x - x^2$$

We now compute the double integral of $f(x, y) = x$ over $\mathcal{D}$ by computing the following iterated integral:

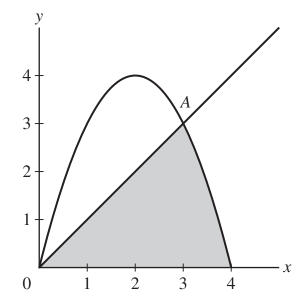
$$\iint_{\mathcal{D}} f(x, y)\, dA = \int_0^3 \int_x^{4x-x^2} (x)\, dy\, dx = \int_0^3 xy\Big|_{y=x}^{4x-x^2} dx$$

$$= \int_0^3 (4x^2 - x^3 - x^2)\, dx$$

$$= \int_0^3 3x^2 - x^3\, dx$$

$$= x^3 - \frac{x^4}{4}\Big|_0^3 = 27 - \frac{81}{4} = \frac{27}{4}$$

(b) The region (shown in the figure) is the union of two horizontally simple regions.



To determine the inequalities defining this region, we first find the y-coordinate of A. In part (a) we found that the x-coordinate of this point is $x = 3$, hence also $y = 3$. We now solve the equation of the right curve $y = 4x - x^2$ for x in terms of y:

$$y = 4x - x^2$$
$$x^2 - 4x + y = 0$$
$$x_{1,2} = 2 \pm \sqrt{4 - y}$$

In this part of the boundary $x \le 3$, hence the negative root must be taken. That is,

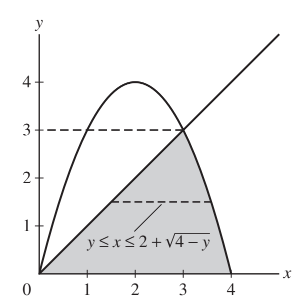
$$x = 2 - \sqrt{4 - y}$$

We obtain the following inequalities for the domain $\mathcal{D}$:

$$0 \le y \le 3, \quad y \le x \le 2 + \sqrt{4 - y}$$

The other part of the domain in question will have to be:

$$3 \le y \le 4, \quad 2 - \sqrt{4 - y} \le x \le 2 + \sqrt{4 - y}$$



The double integral of $f(x, y) = x$ can now be computed by the following iterated integral:

$$\iint_{\mathcal{D}} f(x, y)\, dA = \int_0^3 \int_{2-\sqrt{4-y}}^{y} (x)\, dx\, dy + \int_3^4 \int_{2-\sqrt{4-y}}^{2+\sqrt{4-y}} x\, dx\, dy$$

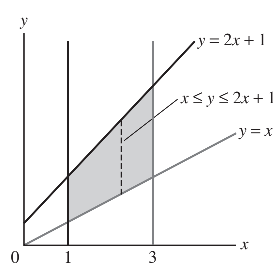
$$= \int_0^3 \frac{1}{2}x^2\Big|_{x=2-\sqrt{4-y}}^{x=y} dy + \int_3^4 \frac{1}{2}x^2\Big|_{x=2-\sqrt{4-y}}^{x=2+\sqrt{4-y}}$$

$$= \frac{1}{2}\int_0^3 \left(y^2 - \left(2-\sqrt{4-y}\right)^2\right) dy + \frac{1}{2}\int_3^4 (2+\sqrt{4-y})^2 - (2-\sqrt{4-y})^2\, dy$$
$$= \frac{1}{2}\int_0^3 \left(y^2 - (4-4\sqrt{4-y}+(4-y))\right) dy + \frac{1}{2}\int_3^4 8\sqrt{4-y}\,dy$$
$$= \frac{1}{2}\int_0^3 \left(y^2 - 8 + 4\sqrt{4-y}+y\right) dy + \int_3^4 4\sqrt{4-y}\,dy$$
$$= \frac{1}{2}\left(\frac{y^3}{3} - 8y - \frac{8}{3}(4-y)^{3/2} + \frac{1}{2}y^2\right)\Bigg|_0^3 - \frac{8}{3}(4-y)^{3/2}\Bigg|_3^4$$
$$= \frac{1}{2}\left(9 - 24 - \frac{8}{3} + \frac{9}{2} + \frac{64}{3}\right) - \left(\frac{8}{3}(0-1)\right)$$
$$= \frac{49}{12} + \frac{8}{3} = \frac{27}{4}$$

In Exercises 17–24, compute the double integral of $f(x, y)$ over the domain $\mathcal{D}$ indicated.

17. $f(x,y) = x^2y$; $1 \le x \le 3$, $x \le y \le 2x+1$

SOLUTION These inequalities describe $\mathcal{D}$ as a vertically simple region.

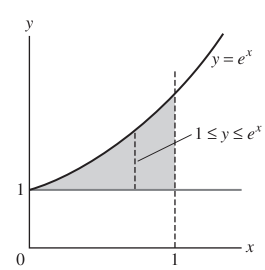


We compute the double integral of $f(x,y) = x^2y$ on $\mathcal{D}$ by the following iterated integral:

$$\iint_{\mathcal{D}} x^2y\,dA = \int_1^3 \int_x^{2x+1} x^2y\,dy\,dx = \int_1^3 \frac{x^2y^2}{2}\Bigg|_{y=x}^{2x+1} dx = \int_1^3 \frac{x^2}{2}\left((2x+1)^2 - x^2\right) dx$$
$$= \int_1^3 \left(\frac{3}{2}x^4 + 2x^3 + \frac{x^2}{2}\right) dx = \frac{3}{10}x^5 + \frac{x^4}{2} + \frac{x^3}{6}\Bigg|_1^3$$
$$= \frac{3\cdot 3^5}{10} + \frac{3^4}{2} + \frac{3^3}{6} - \left(\frac{3}{10} + \frac{1}{2} + \frac{1}{6}\right) = \frac{1754}{15} \approx 116.93$$

18. $f(x,y) = 1$; $0 \le x \le 1$, $1 \le y \le e^x$

SOLUTION The domain $\mathcal{D}$ is a vertically simple region.



We compute the double integral of $f(x,y) = 1$ over $\mathcal{D}$ as the following iterated integral:

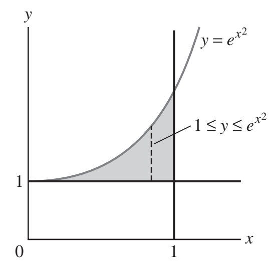
$$\iint_{\mathcal{D}} 1\,dA = \int_0^1 \int_1^{e^x} 1\,dy\,dx = \int_0^1 y\Bigg|_{y=1}^{e^x} dx = \int_0^1 \left(e^x - 1\right) dx = e^x - x\Bigg|_0^1$$
$$= (e^1 - 1) - (e^0 - 0) = e^1 - 1 - 1 = e - 2 \approx 0.718$$

19. $f(x, y) = x; \quad 0 \le x \le 1, \quad 1 \le y \le e^{x^2}$

SOLUTION We compute the double integral of $f(x, y) = x$ over the vertically simple region $\mathcal{D}$, as the following iterated integral:

$$\iint_{\mathcal{D}} x\, dA = \int_0^1 \int_1^{e^{x^2}} x\, dy\, dx = \int_0^1 xy\Big|_{y=1}^{e^{x^2}} dx = \int_0^1 \left(xe^{x^2} - x \cdot 1\right) dx$$

$$= \int_0^1 xe^{x^2}\, dx - \int_0^1 x\, dx = \int_0^1 xe^{x^2} dx - \frac{x^2}{2}\Big|_0^1 = \int_0^1 xe^{x^2} dx - \frac{1}{2} \tag{1}$$



The resulting integral can be computed using the substitution $u = x^2$. The value of this integral is

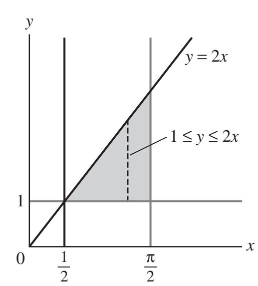
$$\int_0^1 xe^{x^2}\, dx = \frac{e-1}{2}$$

Combining with (1) we get

$$\iint_{\mathcal{D}} x\, dA = \frac{e-1}{2} - \frac{1}{2} = \frac{e-2}{2} \approx 0.359$$

20. $f(x, y) = \cos(2x + y); \quad \frac{1}{2} \le x \le \frac{\pi}{2}, \quad 1 \le y \le 2x$

SOLUTION The vertically simple region $\mathcal{D}$ defined by the given inequalities is shown in the figure:



We compute the double integral of $f(x, y) = \cos(2x + y)$ over $\mathcal{D}$ as an iterated integral, as stated in Theorem 2. This gives

$$\iint_{\mathcal{D}} \cos(2x+y)\, dA = \int_{1/2}^{\pi/2} \int_1^{2x} \cos(2x+y)\, dy\, dx = \int_{1/2}^{\pi/2} \sin(2x+y)\Big|_{y=1}^{2x} dx$$

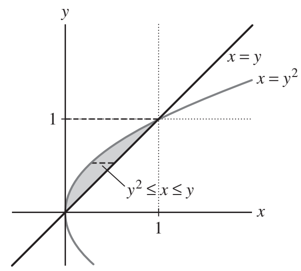
$$= \int_{1/2}^{\pi/2} (\sin(2x+2x) - \sin(2x+1))\, dx = \int_{1/2}^{\pi/2} (\sin(4x) - \sin(2x+1))\, dx$$

$$= -\frac{\cos 4x}{4} + \frac{\cos(2x+1)}{2}\Big|_{x=1/2}^{\pi/2} = -\frac{\cos\frac{4\pi}{2}}{4} + \frac{\cos\left(\frac{2\pi}{2}+1\right)}{2} - \left(-\frac{\cos 2}{4} + \frac{\cos 2}{2}\right)$$

$$= -\frac{1}{4} + \frac{\cos(\pi+1)}{2} - \frac{\cos 2}{4} = -0.416$$

21. $f(x, y) = 2xy$; bounded by $x = y$, $x = y^2$

SOLUTION The intersection points of the graphs $x = y$ and $x = y^2$ are $(0, 0)$ $(1, 1)$. The horizontally simple region $\mathcal{D}$ is shown in the figure:



We compute the double integral of $f(x, y) = 2xy$ over $\mathcal{D}$, using Theorem 2. The limits of integration are determined by the inequalities:

$$0 \le y \le 1, \quad y^2 \le x \le y.$$

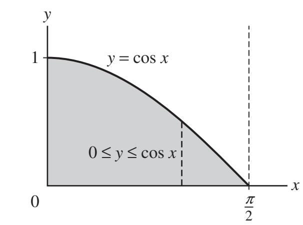
Defining $\mathcal{D}$, we get

$$\iint_{\mathcal{D}} 2xy\, dA = \int_0^1 \int_{y^2}^{y} 2xy\, dx\, dy = \int_0^1 x^2 y \Big|_{x=y^2}^{y} dy = \int_0^1 (y^2 \cdot y - y^4 \cdot y)\, dy$$

$$= \int_0^1 (y^3 - y^5)\, dy = \frac{y^4}{4} - \frac{y^6}{6}\Big|_0^1 = \frac{1}{4} - \frac{1}{6} = \frac{1}{12}$$

22. $f(x, y) = \sin x$; bounded by $x = 0$, $x = 1$, $y = \cos x$

SOLUTION These curves describe $\mathcal{D}$ as a vertically simple region.



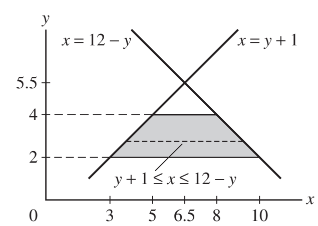
We compute the double integral of $f(x, y) = \sin x$ over $\mathcal{D}$. This gives

$$\iint_{\mathcal{D}} \sin x\, dA = \int_0^1 \int_0^{\cos x} \sin x\, dy\, dx = \int_0^1 y \sin x \Big|_{y=0}^{\cos x} dx = \int_0^1 (\cos x \sin x - 0)\, dx$$

$$= \int_0^1 \frac{\sin 2x}{2}\, dx = -\frac{\cos 2x}{4}\Big|_0^1 = -\left(\frac{\cos(2) - \cos 0}{4}\right) = -\frac{\cos 2}{4} + \frac{1}{4} \approx 0.354$$

23. $f(x, y) = e^{x+y}$; bounded by $y = x - 1$, $y = 12 - x$ for $2 \le y \le 4$

SOLUTION The horizontally simple region $\mathcal{D}$ is shown in the figure:



We compute the double integral of $f(x, y) = e^{x+y}$ over $\mathcal{D}$ by evaluating the following iterated integral:

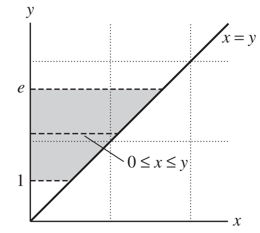
$$\iint_{\mathcal{D}} e^{x+y}\, dA = \int_2^4 \int_{y+1}^{12-y} e^{x+y}\, dx\, dy = \int_2^4 e^{x+y} \Big|_{x=y+1}^{12-y} dy = \int_2^4 \left(e^{12-y+y} - e^{y+1+y}\right) dy$$

$$= \int_2^4 \left(e^{12} - e^{2y+1}\right) dy = e^{12} \cdot y - \frac{1}{2} e^{2y+1}\Big|_2^4 = \left(e^{12} \cdot 4 - \frac{1}{2} e^{2\cdot 4+1}\right) - \left(e^{12} \cdot 2 - \frac{1}{2} e^{2\cdot 2+1}\right)$$

$$= 4e^{12} - \frac{1}{2} e^9 - 2e^{12} + \frac{1}{2} e^5 = 2e^{12} - \frac{1}{2} e^9 + \frac{1}{2} e^5 \approx 321532.2$$

24. $f(x, y) = (x + y)^{-1}$; bounded by $y = x$, $y = 1$, $y = e$, $x = 0$

SOLUTION



The double integral $f(x, y) = (x + y)^{-1}$ over the horizontally simple region $\mathcal{D}$ (shown in the figure) is computed, using Theorem 2, by the following iterated integral:

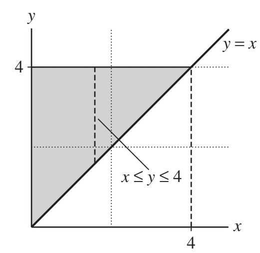
$$\iint_{\mathcal{D}} f(x, y)\, dA = \int_1^e \int_0^y (x + y)^{-1}\, dx\, dy = \int_1^e \ln(x + y)\Big|_{x=0}^{y} dy = \int_1^e (\ln(y + y) - \ln(0 + y))\, dy$$
$$= \int_1^e (\ln(2y) - \ln y)\, dy = \int_1^e \ln \frac{2y}{y}\, dy = \int_1^e \ln 2\, dy = (e - 1) \cdot \ln 2 \approx 1.19$$

In Exercises 25–28, sketch the domain of integration and express as an iterated integral in the opposite order.

25. $\int_0^4 \int_x^4 f(x, y)\, dy\, dx$

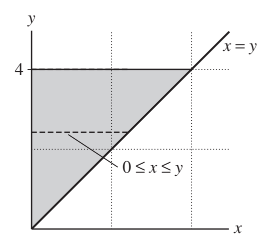
SOLUTION The limits of integration correspond to the inequalities describing the following domain $\mathcal{D}$:

$$0 \le x \le 4, \quad x \le y \le 4$$



From the sketch of $\mathcal{D}$ we see that $\mathcal{D}$ can also be expressed as a horizontally simple region as follows:

$$0 \le y \le 4, \quad 0 \le x \le y$$



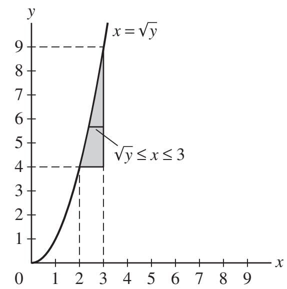
Therefore we can reverse the order of integration as follows:

$$\int_0^4 \int_x^4 f(x, y)\, dy\, dx = \int_0^4 \int_0^y f(x, y)\, dx\, dy.$$

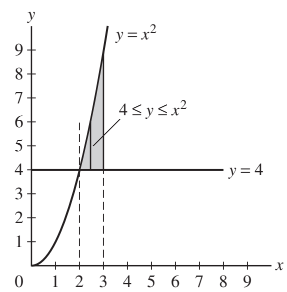
26. $\int_4^9 \int_{\sqrt{y}}^3 f(x, y)\, dx\, dy$

SOLUTION The limits of integration correspond to the inequalities describing the following horizontally simple region $\mathcal{D}$:

$$4 \le y \le 9, \quad \sqrt{y} \le x \le 3$$



The sketch of $\mathcal{D}$ shows that $\mathcal{D}$ can also be expressed as a vertically simple region. We first express the curve $x = \sqrt{y}$ in the form $y = x^2$.



Now we get

$$2 \le x \le 3, \quad 4 \le y \le x^2$$

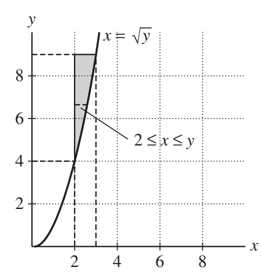
We obtain the following equality:

$$\int_4^9 \int_{\sqrt{y}}^3 f(x, y)\,dx\,dy = \int_2^3 \int_4^{x^2} f(x, y)\,dy\,dx.$$

27. $\displaystyle\int_4^9 \int_2^{\sqrt{y}} f(x, y)\,dx\,dy$

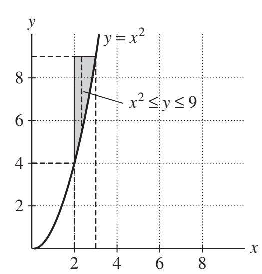
SOLUTION The limits of integration correspond to the following inequalities defining the horizontally simple region $\mathcal{D}$:

$$4 \le y \le 9, \quad 2 \le x \le \sqrt{y}$$



The region $\mathcal{D}$ can also be expressed as a vertically simple region. We first need to write the equation of the curve $x = \sqrt{y}$ in the form $y = x^2$. The corresponding inequalities are

$$2 \le x \le 3, \quad x^2 \le y \le 9$$



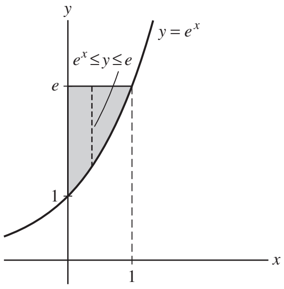
We now can write the iterated integral with reversed order of integration:

$$\int_4^9 \int_2^{\sqrt{y}} f(x, y)\, dx\, dy = \int_2^3 \int_{x^2}^9 f(x, y)\, dy\, dx.$$

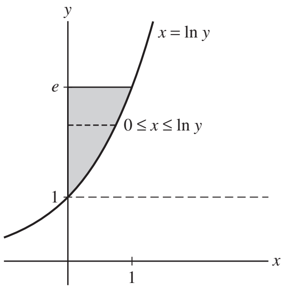
28. $\int_0^1 \int_{e^x}^e f(x, y)\, dy\, dx$

SOLUTION The limits of integration define a vertically simple region $\mathcal{D}$ by the following inequalities:

$$0 \le x \le 1, \quad e^x \le y \le e$$



This region can also be expressed as a horizontally simple region.



The curve $y = e^x$ can be rewritten as $x = \ln y$, and we obtain the following inequalities for $\mathcal{D}$ (see figure):

$$1 \le y \le e, \quad 0 \le x \le \ln y$$

Using this description we obtain the integral with reversed order of integration:

$$\int_0^1 \int_{e^x}^e f(x, y)\, dy\, dx = \int_1^e \int_0^{\ln y} f(x, y)\, dx\, dy.$$

29. Sketch the domain $\mathcal{D}$ corresponding to

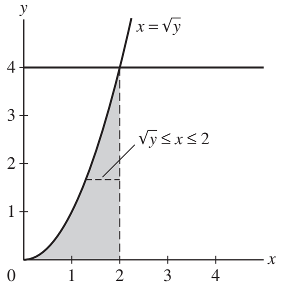
$$\int_0^4 \int_{\sqrt{y}}^2 \sqrt{4x^2 + 5y}\, dx\, dy$$

Then change the order of integration and evaluate.

SOLUTION The limits of integration correspond to the following inequalities describing the domain $\mathcal{D}$:

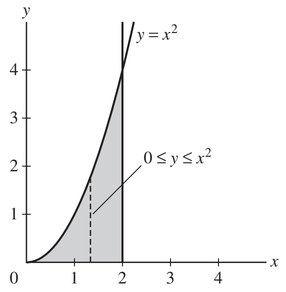
$$0 \le y \le 4, \quad \sqrt{y} \le x \le 2$$

The horizontally simple region $\mathcal{D}$ is shown in the figure:



The domain $\mathcal{D}$ can also be described as a vertically simple region. Rewriting the equation $x = \sqrt{y}$ in the form $y = x^2$, we define $\mathcal{D}$ by the following inequalities (see figure):

$$0 \le x \le 2, \quad 0 \le y \le x^2$$



The corresponding iterated integral is

$$\int_0^2 \int_0^{x^2} \sqrt{4x^2 + 5y}\, dy\, dx$$

We evaluate this integral:

$$\begin{aligned}
\int_0^2 \int_0^{x^2} \sqrt{4x^2 + 5y}\, dy\, dx &= \int_0^2 \left(\int_0^{x^2} \left(4x^2 + 5y\right)^{1/2} dy \right) dx \\
&= \int_0^2 \frac{2}{15}\left(4x^2 + 5y\right)^{3/2} \Big|_{y=0}^{x^2} dx \\
&= \int_0^2 \left(\frac{2}{15}\left(4x^2 + 5x^2\right)^{3/2} - \frac{2}{15}\left(4x^2 + 0\right)^{3/2} \right) dx \\
&= \int_0^2 \left(\frac{2}{15}\left(9x^2\right)^{3/2} - \frac{2}{15}\left(4x^2\right)^{3/2} \right) dx \\
&= \int_0^2 \frac{18}{5}x^3 - \frac{16}{15}x^3\, dx \\
&= \int_0^2 \frac{38}{15}x^3\, dx \\
&= \frac{38}{15} \cdot \frac{x^4}{4}\Big|_0^2 = \frac{38}{15} \cdot \frac{2^4}{4} = \frac{152}{15} \approx 10.133
\end{aligned}$$

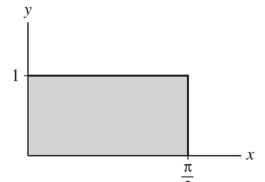
30. Change the order of integration and evaluate

$$\int_0^1 \int_0^{\pi/2} x\cos(xy)\, dx\, dy$$

Explain the simplification achieved by changing the order.

SOLUTION The domain of integration is the rectangle defined by the following inequalities:

$$0 \le y \le 1, \quad 0 \le x \le \frac{\pi}{2}$$



By Fubini's Theorem, the double integral of $f(x, y) = x\cos(xy)$ over the rectangle is equal to the iterated integral in either order. Hence,

$$\int_0^1 \int_0^{\pi/2} x\cos(xy)\, dx\, dy = \int_0^{\pi/2} \int_0^1 x\cos(xy)\, dy\, dx = \int_0^{\pi/2} x \cdot \frac{1}{x}(\sin xy)\Big|_{y=0}^1 dx = \int_0^{\pi/2} \sin(xy)\Big|_{y=0}^1 dx$$

$$= \int_0^{\pi/2} (\sin x - \sin 0)\,dx = \int_0^{\pi/2} \sin x\,dx = -\cos x \Big|_0^{\pi/2}$$

$$= -\left(\cos\frac{\pi}{2} - \cos 0\right) = -(0-1) = 1$$

Trying to integrate in the original order of integration, we obtain

$$\int_0^1 \int_0^{\pi/2} x\cos(xy)\,dx\,dy = \int_0^1 \left(\int_0^{\pi/2} x\cos(xy)\,dx\right) dy \tag{1}$$

To compute the inner integral we would have to use integration by parts, whereas the integrals involved in computing the integral first with respect to x and then with respect to y were quite easy to compute.

31. Compute the integral of $f(x, y) = (\ln y)^{-1}$ over the domain $\mathcal{D}$ bounded by $y = e^x$ and $y = e^{\sqrt{x}}$. *Hint:* Choose the order of integration that enables you to evaluate the integral.

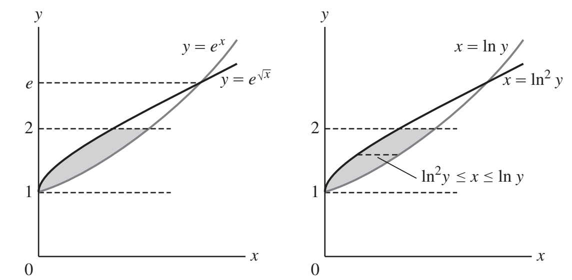
SOLUTION To express $\mathcal{D}$ as a horizontally simple region, we first must rewrite the equations of the curves $y = e^x$ and $y = e^{\sqrt{x}}$ with x as a function of y. That is,

$$y = e^x \quad \Rightarrow \quad x = \ln y$$

$$y = e^{\sqrt{x}} \quad \Rightarrow \quad \sqrt{x} = \ln y \quad \Rightarrow \quad x = \ln^2 y$$

We obtain the following inequalities:

$$1 \le y \le e, \quad \ln^2 y \le x \le \ln y$$



Using Theorem 2, we compute the double integral of $f(x, y) = (\ln y)^{-1}$ over $\mathcal{D}$ as the following iterated integral:

$$\iint_{\mathcal{D}} (\ln y)^{-1}\,dA = \int_1^e \int_{\ln^2 y}^{\ln y} (\ln y)^{-1}\,dx\,dy = \int_1^e (\ln y)^{-1} x \Big|_{x=\ln^2 y}^{\ln y} dy = \int_1^e (\ln y)^{-1}\left(\ln y - \ln^2 y\right) dy$$

$$= \int_1^e (1 - \ln y)\,dy = \int_1^e 1\,dy - \int_1^e \ln y\,dy = y\Big|_1^e - y(\ln y - 1)\Big|_1^e$$

$$= (e-1) - [e(0) - 1(-1)] = e - 2$$

32. Evaluate by changing the order of integration: $\displaystyle\int_0^9 \int_0^{\sqrt{y}} \frac{x\,dx\,dy}{(3x^2 + y)^{1/2}}$

SOLUTION The region of integration is bounded by:

$$0 \le y \le 9, \quad 0 \le x \le \sqrt{y}$$

which also gives the region

$$0 \le x \le 3, \quad x^2 \le y \le 9$$

So changing the order of integration gives the integral:

$$\int_0^3 \int_{x^2}^9 \frac{x\,dy\,dx}{(3x^2 + y)^{1/2}}$$

Now evaluating we get

$$\int_0^3 \int_{x^2}^9 \frac{x\,dy\,dx}{(3x^2 + y)^{1/2}} = \int_0^3 x\left(\int_{x^2}^9 \frac{1}{(3x^2 + y)^{1/2}}\,dy\right) dx$$

$$= \int_0^3 x\left(2(3x^2 + y)^{1/2}\Big|_{x^2}^9\right) dx$$

$$= \int_0^3 2x(3x^2+9)^{1/2} - 2x(3x^2+x^2)^{1/2}\,dx$$
$$= \int_0^3 2x(3x^2+9)^{1/2} - 4x^2\,dx$$
$$= \frac{2}{9}(3x^2+9)^{3/2} - \frac{4}{3}x^3\Big|_0^3$$
$$= \frac{2}{9}(36)^{3/2} - \frac{4}{3}(27) - \frac{2}{9}(9)^{3/2} = 6$$

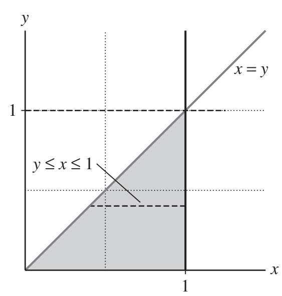
In Exercises 33–36, sketch the domain of integration. Then change the order of integration and evaluate. Explain the simplification achieved by changing the order.

33. $\int_0^1 \int_y^1 \frac{\sin x}{x}\,dx\,dy$

SOLUTION The limits of integration correspond to the following inequalities:

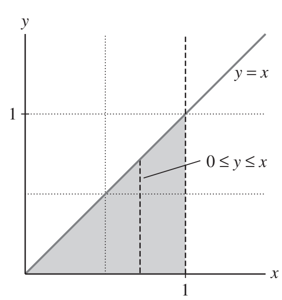
$$0 \le y \le 1, \quad y \le x \le 1$$

The horizontally simple region $\mathcal{D}$ is shown in the figure.



We see that $\mathcal{D}$ can also be described as a vertically simple region, by the following inequalities:

$$0 \le x \le 1, \quad 0 \le y \le x$$



We evaluate the corresponding iterated integral:

$$\int_0^1 \int_0^x \frac{\sin x}{x}\,dy\,dx = \int_0^1 \frac{\sin x}{x} y\Big|_{y=0}^{x} dx = \int_0^1 \frac{\sin x}{x}(x-0)\,dx = \int_0^1 \sin x\,dx = -\cos x\Big|_0^1 = 1 - \cos 1 \approx 0.46$$

Trying to integrate in reversed order we obtain a complicated integral in the inner integral. That is,

$$\int_0^1 \int_y^1 \frac{\sin x}{x}\,dx\,dy = \int_0^1 \left(\int_y^1 \frac{\sin x}{x}\,dx \right) dy$$

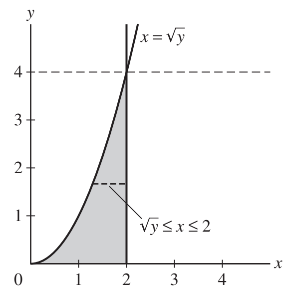
Remark: $f(x, y) = \frac{\sin x}{x}$ is not continuous at the point $(0, 0)$ in $\mathcal{D}$. To make it continuous we need to define $f(0, 0) = 1$.

34. $\int_0^4 \int_{\sqrt{y}}^2 \sqrt{x^3+1}\,dx\,dy$

SOLUTION The limits of integration correspond to the following inequalities describing the domain $\mathcal{D}$:

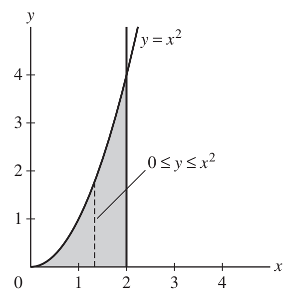
$$0 \le y \le 4, \quad \sqrt{y} \le x \le 2$$

The domain $\mathcal{D}$ is a horizontally simple region, as shown in the figure.



From the sketch of $\mathcal{D}$, we see that $\mathcal{D}$ can be expressed as a vertically simple region. Rewriting the equation of the curve $x = \sqrt{y}$ as $y = x^2$, we obtain the following inequalities for $\mathcal{D}$:

$$0 \le x \le 2, \quad 0 \le y \le x^2$$



The integral in reversed order of integration is thus

$$\int_0^2 \int_0^{x^2} \sqrt{x^3+1}\,dy\,dx = \int_0^2 \sqrt{x^3+1}\,y\Big|_{y=0}^{x^2} dx = \int_0^2 \sqrt{x^3+1}\left(x^2-0\right) dx = \int_0^2 \sqrt{x^3+1}\cdot x^2\,dx$$

This integral is easy to compute using the substitution $u = x^3+1$, $du = 3x^2\,dx$. This gives

$$\int_0^2 \int_0^{x^2} \sqrt{x^3+1}\,dy\,dx = \int_0^2 \sqrt{x^3+1}\cdot x^2\,dx = \int_1^9 \sqrt{u}\cdot\frac{du}{3} = \frac{2}{9}u^{3/2}\Big|_1^9 = \frac{2}{9}\left(9^{3/2}-1\right) = \frac{52}{9} \approx 5.78$$

Trying to compute the double integral in the original order we find that the inner integral is impossible to compute:

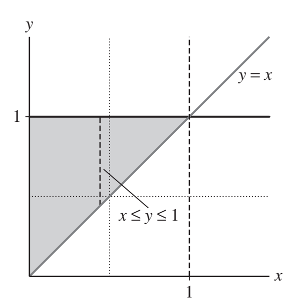
$$\int_0^4 \int_{\sqrt{y}}^2 \sqrt{x^3+1}\,dx\,dy = \int_0^4 \left(\int_{\sqrt{y}}^2 \sqrt{x^3+1}\,dx\right) dy$$

35. $\displaystyle\int_0^1 \int_{y=x}^1 xe^{y^3}\,dy\,dx$

SOLUTION The limits of integration define a vertically simple region $\mathcal{D}$ by the following inequalities:

$$0 \le x \le 1, \quad x \le y \le 1$$

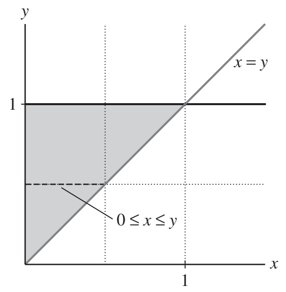
This region can also be described as a horizontally simple region by the following inequalities (see figure):



$$0 \le y \le 1, \quad 0 \le x \le y$$

We thus can rewrite the given integral in reversed order of integration as follows:

$$\int_0^1 \int_0^y xe^{y^3}\,dx\,dy = \int_0^1 \frac{x^2}{2}e^{y^3}\Big|_{x=0}^{y}\,dy = \int_0^1 e^{y^3}\left(\frac{y^2}{2} - 0\right)dy = \int_0^1 \frac{1}{2}e^{y^3}y^2\,dy$$



We compute this integral using the substitution $u = y^3,\ du = 3y^2\,dy$. This gives

$$\int_0^1 \int_0^y xe^{y^3}\,dx\,dy = \int_0^1 \frac{1}{2}e^{y^3}y^2\,dy = \int_0^1 e^u \cdot \frac{1}{6}\,du = \frac{e^u}{6}\Big|_0^1 = \frac{e-1}{6} \approx 0.286$$

Trying to evaluate the double integral in the original order of integration, we find that the inner integral is impossible to compute:

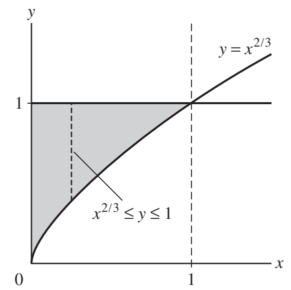
$$\int_0^1 \int_x^1 xe^{y^3}\,dy\,dx = \int_0^1 \left(\int_x^1 xe^{y^3}\,dy\right)dx$$

36. $\displaystyle\int_0^1 \int_{y=x^{2/3}}^1 xe^{y^4}\,dy\,dx$

SOLUTION The limits of integration define a vertically simple region $\mathcal{D}$ by the following inequalities:

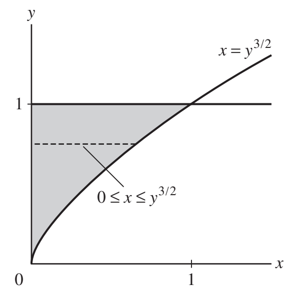
$$0 \le x \le 1, \quad x^{2/3} \le y \le 1$$

The region $\mathcal{D}$ shown in the figure can also be described as a horizontally simple region.



We rewrite the equation of the curve $y = x^{2/3}$ as $x = y^{3/2}$ and express the domain $\mathcal{D}$ as a horizontally simple region by the following inequalities:

$$0 \le y \le 1, \quad 0 \le x \le y^{3/2}$$



The corresponding iterated integral is:

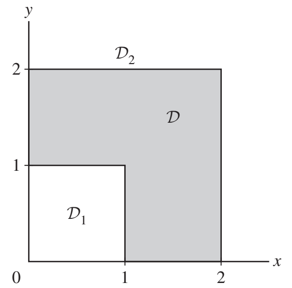
$$\int_0^1 \int_0^{y^{3/2}} xe^{y^4}\,dx\,dy = \int_0^1 \frac{x^2}{2}e^{y^4}\bigg|_{x=0}^{y^{3/2}} dy = \int_0^1 \left(\frac{(y^{3/2})^2}{2}e^{y^4} - 0\right) dy = \int_0^1 \frac{1}{2}y^3 e^{y^4}\,dy$$
$$= \int_0^1 \frac{1}{8}\left(\frac{d}{dy}e^{y^4}\right) dy = \frac{1}{8}e^{y^4}\bigg|_0^1 = \frac{1}{8}\left(e^1 - e^0\right) = \frac{1}{8}(e-1) \approx 0.215$$

Trying to evaluate the original integral we find that the inner integral is impossible to evaluate:

$$\int_0^1 \int_{x^{2/3}}^1 xe^{y^4}\,dy\,dx = \int_0^1 \left(\int_{x^{2/3}}^1 xe^{y^4}\,dy\right) dx$$

37. Sketch the domain $\mathcal{D}$ where $0 \le x \le 2$, $0 \le y \le 2$, and x *or* y is greater than 1. Then compute $\iint_{\mathcal{D}} e^{x+y}\,dA$.

SOLUTION The domain $\mathcal{D}$ within the square $0 \le x,\ y \le 2$ is shown in the figure.



We denote the unit square $0 \le x,\ y \le 1$ and the square $0 \le x,\ y \le 2$ by $\mathcal{D}_1$ and $\mathcal{D}_2$ respectively. Then $\mathcal{D}_2$ is the union of $\mathcal{D}_1$ and $\mathcal{D}$, and these two domains do not overlap except on the boundary of $\mathcal{D}_1$. Therefore, by properties of the double integral, we have

$$\iint_{\mathcal{D}_2} e^{x+y}dA = \iint_{\mathcal{D}_1} e^{x+y}dA + \iint_{\mathcal{D}} e^{x+y}dA$$

Hence,

$$\iint_{\mathcal{D}} e^{x+y}dA = \iint_{\mathcal{D}_2} e^{x+y}\,dA - \iint_{\mathcal{D}_1} e^{x+y}\,dA = \int_0^2 \int_0^2 e^{x+y}\,dx\,dy - \int_0^1 \int_0^1 e^{x+y}\,dx\,dy$$
$$= \int_0^2 e^{x+y}\bigg|_{x=0}^2 dy - \int_0^1 e^{x+y}\bigg|_{x=0}^1 dy = \int_0^2 (e^{2+y} - e^y)\,dy - \int_0^1 (e^{1+y} - e^y)\,dy$$
$$= e^{2+y} - e^y\bigg|_{y=0}^2 - (e^{1+y} - e^y)\bigg|_{y=0}^1 = e^4 - e^2 - (e^2 - e^0) - \left(e^2 - e - (e - e^0)\right)$$
$$= e^4 - 3e^2 + 2e \approx 37.87$$

38. Calculate $\iint_{\mathcal{D}} e^x\,dA$, where $\mathcal{D}$ is bounded by the lines $y = x+1$, $y = x$, $x = 0$, and $x = 1$.

SOLUTION This region is a vertically simple region

$$\mathcal{D} : 0 \le x \le 1, \quad x \le y \le x+1$$

So that

$$\int_{\mathcal{D}} e^x\,dA = \int_0^1 \int_x^{x+1} e^x\,dy\,dx = \int_0^1 ye^x\bigg|_x^{x+1} dx$$
$$= \int_0^1 e^x(x+1-x)\,dx = \int_0^1 e^x\,dx = e^x\bigg|_0^1 = e - 1$$

In Exercises 39–42, calculate the double integral of $f(x, y)$ over the triangle indicated in Figure 25.

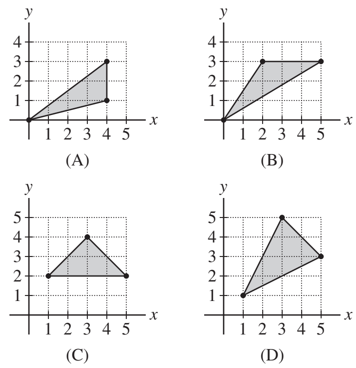


FIGURE 25

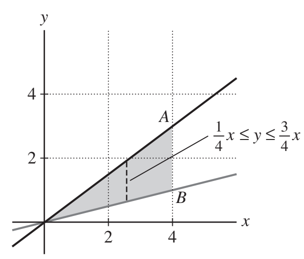
39. $f(x, y) = e^{x^2}$, (A)

SOLUTION The equations of the lines OA and OB are $y = \frac{3}{4}x$ and $y = \frac{1}{4}x$, respectively. Therefore, the triangle may be expressed as a vertically simple region by the following inequalities:

$$0 \le x \le 4, \quad \frac{x}{4} \le y \le \frac{3x}{4}$$



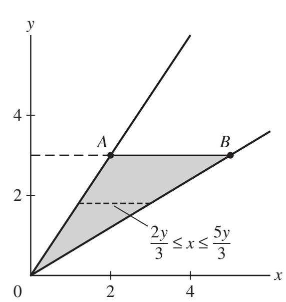
The double integral of $f(x, y) = e^{x^2}$ over the triangle is the following iterated integral:

$$\begin{aligned}
\int_0^4 \int_{x/4}^{3x/4} e^{x^2}\, dy\, dx &= \int_0^4 y e^{x^2} \Big|_{y=x/4}^{3x/4} dx \\
&= \int_0^4 e^{x^2} \left(\frac{3x}{4} - \frac{x}{4} \right) dx \\
&= \frac{1}{2} \int_0^4 x e^{x^2}\, dx \\
&= \frac{1}{4} e^{x^2} \Big|_0^4 = \frac{1}{4}(e^{16} - 1)
\end{aligned}$$

40. $f(x, y) = 1 - 2x$, (B)

SOLUTION The equations of the lines OA and OB are $y = \frac{3x}{2}$ and $y = \frac{3x}{5}$, respectively. We describe the triangle as a horizontally simple region. The equations $y = \frac{3x}{2}$ and $y = \frac{3x}{5}$ can be written as $x = \frac{2y}{3}$ and $x = \frac{5y}{3}$, therefore the inequalities defining the triangle are

$$0 \le y \le 3, \quad \frac{2}{3}y \le x \le \frac{5}{3}y$$



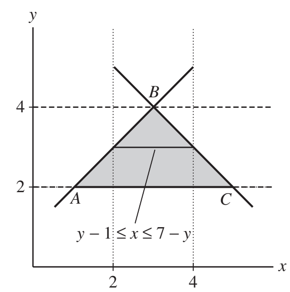
We now compute the double integral of $f(x, y) = 1 - 2x$ over the triangle by evaluating the following iterated integral:

$$\int_0^3 \int_{2y/3}^{5y/3} (1-2x)\,dx\,dy = \int_0^3 x - x^2\Big|_{y=2y/3}^{5y/3} dy = \int_0^3 \left(\left(\frac{5y}{3} - \frac{25y^2}{9}\right) - \left(\frac{2y}{3} - \frac{4y^2}{9}\right)\right) dy$$

$$= \int_0^3 \left(y - \frac{7}{3}y^2\right) dy = \frac{y^2}{2} - \frac{7y^3}{9}\Big|_0^3 = \frac{9}{2} - \frac{7 \cdot 3^3}{9} = -16.5$$

41. $f(x, y) = \dfrac{x}{y^2}$, (C)

SOLUTION To find the inequalities defining the triangle as a horizontally simple region, we first find the inequalities of the lines AB and BC:



$$AB:\quad y - 2 = \frac{4-2}{3-1}(x-1) \quad \Rightarrow \quad y - 2 = x - 1 \quad \Rightarrow \quad x = y - 1$$

$$BC:\quad y - 2 = \frac{4-2}{3-5}(x-5) \quad \Rightarrow \quad y - 2 = 5 - x \quad \Rightarrow \quad x = 7 - y$$

We obtain the following inequalities for the triangle:

$$2 \le y \le 4, \quad y - 1 \le x \le 7 - y$$

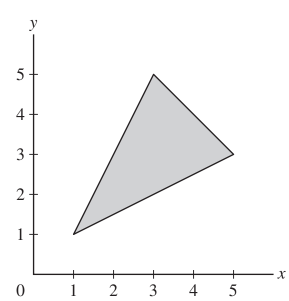
The double integral of $f(x, y) = \frac{x}{y^2}$ over the triangle is the following iterated integral:

$$\int_2^4 \int_{y-1}^{7-y} \frac{x}{y^2}\,dx\,dy = \int_2^4 \frac{x^2}{2y^2}\Big|_{x=y-1}^{7-y} dy = \int_2^4 \frac{(7-y)^2 - (y-1)^2}{2y^2}\,dy = \int_2^4 \left(\frac{24}{y^2} - \frac{6}{y}\right) dy$$

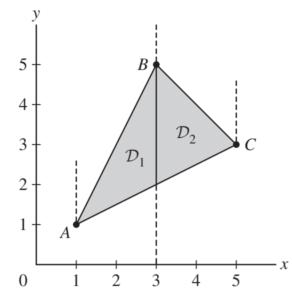
$$= -\frac{24}{y} - 6\ln y\Big|_2^4 = -\frac{24}{4} - 6\ln 4 - \left(-\frac{24}{2} - 6\ln 2\right) = 6 - 6\ln 2 = 1.84$$

42. $f(x, y) = x + 1$, (D)

SOLUTION



This triangle is not a simple region, therefore we decompose it into two vertically simple regions $\mathcal{D}_1$ and $\mathcal{D}_2$, shown in the figure.



By properties of the double integral, the double integral of $f(x, y) = x + 1$ over the given triangle $\mathcal{D}$ is the following sum:

$$\iint_{\mathcal{D}} x + 1\, dA = \iint_{\mathcal{D}_1} x + 1\, dA + \iint_{\mathcal{D}_2} x + 1\, dA \tag{1}$$

To describe $\mathcal{D}_1$ and $\mathcal{D}_2$ as vertically simple regions we first must find the equations of the lines AB, AC, BC:

$$AB:\quad y - 1 = \frac{5-1}{3-1}(x-1) \quad\Rightarrow\quad y - 1 = 2(x-1) \quad\Rightarrow\quad y = 2x - 1$$

$$AC:\quad y - 1 = \frac{3-1}{5-1}(x-1) \quad\Rightarrow\quad y - 1 = \frac{1}{2}(x-1) \quad\Rightarrow\quad y = \frac{1}{2}x + \frac{1}{2}$$

$$BC:\quad y - 3 = \frac{5-3}{3-5}(x-5) \quad\Rightarrow\quad y - 3 = -(x-5) \quad\Rightarrow\quad y = -x + 8$$

We obtain the following inequalities for $\mathcal{D}_1$ and $\mathcal{D}_2$:

$\mathcal{D}_1$	$\mathcal{D}_2$
$1 \le x \le 3$	$3 \le x \le 5$
$\frac{1}{2}x + \frac{1}{2} \le y \le 2x - 1$	$\frac{1}{2}x + \frac{1}{2} \le y \le -x + 8$

We compute the double integral of f over $\mathcal{D}_1$ and $\mathcal{D}_2$:

$$\begin{aligned}
\iint_{\mathcal{D}_1} (x+1)\, dA &= \int_1^3 \int_{\frac{x+1}{2}}^{2x-1} (x+1)\, dy\, dx \\
&= \int_1^3 (x+1) \left(y \Big|_{\frac{x+1}{2}}^{2x-1} \right) dx \\
&= \int_1^3 (x+1) \left(2x - 1 - \frac{x+1}{2} \right) dx \\
&= \int_1^3 \left(\frac{3}{2}x^2 - \frac{3}{2} \right) dx \\
&= \frac{1}{2}x^3 - \frac{3}{2}x \Big|_1^3 = 10
\end{aligned}$$

The double integral of f over $\mathcal{D}_2$ is

$$\begin{aligned}
\iint_{\mathcal{D}_2} (x+1)\, dA &= \int_3^5 \int_{\frac{x+1}{2}}^{-x+8} (x+1)\, dy\, dx \\
&= \int_3^5 (x+1) \left(y \Big|_{\frac{x+1}{2}}^{-x+8} \right) dx \\
&= \int_3^5 (x+1) \left(-x + 8 - \frac{x+1}{2} \right) dx \\
&= \int_3^5 -\frac{3}{2}x^2 + 6x + \frac{15}{2}x\, dx \\
&= -\frac{1}{2}x^3 + 3x^2 + \frac{15}{2}x \Big|_3^5 \\
&= \left(-\frac{125}{2} + 75 + \frac{75}{2} \right) - \left(-\frac{27}{2} + 27 + \frac{45}{2} \right) = 14
\end{aligned}$$

Finally we substitute the results above to obtain the following solution:

$$\iint_{\mathcal{D}} (x+1)\,dA = \iint_{\mathcal{D}_1} (x+1)\,dA + \iint_{\mathcal{D}_2} (x+1)\,dA = 10 + 14 = 24$$

43. Calculate the double integral of $f(x, y) = \dfrac{\sin y}{y}$ over the region $\mathcal{D}$ in Figure 26.

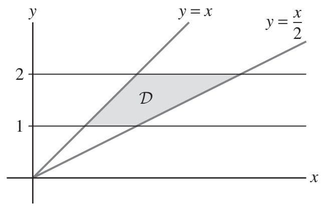


FIGURE 26

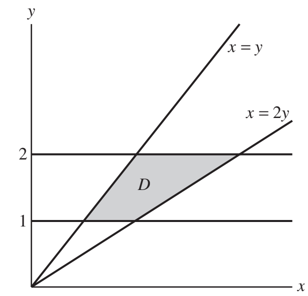
SOLUTION To describe $\mathcal{D}$ as a horizontally simple region, we rewrite the equations of the lines with x as a function of y, that is, $x = y$ and $x = 2y$. The inequalities for $\mathcal{D}$ are

$$1 \le y \le 2, \quad y \le x \le 2y$$



We now compute the double integral of $f(x, y) = \frac{\sin y}{y}$ over $\mathcal{D}$ by the following iterated integral:

$$\begin{aligned}\iint_{\mathcal{D}} \frac{\sin y}{y}\,dA &= \int_1^2 \int_y^{2y} \frac{\sin y}{y}\,dx\,dy = \int_1^2 \frac{\sin y}{y} x\Big|_{x=y}^{2y}\,dy = \int_1^2 \frac{\sin y}{y}(2y - y)\,dy \\ &= \int_1^2 \frac{\sin y}{y} \cdot y\,dy = \int_1^2 \sin y\,dy = -\cos y\Big|_1^2 = \cos 1 - \cos 2 \approx 0.956\end{aligned}$$

44. Evaluate $\iint_{\mathcal{D}} x\,dA$ for $\mathcal{D}$ in Figure 27.

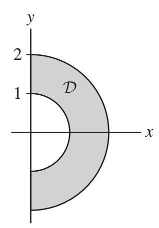


FIGURE 27

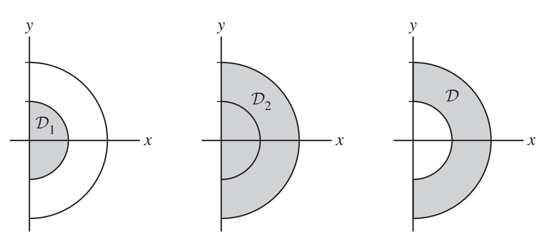
SOLUTION We compute the integral using decomposition of a domain into smaller domains. We denote by $\mathcal{D}_2$ and $\mathcal{D}_1$ the right semicircles of radius 2 and 1, respectively.



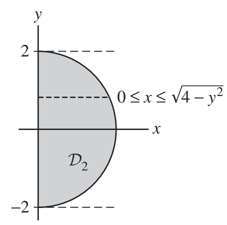
Then $\mathcal{D}_2$ is the union of $\mathcal{D}_1$ and $\mathcal{D}$, which do not overlap except on a boundary curve. Therefore,

$$\iint_{\mathcal{D}_2} x\,dA = \iint_{\mathcal{D}_1} x\,dA + \iint_{\mathcal{D}} x\,dA$$

or

$$\iint_{\mathcal{D}} x\,dA = \iint_{\mathcal{D}_2} x\,dA - \iint_{\mathcal{D}_1} x\,dA \tag{1}$$

To express $\mathcal{D}_1$ and $\mathcal{D}_2$ as horizontally simple regions, we write the equations of the circles in the form $x = \sqrt{1-y^2}$ and $x = \sqrt{4-y^2}$, respectively. The equations describing the regions $\mathcal{D}_1$ and $\mathcal{D}_2$ are

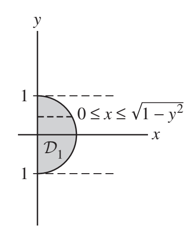


$$\begin{array}{cc} -2 \le y \le 2, & -1 \le y \le 1, \\ 0 \le x \le \sqrt{4-y^2} & 0 \le x \le \sqrt{1-y^2} \\ \mathcal{D}_2 & \mathcal{D}_1 \end{array}$$

We compute the double integrals over $\mathcal{D}_2$:

$$\iint_{\mathcal{D}_2} x\,dA = \int_{-2}^{2}\int_{0}^{\sqrt{4-y^2}} x\,dx\,dy = \int_{-2}^{2} \frac{x^2}{2}\bigg|_{x=0}^{\sqrt{4-y^2}} dy = \int_{-2}^{2} \frac{\left(\sqrt{4-y^2}\right)^2 - 0^2}{2}\,dy = \int_{-2}^{2}\left(2 - \frac{y^2}{2}\right) dy$$

$$= \int_{0}^{2} (4-y^2)\,dy = 4y - \frac{y^3}{3}\bigg|_{0}^{2} = 8 - \frac{8}{3} = \frac{16}{3} \tag{2}$$



The integral over $\mathcal{D}_1$ is

$$\iint_{\mathcal{D}_1} x\,dA = \int_{-1}^{1}\int_{0}^{\sqrt{1-y^2}} x\,dx\,dy = \int_{-1}^{1} \frac{x^2}{2}\bigg|_{x=0}^{\sqrt{1-y^2}} dy = \int_{-1}^{1} \frac{\left(\sqrt{1-y^2}\right)^2 - 0^2}{2}\,dy = \int_{-1}^{1}\left(\frac{1}{2} - \frac{y^2}{2}\right) dy$$

$$= \int_{0}^{1} (1-y^2)\,dy = y - \frac{y^3}{3}\bigg|_{0}^{1} = 1 - \frac{1}{3} = \frac{2}{3} \tag{3}$$

We now combine (1), (2), and (3) to obtain the following solution:

$$\iint_{\mathcal{D}} x\,dA = \frac{16}{3} - \frac{2}{3} = \frac{14}{3} \approx 4.67$$

45. Find the volume of the region bounded by $z = 40 - 10y$, $z = 0$, $y = 0$, $y = 4 - x^2$.

SOLUTION The volume of the region is the double integral of $f(x, y) = 40 - 10y$ over the domain $\mathcal{D}$ in the xy-plane between the curves $y = 0$ and $y = 4 - x^2$. This is a vertically simple region described by the inequalities:

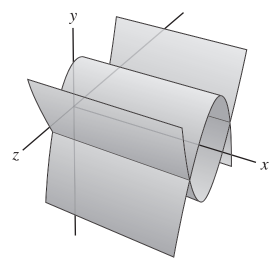
$$-2 \le x \le 2, \quad 0 \le y \le 4 - x^2$$

We compute the double integral as the following iterated integral:

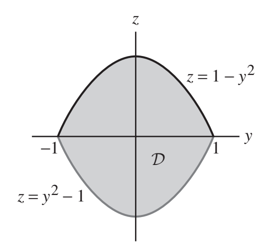
$$\begin{aligned}
V &= \iint_{\mathcal{D}} 40 - 10y\, dA = \int_{-2}^{2} \int_{0}^{4-x^2} (40 - 10y)\, dy\, dx \\
&= \int_{-2}^{2} \left(40y - 5y^2 \Big|_{0}^{4-x^2} \right) dx \\
&= \int_{-2}^{2} 40(4 - x^2) - 5(4 - x^2)^2\, dx = \int_{-2}^{2} 160 - 40x^2 - 5(16 - 8x^2 + x^4)\, dx \\
&= \int_{-2}^{2} 80 - 5x^4\, dx = 80x - x^5 \Big|_{-2}^{2} \\
&= (160 - 32) - (-160 + 32) = 256
\end{aligned}$$

46. Find the volume of the region enclosed by $z = 1 - y^2$ and $z = y^2 - 1$ for $0 \le x \le 2$.

SOLUTION



The volume of the region is the double integral of $f(y, z) = 2$ over the domain $\mathcal{D}$ in the yz-plane between the curves $z = 1 - y^2$ and $z = y^2 - 1$.



This domain is the vertically simple region described by the inequalities

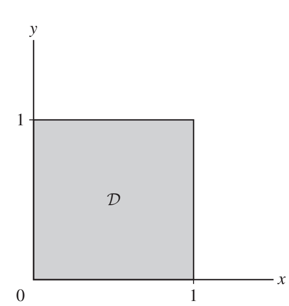
$$-1 \le y \le 1, \quad y^2 - 1 \le z \le 1 - y^2$$

We compute the double integral as the following iterated integral:

$$\begin{aligned}
V &= \iint_{\mathcal{D}} 2\, dA = \int_{-1}^{1} \int_{y^2-1}^{1-y^2} 2\, dz\, dy = \int_{-1}^{1} 2z \Big|_{z=y^2-1}^{1-y^2} dy = \int_{-1}^{1} 2\left((1 - y^2) - (y^2 - 1) \right) dy \\
&= \int_{-1}^{1} (4 - 4y^2)\, dy = \int_{0}^{1} (8 - 8y^2)\, dy = 8y - \frac{8}{3}y^3 \Big|_{0}^{1} = 8 - \frac{8}{3} = \frac{16}{3} \approx 5.33
\end{aligned}$$

47. Calculate the average value of $f(x, y) = e^{x+y}$ on the square $[0, 1] \times [0, 1]$.

SOLUTION



Since the area of the square $\mathcal{D}$ is 1, the average value of $f(x, y) = e^{x+y}$ on $\mathcal{D}$ is the following value:

$$\overline{f} = \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} f(x, y)\, dA = \frac{1}{1} \int_0^1 \int_0^1 e^{x+y}\, dx\, dy = \int_0^1 e^{x+y} \Big|_{x=0}^{1} dy = \int_0^1 \left(e^{1+y} - e^{0+y} \right) dy$$
$$= \int_0^1 \left(e^{1+y} - e^{y} \right) dy = e^{1+y} - e^{y} \Big|_0^1 = \left(e^2 - e \right) - \left(e^1 - e^0 \right) = e^2 - 2e + 1 \approx 2.95$$

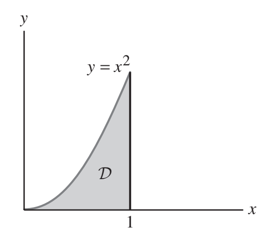
48. Calculate the average height above the x-axis of a point in the region $0 \le x \le 1$, $0 \le y \le x^2$.

SOLUTION The height of the point (x, y) in the region $\mathcal{D}$ above the x-axis is $f(x, y) = y$. Therefore, the average height is the following value:

$$\overline{H} = \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} y\, dA \tag{1}$$

We first compute the integral. The region $\mathcal{D}$ is a vertically simple region defined by the inequalities

$$0 \le x \le 1, \quad 0 \le y \le x^2$$



Therefore,

$$\iint_{\mathcal{D}} y\, dA = \int_0^1 \int_0^{x^2} y\, dy\, dx = \int_0^1 \frac{1}{2} y^2 \Big|_{y=0}^{x^2} dx = \int_0^1 \frac{1}{2} \left(x^4 - 0 \right) dx = \int_0^1 \frac{1}{2} x^4\, dx = \frac{x^5}{10} \Big|_0^1 = \frac{1}{10} \tag{2}$$

We compute the area of $\mathcal{D}$ using the formula for the area as a double integral:

$$\text{Area}(\mathcal{D}) = \iint_{\mathcal{D}} 1\, dA = \int_0^1 \int_0^{x^2} dy\, dx = \int_0^1 y \Big|_{y=0}^{x^2} dx = \int_0^1 x^2\, dx = \frac{x^3}{3} \Big|_0^1 = \frac{1}{3} \tag{3}$$

Substituting (2) and (3) in (1) we obtain

$$\overline{H} = \frac{1}{\frac{1}{3}} \cdot \frac{1}{10} = \frac{3}{10}$$

49. Find the average height of the "ceiling" in Figure 28 defined by $z = y^2 \sin x$ for $0 \le x \le \pi$, $0 \le y \le 1$.

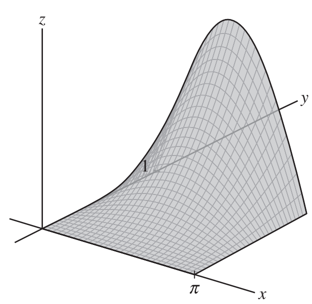


FIGURE 28

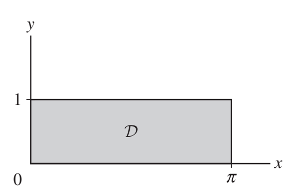
SOLUTION



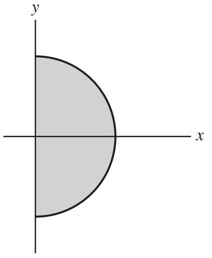
The average height is

$$\overline{H} = \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} y^2 \sin x \, dA = \frac{1}{\pi \cdot 1} \int_0^1 \int_0^\pi y^2 \sin x \, dx \, dy = \frac{1}{\pi} \int_0^1 y^2(-\cos x) \Big|_{x=0}^{\pi} dy$$
$$= \frac{1}{\pi} \int_0^1 y^2(-\cos \pi + \cos 0) \, dy = \frac{1}{\pi} \int_0^1 2y^2 \, dy = \frac{1}{\pi} \cdot \frac{2}{3} y^3 \Big|_0^1 = \frac{2}{3\pi}$$

50. Calculate the average value of the x-coordinate of a point on the semicircle $x^2 + y^2 \le R^2$, $x \ge 0$. What is the average value of the y-coordinate?

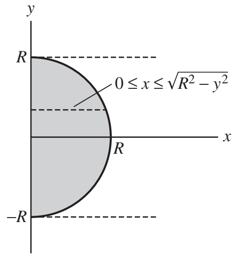
SOLUTION The average value of the x-coordinates of a point on the semicircle $\mathcal{D}$ is

$$\overline{x} = \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} x \, dA$$



The area of the semicircle is $\frac{\pi R^2}{2}$. To compute the double integral, we identify the inequalities defining $\mathcal{D}$ as a horizontally simple region:

$$-R \le y \le R, \quad 0 \le x \le \sqrt{R^2 - y^2}$$



Therefore,

$$\overline{x} = \frac{1}{\frac{\pi R^2}{2}} \int_{-R}^{R} \int_0^{\sqrt{R^2-y^2}} x \, dx \, dy = \frac{2}{\pi R^2} \int_{-R}^{R} \frac{x^2}{2} \Big|_{x=0}^{\sqrt{R^2-y^2}} dy = \frac{2}{\pi R^2} \int_{-R}^{R} \frac{\left(\sqrt{R^2 - y^2}\right)^2 - 0^2}{2} \, dy$$
$$= \frac{1}{\pi R^2} \int_{-R}^{R} \left(R^2 - y^2\right) dy = \frac{2}{\pi R^2} \int_0^R \left(R^2 - y^2\right) dy = \frac{2}{\pi R^2} \left(R^2 y - \frac{y^3}{3}\right) \Big|_{y=0}^{R}$$
$$= \frac{2}{\pi R^2} \left(R^3 - \frac{R^3}{3}\right) = \frac{2}{\pi R^2} \cdot \frac{2R^3}{3} = \frac{4R}{3\pi}$$

The average value of the x-coordinate is $\overline{x} = \frac{4R}{3\pi}$. The average value of the y-coordinate is

$$\overline{y} = \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} y \, dA = \frac{1}{\frac{\pi R^2}{2}} \int_{-R}^{R} \int_0^{\sqrt{R^2-y^2}} y \, dx \, dy = \frac{2}{\pi R^2} \int_{-R}^{R} yx \Big|_{x=0}^{\sqrt{R^2-y^2}} dy$$
$$= \frac{2}{\pi R^2} \int_{-R}^{R} y \left(\sqrt{R^2 - y^2} - 0\right) dy = \frac{2}{\pi R^2} \int_{-R}^{R} y \sqrt{R^2 - y^2} \, dy = 0$$

(The integral of an odd function over a symmetric interval with respect to the x-axis is zero). The average value of the y-coordinate is $\overline{y} = 0$.

Remark: Since the region is symmetric with respect to the x-axis, we expect the average value of y to be zero.

51. What is the average value of the linear function

$$f(x,y) = mx + ny + p$$

on the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 \le 1$? Argue by symmetry rather than calculation.

SOLUTION The average value of the linear function $f(x,y) = mx + ny + p$ over the ellipse $\mathcal{D}$ is

$$\begin{aligned}\overline{f} &= \frac{1}{\text{Area}(\mathcal{D})}\iint_{\mathcal{D}} f(x,y)\,dA = \frac{1}{\text{Area}(\mathcal{D})}\iint_{\mathcal{D}} (mx+ny+p)\,dA \\ &= m\cdot\underbrace{\frac{1}{\text{Area}(\mathcal{D})}\iint_{\mathcal{D}} x\,dA}_{I_1} + n\cdot\underbrace{\frac{1}{\text{Area}(\mathcal{D})}\iint_{\mathcal{D}} y\,dA}_{I_2} + \frac{1}{\text{Area}(\mathcal{D})}\iint_{\mathcal{D}} p\,dA \qquad (1)\end{aligned}$$

I_1 and I_2 are the average values of the x and y coordinates of a point in the region enclosed by the ellipse. This region is symmetric with respect to the y-axis, hence $I_1 = 0$. It is also symmetric with respect to the x-axis, hence $I_2 = 0$. We use the formula

$$\iint_{\mathcal{D}} p\,dA = p\cdot\text{Area}(\mathcal{D})$$

to conclude by (1) that

$$\overline{f} = m\cdot 0 + n\cdot 0 + \frac{1}{\text{Area}(\mathcal{D})}\cdot p\cdot\text{Area}(\mathcal{D}) = p$$

52. Find the average square distance from the origin to a point in the domain $\mathcal{D}$ in Figure 29.

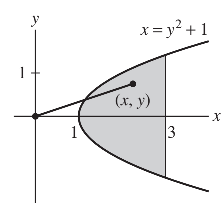


FIGURE 29

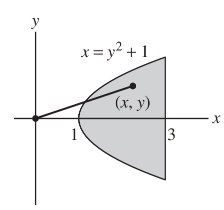
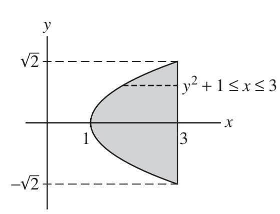
SOLUTION The square distance from the origin to a point (x,y) is given by the following function:

$$f(x,y) = (x-0)^2 + (y-0)^2 = x^2 + y^2$$



The domain $\mathcal{D}$ is a horizontally simple region described by the inequalities (see figure)

$$-\sqrt{2} \le y \le \sqrt{2}, \quad y^2 + 1 \le x \le 3$$



The average value of f in $\mathcal{D}$ is

$$\overline{f} = \frac{1}{\text{Area}(\mathcal{D})}\iint_{\mathcal{D}} \left(x^2 + y^2\right)\,dA \qquad (1)$$

We first compute the integral:

$$\iint_{\mathcal{D}} \left(x^2+y^2\right) dA = \int_{-\sqrt{2}}^{\sqrt{2}} \int_{y^2+1}^{3} \left(x^2+y^2\right) dx\,dy = \int_{-\sqrt{2}}^{\sqrt{2}} \frac{x^3}{3} + y^2 x \bigg|_{x=y^2+1}^{3} dy$$

$$= \int_{-\sqrt{2}}^{\sqrt{2}} \left(9 + 3y^2 - \left(\frac{(y^2+1)^3}{3} + y^2(y^2+1)\right)\right) dy$$

$$= \int_{-\sqrt{2}}^{\sqrt{2}} \left(-\frac{y^6}{3} - 2y^4 + y^2 + \frac{26}{3}\right) dy = \int_{0}^{\sqrt{2}} \left(-\frac{2y^6}{3} - 4y^4 + 2y^2 + \frac{52}{3}\right) dy$$

$$= -\frac{2y^7}{21} - \frac{4}{5}y^5 + \frac{2}{3}y^3 + \frac{52}{3}y \bigg|_0^{\sqrt{2}} = -\frac{2\left(\sqrt{2}\right)^7}{21} - \frac{4\left(\sqrt{2}\right)^5}{5} + \frac{2\left(\sqrt{2}\right)^3}{3} + \frac{52\sqrt{2}}{3}$$

$$= -\frac{16\sqrt{2}}{21} - \frac{16\sqrt{2}}{5} + \frac{4\sqrt{2}}{3} + \frac{52\sqrt{2}}{3} = \frac{1544}{105}\sqrt{2} \tag{2}$$

We compute the area of $\mathcal{D}$:

$$\text{Area}(\mathcal{D}) = \iint_{\mathcal{D}} 1\,dA = \int_{-\sqrt{2}}^{\sqrt{2}} \int_{y^2+1}^{3} 1\,dx\,dy = \int_{-\sqrt{2}}^{\sqrt{2}} x \bigg|_{x=y^2+1}^{3} dy = \int_{-\sqrt{2}}^{\sqrt{2}} \left(3-(y^2+1)\right) dy$$

$$= \int_{-\sqrt{2}}^{\sqrt{2}} (2-y^2)\,dy = \int_0^{\sqrt{2}} (4-2y^2)\,dy = 4y - \frac{2}{3}y^3 \bigg|_0^{\sqrt{2}} = 4\sqrt{2} - \frac{2}{3}\left(\sqrt{2}\right)^3 = \frac{8}{3}\sqrt{2} \tag{3}$$

Substituting (2) and (3) into (1), we obtain the following solution:

$$\overline{f} = \frac{1}{\frac{8\sqrt{2}}{3}} \cdot \frac{1544}{105}\sqrt{2} = \frac{3 \cdot 1544\sqrt{2}}{8\sqrt{2} \cdot 105} = \frac{193}{35} \approx 5.51$$

53. Let $\mathcal{D}$ be the rectangle $0 \le x \le 2$, $-\frac{1}{8} \le y \le \frac{1}{8}$, and let $f(x,y) = \sqrt{x^3+1}$. Prove that

$$\iint_{\mathcal{D}} f(x,y)\,dA \le \frac{3}{2}$$

SOLUTION Recall that we can write

$$\iint_{\mathcal{D}} f(x,y)\,dA \le M \cdot \text{Area}(\mathcal{D})$$

where M is a constant such that $f(x,y) \le M$. We can see that $\text{Area}(\mathcal{D}) = 2(1/4) = 1/2$. So it remains to show that there is some constant M so that $f(x,y) \le M$. Consider the following:

$$x \le 2 \quad \Rightarrow \quad x^3 + 1 \le 0 \quad \Rightarrow \quad \sqrt{x^3+1} \le 3$$

Thus we can let $M = 3$. So then we have

$$\iint_{\mathcal{D}} f(x,y)\,dA \le M \cdot \text{Area}(\mathcal{D}) \quad \Rightarrow \quad \iint_{\mathcal{D}} \sqrt{x^3+1}\,dA \le 3 \cdot \frac{1}{2} = \frac{3}{2}$$

54. (a) Use the inequality $0 \le \sin x \le x$ for $x \ge 0$ to show that

$$\int_0^1 \int_0^1 \sin(xy)\,dx\,dy \le \frac{1}{4}$$

(b) Use a computer algebra system to evaluate the double integral to three decimal places.

SOLUTION Since $\sin(xy) \le xy$, we get that

$$\int_0^1 \int_0^1 \sin(xy)\,dx\,dy \le \int_0^1 \int_0^1 xy\,dx\,dy = \int_0^1 \frac{y}{2}\,dy = \frac{1}{4}$$

Using a CAS, we find that the double integral is approximately 0.240.

55. Prove the inequality $\iint_{\mathcal{D}} \frac{dA}{4+x^2+y^2} \le \pi$, where $\mathcal{D}$ is the disk $x^2+y^2 \le 4$.

SOLUTION The function $f(x,y) = \frac{1}{4+x^2+y^2}$ satisfies

$$f(x,y) = \frac{1}{4+x^2+y^2} \le \frac{1}{4}$$

Also, the area of the disk is

$$\text{Area}(\mathcal{D}) = \pi \cdot 2^2 = 4\pi$$

Therefore, by Theorem 3, we have

$$\iint_{\mathcal{D}} \frac{dA}{4+x^2+y^2} \le \frac{1}{4} \cdot 4\pi = \pi.$$

56. Let $\mathcal{D}$ be the domain bounded by $y = x^2+1$ and $y = 2$. Prove the inequality

$$\frac{4}{3} \le \iint_{\mathcal{D}} (x^2+y^2)dA \le \frac{20}{3}$$

SOLUTION Recall that we can write:

$$m \cdot \text{Area}(\mathcal{D}) \le \iint_{\mathcal{D}} f(x,y)\,dA \le M \cdot \text{Area}(\mathcal{D})$$

where m and M are constants such that $m \le f(x,y) \le M$.

First let us compute the area of the domain, $\mathcal{D}$:

$$\text{Area} = \int_{-1}^{1}\int_{x^2+1}^{2} 1\,dy\,dx = \int_{-1}^{1} 2-(x^2+1)\,dy\,dx$$

$$= \int_{-1}^{1} 1-x^2\,dy\,dx = x - \frac{1}{3}x^3\Big|_{-1}^{1}$$

$$= \left(1-\frac{1}{3}\right) - \left(-1+\frac{1}{3}\right) = \frac{4}{3}$$

Then we must bound $f(x,y) = x^2+y^2$ by constants (above and below). We know that $-1 \le x \le 1$ and the largest x^2 can be is 1 and the smallest x^2 can be is 0. The largest y can be is 2 and the smallest y can be is 0. Therefore,

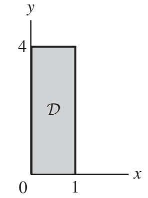
$$(-1)^2+0^2 \le x^2+y^2 \le 1^2+2^2 \quad\Rightarrow\quad 1 \le x^2+y^2 \le 5$$

Putting this all together for the inequality we see

$$m \cdot \text{Area}(\mathcal{D}) \le \iint_{\mathcal{D}} f(x,y)\,dA \le M \cdot \text{Area}(\mathcal{D}) \quad\Rightarrow\quad \frac{4}{3} \le \iint f(x,y)\,dA \le 5 \cdot \frac{4}{3} = \frac{20}{3}$$

57. Let $\overline{f}$ be the average of $f(x,y) = xy^2$ on $\mathcal{D} = [0,1]\times[0,4]$. Find a point $P \in \mathcal{D}$ such that $f(P) = \overline{f}$ (the existence of such a point is guaranteed by the Mean Value Theorem for Double Integrals).

SOLUTION We first compute the average $\overline{f}$ of $f(x,y) = xy^2$ on $\mathcal{D}$.



$\overline{f}$ is

$$\overline{f} = \frac{1}{\text{Area}(\mathcal{D})}\iint_{\mathcal{D}} xy^2\,dA = \frac{1}{4\cdot 1}\int_0^1\int_0^4 xy^2\,dy\,dx = \frac{1}{4}\int_0^1 \frac{xy^3}{3}\Big|_{y=0}^{4}\,dx$$

$$= \frac{1}{4}\int_0^1 \left(\frac{x\cdot 4^3}{3} - \frac{x\cdot 0^3}{3}\right)dx = \int_0^1 \frac{16x}{3}\,dx = \frac{8x^2}{3}\Big|_0^1 = \frac{8}{3}$$

We now must find a point $P = (a, b)$ in $\mathcal{D}$ such that

$$f(P) = ab^2 = \frac{8}{3}$$

We choose $b = 2$, obtaining

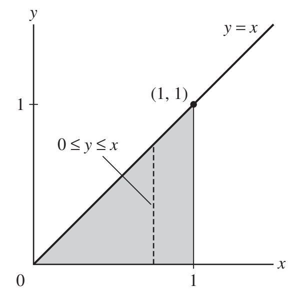
$$a \cdot 2^2 = \frac{8}{3} \quad \Rightarrow \quad a = \frac{2}{3}$$

The point $P = \left(\frac{2}{3}, 2\right)$ in the rectangle $\mathcal{D}$ satisfies

$$f(P) = \overline{f} = \frac{8}{3}$$

58. Verify the Mean Value Theorem for Double Integrals for $f(x, y) = e^{x-y}$ on the triangle bounded by $y = 0$, $x = 1$, and $y = x$.

SOLUTION



We must find a point $P = (a, b)$ in the triangle $\mathcal{D}$ such that

$$\iint_{\mathcal{D}} e^{x-y}\, dA = e^{a-b} \cdot \frac{1}{2} \tag{1}$$

(The area of the triangle is $\frac{1\cdot 1}{2} = \frac{1}{2}$.) We first compute the double integral. The inequalities defining $\mathcal{D}$ as a vertically simple region are

$$0 \le x \le 1, \quad 0 \le y \le x \tag{2}$$

Therefore,

$$\iint_{\mathcal{D}} e^{x-y}\, dA = \int_0^1 \int_0^x e^{x-y}\, dy\, dx = \int_0^1 -e^{x-y}\Big|_{y=0}^{x} dx = \int_0^1 -(e^{x-x} - e^{x-0})\, dx = \int_0^1 (e^x - 1)\, dx$$
$$= e^x - x\Big|_0^1 = (e^1 - 1) - (e^0 - 0) = e - 2$$

Substituting in (1) we get

$$e - 2 = e^{a-b} \cdot \frac{1}{2} \qquad \text{or} \qquad e^{a-b} = 2e - 4$$

or

$$a - b = \ln(2e - 4) \quad \Rightarrow \quad b = a - \ln(2e - 4)$$

We choose $a = 0.5$ and find b:

$$b = 0.5 - \ln(2e - 4) \approx 0.138$$

The point $(a, b) = (0.5, 0.138)$ satisfies the inequalities (2), hence it lies in $\mathcal{D}$. This point satisfies

$$\iint_{\mathcal{D}} e^{x-y}\, dA = e^{a-b} \text{Area}(\mathcal{D})$$

In Exercises 59 and 60, use (11) to estimate the double integral.

59. The following table lists the areas of the subdomains $\mathcal{D}_j$ of the domain $\mathcal{D}$ in Figure 30 and the values of a function $f(x, y)$ at sample points $P_j \in \mathcal{D}_j$. Estimate $\iint_{\mathcal{D}} f(x, y)\, dA$.

j	1	2	3	4	5	6
Area($\mathcal{D}_j$)	1.2	1.1	1.4	0.6	1.2	0.8
$f(P_j)$	9	9.1	9.3	9.1	8.9	8.8

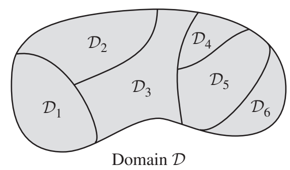


FIGURE 30

SOLUTION By Eq. (11) we have

$$\iint_{\mathcal{D}} f(x, y)\, dA \approx \sum_{j=1}^{6} f\left(P_j\right) \text{Area}\left(\mathcal{D}_j\right)$$

Substituting the data given in the table, we obtain

$$\iint_{\mathcal{D}} f(x, y)\, dA \approx 9 \cdot 1.2 + 9.1 \cdot 1.1 + 9.3 \cdot 1.4 + 9.1 \cdot 0.6 + 8.9 \cdot 1.2 + 8.8 \cdot 0.8 = 57.01$$

Thus,

$$\iint_{\mathcal{D}} f(x, y)\, dA \approx 57.01$$

60. The domain $\mathcal{D}$ between the circles of radii 5 and 5.2 in the first quadrant in Figure 31 is divided into six subdomains of angular width $\Delta\theta = \frac{\pi}{12}$, and the values of a function $f(x, y)$ at sample points are given. Compute the area of the subdomains and estimate $\iint_{\mathcal{D}} f(x, y)\, dA$.

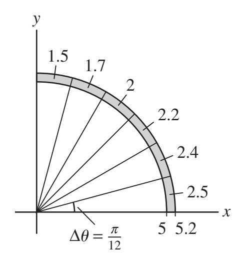

FIGURE 31

SOLUTION The area of a sector of angular width θ in a circle of radius $\mathcal{R}$ is $\frac{\mathcal{R}^2\theta}{2}$. Hence, the area of each subdomain is the following difference:

$$\text{Area}\left(\mathcal{D}_j\right) = \frac{(5.2)^2 \cdot \frac{\pi}{12}}{2} - \frac{5^2 \cdot \frac{\pi}{12}}{2} = \frac{2.04 \cdot \frac{\pi}{12}}{2} = 0.085\pi$$

We now use Eq. (11) and the given values at sample points to estimate the double integral:

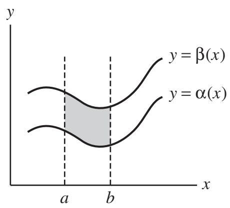
$$\iint_{\mathcal{D}} f(x, y)\, dA \approx \sum_{j=1}^{6} f\left(P_j\right) \text{Area}\left(\mathcal{D}_j\right) = 0.085\pi(2.5 + 2.4 + 2.2 + 2 + 1.7 + 1.5) = 1.0455\pi \approx 3.285$$

61. According to Eq. (3), the area of a domain $\mathcal{D}$ is equal to $\iint_{\mathcal{D}} 1\, dA$. Prove that if $\mathcal{D}$ is the region between two curves $y = g_1(x)$ and $y = g_2(x)$ with $g_2(x) \le g_1(x)$ for $a \le x \le b$, then

$$\iint_{\mathcal{D}} 1\, dA = \int_a^b (g_1(x) - g_2(x))\, dx$$

SOLUTION The region $\mathcal{D}$ is defined by the inequalities

$$a \le x \le b, \quad g_1(x) \le y \le g_2(x)$$



We compute the double integral of $f(x, y) = 1$ on $\mathcal{D}$, using Theorem 2, by evaluating the following iterated integral:

$$\int_{\mathcal{D}} 1\, dA = \int_a^b \int_{g_1(x)}^{g_2(x)} 1\, dy\, dx = \int_a^b \left(\int_{g_1(x)}^{g_2(x)} 1\, dy \right) dx = \int_a^b y \Big|_{y=g_1(x)}^{g_2(x)} dx = \int_a^b (g_2(x) - g_1(x))\, dx$$

Further Insights and Challenges

62. Let $\mathcal{D}$ be a closed connected domain and let $P, Q \in \mathcal{D}$. The Intermediate Value Theorem (IVT) states that if f is continuous on $\mathcal{D}$, then $f(x, y)$ takes on every value between $f(P)$ and $f(Q)$ at some point in $\mathcal{D}$.

(a) Show, by constructing a counterexample, that the IVT is false if $\mathcal{D}$ is not connected.

(b) Prove the IVT as follows: Let $\mathbf{c}(t)$ be a path such that $\mathbf{c}(0) = P$ and $\mathbf{c}(1) = Q$ (such a path exists because $\mathcal{D}$ is connected). Apply the IVT in one variable to the composite function $f(\mathbf{c}(t))$.

SOLUTION

(a) Let $\mathcal{D}$ be the union of the disc $\mathcal{D}_1$ of radius $\frac{1}{2}$ centered at the origin, and the disc $\mathcal{D}_2$ of radius $\frac{1}{2}$ centered at $(1, 1)$.

Obviously $\mathcal{D}$ is not connected. We define a function $f(x, y)$ on $\mathcal{D}$ as follows:

$$f(x, y) = \begin{cases} 1 & (x, y) \in \mathcal{D}_1 \\ 2 & (x, y) \in \mathcal{D}_2 \end{cases}$$

f is continuous on $\mathcal{D}$, but it does not take on any value between 1 and 2.

(b) Let $\mathcal{D}$ be a closed connected domain and $f(x, y)$ a continuous function on $\mathcal{D}$. Suppose that $f(P) = a$ and $f(Q) = b$ where $P, Q \in \mathcal{D}$, and $a < c < b$. We show that f takes on the value c at a point in $\mathcal{D}$. Since $\mathcal{D}$ is connected, there is a curve $\gamma(t) = (x(t), y(t))$ lying entirely in $\mathcal{D}$, such that $\gamma(0) = P$ and $\gamma(1) = Q$. We consider the function

$$g(t) = f(x(t), y(t)), \quad 0 \le t \le 1$$

The composition $g(t)$ is continuous on the segment $0 \le t \le 1$, and c is an intermediate value of g on this segment (since $g(0) = a < c < b = g(1)$). Therefore, by the IVT, there exists $t_0 \in (0, 1)$ such that $g(t_0) = c$. The curve $\gamma(t)$ lies in $\mathcal{D}$, hence the point $\mathcal{R} = \gamma(t_0) = (x(t_0), y(t_0))$ is in $\mathcal{D}$ and the following holds:

$$f(\mathcal{R}) = f(x(t_0), y(t_0)) = g(t_0) = c.$$

63. Use the fact that a continuous function on a closed domain $\mathcal{D}$ attains both a minimum value m and a maximum value M, together with Theorem 3, to prove that the average value $\overline{f}$ lies between m and M. Then use the IVT in Exercise 62 to prove the Mean Value Theorem for Double Integrals.

SOLUTION Suppose that $f(x, y)$ is continuous and $\mathcal{D}$ is closed, bounded, and connected. By Theorem 3 in Chapter 15.7 ("Existence of Global Extrema"), $f(x, y)$ takes on a minimum value (call it m) at some point (x_m, y_m) and a maximum value (call it M) at some point (x_M, y_M) in the domain $\mathcal{D}$. Now, by Theorem 3,

$$m \,\text{Area}(\mathcal{D}) \le \iint_{\mathcal{D}} f(x, y)\, dA \le M \,\text{Area}(\mathcal{D})$$

which can be restated as

$$m \le \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} f(x, y)\, dA \le M$$

By the IVT in two variables (stated and proved in the previous problem), $f(x, y)$ takes on every value between m and M at some point in $\mathcal{D}$. In particular, f must take on the value $\frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} f(x, y)\, dA$ at some point P. So, $f(P) = \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} f(x, y)\, dA$, which is rewritten as

$$f(P)\,\text{Area}(\mathcal{D}) = \iint_{\mathcal{D}} f(x, y)\, dA$$

64. Let $f(y)$ be a function of y alone and set $G(t) = \int_0^t \int_0^x f(y)\,dy\,dx$.

(a) Use the Fundamental Theorem of Calculus to prove that $G''(t) = f(t)$.

(b) Show, by changing the order in the double integral, that $G(t) = \int_0^t (t-y) f(y)\,dy$. This shows that the "second antiderivative" of $f(y)$ can be expressed as a single integral.

SOLUTION

(a) Let $H(x) = \int_0^x f(y)\,dy$. Then $G(t) = \int_0^t H(x)\,dx$, and by the FTC we have

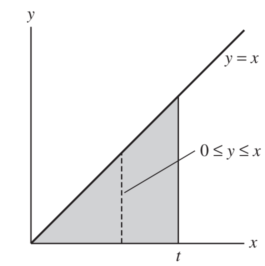
$$G'(t) = \frac{d}{dt}\int_0^t H(x)\,dx = H(t) = \int_0^t f(y)\,dy$$

We again use the FTC to differentiate $G'(t)$. This gives

$$G''(t) = \frac{d}{dt}\int_0^t f(y)\,dy = f(t)$$

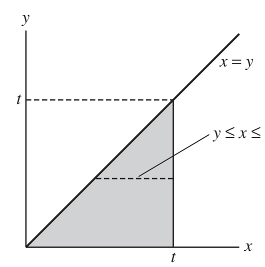
(b) For a fixed t, the domain of integration is described by the following inequalities:

$$0 \le x \le t, \quad 0 \le y \le x$$



We describe the domain as a horizontally simple region by the inequalities

$$0 \le y \le t, \quad y \le x \le t$$



Then, the iterated integral for $G(t)$ can be computed in reverse order of integration as follows:

$$G(t) = \int_0^t \int_y^t f(y)\,dx\,dy = \int_0^t f(y)x\Big|_{x=y}^{t}\,dy = \int_0^t f(y)(t-y)\,dy = \int_0^t (t-y)f(y)\,dy$$

We, thus showed that

$$G(t) = \int_0^t (t-y)f(y)\,dy$$

15.3 Triple Integrals (LT Section 16.3)

Preliminary Questions

1. Which of (a)–(c) is not equal to $\int_0^1 \int_3^4 \int_6^7 f(x, y, z)\,dz\,dy\,dx$?

(a) $\int_6^7 \int_0^1 \int_3^4 f(x, y, z)\,dy\,dx\,dz$

(b) $\int_3^4 \int_0^1 \int_6^7 f(x, y, z)\,dz\,dx\,dy$

(c) $\int_0^1 \int_3^4 \int_6^7 f(x, y, z)\,dx\,dz\,dy$

SOLUTION The given integral, I, is a triple integral of f over the box $B = [0, 1] \times [3, 4] \times [6, 7]$. In (a) the limits of integration are $0 \le x \le 1$, $3 \le y \le 4$, $6 \le z \le 7$, hence this integral is equal to I. In (b) the limits of integration are $0 \le x \le 1$, $3 \le y \le 4$, $6 \le z \le 7$, hence it is also equal to I. In (c) the limits of integration are $6 \le x \le 7$, $0 \le y \le 1$, $3 \le z \le 4$. This is the triple integral of f over the box $[6, 7] \times [0, 1] \times [3, 4]$, which is different from $\mathcal{B}$. Therefore, the triple integral is usually unequal to I.

2. Which of the following is not a meaningful triple integral?

(a) $\displaystyle\int_0^1 \int_0^x \int_{x+y}^{2x+y} e^{x+y+z}\,dz\,dy\,dx$

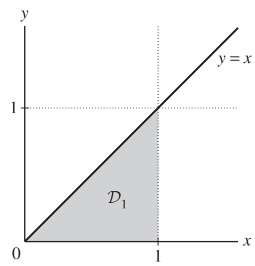
(b) $\displaystyle\int_0^1 \int_0^z \int_{x+y}^{2x+y} e^{x+y+z}\,dz\,dy\,dx$

SOLUTION

(a) The limits of integration determine the following inequalities:

$$0 \le x \le 1, \quad 0 \le y \le x, \quad x + y \le z \le 2x + y$$

The integration is over the simple region $\mathcal{W}$, which lies between the planes $z = x + y$ and $z = 2x + y$ over the domain $\mathcal{D}_1 = \{(x, y) : 0 \le x \le 1,\ 0 \le y \le x\}$ in the xy-plane.



Thus, the integral represents a meaningful triple integral.

(b) Note that the inner integral is with respect to z, but then the middle integral has limits from 0 to z! This makes no sense.

3. Describe the projection of the region of integration $\mathcal{W}$ onto the xy-plane:

(a) $\displaystyle\int_0^1 \int_0^x \int_0^{x^2+y^2} f(x, y, z)\,dz\,dy\,dx$

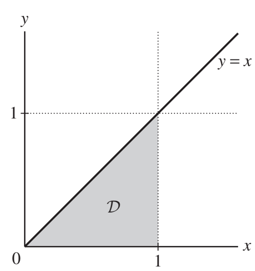
(b) $\displaystyle\int_0^1 \int_0^{\sqrt{1-x^2}} \int_2^4 f(x, y, z)\,dz\,dy\,dx$

SOLUTION

(a) The region of integration is defined by the limits of integration, yielding the following inequalities:

$$0 \le x \le 1, \quad 0 \le y \le x, \quad 0 \le z \le x^2 + y^2$$

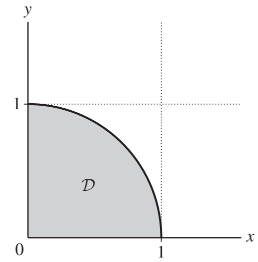
$\mathcal{W}$ is the region between the paraboloid $z = x^2 + y^2$ and the xy-plane which is above the triangle $\mathcal{D} = \{(x, y) : 0 \le x \le 1, 0 \le y \le x\}$ in the xy-plane. This triangle is the projection of $\mathcal{W}$ onto the xy-plane.



(b) The inequalities determined by the limits of integration are

$$0 \le x \le 1, \quad 0 \le y \le \sqrt{1 - x^2}, \quad 2 \le z \le 4$$

This is the region between the planes $z = 2$ and $z = 4$, which is above the region $\mathcal{D} = \left\{(x, y) : 0 \le x \le 1,\ 0 \le y \le \sqrt{1 - x^2}\right\}$ in the xy-plane. The projection $\mathcal{D}$ of $\mathcal{W}$ onto the xy-plane is the part of the unit disk in the first quadrant.



Exercises

In Exercises 1–8, evaluate $\iiint_{\mathcal{B}} f(x, y, z)\, dV$ *for the specified function* f *and box* $\mathcal{B}$.

1. $f(x, y, z) = z^4; \quad 2 \le x \le 8, \quad 0 \le y \le 5, \quad 0 \le z \le 1$

SOLUTION We write the triple integral as an iterated integral and compute it to obtain

$$\iiint_{\mathcal{B}} z^4\, dV = \int_2^8 \int_0^5 \int_0^1 z^4\, dz\, dy\, dx = \int_2^8 \int_0^5 \left(\int_0^1 z^4\, dz \right) dy\, dx = \int_2^8 \int_0^5 \frac{1}{5} z^5 \Big|_{z=0}^{1} dy\, dx$$
$$= \int_2^8 \int_0^5 \frac{1}{5}\, dy\, dx = \frac{1}{5} \int_2^8 \int_0^5 dy\, dx = \frac{1}{5} \cdot 6 \cdot 5 = 6$$

2. $f(x, y, z) = xz^2; \quad [-2, 3] \times [1, 3] \times [1, 4]$

SOLUTION The box $[-2, 3] \times [1, 3] \times [1, 4]$ corresponds to the inequalities $-2 \le x \le 3$, $1 \le y \le 3$, $1 \le z \le 4$. We write the integral as an iterated integral in any order we choose, and evaluate the inner, middle, and outer integral one after the other. This gives

$$\iint_{\mathcal{B}} xz^2\, dV = \int_{-2}^{3} \int_1^3 \int_1^4 xz^2\, dz\, dy\, dx = \int_{-2}^{3} \int_1^3 \left(\int_1^4 xz^2\, dz \right) dy\, dx = \int_{-2}^{3} \int_1^3 \frac{xz^3}{3} \Big|_{z=1}^{4} dy\, dx$$
$$= \int_{-2}^{3} \int_1^3 \frac{x(4^3 - 1^3)}{3}\, dy\, dx = \int_{-2}^{3} \left(\int_1^3 21x\, dy \right) dx = \int_{-2}^{3} 21xy \Big|_{y=1}^{3} dx$$
$$= \int_{-2}^{3} 42x\, dx = 21x^2 \Big|_{-2}^{3} = 21(9 - 4) = 105$$

Alternatively, we can use the form $f(x, y, z) = xz^2 = h(x)g(y)l(z)$ to compute the triple integral as the product:

$$\iint_{\mathcal{B}} xz^2\, dV = \int_{-2}^{3} \int_1^3 \int_1^4 xz^2\, dz\, dy\, dx = \left(\int_{-2}^{3} x\, dx \right) \left(\int_1^3 1\, dy \right) \left(\int_1^4 z^2\, dz \right)$$
$$= \left(\frac{x^2}{2} \Big|_{-2}^{3} \right) \left(y \Big|_1^3 \right) \left(\frac{z^3}{3} \Big|_1^4 \right) = \frac{5}{2} \cdot 2 \cdot \frac{\left(4^3 - 1^3\right)}{3} = 5 \cdot 21 = 105$$

3. $f(x, y, z) = xe^{y-2z}; \quad 0 \le x \le 2, \quad 0 \le y \le 1, \quad 0 \le z \le 1$

SOLUTION We write the triple integral as an iterated integral. Since $f(x, y, z) = xe^y \cdot e^{-2z}$, we may evaluate the iterated integral as the product of three single integrals. We get

$$\iiint_{\mathcal{B}} xe^{y-2z}\, dV = \int_0^2 \int_0^1 \int_0^1 xe^{y-2z}\, dz\, dy\, dx = \left(\int_0^2 x\, dx \right) \left(\int_0^1 e^y\, dy \right) \left(\int_0^1 e^{-2z}\, dz \right)$$
$$= \left(\frac{1}{2} x^2 \Big|_0^2 \right) \left(e^y \Big|_0^1 \right) \left(-\frac{1}{2} e^{-2z} \Big|_0^1 \right) = 2(e - 1) \cdot -\frac{1}{2}(e^{-2} - 1) = (e - 1)(1 - e^{-2})$$

4. $f(x, y, z) = \dfrac{x}{(y+z)^2}$; $[0, 2] \times [2, 4] \times [-1, 1]$

SOLUTION We write the triple integral as an iterated integral in any order we choose, and then evaluate the resulting integrals successively. We get:

$$\begin{aligned}\iiint_{\mathcal{B}} f(x, y, z)\, dx &= \int_{-1}^{1}\int_{2}^{4}\int_{0}^{2} \frac{x}{(y+z)^2}\, dx\, dy\, dz = \int_{-1}^{1}\int_{2}^{4}\left(\int_{0}^{2} \frac{x}{(y+z)^2}\, dx\right) dy\, dz \\ &= \int_{-1}^{1}\int_{2}^{4}\left(\frac{1}{(y+z)^2}\int_{0}^{2} x\, dx\right) dy\, dz = \int_{-1}^{1}\int_{2}^{4} \frac{1}{(y+z)^2}\, \frac{x^2}{2}\bigg|_{x=0}^{2} dy\, dz \\ &= \int_{-1}^{1}\int_{2}^{4} \frac{2}{(y+z)^2}\, dy\, dz = \int_{-1}^{1}\left(\int_{2}^{4} \frac{2}{(y+z)^2}\, dy\right) dz \\ &= \int_{-1}^{1} \frac{-2}{y+z}\bigg|_{y=2}^{4} dz = \int_{-1}^{1}\left(\frac{-2}{4+z} + \frac{2}{2+z}\right) dz = -2\ln(4+z) + 2\ln(2+z)\bigg|_{z=-1}^{1} \\ &= -2\ln 5 + 2\ln 3 - (-2\ln 3 + 2\ln 1) = -2\ln 5 + 4\ln 3 = \ln\frac{3^4}{5^2} \approx 1.176\end{aligned}$$

5. $f(x, y, z) = (x - y)(y - z)$; $[0, 1] \times [0, 3] \times [0, 3]$

SOLUTION We write the triple integral as an iterated integral and evaluate the inner, middle, and outer integrals successively. This gives

$$\begin{aligned}\iiint_{\mathcal{B}} (x-y)(y-z)\, dV &= \int_{0}^{1}\int_{0}^{3}\int_{0}^{3} (x-y)(y-z)\, dz\, dy\, dx = \int_{0}^{1}\int_{0}^{3}\left(\int_{0}^{3} (x-y)(y-z)\, dz\right) dy\, dx \\ &= \int_{0}^{1}\int_{0}^{3} (x-y)\left(yz - \frac{1}{2}z^2\right)\bigg|_{z=0}^{3} dy\, dx = \int_{0}^{1}\int_{0}^{3} (x-y)\left(3y - \frac{9}{2}\right) dy\, dx \\ &= \int_{0}^{1}\int_{0}^{3}\left(\left(3x + \frac{9}{2}\right)y - \frac{9}{2}x - 3y^2\right) dy\, dx = \int_{0}^{1}\left(\frac{3}{2}x + \frac{9}{4}\right)y^2 - \frac{9}{2}xy - y^3\bigg|_{y=0}^{3} dx \\ &= \int_{0}^{1}\left(\left(\frac{3}{2}x + \frac{9}{4}\right)\cdot 9 - \frac{9}{2}x \cdot 3 - 27\right) dx = \int_{0}^{1} -\frac{27}{4}\, dx = -\frac{27}{4} = -6.75\end{aligned}$$

6. $f(x, y, z) = \dfrac{z}{x}$; $1 \le x \le 3$, $0 \le y \le 2$, $0 \le z \le 4$

SOLUTION We write the triple integral as an iterated integral and evaluate it using iterated integral of a product function. We get

$$\begin{aligned}\iiint_{\mathcal{B}} f(x, y, z)\, dV &= \int_{1}^{3}\int_{0}^{2}\int_{0}^{4} \frac{z}{x}\, dz\, dy\, dx = \left(\int_{0}^{4} z\, dz\right)\left(\int_{0}^{2} 1\, dy\right)\left(\int_{1}^{3} \frac{1}{x}\, dx\right) \\ &= \left(\frac{1}{2}z^2\bigg|_{0}^{4}\right)\left(y\bigg|_{0}^{2}\right)\left(\ln x\bigg|_{1}^{3}\right) = 8 \cdot 2 \cdot (\ln 3 - \ln 1) = 16\ln 3\end{aligned}$$

7. $f(x, y, z) = (x + z)^3$; $[0, a] \times [0, b] \times [0, c]$

SOLUTION We write the triple integral as an iterated integral and evaluate it to obtain

$$\begin{aligned}\iiint_{\mathcal{B}} f(x, y, z)\, dV &= \int_{0}^{a}\int_{0}^{b}\int_{0}^{c} (x+z)^3\, dz\, dy\, dx = \int_{0}^{a}\int_{0}^{b} \frac{(x+z)^4}{4}\bigg|_{z=0}^{c} dy\, dx \\ &= \int_{0}^{a}\int_{0}^{b}\left(\frac{(x+c)^4}{4} - \frac{x^4}{4}\right) dy\, dx = \int_{0}^{a} \frac{(x+c)^4 - x^4}{4}\, y\bigg|_{y=0}^{b} dx \\ &= \int_{0}^{a} \frac{b}{4}\left[(x+c)^4 - x^4\right] dx = \frac{b}{4}\left[\frac{(x+c)^5}{5} - \frac{x^5}{5}\right]\bigg|_{x=0}^{a} \\ &= \frac{b}{4}\,\frac{(a+c)^5 - a^5 - c^5}{5} = \frac{b}{20}\left[(a+c)^5 - a^5 - c^5\right]\end{aligned}$$

8. $f(x, y, z) = (x + y - z)^2$; $[0, a] \times [0, b] \times [0, c]$

SOLUTION We evaluate the triple integral using Theorem 1. This gives

$$\iiint_{\mathcal{B}} f(x, y, z)\, dV = \int_0^a \int_0^b \int_0^c (x + y - z)^2\, dz\, dy\, dx = \int_0^a \int_0^b \left(-\frac{(x + y - z)^3}{3} \bigg|_{z=0}^{c} \right) dy\, dx$$

$$= \int_0^a \int_0^b -\frac{(x + y - c)^3}{3} + \frac{(x + y)^3}{3}\, dy\, dx$$

$$= \int_0^a \left(-\frac{(x + y - c)^4}{12} + \frac{(x + y)^4}{12} \bigg|_{y=0}^{b} \right) dx$$

$$= \int_0^a -\frac{(x + b - c)^4}{12} + \frac{(x + b)^4}{12} + \frac{(x - c)^4}{12} - \frac{x^4}{12}\, dx$$

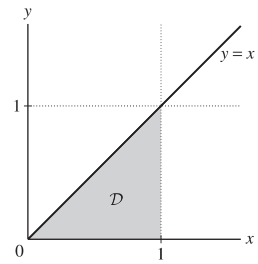
$$= -\frac{(x + b - c)^5}{60} + \frac{(x + b)^5}{60} + \frac{(x - c)^5}{60} - \frac{x^5}{60} \bigg|_{x=0}^{a}$$

$$= -\frac{(a + b - c)^5}{60} + \frac{(a + b)^5}{60} + \frac{(a - c)^5}{60} - \frac{a^5}{60} + \frac{(b - c)^5}{60} - \frac{b^5}{60} + \frac{(-c)^5}{60}$$

In Exercises 9–14, evaluate $\iiint_{\mathcal{W}} f(x, y, z)\, dV$ *for the function* f *and region* $\mathcal{W}$ *specified.*

9. $f(x, y, z) = x + y$; $\mathcal{W} : y \le z \le x,\ \ 0 \le y \le x,\ \ 0 \le x \le 1$

SOLUTION $\mathcal{W}$ is the region between the planes $z = y$ and $z = x$ lying over the triangle $\mathcal{D}$ in the xy-plane defined by the inequalities $0 \le y \le x$, $0 \le x \le 1$.



We compute the integral, using Theorem 2, by evaluating the following iterated integral:

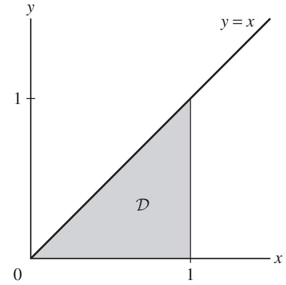
$$\iiint_{\mathcal{W}} (x + y)\, dV = \iint_{\mathcal{D}} \left(\int_y^x (x + y)\, dz \right) dA = \iint_{\mathcal{D}} (x + y)z \bigg|_{z=y}^{x} dA = \iint_{\mathcal{D}} (x + y)(x - y)\, dA$$

$$= \iint_{\mathcal{D}} \left(x^2 - y^2 \right) dA = \int_0^1 \int_0^x \left(x^2 - y^2 \right) dy\, dx = \int_0^1 \left(\int_0^x \left(x^2 - y^2 \right) dy \right) dx$$

$$= \int_0^1 x^2 y - \frac{y^3}{3} \bigg|_{y=0}^{x} dx = \int_0^1 \frac{2x^3}{3}\, dx = \frac{2}{12} x^4 \bigg|_0^1 = \frac{1}{6}$$

10. $f(x, y, z) = e^{x+y+z}$; $\mathcal{W} : 0 \le z \le 1,\ \ 0 \le y \le x,\ \ 0 \le x \le 1$

SOLUTION $\mathcal{W}$ is the region between the planes $z = 0$ and $z = 1$ lying over the triangle $\mathcal{D}$ in the xy-plane described in Exercise 9.

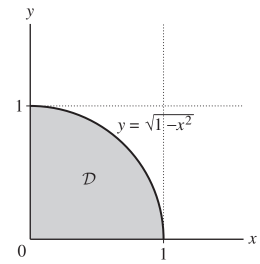


We compute the triple integral as the following iterated integral:

$$\begin{aligned}
\iiint_{\mathcal{W}} e^{x+y+z}\,dV &= \iint_{\mathcal{D}} \left(\int_0^1 e^{x+y+z}\,dz\right) dA = \iint_{\mathcal{D}} e^{x+y+z}\Big|_{z=0}^{1} dA \\
&= \iint_{\mathcal{D}} (e^{x+y+1} - e^{x+y})\,dA = \int_0^1 \int_0^x (e^{x+y+1} - e^{x+y})\,dy\,dx \\
&= \int_0^1 \left(\int_0^x (e^{x+y+1} - e^{x+y})\,dy\right) dx = \int_0^1 e^{x+y+1} - e^{x+y}\Big|_{y=0}^{x} dx \\
&= \int_0^1 \left(e^{2x+1} - e^{2x} - e^{x+1} + e^x\right) dx = \frac{1}{2}e^{2x+1} - \frac{1}{2}e^{2x} - e^{x+1} + e^x\Big|_0^1 \\
&= \frac{1}{2}e^3 - \frac{1}{2}e^2 - e^2 + e - \left(\frac{1}{2}e - \frac{1}{2}e^0 - e + e^0\right) \\
&= \frac{1}{2}e^3 - \frac{3}{2}e^2 + \frac{3}{2}e - \frac{1}{2} = \frac{1}{2}(e^3 - 3e^2 + 3e - 1)
\end{aligned}$$

11. $f(x, y, z) = xyz;\ \mathcal{W}: 0 \le z \le 1,\quad 0 \le y \le \sqrt{1-x^2},\quad 0 \le x \le 1$

SOLUTION $\mathcal{W}$ is the region between the planes $z = 0$ and $z = 1$, lying over the part $\mathcal{D}$ of the disk in the first quadrant.



Using Theorem 2, we compute the triple integral as the following iterated integral:

$$\begin{aligned}
\iiint_{\mathcal{W}} xyz\,dV &= \iint_{\mathcal{D}} \left(\int_0^1 xyz\,dz\right) dA = \iint_{\mathcal{D}} \frac{xyz^2}{2}\Big|_{z=0}^{1} dA = \iint_{\mathcal{D}} \frac{xy}{2}\,dA \\
&= \int_0^1 \left(\int_0^{\sqrt{1-x^2}} \frac{xy}{2}\,dy\right) dx = \int_0^1 \frac{xy^2}{4}\Big|_{y=0}^{\sqrt{1-x^2}} dx = \int_0^1 \frac{x(1-x^2)}{4}\,dx \\
&= \int_0^1 \frac{x - x^3}{4}\,dx = \frac{x^2}{8} - \frac{x^4}{16}\Big|_0^1 = \frac{1}{8} - \frac{1}{16} = \frac{1}{16}
\end{aligned}$$

12. $f(x, y, z) = x;\quad \mathcal{W}: x^2 + y^2 \le z \le 4$

SOLUTION Here, $\mathcal{W}$ is the upper half of the solid cone underneath the plane $z = 4$. First we must determine the projection $\mathcal{D}$ of $\mathcal{W}$ onto the xy-plane. First considering the intersection of the cone and the plane $z = 4$ we have:

$$x^2 + y^2 = 4$$

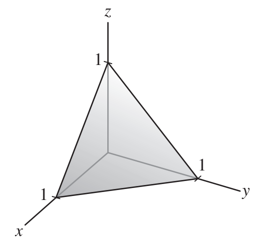
which is a circle centered at the origin with radius 2. The projection into the xy-plane is still $x^2 + y^2 = 4$.

The triple integral can be written as the following iterated integral:

$$\begin{aligned}
\iiint_{\mathcal{W}} x\,dV &= \iint_{\mathcal{D}} \left(\int_{x^2+y^2}^{4} x\,dz\right) dA = \iint_{\mathcal{D}} xz\Big|_{z=x^2+y^2}^{4} dA \\
&= \iint_{\mathcal{D}} x(4 - x^2 - y^2)\,dA = \int_0^{2\pi} \int_0^2 r\cos\theta(4 - r^2\cos^2\theta - r^2\sin^2\theta)r\,dr\,d\theta \\
&= \int_0^{2\pi} \int_0^2 4r^2\cos\theta - r^4\cos\theta\,dr\,d\theta \\
&= \int_0^{2\pi} \frac{4}{3}r^3\cos\theta - \frac{1}{5}r^5\cos\theta\Big|_0^2 d\theta \\
&= \int_0^{2\pi} \frac{64}{15}\cos\theta\,d\theta = \frac{64}{15}\sin\theta\Big|_0^{2\pi} = 0
\end{aligned}$$

13. $f(x, y, z) = e^z$; $\mathcal{W} : x + y + z \le 1$, $x \ge 0$, $y \ge 0$, $z \ge 0$

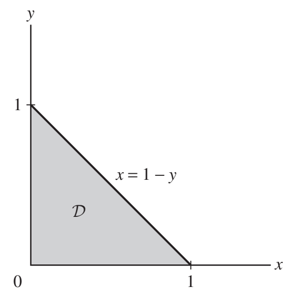
SOLUTION Notice that $\mathcal{W}$ is the tetrahedron under the plane $x + y + z = 1$ above the first quadrant.



First, we must determine the projection $\mathcal{D}$ of $\mathcal{W}$ onto the xy-plane. The intersection of the plane $x + y + z = 1$ with the xy-plane is obtained by solving

$$\begin{aligned} x + y + z &= 1 \\ z &= 0 \end{aligned} \quad \Rightarrow \quad x + y = 1$$

Therefore, the projection $\mathcal{D}$ of $\mathcal{W}$ onto the xy-plane is the triangle enclosed by the line $x + y = 1$ and the positive axes.



The region $\mathcal{W}$ is the region between the planes $z = 1 - x - y$ and $z = 0$, lying above the triangle $\mathcal{D}$ in the xy-plane. The triple integral can be written as the following iterated integral:

$$\begin{aligned} \iiint_{\mathcal{W}} e^z \, dV &= \iint_{\mathcal{D}} \left(\int_0^{1-x-y} e^z \, dz \right) dA = \iint_{\mathcal{D}} e^z \Big|_{z=0}^{1-x-y} dA \\ &= \iint_{\mathcal{D}} \left(e^{1-x-y} - 1 \right) dA \\ &= \int_0^1 \left(\int_0^{1-y} \left(e^{1-x-y} - 1 \right) dx \right) dy = \int_0^1 -e^{1-x-y} - x \Big|_{x=0}^{1-y} dy \\ &= \int_0^1 -e^{1-1+y-y} - (1-y) + e^{1-y} \, dy \\ &= \int_0^1 e^{1-y} + y - 2 \, dy = -e^{1-y} + \frac{1}{2} y^2 - 2y \Big|_{y=0}^{1} \\ &= -1 + \frac{1}{2} - 2 - \left(-e^1 \right) = e - \frac{5}{2} \end{aligned}$$

14. $f(x, y, z) = z$; $\mathcal{W} : x^2 \le y \le 2$, $0 \le x \le 1$, $x - y \le z \le x + y$

SOLUTION The triple integral can be written as the following iterated integral:

$$\begin{aligned} \iiint_{\mathcal{W}} z \, dV &= \int_0^1 \int_{x^2}^2 \int_{x-y}^{x+y} z \, dz \, dy \, dx = \int_0^1 \int_{x^2}^2 \frac{1}{2} z^2 \Big|_{z=x-y}^{x+y} dy \, dx \\ &= \frac{1}{2} \int_0^1 \int_{x^2}^2 (x+y)^2 - (x-y)^2 \, dy \, dx = \frac{1}{2} \int_0^1 \int_{x^2}^2 4xy \, dy \, dx \\ &= \int_0^1 xy^2 \Big|_{y=x^2}^2 dx = \int_0^1 4x - x^5 \, dx \\ &= 2x^2 - \frac{1}{6} x^6 \Big|_0^1 = 2 - \frac{1}{6} = \frac{11}{6} \end{aligned}$$

15. Calculate the integral of $f(x, y, z) = z$ over the region $\mathcal{W}$ in Figure 10 below the hemisphere of radius 3 and lying over the triangle $\mathcal{D}$ in the xy-plane bounded by $x = 1$, $y = 0$, and $x = y$.

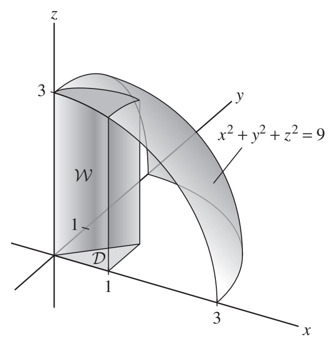


FIGURE 10

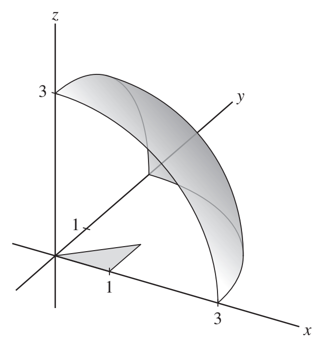
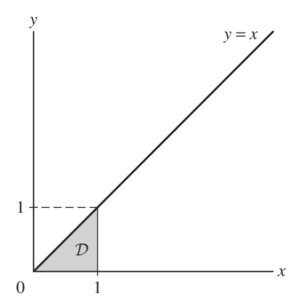
SOLUTION



The upper surface is the hemisphere $z = \sqrt{9 - x^2 - y^2}$ and the lower surface is the xy-plane $z = 0$. The projection of $\mathcal{V}$ onto the xy-plane is the triangle $\mathcal{D}$ shown in the figure.



We compute the triple integral as the following iterated integral:

$$\iiint_{\mathcal{V}} z\,dV = \iint_{\mathcal{D}} \left(\int_0^{\sqrt{9-x^2-y^2}} z\,dz \right) dA = \iint_{\mathcal{D}} \left. \frac{z^2}{2} \right|_0^{\sqrt{9-x^2-y^2}} dA = \iint_{\mathcal{D}} \frac{9 - x^2 - y^2}{2}\,dA$$

$$= \int_0^1 \left(\int_0^x \frac{9 - x^2 - y^2}{2}\,dy \right) dx = \int_0^1 \left. \frac{9y - x^2 y - \frac{y^3}{3}}{2} \right|_{y=0}^{x} dx = \int_0^1 \left(\frac{9x}{2} - \frac{2x^3}{3} \right) dx$$

$$= \left. \frac{9x^2}{4} - \frac{x^4}{6} \right|_0^1 = 2\frac{1}{12}$$

16. Calculate the integral of $f(x, y, z) = e^{2z}$ over the tetrahedron $\mathcal{W}$ in Figure 11.

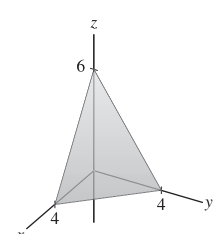


FIGURE 11

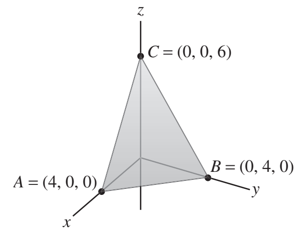
SOLUTION We first must find the equation of the upper surface, which is the plane through the points $A = (4, 0, 0)$, $B = (0, 4, 0)$, and $C = (0, 0, 6)$.



A vector normal to the plane is the following cross product:

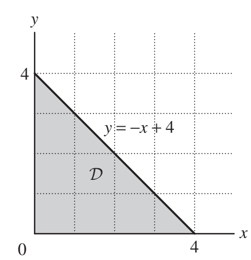
$$\mathbf{n} = \overrightarrow{AB} \times \overrightarrow{AC} = \langle -4, 4, 0\rangle \times \langle -4, 0, 6\rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -4 & 4 & 0 \\ -4 & 0 & 6 \end{vmatrix} = 24\mathbf{i} + 24\mathbf{j} + 16\mathbf{k} = 8\,(3\mathbf{i} + 3\mathbf{j} + 2\mathbf{k})$$

The equation of the plane with normal $3\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}$ passing through $A = (4, 0, 0)$ is

$$3(x-4) + 3y + 2z = 0$$
$$3x + 3y + 2z = 12 \quad \Rightarrow \quad z = 6 - \frac{3}{2}x - \frac{3}{2}y$$

Thus, the tetrahedron $\mathcal{V}$ lies between the planes $z = 6 - \frac{3x}{2} - \frac{3y}{2}$ and $z = 0$. The projection $\mathcal{D}$ of $\mathcal{V}$ onto the xy-plane is the triangle enclosed by the line AB and the positive axes. We compute the equation of the line AB:

$$y - 0 = \frac{4-0}{0-4}(x-4) \quad \Rightarrow \quad y = -x + 4$$



We now compute the triple integral of f over $\mathcal{V}$ as the following iterated integral:

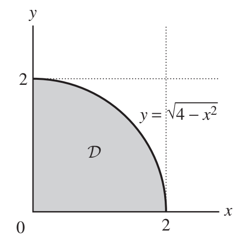
$$\iiint_{\mathcal{V}} e^{2z}\,dV = \iint_{\mathcal{D}} \left(\int_0^{6-\frac{3x}{2}-\frac{3y}{2}} e^{2z}\,dz\right) dA = \frac{1}{2}\iint_{\mathcal{D}} e^{2z}\Big|_{z=0}^{6-\frac{3x}{2}-\frac{3y}{2}} dA$$
$$= \frac{1}{2}\iint_{\mathcal{D}} e^{12-3x-3y} - 1\,dA = \frac{1}{2}\int_0^4 \int_0^{4-x} e^{12-3x-3y} - 1\,dy\,dx$$
$$= \frac{1}{2}\int_0^4 -\frac{1}{3}e^{12-3x-3y} - y\Big|_{y=0}^{4-x} dx = \frac{1}{2}\int_0^4 -\frac{1}{3}e^{12-3x-3(4-x)} - (4-x) + \frac{1}{3}e^{12-3x}\,dx$$
$$= \frac{1}{2}\int_0^4 x - \frac{13}{3} + \frac{1}{3}e^{12-3x}\,dx = \frac{1}{2}\left(\frac{1}{2}x^2 - \frac{13}{3}x - \frac{1}{9}e^{12-3x}\right)\Big|_0^4$$
$$= \frac{1}{2}\left(8 - \frac{52}{3} - \frac{1}{9}\right) - \frac{1}{2}\left(-\frac{1}{9}e^{12}\right) = \frac{1}{18}e^{12} - \frac{85}{18} \approx 9037$$

17. Integrate $f(x, y, z) = x$ over the region in the first octant $(x \ge 0, y \ge 0, z \ge 0)$ above $z = y^2$ and below $z = 8 - 2x^2 - y^2$.

SOLUTION We first find the projection of the region $\mathcal{W}$ onto the xy-plane. We find the curve of intersection between the upper and lower surfaces, by solving the following equation for $x, y \ge 0$:

$$8 - 2x^2 - y^2 = y^2 \quad \Rightarrow \quad y^2 = 4 - x^2 \quad \Rightarrow \quad y = \sqrt{4 - x^2},\, x \ge 0$$

The projection $\mathcal{D}$ of $\mathcal{W}$ onto the xy-plane is the region bounded by the circle $x^2 + y^2 = 4$ and the positive axes.



We now compute the triple integral over $\mathcal{W}$ by evaluating the following iterated integral:

$$\begin{aligned}\iiint_{\mathcal{W}} x\,dV &= \iint_{\mathcal{D}} \left(\int_{y^2}^{8-2x^2-y^2} x\,dz\right) dA = \iint_{\mathcal{D}} xz\Big|_{z=y^2}^{8-2x^2-y^2} dA \\ &= \iint_{\mathcal{D}} x(8-2x^2-y^2-y^2)\,dA = \iint_{\mathcal{D}} 8x-2x^3-2xy^2\,dA \\ &= \int_0^2\int_0^{\sqrt{4-x^2}} 8x-2x^3-2xy^2\,dy\,dx = \int_0^2 8xy-2x^3y-x^2y^2\Big|_{y=0}^{\sqrt{4-x^2}} dx \\ &= \int_0^2 8x\sqrt{4-x^2}\,dx - \int_0^2 2x^3\sqrt{4-x^2}\,dx - \int_0^2 x^2(4-x^2)\,dx \\ &= 8\int_0^2 x\sqrt{4-x^2}\,dx - 2\int_0^2 x^3\sqrt{4-x^2}\,dx - \int_0^2 4x^2-x^4\,dx\end{aligned}$$

The first and third integrals are easily computing using u-substitution and term by term integration, respectively. The second integral requires a clever u-substitution, let $u = 4-x^2$, then $du = -2x\,dx$ and $x^2 = 4-u$. Using this information we see

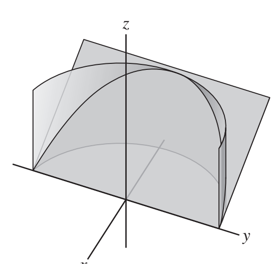
$$\begin{aligned}-2\int_0^2 x^3\sqrt{4-x^2}\,dx &= -2\int_0^2 x\cdot x^2\sqrt{4-x^2}\,dx \\ &= \int_{u=4}^0 (4-u)\sqrt{u}\,du \\ &= \int_4^0 4\sqrt{u}-u^{3/2}\,du \\ &= \frac{8}{3}u^{3/2}-\frac{2}{5}u^{5/2}\Big|_{u=4}^0 \\ &= -\left(\frac{64}{3}-\frac{64}{5}\right) = -\frac{128}{15}\end{aligned}$$

Hence,

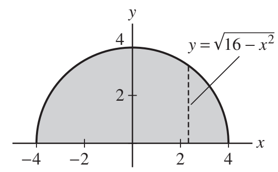
$$\begin{aligned}\iiint_{\mathcal{W}} x\,dV &= 8\int_0^2 x\sqrt{4-x^2}\,dx - 2\int_0^2 x^3\sqrt{4-x^2}\,dx - \int_0^2 4x^2-x^4\,dx \\ &= 8\int_0^2 x\sqrt{4-x^2}\,dx - \frac{128}{15} - \int_0^2 4x^2-x^4\,dx \\ &= 8\cdot -\frac{1}{3}(4-x^2)^{3/2}\Big|_0^2 - \frac{128}{15} - \left(\frac{4}{3}x^3-\frac{1}{5}x^5\Big|_0^2\right) \\ &= -\frac{8}{3}(0-8) - \frac{128}{15} - \left(\frac{32}{3}-\frac{32}{5}\right) = \frac{128}{15}\end{aligned}$$

18. Compute the integral of $f(x,y,z) = y^2$ over the region within the cylinder $x^2+y^2=4$ where $0 \le z \le y$.

SOLUTION



The upper surface is the plane $z = y$ and the lower surface is the plane $z = 0$. The region of integration, $\mathcal{W}$, projects onto the domain $\mathcal{D}$ bounded by the semicircle and the x-axis.



The triple integral of f over $\mathcal{W}$ is equal to the following iterated integral:

$$\begin{aligned}\iiint_{\mathcal{W}} f(x,y,z)\,dx &= \iint_{\mathcal{D}}\left(\int_0^y y^2\,dz\right)dA = \iint_{\mathcal{D}} y^2 z\Big|_{z=0}^{y}\,dA\\ &= \iint_{\mathcal{D}} y^3\,dA = \int_{-4}^{4}\int_0^{\sqrt{16-x^2}} y^3\,dy\,dx\\ &= \int_{-4}^{4}\frac{y^4}{4}\Big|_{y=0}^{\sqrt{16-x^2}}dx = \frac{1}{4}\int_{-4}^{4}(16-x^2)^2\,dx\\ &= \frac{1}{4}\int_{-4}^{4}256-32x^2+x^4\,dx = 256x-\frac{32}{3}x^3+\frac{1}{5}x^5\Big|_{-4}^{4}\\ &= \frac{1}{4}\left(256\cdot 4-\frac{32}{3}\cdot 64-\frac{1024}{5}\right)-\frac{1}{4}\left(256\cdot -4+\frac{32}{3}\cdot 64-\frac{1024}{5}\right)\\ &= \frac{4096}{15}\approx 273.067\end{aligned}$$

19. Find the triple integral of the function z over the ramp in Figure 12. Here, z is the height above the ground.

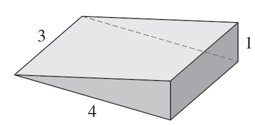


FIGURE 12

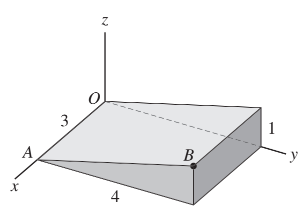
SOLUTION We place the coordinate axes as shown in the figure:



The upper surface is the plane passing through the points $O = (0,0,0)$, $A = (3,0,0)$, and $B = (3,4,1)$. We find a normal to this plane and then determine the equation of the plane. We get

$$\overrightarrow{OA}\times\overrightarrow{AB} = \langle 3,0,0\rangle\times\langle 0,4,1\rangle = \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 3 & 0 & 0\\ 0 & 4 & 1\end{vmatrix} = -3\mathbf{j}+12\mathbf{k} = 3(-\mathbf{j}+4\mathbf{k})$$

The plane is orthogonal to the vector $\langle 0,-1,4\rangle$ and passes through the origin, hence the equation of the plane is

$$0\cdot x - y + 4z = 0 \quad\Rightarrow\quad z = \frac{y}{4}$$

The projection of the region of integration $\mathcal{W}$ onto the xy-plane is the rectangle $\mathcal{D}$ defined by

$$0\le x\le 3,\quad 0\le y\le 4.$$

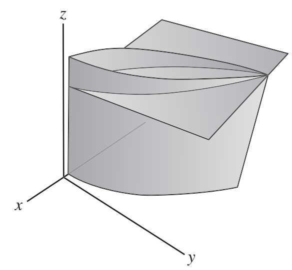
We now compute the triple integral of f over $\mathcal{W}$, as the following iterated integral:

$$\iiint_{\mathcal{W}} z\,dV = \iint_{\mathcal{D}} \left(\int_0^{y/4} z\,dz \right) dA = \iint_{\mathcal{D}} \frac{z^2}{2} \Big|_{z=0}^{y/4} dA = \iint_{\mathcal{D}} \frac{y^2}{32}\,dA = \int_0^4 \left(\int_0^3 \frac{y^2}{32}\,dx \right) dy$$

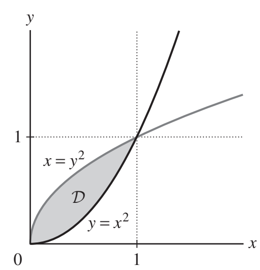
$$= \int_0^4 \frac{y^2 x}{32} \Big|_{x=0}^{3} dy = \int_0^4 \frac{3y^2}{32}\,dy = \frac{y^3}{32} \Big|_0^4 = \frac{4^3}{32} = 2$$

20. Find the volume of the solid in $\mathbf{R}^3$ bounded by $y = x^2$, $x = y^2$, $z = x + y + 5$, and $z = 0$.

SOLUTION The solid $\mathcal{W}$ is shown in the following figure:



The upper surface is the plane $z = x + y + 5$ and the lower surface is the plane $z = 0$. The projection of $\mathcal{W}$ onto the xy-plane is the region in the first quadrant enclosed by the curves $y = x^2$ and $x = y^2$.



We use the formula for the volume as a triple integral to write

$$\text{Volume}(\mathcal{W}) = \iiint_{\mathcal{W}} 1\,dV$$

The triple integral is equal to the following iterated integral:

$$\text{Volume}(\mathcal{W}) = \iiint_{\mathcal{W}} 1\,dV = \iint_{\mathcal{D}} \left(\int_0^{x+y+5} 1\,dz \right) dA = \iint_{\mathcal{D}} z \Big|_{z=0}^{x+y+5} dA$$

$$= \iint_{\mathcal{D}} (x + y + 5)\,dA = \int_0^1 \left(\int_{x^2}^{\sqrt{x}} (x + y + 5)\,dy \right) dx = \int_0^1 xy + \frac{y^2}{2} + 5y \Big|_{y=x^2}^{\sqrt{x}} dx$$

$$= \int_0^1 \left(x\sqrt{x} + \frac{x}{2} + 5\sqrt{x} - \left(x^3 + \frac{x^4}{2} + 5x^2 \right) \right) dx$$

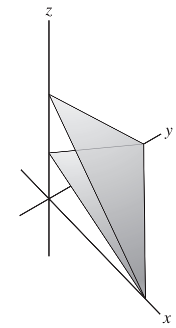
$$= \int_0^1 \left(-\frac{x^4}{2} - x^3 - 5x^2 + x^{3/2} + \frac{x}{2} + 5x^{1/2} \right) dx$$

$$= -\frac{x^5}{10} - \frac{x^4}{4} - \frac{5x^3}{3} + \frac{2}{5}x^{5/2} + \frac{x^2}{4} + \frac{10}{3}x^{3/2} \Big|_0^1$$

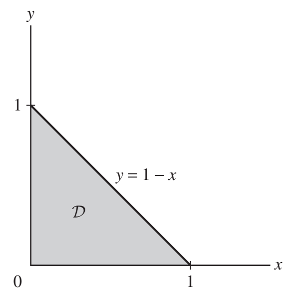
$$= -\frac{1}{10} - \frac{1}{4} - \frac{5}{3} + \frac{2}{5} + \frac{1}{4} + \frac{10}{3} = \frac{59}{30} = 1\frac{29}{30}$$

21. Find the volume of the solid in the octant $x \geq 0$, $y \geq 0$, $z \geq 0$ bounded by $x + y + z = 1$ and $x + y + 2z = 1$.

SOLUTION The solid $\mathcal{W}$ is shown in the figure:



The upper and lower surfaces are the planes $x + y + z = 1$ (or $z = 1 - x - y$) and $x + y + 2z = 1$ (or $z = \frac{1-x-y}{2}$), respectively. The projection of $\mathcal{W}$ onto the xy-plane is the triangle enclosed by the line $AB : y = 1 - x$ and the positive x and y-axes.

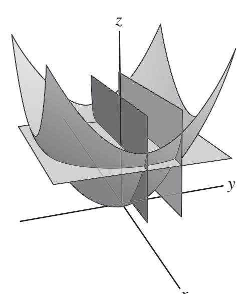


Using the volume of a solid as a triple integral, we have

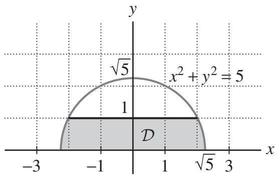
$$\begin{aligned}
\text{Volume}(\mathcal{W}) &= \iiint_{\mathcal{W}} 1\, dV = \iint_{\mathcal{D}} \left(\int_{(1-x-y)/2}^{1-x-y} 1\, dz \right) dA = \iint_{\mathcal{D}} z \Big|_{z=(1-x-y)/2}^{1-x-y} dA \\
&= \iint_{\mathcal{D}} \left((1-x-y) - \frac{1-x-y}{2} \right) dA = \iint_{\mathcal{D}} \frac{1-x-y}{2}\, dA \\
&= \int_0^1 \left(\int_0^{1-x} \frac{1-x-y}{2}\, dy \right) dx = \int_0^1 \frac{y - xy - \frac{y^2}{2}}{2} \Big|_{y=0}^{1-x} dx \\
&= \int_0^1 \frac{1 - x - x(1-x) - \frac{(1-x)^2}{2}}{2}\, dx = \frac{1}{2} \int_0^1 \left(\frac{x^2}{2} - x + \frac{1}{2} \right) dx \\
&= \frac{1}{2} \left(\frac{x^3}{6} - \frac{x^2}{2} + \frac{1}{2}x \right) \Big|_0^1 = \frac{1}{2} \left(\frac{1}{6} - \frac{1}{2} + \frac{1}{2} \right) = \frac{1}{12}
\end{aligned}$$

22. Calculate $\iiint_{\mathcal{W}} y\, dV$, where $\mathcal{W}$ is the region above $z = x^2 + y^2$ and below $z = 5$, and bounded by $y = 0$ and $y = 1$.

SOLUTION The region $\mathcal{W}$ is shown in the figure:



The upper surface is the plane $z = 5$ and the lower surface is the paraboloid $z = x^2 + y^2$. The projection of $\mathcal{W}$ onto the xy-plane is the part of the disk $x^2 + y^2 \le 5$ between the lines $y = 0$ and $y = 1$.



The triple integral of $f(x, y, z) = y$ over $\mathcal{W}$ is equal to the following iterated integral:

$$\iiint_{\mathcal{W}} y\,dV = \iint_{\mathcal{D}} \left(\int_{x^2+y^2}^{5} y\,dz\right) dA = \iint_{\mathcal{D}} yz\Big|_{z=x^2+y^2}^{5} dA = \iint_{\mathcal{D}} y\left(5 - x^2 - y^2\right) dA$$

$$= \int_0^1 \left(\int_{-\sqrt{5-y^2}}^{\sqrt{5-y^2}} y\left(5 - x^2 - y^2\right) dx\right) dy = 2\int_0^1 y\left(5x - \frac{x^3}{3} - y^2 x\right)\Big|_{x=0}^{\sqrt{5-y^2}} dy$$

$$= 2\int_0^1 y\left(\left(5 - y^2\right)x - \frac{x^3}{3}\right)\Big|_{x=0}^{\sqrt{5-y^2}} dy = 2\int_0^1 y\left(\left(5 - y^2\right)^{3/2} - \frac{1}{3}\left(5 - y^2\right)^{3/2}\right) dy$$

$$= \int_0^1 \frac{4}{3}\left(5 - y^2\right)^{3/2} y\,dy \qquad (1)$$

We compute the integral using the substitution $u = 5 - y^2$, $du = -2y\,dy$:

$$\iiint_{\mathcal{W}} y\,dV = \int_0^1 \frac{4}{3}\left(5 - y^2\right)^{3/2} y\,dy = \int_5^4 -\frac{2}{3}u^{3/2}\,du = \int_4^5 \frac{2}{3}u^{3/2}\,du = \frac{4}{15}u^{5/2}\Big|_4^5$$

$$= \frac{4}{15}\left(5^{5/2} - 4^{5/2}\right) \approx 6.37$$

23. Evaluate $\iiint_{\mathcal{W}} xz\,dV$, where $\mathcal{W}$ is the domain bounded by the elliptic cylinder $\dfrac{x^2}{4} + \dfrac{y^2}{9} = 1$ and the sphere $x^2 + y^2 + z^2 = 16$ in the first octant $x \ge 0$, $y \ge 0$, $z \ge 0$ (Figure 13).

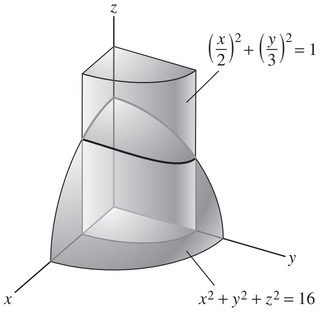


FIGURE 13

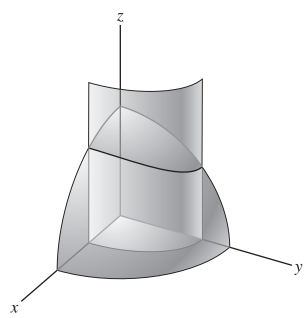
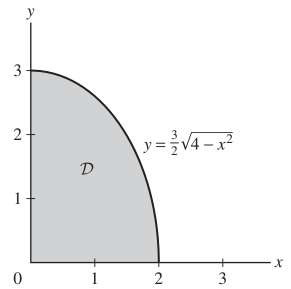
SOLUTION



The upper surface is the sphere $x^2 + y^2 + z^2 = 16$, or $z = \sqrt{16 - x^2 - y^2}$, and the lower surface is the xy-plane, $z = 0$. The projection of $\mathcal{W}$ onto the xy-plane is the region in the first quadrant bounded by the ellipse $(x/2)^2 + (y/3)^2 = 1$, or $y = \frac{3}{2}\sqrt{4 - x^2}$.



Therefore, the triple integral over $\mathcal{W}$ is equal to the following iterated integral:

$$\iiint_{\mathcal{W}} xz\,dV = \iint_{\mathcal{D}} \left(\int_0^{\sqrt{16-x^2-y^2}} xz\,dz\right) dA = \iint_{\mathcal{D}} \frac{1}{2}xz^2\Big|_{z=0}^{\sqrt{16-x^2-y^2}} dA$$
$$= \frac{1}{2}\iint_{\mathcal{D}} x(16-x^2-y^2)\,dA = \frac{1}{2}\int_0^2 \int_0^{\frac{3}{2}\sqrt{4-x^2}} 16x - x^3 - xy^2\,dy\,dx$$
$$= \frac{1}{2}\int_0^2 16xy - x^3y - \frac{1}{3}xy^3\Big|_{y=0}^{\frac{3}{2}\sqrt{4-x^2}}$$
$$= \frac{1}{2}\int_0^2 24x\sqrt{4-x^2} - \frac{3}{2}x^3\sqrt{4-x^2} - \frac{9}{8}x(4-x^2)^{3/2}\,dx$$
$$= 12\int_0^2 x\sqrt{4-x^2}\,dx - \frac{3}{4}\int_0^2 x^3\sqrt{4-x^2}\,dx - \frac{9}{16}\int_0^2 x(4-x^2)^{3/2}\,dx$$

The first and third integrals are simple u-substitution problems. For the second integral, let us use $u = 4 - x^2$ and thus $du = -2x\,dx$ and $x^2 = 4 - u$. Thus, we can write

$$-\frac{3}{4}\int_0^2 x^3\sqrt{4-x^2}\,dx = -\frac{3}{4}\int_0^2 x \cdot x^2\sqrt{4-x^2}\,dx$$
$$= \frac{3}{8}\int_{u=4}^0 (4-u)\sqrt{u}\,du$$
$$= \frac{3}{8}\int_4^0 4u^{1/2} - u^{3/2}\,du$$
$$= \frac{3}{8}\left(\frac{8}{3}u^{3/2} - \frac{2}{5}u^{5/2}\Big|_{u=4}^0\right)$$
$$= -\frac{3}{8}\left(\frac{64}{3} - \frac{64}{5}\right) = -\frac{16}{5}$$

Therefore we have:

$$\iiint_{\mathcal{W}} xz\,dV = 12\int_0^2 x\sqrt{4-x^2}\,dx - \frac{3}{4}\int_0^2 x^3\sqrt{4-x^2}\,dx - \frac{9}{16}\int_0^2 x(4-x^2)^{3/2}$$
$$= 12\int_0^2 x\sqrt{4-x^2}\,dx - \frac{16}{5} - \frac{9}{16}\int_0^2 x(4-x^2)^{3/2}\,dx$$
$$= -6\cdot\frac{2}{3}\left((4-x^2)^{3/2}\Big|_0^2\right) - \frac{16}{5} + \frac{9}{32}\cdot\frac{2}{5}\left((4-x^2)^{5/2}\Big|_0^2\right)$$
$$= -4\,(0-8) - \frac{16}{5} + \frac{9}{80}\,(0-32) = \frac{126}{5}$$

24. Describe the domain of integration and evaluate:

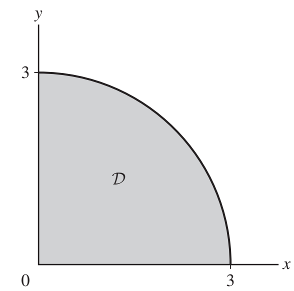
$$\int_0^3 \int_0^{\sqrt{9-x^2}} \int_0^{\sqrt{9-x^2-y^2}} xy\,dz\,dy\,dx$$

SOLUTION The domain of integration $\mathcal{W}$ is defined by the following inequalities:

$$0 \le x \le 3, \quad 0 \le y \le \sqrt{9-x^2}, \quad 0 \le z \le \sqrt{9-x^2-y^2}$$

This domain is the simple region in which the upper surface is the hemisphere of radius 3, $z = \sqrt{9 - x^2 - y^2}$, and the lower surface is the plane $z = 0$. The projection $\mathcal{D}$ of $\mathcal{W}$ onto the xy-plane is defined by the inequalities

$$0 \le x \le 3, \quad 0 \le y \le \sqrt{9 - x^2}$$



$\mathcal{D}$ is the part of the disk of radius 3 that lies in the first quadrant. We conclude that $\mathcal{W}$ is the part of the ball of radius 3 in the first octant. We evaluate the triple integral as the following iterated integral:

$$\iiint_{\mathcal{W}} xy\, dV = \iint_{\mathcal{D}} \left(\int_0^{\sqrt{9-x^2-y^2}} xy\, dz \right) = \iint_{\mathcal{D}} xyz \Big|_{z=0}^{\sqrt{9-x^2-y^2}} dA = \iint_{\mathcal{D}} xy\sqrt{9 - x^2 - y^2}\, dA$$

$$= \int_0^3 \left(x \int_0^{\sqrt{9-x^2}} \sqrt{9 - x^2 - y^2} \cdot y\, dy \right) dx \tag{1}$$

We evaluate the inner integral using the substitution $u = 9 - x^2 - y^2$, $du = -2y\, dy$. The upper limit of integration is $u = 9 - x^2 - (9 - x^2) = 0$ and the lower limit is $u = 9 - x^2 - 0^2 = 9 - x^2$. Therefore,

$$\int_0^{\sqrt{9-x^2}} \sqrt{9 - x^2 - y^2} \cdot y\, dy = \int_{9-x^2}^0 u^{1/2} \left(-\frac{du}{2} \right) = \frac{1}{2} \int_0^{9-x^2} u^{1/2}\, du$$

$$= \frac{1}{3} u^{3/2} \Big|_{u=0}^{9-x^2} = \frac{(9 - x^2)^{3/2}}{3}$$

We substitute in (1) and use the substitution $u = 9 - x^2$, $du = -2x\, dx$ to compute the resulting integral:

$$\iiint_{\mathcal{W}} xy\, dV = \int_0^3 \frac{1}{3} x (9 - x^2)^{3/2}\, dx = \int_9^0 \frac{1}{3} u^{3/2} \left(\frac{du}{-2} \right) = -\int_9^0 \frac{1}{6} u^{3/2}\, du$$

$$= \frac{1}{6} \cdot \frac{2}{5} u^{5/2} \Big|_0^9 = \frac{1}{15} \cdot 9^{5/2} = \frac{3^5}{15} = \frac{243}{15} = 16.2$$

25. Describe the domain of integration of the following integral:

$$\int_{-2}^{2} \int_{-\sqrt{4-z^2}}^{\sqrt{4-z^2}} \int_1^{\sqrt{5-x^2-z^2}} f(x, y, z)\, dy\, dx\, dz$$

SOLUTION The domain of integration of $\mathcal{W}$ is defined by the following inequalities:

$$-2 \le z \le 2, \quad -\sqrt{4 - z^2} \le x \le \sqrt{4 - z^2}, \quad 1 \le y \le \sqrt{5 - x^2 - z^2}$$

This region is bounded by the plane $y = 1$ and the sphere $y^2 = 5 - x^2 - z^2$ or $x^2 + y^2 + z^2 = 5$, lying over the disk $x^2 + z^2 \le 4$ in the xz-plane. This is the central cylinder oriented along the y-axis of radius 2 inside a sphere of radius $\sqrt{5}$.

26. Let $\mathcal{W}$ be the region below the paraboloid

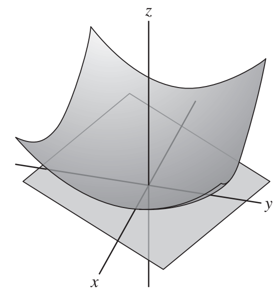
$$x^2 + y^2 = z - 2$$

that lies above the part of the plane $x + y + z = 1$ in the first octant ($x \ge 0$, $y \ge 0$, $z \ge 0$). Express

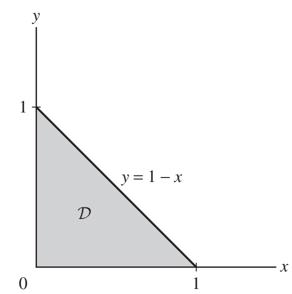
$$\iiint_{\mathcal{W}} f(x, y, z)\, dV$$

as an iterated integral (for an arbitrary function f).

SOLUTION The region of integration is shown in the figure:



The upper surface is $z = 2 + x^2 + y^2$ and the lower surface is the plane $z = 1 - x - y$. The projection $\mathcal{D}$ of W into the xy-plane is the triangle enclosed by the line $y = 1 - x$ (found by setting $z = 0$ in the equation $x + y + z = 1$) and the positive x and y axes.



Therefore, the triple integral over $\mathcal{W}$ is equal to the following iterated integral:

$$\iiint_{\mathcal{W}} f(x, y, z)\, dV = \iint_{\mathcal{D}} \left(\int_{1-x-y}^{2+x^2+y^2} f(x, y, z)\, dz \right) dA = \int_0^1 \int_0^{1-x} \int_{1-x-y}^{2+x^2+y^2} f(x, y, z)\, dz\, dy\, dx$$

27. In Example 5, we expressed a triple integral as an iterated integral in the three orders

$$dz\, dy\, dx, \quad dx\, dz\, dy, \quad \text{and} \quad dy\, dz\, dx$$

Write this integral in the three other orders:

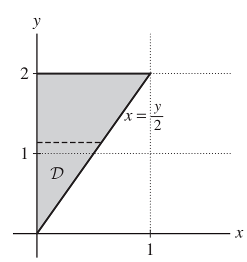
$$dz\, dx\, dy, \quad dx\, dy\, dz, \quad \text{and} \quad dy\, dx\, dz$$

SOLUTION In Example 5 we considered the triple integral $\iiint_{\mathcal{W}} xyz^2\, dV$, where $\mathcal{W}$ is the region bounded by

$$z = 4 - y^2, \quad z = 0, \quad y = 2x, \quad x = 0.$$

We now write the triple integral as an iterated integral in the orders $dz\, dx\, dy$, $dx\, dy\, dz$, and $dy\, dx\, dz$.

- $dz\, dx\, dy$: The upper surface $z = 4 - y^2$ projects onto the xy-plane on the triangle defined by the lines $y = 2$, $y = 2x$, and $x = 0$.

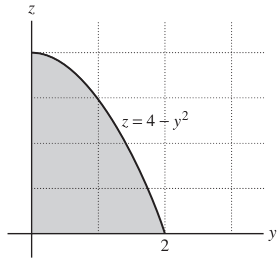


We express the line $y = 2x$ as $x = \frac{y}{2}$ and write the triple integral as

$$\iiint_{\mathcal{W}} xyz^2\, dV = \iint_{\mathcal{D}} \left(\int_0^{4-y^2} xyz^2\, dz \right) dA = \int_0^2 \int_0^{y/2} \int_0^{4-y^2} xyz^2\, dz\, dx\, dy$$

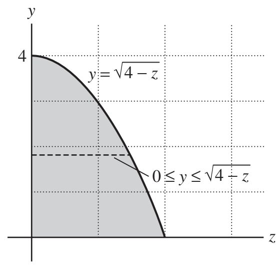
- $dx\,dy\,dz$: The projection of $\mathcal{W}$ onto the yz-plane is the domain T (see Example 5) defined by the inequalities

$$T:\ 0 \le y \le 2,\ 0 \le z \le 4 - y^2$$



This region can also be expressed as

$$0 \le z \le 4, \quad 0 \le y \le \sqrt{4-z}$$



As explained in Example 5, the region $\mathcal{W}$ consists of all points lying between T and the "left-face" $y = 2x$, or $x = \frac{y}{2}$. Therefore, we obtain the following inequalities for $\mathcal{W}$:

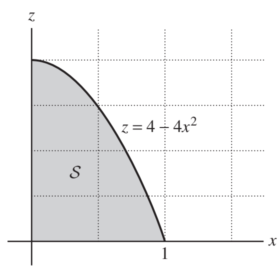
$$0 \le z \le 4, \quad 0 \le y \le \sqrt{4-z}, \quad 0 \le x \le \frac{1}{2}y$$

This yields the following iterated integral:

$$\iiint_{\mathcal{W}} xyz^2\,dV = \iint_T \left(\int_0^{y/2} xyz^2\,dx\right) dA = \int_0^4 \int_0^{\sqrt{4-z}} \int_0^{y/2} xyz^2\,dx\,dy\,dz$$

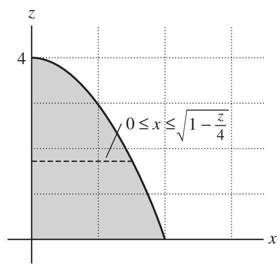
- $dy\,dx\,dz$: As explained in Example 5, the projection of $\mathcal{W}$ onto the xz-plane is determined by the inequalities

$$S:\ 0 \le x \le 1,\ 0 \le z \le 4 - 4x^2$$



This region can also be described if we write x as a function of z:

$$z = 4 - 4x^2 \quad \Rightarrow \quad 4x^2 = 4 - z \quad \Rightarrow \quad x = \sqrt{1 - \frac{z}{4}}$$



This gives the following inequalities of S:

$$S: \ 0 \le z \le 4, \ 0 \le x \le \sqrt{1 - \frac{z}{4}}$$

The upper surface $z = 4 - y^2$ can be described by $y = \sqrt{4 - z}$, hence the limits of y are $2x \le y \le \sqrt{4 - z}$. We obtain the following iterated integral:

$$\iiint_{\mathcal{W}} xyz^2 \, dV = \iint_S \left(\int_{2x}^{\sqrt{4-z}} xyz^2 \, dy \right) dA = \int_0^4 \int_0^{\sqrt{1-\frac{z}{4}}} \int_{2x}^{\sqrt{4-z}} xyz^2 \, dy \, dx \, dz$$

28. Let $\mathcal{W}$ be the region bounded by

$$y + z = 2, \quad 2x = y, \quad x = 0, \quad \text{and } z = 0$$

(Figure 14). Express and evaluate the triple integral of $f(x, y, z) = z$ by projecting $\mathcal{W}$ onto the:

(a) xy-plane **(b)** yz-plane **(c)** xz-plane

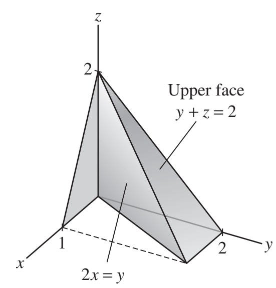


FIGURE 14

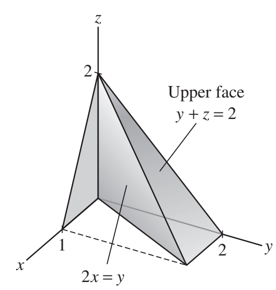
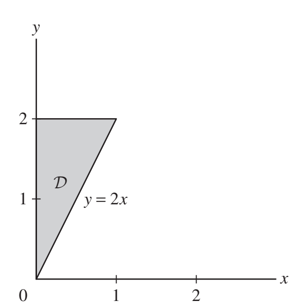
SOLUTION

(a)



The upper face $z = 2 - y$ intersects the first quadrant of the xy-plane ($z = 0$) in the line $y = 2$. Therefore the projection of $\mathcal{W}$ onto the xy-plane is the triangle $\mathcal{D}$ defined by

$$\mathcal{D}: \ 0 \le x \le 1, \ 2x \le y \le 2$$



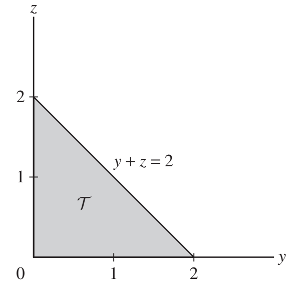
Therefore, $\mathcal{W}$ is the following region:

$$0 \le x \le 1, \quad 2x \le y \le 2, \quad 0 \le z \le 2 - y$$

We obtain the following iterated integral:

$$\iiint_{\mathcal{W}} z\,dV = \int_0^1 \int_{2x}^2 \int_0^{2-y} z\,dz\,dy\,dx = \int_0^1 \int_{2x}^2 \frac{1}{2}z^2\bigg|_{z=0}^{2-y} dy\,dx$$
$$= \frac{1}{2}\int_0^1 \int_{2x}^2 (2-y)^2\,dy\,dx = \frac{1}{2}\int_0^1 -\frac{1}{3}(2-y)^3\bigg|_{2x}^2 dx$$
$$= -\frac{1}{6}\int_0^1 -(2-2x)^3\,dx = \frac{1}{6}\cdot -\frac{1}{8}(2-2x)^4\bigg|_0^1$$
$$= -\frac{1}{48}(0) + \frac{1}{48}\cdot 16 = \frac{1}{3}$$

(b) The projection of $\mathcal{W}$ onto the yz-plane is the triangle defined by the line $y+z=2$ and the positive y and z axes.



That is,

$$T:\ 0 \le y \le 2,\ 0 \le z \le 2-y$$

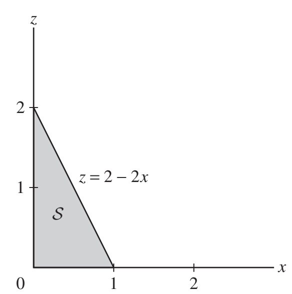
The region $\mathcal{W}$ consists of all points lying between T and the "left-face" $y=2x$. Therefore, $\mathcal{W}$ is defined by the following inequalities:

$$\mathcal{W}:\ 0 \le y \le 2,\ 0 \le z \le 2-y,\ 0 \le x \le \frac{y}{2}$$

We obtain the following iterated integral:

$$\iiint_{\mathcal{W}} z\,dV = \int_0^2 \int_0^{2-y} \int_0^{y/2} z\,dx\,dz\,dy = \int_0^2 \int_0^{2-y} xz\bigg|_{x=0}^{y/2} dz\,dy$$
$$= \int_0^2 \int_0^{2-y} \frac{1}{2}yz\,dz\,dy = \frac{1}{2}\int_0^2 \frac{1}{2}yz^2\bigg|_{z=0}^{2-y} dy$$
$$= \frac{1}{4}\int_0^2 y(2-y)^2\,dy = \frac{1}{4}\int_0^2 4y - 4y^2 + y^3\,dy$$
$$= \frac{1}{4}\left(2y^2 - \frac{4}{3}y^3 - \frac{1}{4}y^4\bigg|_0^2\right) = \frac{1}{4}\left(8 - \frac{4}{3}\cdot 8 + 4\right) = \frac{1}{3}$$

(c) We first find the points on the intersection of the faces $2x-y=0$ and $y+z=2$. These are the points $(x, 2x, 2-2x)$. Therefore, the projection of this intersection onto the xz-plane consists of the points $(x, 0, 2-2x)$. That is, the projection of $\mathcal{W}$ onto the xz-plane is the triangles defined by the line $z=2-2x$ and the positive x and z axes.



The corresponding inequalities are

$$S:\ 0 \le x \le 1,\ 0 \le z \le 2-2x$$

The limits for y are $2x \le y \le 2 - z$, where $y = 2 - z$ is obtained from the equation $y + z = 2$ of the upper face. We obtain the following iterated integral:

$$\begin{aligned}
\iiint_{\mathcal{W}} z\,dV &= \int_0^1 \int_0^{2-2x} \int_{2x}^{2-z} z\,dy\,dz\,dx = \int_0^1 \int_0^{2-2x} yz\Big|_{y=2x}^{2-z} dz\,dx \\
&= \int_0^1 \int_0^{2-2x} (2-z)z - 2xz\,dz\,dx = \int_0^1 \int_0^{2-2x} 2z - z^2 - 2xz\,dz\,dx \\
&= \int_0^1 z^2 - \frac{1}{3}z^3 - xz^2\Big|_{z=0}^{2-2x} dx = \int_0^1 (2-2x)^2 - \frac{1}{3}(2-2x)^3 - x(2-2x)^2\,dx \\
&= \int_0^1 \frac{4}{3} - 4x - \frac{4}{3}x^3 + 4x^2\,dx = \frac{4}{3}x - 2x^2 - \frac{1}{3}x^3 + \frac{4}{3}x^3\Big|_0^1 \\
&= \frac{4}{3} - 2 - \frac{1}{3} + \frac{4}{3} = \frac{1}{3}
\end{aligned}$$

The three answers agree as expected.

29. Let

$$\mathcal{W} = \left\{(x, y, z) : \sqrt{x^2 + y^2} \le z \le 1\right\}$$

(see Figure 15). Express $\iiint_{\mathcal{W}} f(x, y, z)\,dV$ as an iterated integral in the order $dz\,dy\,dx$ (for an arbitrary function f).

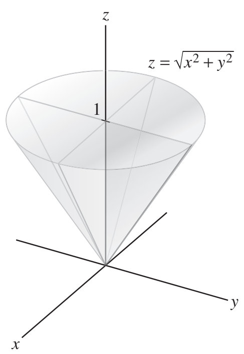


FIGURE 15

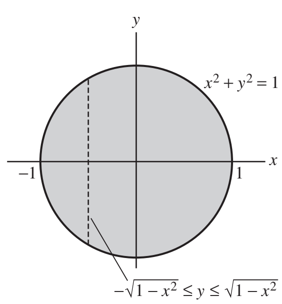
SOLUTION To express the triple integral as an iterated integral in order $dz\,dy\,dx$, we must find the projection of $\mathcal{W}$ onto the xy-plane. The upper circle is $\sqrt{x^2 + y^2} = 1$ or $x^2 + y^2 = 1$, hence the projection of $\mathcal{W}$ onto the xy plane is the disk

$$\mathcal{D} : x^2 + y^2 \le 1$$

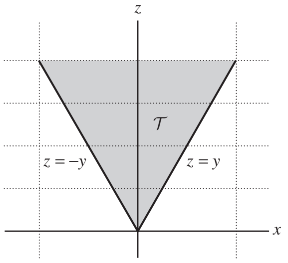


The upper surface is the plane $z = 1$ and the lower surface is $z = \sqrt{x^2 + y^2}$, therefore the triple integral over $\mathcal{W}$ is equal to the following iterated integral:

$$\iiint_{\mathcal{W}} f(x, y, z)\,dV = \iint_{\mathcal{D}} \left(\int_{\sqrt{x^2+y^2}}^1 f(x, y, z)\,dz\right) dA = \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{\sqrt{x^2+y^2}}^1 f(x, y, z)\,dz\,dy\,dx$$

30. Repeat Exercise 29 for the order $dx\,dy\,dz$.

SOLUTION To express the triple integral as an iterated integral in order $dx\,dy\,dz$, we must find the projection of $\mathcal{W}$ onto the yz-plane. The points on the surface $z = \sqrt{x^2 + y^2}$ are $\left(x, y, \sqrt{x^2 + y^2}\right)$, hence the projection on the yz-plane consists of the points $(0, y, |y|)$, that is, $z = |y|$.



Therefore, the projection of $\mathcal{W}$ onto the yz-plane is the triangle defined by the lines $z = |y|$ and $z = 1$. The region $\mathcal{W}$ consists of all points lying between T and the surface $z = \sqrt{x^2 + y^2}$, or $x = \pm\sqrt{z^2 - y^2}$. $\mathcal{W}$ can be described by the inequalities

$$0 \le z \le 1$$
$$-z \le y \le z$$
$$-\sqrt{z^2 - y^2} \le x \le \sqrt{z^2 - y^2}$$

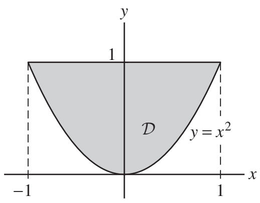
The triple integral is equal to the following iterated integral:

$$\iiint_{\mathcal{W}} f(x, y, z)\, dV = \int_0^1 \int_{-z}^{z} \int_{-\sqrt{z^2-y^2}}^{\sqrt{z^2-y^2}} f(x, y, z)\, dx\, dy\, dz.$$

31. Let $\mathcal{W}$ be the region bounded by $z = 1 - y^2$, $y = x^2$, and the planes $z = 0$, $y = 1$. Calculate the volume of $\mathcal{W}$ as a triple integral in the order $dz\, dy\, dx$.

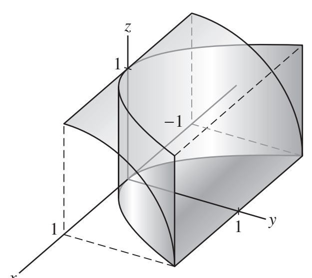
SOLUTION $dz\, dy\, dx$:

The projection of $\mathcal{W}$ onto the xy-plane is the region $\mathcal{D}$ bounded by the curve $y = x^2$ and the line $y = 1$. The region $\mathcal{W}$ consists of all points lying between $\mathcal{D}$ and the cylinder $z = 1 - y^2$.



Therefore, $\mathcal{W}$ can be described by the following inequalities:

$$-1 \le x \le 1, \quad x^2 \le y \le 1, \quad 0 \le z \le 1 - y^2$$



We use the formula for the volume as a triple integral, write the triple integral as an iterated integral, and compute it. We obtain

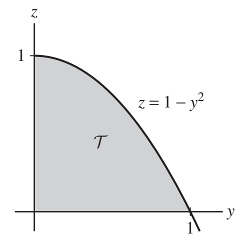
$$\begin{aligned}
\text{Volume}(\mathcal{W}) &= \iiint_{\mathcal{W}} 1\, dV = \int_{-1}^{1} \int_{x^2}^{1} \int_0^{1-y^2} 1\, dz\, dy\, dx = \int_{-1}^{1} \int_{x^2}^{1} z \Big|_{z=0}^{1-y^2} dy\, dx \\
&= \int_{-1}^{1} \int_{x^2}^{1} \left(1 - y^2\right) dy\, dx = \int_{-1}^{1} y - \frac{y^3}{3} \Big|_{y=x^2}^{1} dx = \int_{-1}^{1} \left(1 - \frac{1}{3} - \left(x^2 - \frac{x^6}{3}\right)\right) dx \\
&= 2 \int_0^1 \left(\frac{x^6}{3} - x^2 + \frac{2}{3}\right) dx = 2\left(\frac{x^7}{21} - \frac{x^3}{3} + \frac{2x}{3}\right)\Big|_0^1 = 2\left(\frac{1}{21} - \frac{1}{3} + \frac{2}{3}\right) = \frac{16}{21}
\end{aligned}$$

32. Calculate the volume of the region $\mathcal{W}$ in Exercise 31 as a triple integral in the following orders:

(a) $dx\,dz\,dy$ **(b)** $dy\,dz\,dx$

SOLUTION $dx\,dz\,dy$:

The projection of $\mathcal{W}$ onto the yz-plane is the region $\mathcal{T}$ in the first quadrant bounded by the curve $z = 1 - y^2$.



The region $\mathcal{W}$ consists of all points lying between $\mathcal{T}$ and the faces $y = x^2$ or $x = \pm\sqrt{y}$. Therefore, $\mathcal{W}$ is described by the following inequalities:

$$0 \le y \le 1, \quad 0 \le z \le 1 - y^2, \quad -\sqrt{y} \le x \le \sqrt{y}$$

We obtain the following iterated integral:

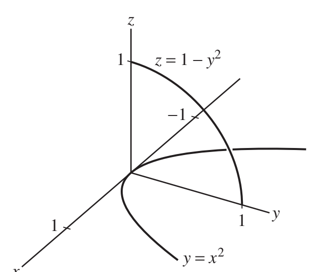
$$\text{Volume}(\mathcal{W}) = \int_0^1 \int_0^{1-y^2} \int_{-\sqrt{y}}^{\sqrt{y}} 1 \cdot dx\,dz\,dy = \int_0^1 \int_0^{1-y^2} x\Big|_{x=-\sqrt{y}}^{\sqrt{y}} dz\,dy = \int_0^1 \int_0^{1-y^2} 2\sqrt{y}dz\,dy$$

$$= \int_0^1 2\sqrt{y}z\Big|_{z=0}^{1-y^2} dy = \int_0^1 2\sqrt{y}\left(1-y^2\right) dy = \int_0^1 \left(2y^{1/2} - 2y^{5/2}\right) dy$$

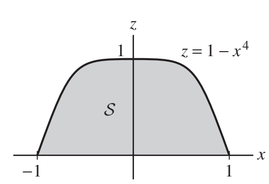
$$= \frac{4}{3}y^{3/2} - \frac{4}{7}y^{7/2}\Big|_0^1 = \frac{4}{3} - \frac{4}{7} = \frac{16}{21}$$

$dy\,dz\,dx$:

To find the projection of $\mathcal{W}$ onto the xz-plane we first must find the points Q that lie on both cylinders $y = x^2$ and $z = 1 - y^2$.



At these points $y = x^2$ and $z = 1 - y^2$, hence $z = 1 - \left(x^2\right)^2 = 1 - x^4$. Therefore, $Q = (x, x^2, 1 - x^4)$. The projection onto the xz-plane are the points $(x, 0, 1 - x^4)$, that is, the curve $z = 1 - x^4$.



The region $\mathcal{W}$ consists of all points between the cylinders $y = x^2$ and $z = 1 - y^2$, or $y = \sqrt{1-z}$. Therefore, $\mathcal{W}$ can be described by the following inequalities:

$$-1 \le x \le 1, \quad 0 \le z \le 1 - x^4, \quad x^2 \le y \le \sqrt{1-z}$$

We obtain the following integral:

$$\text{Volume}(\mathcal{W}) = \int_{-1}^1 \int_0^{1-x^4} \int_{x^2}^{\sqrt{1-z}} dy\,dz\,dx = \int_{-1}^1 \int_0^{1-x^4} y\Big|_{x^2}^{\sqrt{1-z}} dz\,dx$$

$$= \int_{-1}^1 \int_0^{1-x^4} \left(\sqrt{1-z} - x^2\right) dz\,dx = \int_{-1}^1 \left(-\frac{2}{3}(1-z)^{3/2} - x^2 z\right)\Big|_{z=0}^{1-x^4} dx$$

$$= \int_{-1}^{1} \left(-\frac{2}{3}\left(1 - \left(1 - x^4\right)\right)^{3/2} - x^2\left(1 - x^4\right) + \frac{2}{3} \right) dx$$

$$= \int_{-1}^{1} \left(-\frac{2x^6}{3} - x^2 + x^6 + \frac{2}{3} \right) dx = 2\int_{0}^{1} \left(\frac{x^6}{3} - x^2 + \frac{2}{3} \right) dx$$

$$= 2\left(\frac{x^7}{21} - \frac{x^3}{3} + \frac{2x}{3} \right)\Big|_0^1 = 2\left(\frac{1}{21} - \frac{1}{3} + \frac{2}{3} \right) = \frac{16}{21}$$

(The three answers agree as expected.)

In Exercises 33–36, compute the average value of $f(x, y, z)$ over the region $\mathcal{W}$.

33. $f(x, y, z) = xy\sin(\pi z)$; $\quad \mathcal{W} = [0, 1] \times [0, 1] \times [0, 1]$

SOLUTION The volume of the cube is $V = 1$, hence the average of f over the cube is the following value:

$$\overline{f} = \iiint_{\mathcal{W}} xy\sin(\pi z)\, dV = \int_0^1 \int_0^1 \int_0^1 xy\sin(\pi z)\, dx\, dy\, dz$$

$$= \int_0^1 \int_0^1 \frac{1}{2}x^2 y\sin(\pi z)\Big|_{x=0}^1 dy\, dz = \int_0^1 \int_0^1 \frac{1}{2} y\sin(\pi z)\, dy\, dz$$

$$= \int_0^1 \frac{y^2}{4}\sin(\pi z)\Big|_{y=0}^1 dz = \int_0^1 \frac{1}{4}\sin(\pi z)\, dz = -\frac{1}{4\pi}\cos(\pi z)\Big|_0^1$$

$$= -\frac{1}{4\pi}(\cos\pi - \cos 0) = -\frac{1}{4\pi}(-1 - 1) = \frac{1}{2\pi}$$

34. $f(x, y, z) = xyz$; $\quad \mathcal{W} = [0, 1] \times [0, 1] \times [0, 1]$

SOLUTION This solid is a tetrahedron with vertices $(0, 0, 0)$, $(1, 0, 0)$, $(1, 1, 0)$, and $(1, 1, 1)$ and volume $1/6$. The equation of the plane that forms this tetrahedron is $y + z = 0$. Therefore, the average of f over the tetrahedron is the following value:

$$\overline{f} = \frac{1}{V}\iiint_{\mathcal{W}} xyz\, dV = 6\int_0^1 \int_0^x \int_0^{-y} xyz\, dz\, dy\, dx$$

$$= 6\int_0^1 \int_0^x \frac{1}{2}xyz^2\Big|_{z=0}^{-y} dy\, dx = 3\int_0^1 \int_0^x xy(-y)^2 dy\, dx$$

$$= 3\int_0^1 \int_0^x xy^3 dy\, dx = \frac{3}{4}\int_0^1 xy^4\Big|_{y=0}^x dx$$

$$= \frac{3}{4}\int_0^1 x^5 dx = \frac{1}{8}\left(x^6\Big|_0^1 \right) = \frac{1}{8}$$

35. $f(x, y, z) = e^y$; $\quad \mathcal{W} : 0 \le y \le 1 - x^2, \quad 0 \le z \le x$

SOLUTION First we must calculate the volume of $\mathcal{W}$. We will use the symmetry of $y = 1 - x^2$ to write:

$$V = \iiint_{\mathcal{W}} 1\, dV = 2\int_0^1 \int_0^{1-x^2} \int_0^x 1\, dz\, dy\, dx$$

$$= 2\int_0^1 \int_0^{1-x^2} z\Big|_{z=0}^x dy\, dx = 2\int_0^1 \int_0^{1-x^2} x\, dy\, dx$$

$$= 2\int_0^1 xy\Big|_{y=0}^{1-x^2} dx = 2\int_0^1 x(1 - x^2)\, dx$$

$$= 2\int_0^1 x - x^3\, dx = x^2 - \frac{1}{2}x^4\Big|_0^1 = \frac{1}{2}$$

Now we can compute the average value for $f(x, y, z) = e^y$:

$$\overline{f} = \frac{1}{V}\iiint_{\mathcal{W}} e^y\, dV = 2 \cdot \frac{1}{1/2}\int_0^1 \int_0^{1-x^2} \int_0^x e^y\, dz\, dy\, dx$$

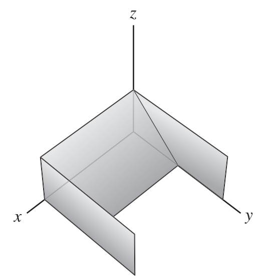
$$= 4\int_0^1 \int_0^{1-x^2} ze^y \Big|_{z=0}^{x} dy\,dx = 4\int_0^1 \int_0^{1-x^2} xe^y\,dy\,dx$$

$$= 4\int_0^1 xe^y \Big|_{y=0}^{1-x^2} dx = 4\int_0^1 xe^{1-x^2} - x\,dx$$

$$= 4\left(-\frac{1}{2}e^{1-x^2} - \frac{1}{2}x^2\right)\Big|_0^1 = \left(-2e^0 - 2\right) - \left(-2e^1 - 0\right) = 2e - 4$$

36. $f(x, y, z) = x^2 + y^2 + z^2$; $\mathcal{W}$ bounded by the planes $2y + z = 1$, $x = 0$, $x = 1$, $z = 0$, and $y = 0$.

SOLUTION The prism $\mathcal{W}$ bounded by the planes $2y + z = 1$, $x = 0$, $x = 1$, $z = 0$, and $y = 0$ is shown in the figure:

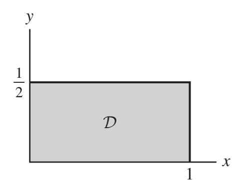


The average of f over $\mathcal{W}$ is

$$\overline{f} = \frac{1}{V}\iiint_{\mathcal{W}} f(x, y, z)\,dV \tag{1}$$

where $V = \text{Volume}(\mathcal{W})$. The projection of $\mathcal{W}$ onto the xy-plane is the rectangle

$$\mathcal{D}:\ 0 \le x \le 1,\ 0 \le y \le \frac{1}{2}$$



The region $\mathcal{W}$ consists of all points lying between the upper plane $z = 1 - 2y$ and the lower plane $z = 0$. The volume of the prism is

$$V = \frac{\frac{1}{2}\cdot 1}{2}\cdot 1 = \frac{1}{4}.$$

We compute the triple integral (1) using an iterated integral. That is,

$$\overline{f} = \frac{1}{\frac{1}{4}}\int_0^1 \int_0^{1/2} \int_0^{1-2y} \left(x^2 + y^2 + z^2\right) dz\,dy\,dx = 4\int_0^1 \int_0^{1/2} \left(x^2 + y^2\right) z + \frac{z^3}{3}\Big|_{z=0}^{1-2y} dy\,dx$$

$$= 4\int_0^1 \int_0^{1/2} \left(\left(x^2 + y^2\right)(1 - 2y) + \frac{(1-2y)^3}{3}\right) dy\,dx$$

$$= 4\int_0^1 \int_0^{1/2} \left(x^2 - 2x^2y + y^2 - 2y^3 + \frac{(1-2y)^3}{3}\right) dy\,dx$$

$$= 4\int_0^1 x^2y - x^2y^2 + \frac{y^3}{3} - \frac{y^4}{2} - \frac{(1-2y)^4}{24}\Big|_{y=0}^{1/2} dx$$

$$= 4\int_0^1 \left(\frac{x^2}{4} + \frac{5}{96}\right) dx = 4\left(\frac{x^3}{12} + \frac{5x}{96}\Big|_0^1\right) = \frac{13}{24}$$

The average value is $\overline{f} = \frac{13}{24}$.

In Exercises 37 and 38, let $I = \int_0^1 \int_0^1 \int_0^1 f(x, y, z)\, dV$ *and let* $S_{N,N,N}$ *be the Riemann sum approximation*

$$S_{N,N,N} = \frac{1}{N^3} \sum_{i=1}^{N} \sum_{j=1}^{N} \sum_{k=1}^{N} f\left(\frac{i}{N}, \frac{j}{N}, \frac{k}{N}\right)$$

37. CAS Calculate $S_{N,N,N}$ for $f(x, y, z) = e^{x^2-y-z}$ for $N = 10, 20, 30$. Then evaluate I and find an N such that $S_{N,N,N}$ approximates I to two decimal places.

SOLUTION Using a CAS, we get $S_{N,N,N} \approx 0.561, 0.572$, and 0.576 for $N = 10, 20$, and 30, respectively. We get $I \approx 0.584$, and using $N = 100$ we get $S_{N,N,N} \approx 0.582$, accurate to two decimal places.

38. CAS Calculate $S_{N,N,N}$ for $f(x, y, z) = \sin(xyz)$ for $N = 10, 20, 30$. Then use a computer algebra system to calculate I numerically and estimate the error $|I - S_{N,N,N}|$.

SOLUTION Using a CAS, we get $S_{N,N,N} \approx 0.162, 0.141$, and 0.135 for $N = 10, 20$, and 30, respectively. We get $I \approx 0.122$, giving an error of 0.040, 0.019, and 0.013, respectively.

Further Insights and Challenges

39. Use Integration by Parts to verify Eq. (7).

SOLUTION If $C_n = \int_{-\pi/2}^{\pi/2} \cos^n \theta\, d\theta$, we use integration by parts to show that

$$C_n = \left(\frac{n-1}{n}\right) C_{n-2}.$$

We use integration by parts with $u = \cos^{n-1}\theta$ and $V' = \cos\theta$. Hence, $u' = (n-1)\cos^{n-2}\theta(-\sin\theta)$ and $v = \sin\theta$. Thus,

$$\begin{aligned}
C_n &= \int_{-\pi/2}^{\pi/2} \cos^n \theta\, d\theta = \int_{-\pi/2}^{\pi/2} \cos^{n-1}\theta \cos\theta\, d\theta = \cos^{n-1}\theta \sin\theta \Big|_{\theta=-\pi/2}^{\pi/2} + \int_{-\pi/2}^{\pi/2} (n-1)\cos^{n-2}\theta \sin^2\theta\, d\theta \\
&= \cos^{n-1}\frac{\pi}{2}\sin\frac{\pi}{2} - \cos^{n+1}\left(-\frac{\pi}{2}\right)\sin\left(-\frac{\pi}{2}\right) + (n-1)\int_{-\pi/2}^{\pi/2} \cos^{n-2}\theta \sin^2\theta\, d\theta \\
&= 0 + (n-1)\int_{-\pi/2}^{\pi/2} \cos^{n-2}\theta\left(1-\cos^2\theta\right) d\theta = (n-1)\int_{-\pi/2}^{\pi/2} \cos^{n-2}\theta\, d\theta - (n-1)\int_{-\pi/2}^{\pi/2} \cos^n\theta\, d\theta \\
&= (n-1)C_{n-2} - (n-1)C_n
\end{aligned}$$

We obtain the following equality:

$$C_n = (n-1)C_{n-2} - (n-1)C_n$$

or

$$\begin{aligned}
C_n + (n-1)C_n &= (n-1)C_{n-2} \\
nC_n &= (n-1)C_{n-2} \\
C_n &= \frac{n-1}{n}C_{n-2}
\end{aligned}$$

40. Compute the volume A_n of the unit ball in $\mathbf{R}^n$ for $n = 8, 9, 10$. Show that $C_n \le 1$ for $n \ge 6$ and use this to prove that of all unit balls, the five-dimensional ball has the largest volume. Can you explain why A_n tends to 0 as $n \to \infty$?

SOLUTION We use the following formulas:

$$A_{2m} = \frac{\pi^m}{m!}, \quad A_{2m+1} = \frac{2^{m+1}\pi^m}{1 \cdot 3 \cdot 5 \cdots (2m+1)}$$

We get

$$\begin{aligned}
A_8 &= A_{2\cdot 4} = \frac{\pi^4}{4!} = \frac{\pi^4}{24} \approx 4.06 \\
A_9 &= A_{2\cdot 4+1} = \frac{2^{4+1}\pi^4}{1\cdot 3\cdot 5\cdot 7\cdot 9} = \frac{32\pi^4}{945} \approx 3.3 \\
A_{10} &= A_{2\cdot 5} = \frac{\pi^5}{5!} = \frac{\pi^5}{120} \approx 2.55
\end{aligned}$$

We now show that $C_n < 1$ for $n \geq 6$. We first compute C_6, using the formula $C_n = \frac{n-1}{n} C_{n-2}$ successively and the value $C_0 = \pi$. This gives

$$C_6 = \frac{6-1}{6} C_4 = \frac{5}{6} \cdot \frac{4-1}{4} C_2 = \frac{5}{8} \cdot \frac{2-1}{2} C_0 = \frac{5\pi}{16} \approx 0.98 < 1$$

$$C_7 = \frac{7-1}{7} C_5 = \frac{6}{7} \cdot \frac{4}{5} \cdot C_3 = \frac{24}{35} \cdot \frac{2}{3} C_1 = \frac{16}{35} C_1$$

$$C_1 = \int_{-\pi/2}^{\pi/2} \cos\theta \, d\theta = \sin\theta \Big|_{-\pi/2}^{\pi/2} = 2$$

Hence,

$$C_7 = \frac{16}{35} \cdot 2 = \frac{32}{35} < 1$$

Thus, $C_n < 1$ for $n = 6$ and 7. We now assume that $C_k < 1$ for all k, $6 \leq k \leq n$, for some $n \geq 7$. We show that $C_{n+1} < 1$.

$$C_{n+1} = \frac{(n+1)-1}{n+1} C_{(n+1)-2} = \frac{n}{n+1} C_{n-1}$$

By the assumption, $n - 1 \geq 6$, and so $C_{n-1} < 1$. Therefore,

$$C_{n+1} = \frac{n}{n+1} C_{n-1} < C_{n-1} < 1 \quad \Rightarrow \quad C_{n+1} < 1$$

We thus proved by mathematical induction that $C_n < 1$ for all $n \geq 6$. We now show that of all unit balls, the five-dimensional ball has the largest volume. The volume of the n-dimensional unit ball is

$$A_n = A_{n-1} C_n$$

Since $A_{n-1} > 0$, and for $n \geq 6$, $C_n < 1$, we have

$$A_n < A_{n-1} \quad \text{for } n \geq 6 \tag{1}$$

Therefore $\{A_n\}_{n=5}^{\infty}$ is a decreasing sequence, and we have

$$A_n < A_5 \text{ for } n \geq 6 \tag{2}$$

Combining (1) and (2) gives

$$A_n < A_5 = \frac{8\pi^2}{15} \approx 5.26 \quad \text{for } n \geq 6 \tag{3}$$

We compute $A_1, \ldots, A_5$:

$$A_1 = A_0 C_1 = 1 \cdot 2 = 2$$

$$A_2 = A_1 C_2 = 2 \cdot \frac{\pi}{2} = \pi \approx 3.14$$

$$A_3 = A_2 C_3 = \pi \cdot \frac{4}{3} = \frac{4\pi}{3} \approx 4.19$$

$$A_4 = A_3 C_4 = \frac{4\pi}{3} \cdot \frac{3\pi}{8} = \frac{\pi^2}{2} \approx 4.93$$

$$A_5 = A_4 C_5 = \frac{\pi^2}{2} \cdot \frac{16}{15} = \frac{8\pi^2}{15} \approx 5.26$$

The maximum value is A_5. Combining with (3) we conclude that the five-dimensional ball has the largest volume. By the closed formulas for A_{2m} and A_{2m+1}, it follows that these sequences tend to zero as $n \to \infty$ (factorials grow faster than exponentials). Therefore, the sequence $\{A_n\}$ also tends to zero as $n \to \infty$.

15.4 Integration in Polar, Cylindrical, and Spherical Coordinates (LT Section 16.4)

Preliminary Questions

1. Which of the following represent the integral of $f(x, y) = x^2 + y^2$ over the unit circle?

(a) $\int_0^1 \int_0^{2\pi} r^2 \, dr \, d\theta$

(b) $\int_0^{2\pi} \int_0^1 r^2 \, dr \, d\theta$

(c) $\int_0^1 \int_0^{2\pi} r^3 \, dr \, d\theta$

(d) $\int_0^{2\pi} \int_0^1 r^3 \, dr \, d\theta$

SOLUTION The unit circle is described in polar coordinates by the inequalities

$$0 \le \theta \le 2\pi, \quad 0 \le r \le 1$$

Using double integral in polar coordinates, we have

$$\iint_{\mathcal{D}} f(x,y)\,dA = \int_0^{2\pi}\int_0^1 \left((r\cos\theta)^2 + (r\sin\theta)^2\right) r\,dr\,d\theta = \int_0^{2\pi}\int_0^1 r^2\left(\cos^2\theta + \sin^2\theta\right) r\,dr\,d\theta$$
$$= \int_0^{2\pi}\int_0^1 r^3\,dr\,d\theta$$

Therefore (d) is the correct answer.

2. What are the limits of integration in $\iiint f(r,\theta,z) r\,dr\,d\theta\,dz$ if the integration extends over the following regions?

(a) $x^2 + y^2 \le 4, \quad -1 \le z \le 2$

(b) Lower hemisphere of the sphere of radius 2, center at origin

SOLUTION

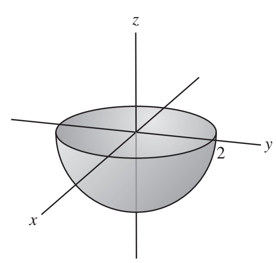
(a) This is a cylinder of radius 2. In the given region the z coordinate is changing between the values -1 and 2, and the angle θ is changing between the values $\theta = 0$ and 2π. Therefore the region is described by the inequalities

$$-1 \le z \le 2, \quad 0 \le \theta < 2\pi, \quad 0 \le r \le 2$$

Using triple integral in cylindrical coordinates gives

$$\int_{-1}^{2}\int_0^{2\pi}\int_0^2 f(P)\,r\,dr\,d\theta\,dz$$

(b) The sphere of radius 2 is $x^2 + y^2 + z^2 = r^2 + z^2 = 4$, or $r = \sqrt{4 - z^2}$.



In the lower hemisphere we have $-2 \le z \le 0$ and $0 \le \theta < 2\pi$. Therefore, it has the description

$$-2 \le z \le 0, \quad 0 \le \theta < 2\pi, \quad 0 \le r \le \sqrt{4 - z^2}$$

We obtain the following integral in cylindrical coordinates:

$$\int_{-2}^{0}\int_0^{2\pi}\int_0^{\sqrt{4-z^2}} r\,dr\,d\theta\,dz$$

3. What are the limits of integration in

$$\iiint f(\rho,\phi,\theta)\rho^2 \sin\phi\,d\rho\,d\phi\,d\theta$$

if the integration extends over the following spherical regions centered at the origin?

(a) Sphere of radius 4

(b) Region between the spheres of radii 4 and 5

(c) Lower hemisphere of the sphere of radius 2

SOLUTION

(a) In the sphere of radius 4, θ varies from 0 to 2π, ϕ varies from 0 to π, and ρ varies from 0 to 4. Using triple integral in spherical coordinates, we obtain the following integral:

$$\int_0^{2\pi}\int_0^{\pi}\int_0^4 f(P)\rho^2 \sin\phi\,d\rho\,d\phi\,d\theta$$

(b) In the region between the spheres of radii 4 and 5, ρ varies from 4 to 5, ϕ varies from 0 to π, and θ varies from 0 to 2π. We obtain the following integral:

$$\int_0^{2\pi} \int_0^{\pi} \int_4^5 f(P)\rho^2 \sin\phi \, d\rho \, d\phi \, d\theta$$

(c) The inequalities in spherical coordinates for the lower hemisphere of radius 2 are

$$0 \le \theta \le 2\pi, \quad \frac{\pi}{2} \le \phi \le \pi, \quad 0 \le \rho \le 2$$

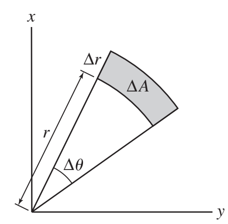
Therefore we obtain the following integral:

$$\int_0^{2\pi} \int_{\pi/2}^{\pi} \int_0^2 f(P)\rho^2 \sin\phi \, d\rho \, d\phi \, d\theta.$$

4. An ordinary rectangle of sides Δx and Δy has area $\Delta x \, \Delta y$, no matter where it is located in the plane. However, the area of a polar rectangle of sides Δr and $\Delta\theta$ depends on its distance from the origin. How is this difference reflected in the Change of Variables Formula for polar coordinates?

SOLUTION The area ΔA of a small polar rectangle is

$$\Delta A = \frac{1}{2}(r+\Delta r)^2 \Delta\theta - \frac{1}{2}r^2\Delta\theta = r\,(\Delta r \Delta\theta) + \frac{1}{2}(\Delta r)^2 \Delta\theta \approx r\,(\Delta r \Delta\theta)$$



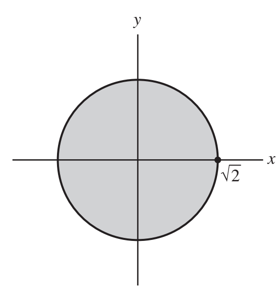
The factor r, due to the distance of the polar rectangle from the origin, appears in $dA = r\,dr\,d\theta$, in the Change of Variables formula.

Exercises

In Exercises 1–6, sketch the region $\mathcal{D}$ indicated and integrate $f(x,y)$ over $\mathcal{D}$ using polar coordinates.

1. $f(x,y) = \sqrt{x^2+y^2}, \quad x^2+y^2 \le 2$

SOLUTION The domain $\mathcal{D}$ is the disk of radius $\sqrt{2}$ shown in the figure:



The inequalities defining $\mathcal{D}$ in polar coordinates are

$$0 \le \theta \le 2\pi, \quad 0 \le r \le \sqrt{2}$$

We describe $f(x,y) = \sqrt{x^2+y^2}$ in polar coordinates:

$$f(x,y) = \sqrt{x^2+y^2} = \sqrt{r^2} = r$$

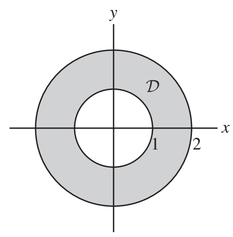
Using change of variables in polar coordinates, we get

$$\iint_{\mathcal{D}} \sqrt{x^2+y^2}\, dA = \int_0^{2\pi} \int_0^{\sqrt{2}} r \cdot r \, dr \, d\theta = \int_0^{2\pi} \int_0^{\sqrt{2}} r^2 \, dr \, d\theta = \int_0^{2\pi} \left. \frac{r^3}{3} \right|_{r=0}^{\sqrt{2}} d\theta$$

$$= \int_0^{2\pi} \frac{\left(\sqrt{2}\right)^3}{3} \, d\theta = \left. \frac{2\sqrt{2}}{3}\theta \right|_0^{2\pi} = \frac{4\sqrt{2}\pi}{3}$$

2. $f(x, y) = x^2 + y^2; \quad 1 \le x^2 + y^2 \le 4$

SOLUTION The domain $\mathcal{D}$ is shown in the figure:



The inequalities defining $\mathcal{D}$ in polar coordinates are

$$0 \le \theta \le 2\pi, \quad 1 \le r \le 2$$

We describe f in polar coordinates:

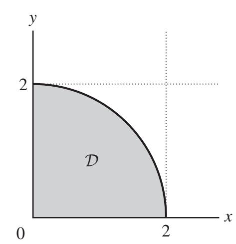
$$f(x, y) = x^2 + y^2 = r^2$$

Using change of variables in polar coordinates gives

$$\iint_{\mathcal{D}} \left(x^2 + y^2\right) dA = \int_0^{2\pi} \int_1^2 r^2 \cdot r\, dr\, d\theta = \int_0^{2\pi} \int_1^2 r^3\, dr\, d\theta = \int_0^{2\pi} \frac{r^4}{4}\bigg|_{r=1}^2 d\theta$$
$$= \int_0^{2\pi} \left(\frac{2^4}{4} - \frac{1}{4}\right) d\theta = 2\pi \cdot 3\frac{3}{4} = \frac{15\pi}{2}$$

3. $f(x, y) = xy; \quad x \ge 0, \quad y \ge 0, \quad x^2 + y^2 \le 4$

SOLUTION The domain $\mathcal{D}$ is the quarter circle of radius 2 in the first quadrant.



It is described by the inequalities

$$0 \le \theta \le \frac{\pi}{2}, \quad 0 \le r \le 2$$

We write f in polar coordinates:

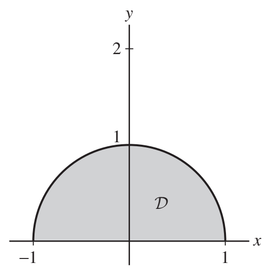
$$f(x, y) = xy = (r\cos\theta)(r\sin\theta) = r^2 \cos\theta \sin\theta = \frac{1}{2} r^2 \sin 2\theta$$

Using change of variables in polar coordinates gives

$$\iint_{\mathcal{D}} xy\, dA = \int_0^{\pi/2} \int_0^2 \left(\frac{1}{2} r^2 \sin 2\theta\right) r\, dr\, d\theta = \int_0^{\pi/2} \int_0^2 \frac{1}{2} r^3 \sin 2\theta\, dr\, d\theta = \int_0^{\pi/2} \frac{1}{2} \cdot \frac{r^4}{4} \sin 2\theta \bigg|_{r=0}^2 d\theta$$
$$= \int_0^{\pi/2} 2\sin 2\theta\, d\theta = -\cos 2\theta \bigg|_0^{\pi/2} = -(\cos\pi - \cos 0) = 2$$

4. $f(x, y) = y(x^2 + y^2)^3; \quad y \geq 0, \quad x^2 + y^2 \leq 1$

SOLUTION The region $\mathcal{D}$ is the upper half of the unit circle, shown in the figure:



In this region, θ varies from 0 to π, and r varies from 0 to 1. Therefore, $\mathcal{D}$ is described by the inequalities

$$0 \leq \theta \leq \pi, \quad 0 \leq r \leq 1$$

We write f in polar coordinates:

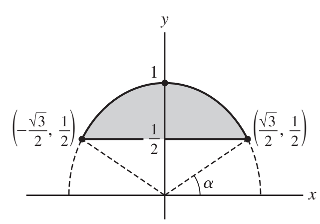
$$f(x, y) = y(x^2 + y^2)^3 = (r \sin\theta)(r^2)^3 = r^7 \sin\theta$$

Using change of variables in polar coordinates, we get

$$\iint_{\mathcal{D}} y\left(x^2 + y^2\right)^3 dA = \int_0^{\pi} \int_0^1 \left(r^7 \sin\theta\right) r\, dr\, d\theta = \int_0^{\pi} \int_0^1 r^8 \sin\theta\, dr\, d\theta = \int_0^{\pi} \frac{r^9}{9} \sin\theta \Big|_{r=0}^{1} d\theta$$
$$= \int_0^{\pi} \frac{1}{9} \sin\theta\, d\theta = -\frac{1}{9}\cos\theta \Big|_0^{\pi} = -\frac{1}{9}(\cos\pi - \cos 0) = \frac{2}{9}$$

5. $f(x, y) = y(x^2 + y^2)^{-1}; \quad y \geq \frac{1}{2}, \quad x^2 + y^2 \leq 1$

SOLUTION The region $\mathcal{D}$ is the part of the unit circle lying above the line $y = \frac{1}{2}$.

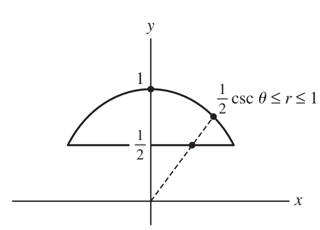


The angle α in the figure is

$$\alpha = \tan^{-1} \frac{\frac{1}{2}}{\frac{\sqrt{3}}{2}} = \tan^{-1} \frac{1}{\sqrt{3}} = \frac{\pi}{6}$$

Therefore, θ varies between $\frac{\pi}{6}$ and $\pi - \frac{\pi}{6} = \frac{5\pi}{6}$. The horizontal line $y = \frac{1}{2}$ has polar equation $r \sin\theta = \frac{1}{2}$ or $r = \frac{1}{2}\csc\theta$. The circle of radius 1 centered at the origin has polar equation $r = 1$. Therefore, r varies between $\frac{1}{2}\csc\theta$ and 1. The inequalities describing $\mathcal{D}$ in polar coordinates are thus

$$\frac{\pi}{6} \leq \theta \leq \frac{5\pi}{6}, \quad \frac{1}{2}\csc\theta \leq r \leq 1$$



We write f in polar coordinates:

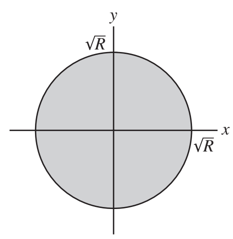
$$f(x, y) = y(x^2 + y^2)^{-1} = (r \sin\theta)(r^2)^{-1} = r^{-1} \sin\theta$$

Using change of variables in polar coordinates, we obtain

$$\iint_{\mathcal{D}} y(x^2+y^2)^{-1}\,dA = \int_{\pi/6}^{5\pi/6}\int_{\frac{1}{2}\csc\theta}^{1} r^{-1}\sin\theta\, r\,dr\,d\theta = \int_{\pi/6}^{5\pi/6}\int_{\frac{1}{2}\csc\theta}^{1}\sin\theta\,dr\,d\theta$$
$$= \int_{\pi/6}^{5\pi/6} r\sin\theta\Big|_{r=\frac{1}{2}\csc\theta}^{1}\,d\theta = \int_{\pi/6}^{5\pi/6}\left(\sin\theta - \frac{1}{2}\sin\theta\csc\theta\right)d\theta$$
$$= \int_{\pi/6}^{5\pi/6}\left(\sin\theta - \frac{1}{2}\right)d\theta = -\cos\theta - \frac{\theta}{2}\Big|_{\pi/6}^{5\pi/6} = -\cos\frac{5\pi}{6} - \frac{5\pi}{12} - \left(-\cos\frac{\pi}{6} - \frac{\pi}{12}\right)$$
$$= \frac{\sqrt{3}}{2} - \frac{\pi}{3} + \frac{\sqrt{3}}{2} = \sqrt{3} - \frac{\pi}{3} \approx 0.685$$

6. $f(x, y) = e^{x^2+y^2}$; $\quad x^2 + y^2 \le R$

SOLUTION The region $\mathcal{D}$ is the circle of radius $\sqrt{R}$.



The inequalities describing $\mathcal{D}$ in polar coordinates are

$$0 \le \theta \le 2\pi, \quad 0 \le r \le \sqrt{R}$$

We write f in polar coordinates as $f(x, y) = e^{x^2+y^2} = e^{r^2}$, and use change of variables in polar coordinates to obtain

$$\iint_{\mathcal{D}} e^{x^2+y^2}\,dA = \int_0^{2\pi}\int_0^{\sqrt{R}} e^{r^2} r\,dr\,d\theta = \int_0^{2\pi}\left(\int_0^{\sqrt{R}} e^{r^2} r\,dr\right)d\theta \tag{1}$$

We compute the inner integral using the substitution $u = e^{r^2}$, $du = 2re^{r^2}\,dr$. We get

$$\int_0^{\sqrt{R}} e^{r^2} r\,dr = \int_1^{e^R}\frac{1}{2}\,du = \frac{1}{2}u\Big|_1^{e^R} = \frac{1}{2}\left(e^R - 1\right)$$

Substituting in (1) gives

$$\iint_{\mathcal{D}} e^{x^2+y^2}\,dA = \int_0^{2\pi}\frac{1}{2}(e^R-1)\,d\theta = \frac{1}{2}(e^R-1)\theta\Big|_0^{2\pi} = \pi(e^R-1)$$

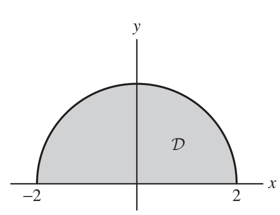
In Exercises 7–14, sketch the region of integration and evaluate by changing to polar coordinates.

7. $\displaystyle\int_{-2}^{2}\int_0^{\sqrt{4-x^2}}(x^2+y^2)\,dy\,dx$

SOLUTION The domain $\mathcal{D}$ is described by the inequalities

$$\mathcal{D}:\ -2 \le x \le 2,\ 0 \le y \le \sqrt{4-x^2}$$

That is, $\mathcal{D}$ is the semicircle $x^2 + y^2 \le 4$, $0 \le y$.



We describe $\mathcal{D}$ in polar coordinates:

$$\mathcal{D}: 0 \le \theta \le \pi,\ 0 \le r \le 2$$

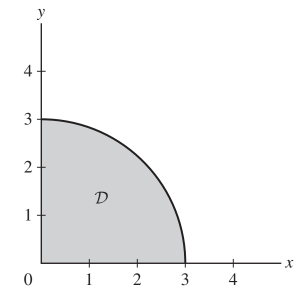
The function f in polar coordinates is $f(x, y) = x^2 + y^2 = r^2$. We use the Change of Variables Formula to write

$$\int_{-2}^{2} \int_{0}^{\sqrt{4-x^2}} \left(x^2 + y^2\right) dy\, dx = \int_{0}^{\pi} \int_{0}^{2} r^2 \cdot r\, dr\, d\theta = \int_{0}^{\pi} \int_{0}^{2} r^3\, dr\, d\theta = \int_{0}^{\pi} \frac{r^4}{4}\bigg|_{r=0}^{2} d\theta = \int_{0}^{\pi} \frac{2^4}{4}\, d\theta = 4\pi$$

8. $\displaystyle\int_{0}^{3} \int_{0}^{\sqrt{9-y^2}} \sqrt{x^2 + y^2}\, dx\, dy$

SOLUTION The region $\mathcal{D}$ is defined by the following inequalities:

$$0 \le y \le 3, \quad 0 \le x \le \sqrt{9 - y^2}$$



We see that $\mathcal{D}$ is the quarter of the circle $x^2 + y^2 = 9$, $x \ge 0$, $y \ge 0$. We describe $\mathcal{D}$ in polar coordinates by the following inequalities:

$$0 \le \theta \le \frac{\pi}{2}, \quad 0 \le r \le 3$$

The function in polar coordinates is $f(x, y) = \sqrt{x^2 + y^2} = r$. Using change of variables we get

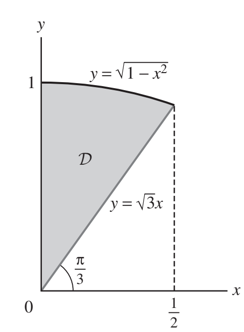
$$\int_{0}^{3} \int_{0}^{\sqrt{9-y^2}} \sqrt{x^2 + y^2}\, dx\, dy = \int_{0}^{\pi/2} \int_{0}^{3} r \cdot r dr\, d\theta = \int_{0}^{\pi/2} \int_{0}^{3} r^2\, dr\, d\theta$$
$$= \int_{0}^{\pi/2} \frac{r^3}{3}\bigg|_{0}^{3} d\theta = \int_{0}^{\pi/2} 9\, d\theta = 9 \cdot \frac{\pi}{2} = 4.5\pi$$

9. $\displaystyle\int_{0}^{1/2} \int_{\sqrt{3}x}^{\sqrt{1-x^2}} x\, dy\, dx$

SOLUTION The region of integration is described by the inequalities

$$0 \le x \le \frac{1}{2}, \quad \sqrt{3}x \le y \le \sqrt{1 - x^2}$$

$\mathcal{D}$ is the circular sector shown in the figure.



The ray $y = \sqrt{3}x$ in the first quadrant has the polar equation

$$r \sin\theta = \sqrt{3} r \cos\theta \quad \Rightarrow \quad \tan\theta = \sqrt{3} \quad \Rightarrow \quad \theta = \frac{\pi}{3}$$

Therefore, $\mathcal{D}$ lies in the angular sector $\frac{\pi}{3} \le \theta \le \frac{\pi}{2}$. Also, the circle $y = \sqrt{1-x^2}$ has the polar equation $r = 1$, hence $\mathcal{D}$ can be described by the inequalities

$$\frac{\pi}{3} \le \theta \le \frac{\pi}{2}, \quad 0 \le r \le 1$$

We use change of variables to obtain

$$\int_0^{1/2} \int_{\sqrt{3}x}^{\sqrt{1-x^2}} x\,dy\,dx = \int_{\pi/3}^{\pi/2} \int_0^1 r(\cos\theta) r\,dr\,d\theta = \int_{\pi/3}^{\pi/2} \int_0^1 r^2 \cos\theta\,dr\,d\theta = \int_{\pi/3}^{\pi/2} \frac{r^3 \cos\theta}{3}\bigg|_{r=0}^{1} d\theta$$

$$= \int_{\pi/3}^{\pi/2} \frac{\cos\theta}{3}\,d\theta = \frac{\sin\theta}{3}\bigg|_{\pi/3}^{\pi/2} = \frac{1}{3}\left(\sin\frac{\pi}{2} - \sin\frac{\pi}{3}\right) = \frac{1}{3}\left(1 - \frac{\sqrt{3}}{2}\right) \approx 0.045$$

10. $\displaystyle\int_0^4 \int_0^{\sqrt{16-x^2}} \tan^{-1}\frac{y}{x}\,dy\,dx$

SOLUTION We note that this is an integral over the quarter circle of radius 4 in the first quadrant. Using the standard polar coordinates, we get:

$$\int_0^4 \int_0^{\sqrt{16-x^2}} \tan^{-1}\frac{y}{x}\,dy\,dx = \int_0^{\pi/2} \int_0^4 \tan^{-1}\frac{r\sin\theta}{r\cos\theta}\,r\,dr\,d\theta = \int_0^{\pi/2} \int_0^4 \tan^{-1}\tan\theta\,r\,dr\,d\theta$$

$$= \int_0^{\pi/2} \int_0^4 \theta\,r\,dr\,d\theta = \frac{1}{2}r^2\bigg|_0^4 \cdot \frac{1}{2}\theta^2\bigg|_0^{\pi/2} = \pi^2$$

11. $\displaystyle\int_0^5 \int_0^y x\,dx\,dy$

SOLUTION

$$\int_0^5 \int_0^y x\,dx\,dy = \int_{\pi/4}^{\pi/2} \int_{r=0}^{5/\sin\theta} r^2\cos\theta\,dr\,d\theta = \int_{\pi/4}^{\pi/2} \frac{1}{3}r^3\cos\theta\bigg|_{r=0}^{5/\sin\theta} d\theta$$

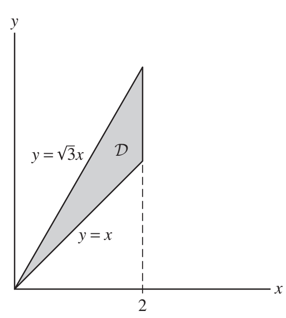
$$= \frac{1}{3}\int_{\pi/4}^{\pi/2} \frac{125}{\sin^3\theta}\cos\theta\,d\theta = \frac{125}{3}\int_{\pi/4}^{\pi/2} \frac{\cos\theta}{\sin^3\theta}\,d\theta$$

$$= -\frac{125}{6}\frac{1}{\sin^2\theta}\bigg|_{\pi/4}^{\pi/2} = -\frac{125}{6}(1-2) = \frac{125}{6}$$

12. $\displaystyle\int_0^2 \int_x^{\sqrt{3}x} y\,dy\,dx$

SOLUTION The region is determined by the inequalities

$$\mathcal{D}: \ 0 \le x \le 2, \ x \le y \le \sqrt{3}x$$



The rays $y = x$ and $y = \sqrt{3}x$ in the first quadrant have polar equations $\theta = \frac{\pi}{4}$ and $\theta = \frac{\pi}{3}$, respectively, hence the region lies in the angular sector $\frac{\pi}{4} \le \theta \le \frac{\pi}{3}$. The line $x = 2$ has polar equation $r\cos\theta = 2$ or $r = 2\sec\theta$. Therefore, the inequalities describing $\mathcal{D}$ in polar equations are

$$\mathcal{D}: \ \frac{\pi}{4} \le \theta \le \frac{\pi}{3}, \ 0 \le r \le 2\sec\theta$$

Using change of variables we have

$$\int_0^2 \int_x^{\sqrt{3}x} y\,dy\,dx = \int_{\pi/4}^{\pi/3} \int_0^{2\sec\theta} (r\sin\theta) r\,dr\,d\theta = \int_{\pi/4}^{\pi/3} \int_0^{2\sec\theta} r^2 \sin\theta\,dr\,d\theta$$
$$= \int_{\pi/4}^{\pi/3} \frac{r^3 \sin\theta}{3}\bigg|_{r=0}^{2\sec\theta} d\theta = \int_{\pi/4}^{\pi/3} \frac{8\sec^3\theta\sin\theta}{3}\,d\theta = \int_{\pi/4}^{\pi/3} \frac{8}{3}\frac{\sin\theta}{\cos^3\theta}\,d\theta$$

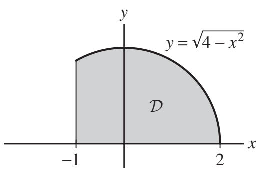
We compute the integral using the substitution $u = \cos\theta$, $du = -\sin\theta\,d\theta$. We get

$$\int_0^2 \int_x^{\sqrt{3}x} y\,dy\,dx = \int_{1/\sqrt{2}}^{1/2} \frac{8}{3}u^{-3}(-du) = \int_{1/2}^{1/\sqrt{2}} \frac{8}{3}u^{-3}\,du = -\frac{4}{3}u^{-2}\bigg|_{1/2}^{1/\sqrt{2}} = -\frac{4}{3}(2-4) = \frac{8}{3}$$

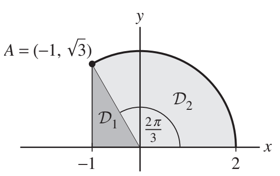
13. $\displaystyle\int_{-1}^2 \int_0^{\sqrt{4-x^2}} (x^2+y^2)\,dy\,dx$

SOLUTION The domain $\mathcal{D}$, shown in the figure, is described by the inequalities

$$-1 \le x \le 2, \quad 0 \le y \le \sqrt{4-x^2}$$



We denote by $\mathcal{D}_1$ and $\mathcal{D}_2$ the triangle and the circular sections, respectively, shown in the figure.



By properties of integrals we have

$$\iint_{\mathcal{D}} \left(x^2+y^2\right) dA = \iint_{\mathcal{D}_1} \left(x^2+y^2\right) dA + \iint_{\mathcal{D}_2} \left(x^2+y^2\right) dA \tag{1}$$

We compute each integral separately, starting with $\mathcal{D}_1$. The vertical line $x = -1$ has polar equation $r\cos\theta = -1$ or $r = -\sec\theta$. The ray OA has polar equation $\theta = \frac{2\pi}{3}$. Therefore $\mathcal{D}_1$ is described by

$$\frac{2\pi}{3} \le \theta \le \pi, \quad 0 \le r \le -\sec\theta$$

Using change of variables gives

$$\iint_{\mathcal{D}_1} \left(x^2+y^2\right) dA = \int_{2\pi/3}^{\pi} \int_0^{-\sec\theta} r^2 \cdot r\,dr\,d\theta = \int_{2\pi/3}^{\pi} \int_0^{-\sec\theta} r^3\,dr\,d\theta$$
$$= \int_{2\pi/3}^{\pi} \frac{r^4}{4}\bigg|_{r=0}^{-\sec\theta} d\theta = \int_{2\pi/3}^{\pi} \frac{\sec^4\theta}{4}\,d\theta = \frac{1}{4}\int_{2\pi/3}^{\pi} \sec^4\theta\,d\theta \tag{2}$$

We compute the integral (we use substitution $u = \tan\theta$ for the second integral):

$$\int_{2\pi/3}^{\pi} \frac{1}{\cos^4\theta}\,d\theta = \int_{2\pi/3}^{\pi} \frac{\sin^2\theta + \cos^2\theta}{\cos^4\theta}\,d\theta = \int_{2\pi/3}^{\pi} \frac{d\theta}{\cos^2\theta} + \int_{2\pi/3}^{\pi} \tan^2\theta \cdot \frac{1}{\cos^2\theta}\,d\theta$$
$$= \tan\theta\bigg|_{\theta=2\pi/3}^{\pi} + \int_{-\sqrt{3}}^{0} u^2\,du = \tan\pi - \tan\frac{2\pi}{3} + \frac{u^3}{3}\bigg|_{-\sqrt{3}}^{0} = \sqrt{3} + \frac{3\sqrt{3}}{3} = 2\sqrt{3}$$

Hence, by (2) we get

$$\iint_{\mathcal{D}_1} \left(x^2+y^2\right) dA = \frac{\sqrt{3}}{2} \tag{3}$$

$\mathcal{D}_2$ is described by the inequalities

$$0 \le \theta \le \frac{2\pi}{3}, \quad 0 \le r \le 2$$

Hence,

$$\iint_{\mathcal{D}_2} \left(x^2 + y^2\right) dA = \int_0^{2\pi/3} \int_0^2 r^2 \cdot r \, dr \, d\theta = \int_0^{2\pi/3} \int_0^2 r^3 \, dr \, d\theta$$
$$= \int_0^{2\pi/3} \left.\frac{r^4}{4}\right|_{r=0}^{2} d\theta = \int_0^{2\pi/3} 4 \, d\theta = 4 \cdot \theta \Big|_0^{2\pi/3} = \frac{8\pi}{3} \qquad (4)$$

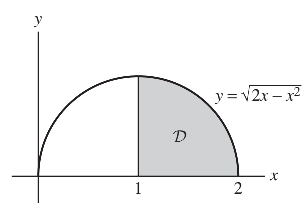
Combining (1), (3) and (4) we obtain the following solution:

$$\iint_{\mathcal{D}} \left(x^2 + y^2\right) dA = \frac{\sqrt{3}}{2} + \frac{8\pi}{3} \approx 9.24$$

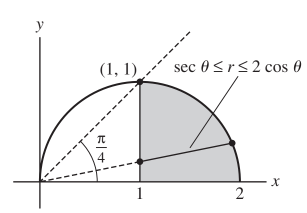
14. $\displaystyle\int_1^2 \int_0^{\sqrt{2x-x^2}} \frac{1}{\sqrt{x^2+y^2}} \, dy \, dx$

SOLUTION The region is described by the inequalities

$$1 \le x \le 2, \quad 0 \le y \le \sqrt{2x - x^2}$$



We first describe $\mathcal{D}$ in polar coordinates. The region lies in the angular sector $0 \le \theta \le \frac{\pi}{4}$. The circle $y = \sqrt{2x - x^2}$ or $(x-1)^2 + y^2 = 1$, $y \ge 0$ (obtained by completing the square) is the circle of radius 1 and center $(1, 0)$. Its polar equation is $r = 2\cos\theta$. The polar equation of the line $x = 1$ is $r\cos\theta = 1$ or $r = \sec\theta$.



Therefore, $\mathcal{D}$ has the following description:

$$0 \le \theta \le \frac{\pi}{4}, \quad \sec\theta \le r \le 2\cos\theta$$

Using change of variables we get

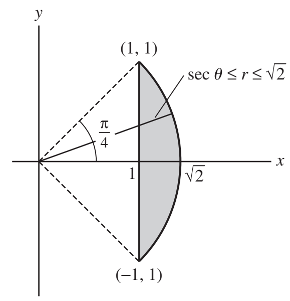
$$\int_1^2 \int_0^{\sqrt{2x-x^2}} \frac{dy\,dx}{\sqrt{x^2+y^2}} = \int_0^{\pi/4} \int_{\sec\theta}^{2\cos\theta} \frac{1}{r} \cdot r \, dr \, d\theta = \int_0^{\pi/4} \int_{\sec\theta}^{2\cos\theta} dr \, d\theta = \int_0^{\pi/4} r \Big|_{r=\sec\theta}^{2\cos\theta} d\theta$$
$$= \int_0^{\pi/4} (2\cos\theta - \sec\theta) \, d\theta = 2\sin\theta \Big|_0^{\pi/4} - \ln(\sec\theta + \tan\theta) \Big|_0^{\pi/4}$$
$$= 2\sin\frac{\pi}{4} - \left(\ln\left(\sec\frac{\pi}{4} + \tan\frac{\pi}{4}\right) - \ln 1\right) = 2 \cdot \frac{\sqrt{2}}{2} - \ln\left(\sqrt{2} + 1\right)$$
$$= \sqrt{2} - \ln\left(1 + \sqrt{2}\right) \approx 0.533$$

In Exercises 15–20, calculate the integral over the given region by changing to polar coordinates.

15. $f(x, y) = (x^2 + y^2)^{-2}$; $x^2 + y^2 \le 2$, $x \ge 1$

SOLUTION The region $\mathcal{D}$ lies in the angular sector

$$-\frac{\pi}{4} \le \theta \le \frac{\pi}{4}$$



The vertical line $x = 1$ has polar equation $r\cos\theta = 1$ or $r = \sec\theta$. The circle $x^2 + y^2 = 2$ has polar equation $r = \sqrt{2}$. Therefore, $\mathcal{D}$ has the following description:

$$-\frac{\pi}{4} \le \theta \le \frac{\pi}{4}, \quad \sec\theta \le r \le \sqrt{2}$$

The function in polar coordinates is

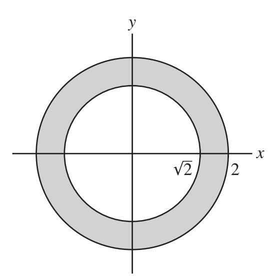
$$f(x, y) = \left(x^2 + y^2\right)^{-2} = \left(r^2\right)^{-2} = r^{-4}.$$

Using change of variables we obtain

$$\iint_{\mathcal{D}} \left(x^2 + y^2\right)^{-2} dA = \int_{-\pi/4}^{\pi/4} \int_{\sec\theta}^{\sqrt{2}} r^{-4} r \, dr \, d\theta = \int_{-\pi/4}^{\pi/4} \int_{\sec\theta}^{\sqrt{2}} r^{-3} \, dr \, d\theta = \int_{-\pi/4}^{\pi/4} \left. \frac{r^{-2}}{-2} \right|_{\sec\theta}^{\sqrt{2}} d\theta$$
$$= \int_{-\pi/4}^{\pi/4} \left(\frac{1}{2\sec^2\theta} - \frac{1}{4} \right) d\theta = 2\int_0^{\pi/4} \left(\frac{1}{2}\cos^2\theta - \frac{1}{4} \right) d\theta$$
$$= \left. \left(\frac{\theta}{2} + \frac{\sin 2\theta}{4} \right) \right|_0^{\pi/4} - \left. \frac{\theta}{2} \right|_0^{\pi/4} = \frac{\pi}{8} + \frac{1}{4} - \frac{\pi}{8} = \frac{1}{4}$$

16. $f(x, y) = x$; $2 \le x^2 + y^2 \le 4$

SOLUTION $\mathcal{D}$ is the annulus shown in the figure.



The inequalities describing $\mathcal{D}$ in polar coordinates are

$$0 \le \theta \le 2\pi, \quad \sqrt{2} \le r \le 2$$

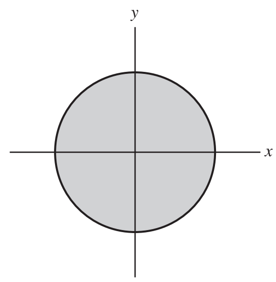
The function is $f(x, y) = x = r\cos\theta$, therefore using change of variables gives

$$\iint_{\mathcal{D}} x \, dA = \int_0^{2\pi} \int_{\sqrt{2}}^{2} (r\cos\theta) r \, dr \, d\theta = \int_0^{2\pi} \int_{\sqrt{2}}^{2} r^2 \cos\theta \, dr \, d\theta = \int_0^{2\pi} \left. \frac{r^3 \cos\theta}{3} \right|_{r=\sqrt{2}}^{2} d\theta$$
$$= \int_0^{2\pi} \frac{8 - 2\sqrt{2}}{3} \cos\theta \, d\theta = \left. \frac{8 - 2\sqrt{2}}{3} \sin\theta \right|_0^{2\pi} = 0$$

17. $f(x, y) = |xy|; \quad x^2 + y^2 \le 1$

SOLUTION The unit disk is described in polar coordinates by

$$\mathcal{D}: 0 \le \theta \le 2\pi, \ 0 \le r \le 1$$



$x^2 + y^2 \le 1$

The function is $f(x, y) = |xy| = |r\cos\theta \cdot r\sin\theta| = \frac{1}{2}r^2|\sin 2\theta|$. Using change of variables we obtain

$$\begin{aligned}\iint_{\mathcal{D}} |xy|\, dA &= \int_0^{2\pi}\int_0^1 \frac{1}{2}r^2|\sin 2\theta| \cdot r\, dr\, d\theta = \int_0^{2\pi}\int_0^1 \frac{1}{2}r^3|\sin 2\theta|\, dr\, d\theta \\ &= \int_0^{2\pi} \frac{r^4}{8}|\sin 2\theta|\Big|_{r=0}^{1} d\theta = \int_0^{2\pi} \frac{1}{8}|\sin 2\theta|\, d\theta \qquad (1)\end{aligned}$$

The signs of $\sin 2\theta$ in the interval of integration are

For $0 \le \theta \le \frac{\pi}{2}$ or $\pi \le \theta \le \frac{3\pi}{2}$, $\sin 2\theta \ge 0$, hence $|\sin 2\theta| = \sin 2\theta$.
For $\frac{\pi}{2} \le \theta \le \pi$ or $\frac{3\pi}{2} \le \theta \le 2\pi$, $\sin 2\theta \le 0$, hence $|\sin 2\theta| = -\sin 2\theta$.

Therefore, by (1) we get

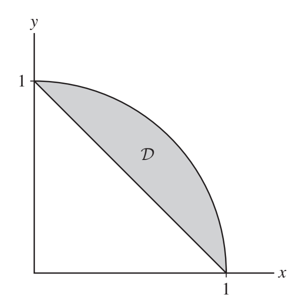
$$\begin{aligned}\iint_{\mathcal{D}} |xy|\, dA &= \int_0^{\pi/2} \frac{1}{8}\sin 2\theta\, d\theta - \int_{\pi/2}^{\pi} \frac{1}{8}\sin 2\theta\, d\theta + \int_{\pi}^{3\pi/2} \frac{1}{8}\sin 2\theta\, d\theta - \int_{3\pi/2}^{2\pi} \frac{1}{8}\sin 2\theta\, d\theta \\ &= -\frac{1}{16}\cos 2\theta\Big|_0^{\pi/2} + \frac{1}{16}\cos 2\theta\Big|_{\pi/2}^{\pi} - \frac{1}{16}\cos 2\theta\Big|_{\pi}^{3\pi/2} + \frac{1}{16}\cos 2\theta\Big|_{3\pi/2}^{2\pi} \\ &= -\frac{1}{16}(\cos\pi - 1) + \frac{1}{16}(\cos 2\pi - \cos\pi) - \frac{1}{16}(\cos 3\pi - \cos 2\pi) + \frac{1}{16}(\cos 4\pi - \cos 3\pi) \\ &= \frac{2}{16} + \frac{2}{16} + \frac{2}{16} + \frac{2}{16} = \frac{1}{2}\end{aligned}$$

That is,

$$\iint_{\mathcal{D}} |xy|\, dA = \frac{1}{2}$$

18. $f(x, y) = (x^2 + y^2)^{-3/2}; \quad x^2 + y^2 \le 1, \quad x + y \ge 1$

SOLUTION The domain $\mathcal{D}$ is shown in the figure.

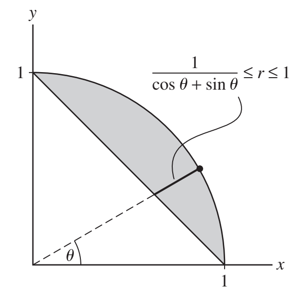


Step 1. Describe $\mathcal{D}$ and f in polar coordinates. In $\mathcal{D}$, the angle θ is changing from 0 to $\frac{\pi}{2}$. The circle $x^2 + y^2 = 1$ has polar equation $r = 1$. The line $x + y = 1$ has the following polar equation:

$$r\cos\theta + r\sin\theta = 1 \quad \Rightarrow \quad r = \frac{1}{\cos\theta + \sin\theta}$$

Therefore, the polar inequalities describing the region $\mathcal{D}$ are

$$\mathcal{D}: \ 0 \le \theta \le \frac{\pi}{2}, \ \frac{1}{\cos\theta + \sin\theta} \le r \le 1$$



The function f in polar coordinates is

$$f(x, y) = (x^2 + y^2)^{-3/2} = (r^2)^{-3/2} = r^{-3}$$

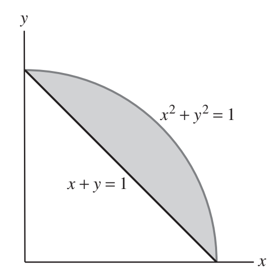
Step 2. Change variables in the Integral and Evaluate. Using the Change of Variables Formula we get

$$\begin{aligned}
\iint_{\mathcal{D}} \left(x^2 + y^2\right)^{-3/2} dA &= \int_0^{\pi/2} \int_{\frac{1}{\cos\theta+\sin\theta}}^{1} r^{-3} \cdot r\,dr\,d\theta = \int_0^{\pi/2} \int_{\frac{1}{\cos\theta+\sin\theta}}^{1} r^{-2}\,dr\,d\theta \\
&= \int_0^{\pi/2} -\frac{1}{r}\bigg|_{r=\frac{1}{\cos\theta+\sin\theta}}^{1} d\theta = \int_0^{\pi/2} (-1 + \cos\theta + \sin\theta)\,d\theta \\
&= -\theta + \sin\theta - \cos\theta\bigg|_0^{\pi/2} = \left(-\frac{\pi}{2} + \sin\frac{\pi}{2} - \cos\frac{\pi}{2}\right) - (0 + 0 - 1) \\
&= 2 - \frac{\pi}{2} \approx 0.43
\end{aligned}$$

19. $f(x, y) = x - y; \quad x^2 + y^2 \le 1, \quad x + y \ge 1$

SOLUTION As shown in Exercise 24, the region $\mathcal{D}$ is described by the following inequalities:

$$\mathcal{D}: \ 0 \le \theta \le \frac{\pi}{2}, \ \frac{1}{\cos\theta + \sin\theta} \le r \le 1$$



The function in polar coordinates is

$$f(x, y) = x - y = r\cos\theta - r\sin\theta = r(\cos\theta - \sin\theta)$$

Using the Change of Variables Formula we get

$$\begin{aligned}
\iint_{\mathcal{D}} (x - y)\,dA &= \int_0^{\pi/2} \int_{\frac{1}{\cos\theta+\sin\theta}}^{1} r(\cos\theta - \sin\theta) r\,dr\,d\theta = \int_0^{\pi/2} \int_{\frac{1}{\cos\theta+\sin\theta}}^{1} r^2(\cos\theta - \sin\theta)\,dr\,d\theta \\
&= \int_0^{\pi/2} \frac{r^3(\cos\theta - \sin\theta)}{3}\bigg|_{r=\frac{1}{\cos\theta+\sin\theta}}^{1} d\theta = \int_0^{\pi/2} \frac{\cos\theta - \sin\theta}{3}\left(1 - \frac{1}{(\cos\theta + \sin\theta)^3}\right) d\theta \\
&= \int_0^{\pi/2} \frac{\cos\theta - \sin\theta}{3}\,d\theta - \frac{1}{3}\int_0^{\pi/2} \frac{\cos\theta - \sin\theta}{(\cos\theta + \sin\theta)^3}\,d\theta \qquad (1)
\end{aligned}$$

We compute the two integrals:

$$\int_0^{\pi/2} \frac{\cos\theta - \sin\theta}{3}\,d\theta = \frac{\sin\theta + \cos\theta}{3}\bigg|_0^{\pi/2} = \frac{(1 + 0) - (0 + 1)}{3} = 0 \qquad (2)$$

To compute the second integral we will use u-substitution and let $u = \sin\theta + \cos\theta$:

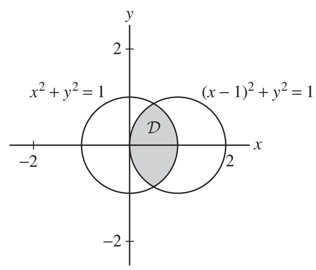
$$\int_0^{\pi/2} \frac{\cos\theta - \sin\theta}{(\cos\theta + \sin\theta)^3}\,d\theta = \int_{u=1}^{1} u^{-3}\,du = 0 \tag{3}$$

Combining (1), (2), and (3) we conclude that

$$\iint_{\mathcal{D}} (x - y)\,dA = 0$$

20. $f(x, y) = y;\quad x^2 + y^2 \le 1,\quad (x - 1)^2 + y^2 \le 1$

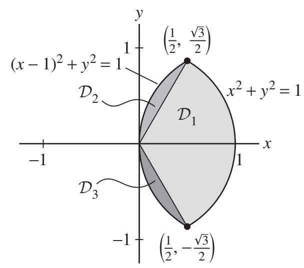
SOLUTION $\mathcal{D}$ is the common region of the two circles shown in the figure.



To evaluate the integral we decompose $\mathcal{D}$ into three regions $\mathcal{D}_1$, $\mathcal{D}_2$, and $\mathcal{D}_3$ shown in the figure. Thus,

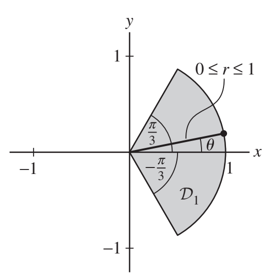
$$\iint_{\mathcal{D}} y\,dA = \iint_{\mathcal{D}_1} y\,dA + \iint_{\mathcal{D}_2} y\,dA + \iint_{\mathcal{D}_3} y\,dA \tag{1}$$

We compute each integral separately.



$\mathcal{D}_1$: The domain $\mathcal{D}_1$ lies in the angular sector $-\frac{\pi}{3} \le \theta \le \frac{\pi}{3}$ (where $\frac{\pi}{3} = \tan^{-1}\frac{\frac{\sqrt{3}}{2}}{\frac{1}{2}} = \tan^{-1}\sqrt{3}$). The circle $x^2 + y^2 = 1$ has polar equation $r = 1$, therefore $\mathcal{D}_1$ has the following definition:

$$\mathcal{D}_1 : -\frac{\pi}{3} \le \theta \le \frac{\pi}{3},\ 0 \le r \le 1$$



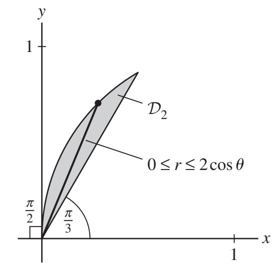
We use change of variables in the integral to write

$$\iint_{\mathcal{D}_1} y\,dA = \int_{-\pi/3}^{\pi/3}\int_0^1 (r\sin\theta)r\,dr\,d\theta = \int_{-\pi/3}^{\pi/3}\int_0^1 r^2\sin\theta\,dr\,d\theta = \int_{-\pi/3}^{\pi/3} \left.\frac{r^3\sin\theta}{3}\right|_{r=0}^{1} d\theta$$

$$= \int_{-\pi/3}^{\pi/3} \frac{\sin\theta}{3}\,d\theta = -\left.\frac{\cos\theta}{3}\right|_{-\pi/3}^{\pi/3} = 0 \tag{2}$$

$\mathcal{D}_2$: The angle θ is changing in $\mathcal{D}_2$ from $\frac{\pi}{3}$ to $\frac{\pi}{2}$. The circle $(x - 1)^2 + y^2 = 1$ has polar equation $r = 2\cos\theta$. Therefore, $\mathcal{D}_2$ has the following description:

$$\mathcal{D}_2 : \frac{\pi}{3} \le \theta \le \frac{\pi}{2},\ 0 \le r \le 2\cos\theta$$



Using the Change of Variables Formula gives

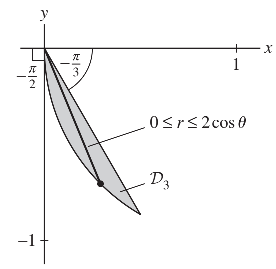
$$\iint_{\mathcal{D}_2} y\,dA = \int_{\pi/3}^{\pi/2}\int_0^{2\cos\theta}(r\sin\theta)r\,dr\,d\theta = \int_{\pi/3}^{\pi/2}\int_0^{2\cos\theta} r^2\sin\theta\,dr\,d\theta$$
$$= \int_{\pi/3}^{\pi/2} \frac{r^3\sin\theta}{3}\bigg|_{r=0}^{2\cos\theta} d\theta = \int_{\pi/3}^{\pi/2}\frac{8}{3}\cos^3\theta\sin\theta\,d\theta$$

We compute the integral using the substitution $u = \cos\theta$, $du = -\sin\theta\,d\theta$:

$$\iint_{\mathcal{D}_2} y\,dA = \int_{1/2}^{0}\frac{8}{3}u^3(-du) = \int_0^{1/2}\frac{8}{3}u^3\,du = \frac{2}{3}u^4\bigg|_0^{1/2} = \frac{1}{24} \tag{3}$$

$\mathcal{D}_3$: The domain $\mathcal{D}_3$ has the following description:

$$\mathcal{D}_3 : -\frac{\pi}{2} \le \theta \le -\frac{\pi}{3},\ 0 \le r \le 2\cos\theta$$



We obtain the integral (the inner integral was computed previously)

$$\iint_{\mathcal{D}_3} y\,dA = \int_{-\pi/2}^{-\pi/3}\int_0^{2\cos\theta}(r\sin\theta)r\,dr\,d\theta = \int_{-\pi/2}^{-\pi/3}\left(\int_0^{2\cos\theta} r^2\sin\theta\,dr\right)d\theta = \int_{-\pi/2}^{-\pi/3}\frac{8}{3}\cos^3\theta\sin\theta\,d\theta$$

We use the substitution $\omega = -\theta$ and the integral computed previously to obtain

$$\iint_{\mathcal{D}_3} y\,dA = \int_{\pi/2}^{\pi/3}\frac{8}{3}\cos^3\omega(\sin-\omega)(-d\omega) = -\int_{\pi/3}^{\pi/2}\frac{8}{3}\cos^3\omega\sin\omega\,d\omega = -\frac{1}{24} \tag{4}$$

Finally, we combine (1), (2), (3), and (4) to obtain the following solution:

$$\iint_{\mathcal{D}} y\,dA = 0 + \frac{1}{24} - \frac{1}{24} = 0$$

Remark: The integral is zero since the average value of the y-coordinates of the points in $\mathcal{D}$ is zero ($\mathcal{D}$ is symmetric with respect to the x-axis).

21. Find the volume of the wedge-shaped region (Figure 17) contained in the cylinder $x^2 + y^2 = 9$, bounded above by the plane $z = x$ and below by the xy-plane.

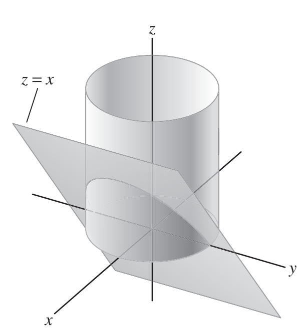


FIGURE 17

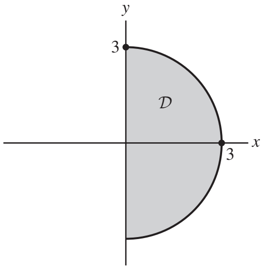
SOLUTION

Step 1. Express $\mathcal{W}$ in cylindrical coordinates. $\mathcal{W}$ is bounded above by the plane $z = x$ and below by $z = 0$, therefore $0 \le z \le x$, in particular $x \ge 0$. Hence, $\mathcal{W}$ projects onto the semicircle $\mathcal{D}$ in the xy-plane of radius 3, where $x \ge 0$.



In polar coordinates,

$$\mathcal{D}: -\frac{\pi}{2} \le \theta \le \frac{\pi}{2},\ 0 \le r \le 3$$

The upper surface is $z = x = r\cos\theta$ and the lower surface is $z = 0$. Therefore,

$$\mathcal{W}: -\frac{\pi}{2} \le \theta \le \frac{\pi}{2},\ 0 \le r \le 3,\ 0 \le z \le r\cos\theta$$

Step 2. Set up an integral in cylindrical coordinates and evaluate. The volume of $\mathcal{W}$ is the triple integral $\iiint_{\mathcal{W}} 1\,dV$. Using change of variables in cylindrical coordinates gives

$$\iiint_{\mathcal{W}} 1\,dV = \int_{-\pi/2}^{\pi/2}\int_0^3\int_0^{r\cos\theta} r\,dz\,dr\,d\theta = \int_{-\pi/2}^{\pi/2}\int_0^3 rz\Big|_{z=0}^{r\cos\theta} dr\,d\theta = \int_{-\pi/2}^{\pi/2}\int_0^3 r^2\cos\theta\,dr\,d\theta$$

$$= \int_{-\pi/2}^{\pi/2} \frac{r^3}{3}\cos\theta\Big|_{r=0}^{3} d\theta = \int_{-\pi/2}^{\pi/2} 9\cos\theta\,d\theta = 9\sin\theta\Big|_{-\pi/2}^{\pi/2} = 9\left(\sin\frac{\pi}{2} - \sin\left(-\frac{\pi}{2}\right)\right) = 18$$

22. Let $\mathcal{W}$ be the region above the sphere $x^2 + y^2 + z^2 = 6$ and below the paraboloid $z = 4 - x^2 - y^2$.
(a) Show that the projection of $\mathcal{W}$ on the xy-plane is the disk $x^2 + y^2 \le 2$ (Figure 18).
(b) Compute the volume of $\mathcal{W}$ using polar coordinates.

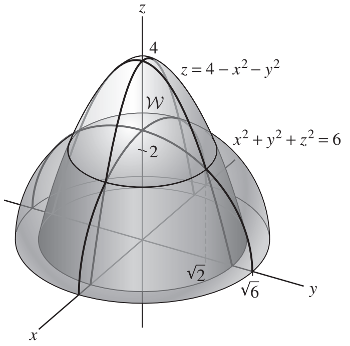


FIGURE 18

SOLUTION

(a) We find the intersection of the sphere $x^2 + y^2 + z^2 = 6$ and the paraboloid $z = 4 - x^2 - y^2$. The equation $z = 4 - x^2 - y^2$ implies $x^2 + y^2 = 4 - z$. Substituting in $x^2 + y^2 + z^2 = 6$ and solving for z gives

$$4 - z + z^2 = 6 \quad\Rightarrow\quad z^2 - z - 2 = (z-2)(z+1) = 0$$
$$\Rightarrow\quad z = 2,\quad z = -1$$

We omit the negative solution $z = -1$, since in $\mathcal{W}$, $z \ge 0$. Substituting $z = 2$ in $z = 4 - x^2 - y^2$, we get

$$2 = 4 - x^2 - y^2 \quad\Rightarrow\quad x^2 + y^2 = 2$$

That is, the projection of $\mathcal{W}$ on the xy-plane is the disk $x^2 + y^2 \le 2$.

(b) Using part (a) we obtain the following inequalities for $\mathcal{D}$:

$$\mathcal{D}: \ 0 \le \theta \le 2\pi, \quad 0 \le r \le \sqrt{2}$$

The upper boundary is the surface $z = 4 - x^2 - y^2$ or $z = 4 - r^2$. The lower boundary is the sphere $x^2 + y^2 + z^2 = 6$, $r^2 + z^2 = 6$, or $z = \sqrt{6 - r^2}$. Therefore, the inequalities describing $\mathcal{W}$ in cylindrical coordinates are

$$0 \le \theta \le 2\pi, \quad 0 \le r \le \sqrt{2}, \quad \sqrt{6 - r^2} \le z \le 4 - r^2$$

We use the volume as a triple integral and the change of variables in cylindrical coordinates to obtain

$$V = \iiint_{\mathcal{W}} 1\, dV = \int_0^{2\pi} \int_0^{\sqrt{2}} \int_{\sqrt{6-r^2}}^{4-r^2} r\, dz\, dr\, d\theta = \int_0^{2\pi} \int_0^{\sqrt{2}} r \cdot z \Big|_{z=\sqrt{6-r^2}}^{4-r^2} dr\, d\theta$$

$$= \int_0^{2\pi} \int_0^{\sqrt{2}} \left(4 - r^2 - \sqrt{6 - r^2}\right) r\, dr\, d\theta = \int_0^{2\pi} \int_0^{\sqrt{2}} \left(4r - r^3 - r\sqrt{6 - r^2}\right) dr\, d\theta \qquad (1)$$

We compute the inner integral. Using the substitution $u = \sqrt{6 - r^2}$, $du = -\frac{r}{u}\, dr$ for the second integral, we get

$$\int_0^{\sqrt{2}} (4r - r^3)\, dr = 2r^2 - \frac{r^4}{4}\Big|_0^{\sqrt{2}} = 4 - 1 = 3$$

$$\int_0^{\sqrt{2}} r\sqrt{6 - r^2}\, dr = \int_{\sqrt{6}}^{2} -u^2\, du = \int_2^{\sqrt{6}} u^2\, du = \frac{u^3}{3}\Big|_2^{\sqrt{6}} = 2\sqrt{6} - \frac{8}{3}$$

Hence,

$$\int_0^{\sqrt{2}} \left(4r - r^3 - r\sqrt{6 - r^2}\right) dr = 3 - \left(2\sqrt{6} - \frac{8}{3}\right) = \frac{17}{3} - 2\sqrt{6} \approx 0.77$$

Substituting in (1) we obtain

$$V = \int_0^{2\pi} 0.77\, d\theta = 1.54\pi \approx 4.84$$

23. Evaluate $\iint_{\mathcal{D}} \sqrt{x^2 + y^2}\, dA$, where $\mathcal{D}$ is the domain in Figure 19. *Hint:* Find the equation of the inner circle in polar coordinates and treat the right and left parts of the region separately.

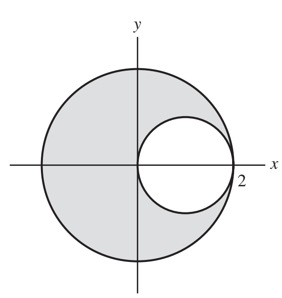

FIGURE 19

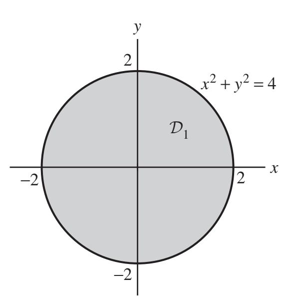
SOLUTION We denote by $\mathcal{D}_1$ and $\mathcal{D}_2$ the regions enclosed by the circles $x^2 + y^2 = 4$ and $(x - 1)^2 + y^2 = 1$. Therefore,

$$\iint_{\mathcal{D}} \sqrt{x^2 + y^2}\, dx\, dy = \iint_{\mathcal{D}_1} \sqrt{x^2 + y^2}\, dx\, dy - \iint_{\mathcal{D}_2} \sqrt{x^2 + y^2}\, dx\, dy \qquad (1)$$

We compute the integrals on the right hand-side.

$\mathcal{D}_1$:



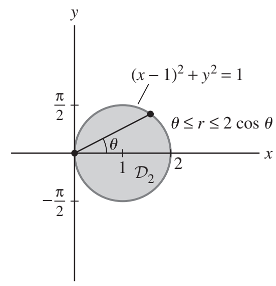
The circle $x^2 + y^2 = 4$ has polar equation $r = 2$, therefore $\mathcal{D}_1$ is determined by the following inequalities:

$$\mathcal{D}_1 : 0 \le \theta \le 2\pi, \ 0 \le r \le 2$$

The function in polar coordinates is $f(x, y) = \sqrt{x^2 + y^2} = r$. Using change of variables in the integral gives

$$\iint_{\mathcal{D}_1} \sqrt{x^2 + y^2}\, dx\, dy = \int_0^{2\pi} \int_0^2 r \cdot r\, dr\, d\theta = \int_0^{2\pi} \int_0^2 r^2\, dr\, d\theta = \int_0^{2\pi} \frac{r^3}{3}\bigg|_{r=0}^{2} d\theta = \int_0^{2\pi} \frac{8}{3}\, d\theta = \frac{16\pi}{3} \tag{2}$$

$\mathcal{D}_2$:



$\mathcal{D}_2$ lies in the angular sector $-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$. We find the polar equation of the circle $(x-1)^2 + y^2 = 1$:

$$\begin{aligned}(x-1)^2 + y^2 = x^2 - 2x + 1 + y^2 = x^2 + y^2 - 2x + 1 = 1 \quad &\Rightarrow \quad x^2 + y^2 = 2x \\ &\Rightarrow \quad r^2 = 2r\cos\theta \\ &\Rightarrow \quad r = 2\cos\theta\end{aligned}$$

Thus, the domain $\mathcal{D}_2$ is defined by the following inequalities:

$$\mathcal{D}_2 : -\frac{\pi}{2} \le \theta \le \frac{\pi}{2}, \ 0 \le r \le 2\cos\theta$$

We use the change of variables in the integral and integration table to obtain

$$\begin{aligned}\iint_{\mathcal{D}_2} \sqrt{x^2 + y^2}\, dx\, dy &= \int_{-\pi/2}^{\pi/2} \int_0^{2\cos\theta} r \cdot r\, dr\, d\theta = \int_{-\pi/2}^{\pi/2} \int_0^{2\cos\theta} r^2\, dr\, d\theta = \int_{-\pi/2}^{\pi/2} \int_0^{2\cos\theta} \frac{r^3}{3}\bigg|_{r=0}^{2\cos\theta} d\theta \\ &= \int_{-\pi/2}^{\pi/2} \frac{8\cos^3\theta}{3}\, d\theta = 2\int_0^{\pi/2} \frac{8\cos^3\theta}{3}\, d\theta = \frac{16}{3}\left(\frac{\cos^2\theta \sin\theta}{3} + \frac{2}{3}\sin\theta\right)\bigg|_{\theta=0}^{\pi/2} \\ &= \frac{16}{3} \cdot \frac{2}{3}\sin\frac{\pi}{2} = \frac{32}{9}\end{aligned} \tag{3}$$

Substituting (2) and (3) in (1), we obtain the following solution:

$$\iint_{\mathcal{D}} \sqrt{x^2 + y^2}\, dx\, dy = \frac{16\pi}{3} - \frac{32}{9} = \frac{48\pi - 32}{9} \approx 13.2.$$

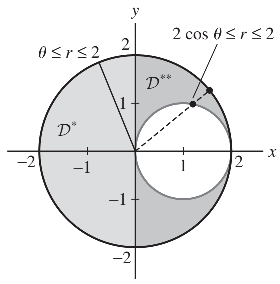
Remark: The integral can also be evaluated using the hint as the sum of

$$\int_{\mathcal{D}^*} \iint \sqrt{x^2 + y^2}\, dA \quad \text{and} \quad \int_{\mathcal{D}^{**}} \iint \sqrt{x^2 + y^2}\, dA$$

where $\mathcal{D}^*$ is the left semicircle $x^2 + y^2 = 4$ and $\mathcal{D}^*$ is the right part of $\mathcal{D}$. Since

$$\mathcal{D}^*: \frac{\pi}{2} \le \theta \le \frac{3\pi}{2}, \ 0 \le r \le 2$$

$$\mathcal{D}^{**}: -\frac{\pi}{2} \le \theta \le \frac{\pi}{2}, \ 2\cos\theta \le r \le 2$$



we get

$$\iint_{\mathcal{D}} \sqrt{x^2+y^2}\, dA = \int_{\pi/2}^{3\pi/2} \int_0^2 r^2\, dr\, d\theta + \int_{-\pi/2}^{\pi/2} \int_{2\cos\theta}^{2} r^2\, dr\, d\theta$$

Obviously, computing the integrals leads to the same result.

24. Evaluate $\iint_{\mathcal{D}} x\sqrt{x^2+y^2}\, dA$, where $\mathcal{D}$ is the shaded region enclosed by the lemniscate curve $r^2 = \sin 2\theta$ in Figure 20.

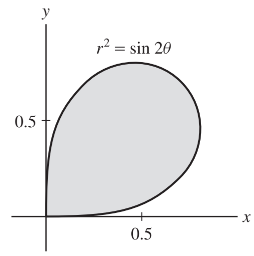


FIGURE 20

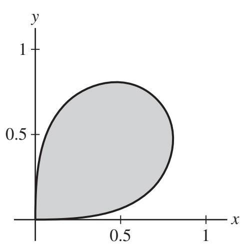
SOLUTION In $\mathcal{D}$, the angle θ varies between 0 and $\frac{\pi}{2}$, and r varies between 0 and $\sqrt{\sin 2\theta}$. Therefore $\mathcal{D}$ has the following description:

$$\mathcal{D}:\ 0 \le \theta \le \frac{\pi}{2},\ 0 \le r \le \sqrt{\sin 2\theta}$$



The function in polar coordinates is $f(x,y) = x\sqrt{x^2+y^2} = r\cos\theta \cdot r = r^2\cos\theta$. Therefore, using the Change of Variables Formula we have

$$\begin{aligned}
\iint_{\mathcal{D}} x\sqrt{x^2+y^2}\, dA &= \int_0^{\pi/2}\int_0^{\sqrt{\sin 2\theta}} r^2\cos\theta \cdot r\, dr\, d\theta = \int_0^{\pi/2}\int_0^{\sqrt{\sin 2\theta}} r^3\cos\theta\, dr\, d\theta \\
&= \int_0^{\pi/2} \frac{r^4\cos\theta}{4}\Bigg|_{r=0}^{\sqrt{\sin 2\theta}} d\theta = \int_0^{\pi/2} \frac{\sin^2 2\theta\cos\theta}{4}\, d\theta = \int_0^{\pi/2} \sin^2\theta\cos^3\theta\, d\theta \\
&= \int_0^{\pi/2} \sin^2\theta(1-\sin^2\theta)\cos\theta\, d\theta = \int_0^{\pi/2} (\sin^2\theta - \sin^4\theta)\cos\theta\, d\theta \\
&= \frac{1}{3}\sin^3\theta - \frac{1}{5}\sin^5\theta\Bigg|_0^{\pi/2} = \frac{1}{3} - \frac{1}{5} = \frac{2}{15}
\end{aligned}$$

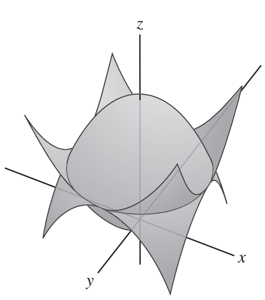
25. Let $\mathcal{W}$ be the region between the paraboloids $z = x^2 + y^2$ and $z = 8 - x^2 - y^2$.

(a) Describe $\mathcal{W}$ in cylindrical coordinates.

(b) Use cylindrical coordinates to compute the volume of $\mathcal{W}$.

SOLUTION

(a)



The paraboloids $z = x^2 + y^2$ and $z = 8 - (x^2 + y^2)$ have the polar equations $z = r^2$ and $z = 8 - r^2$, respectively. We find the curve of intersection by solving

$$8 - r^2 = r^2 \quad \Rightarrow \quad 2r^2 = 8 \quad \Rightarrow \quad r = 2$$

Therefore, the projection $\mathcal{D}$ of $\mathcal{W}$ onto the xy-plane is the region enclosed by the circle $r = 2$, and $\mathcal{D}$ has the following description:

$$\mathcal{D}: 0 \le \theta \le 2\pi,\ 0 \le r \le 2$$

The upper and lower boundaries of $\mathcal{W}$ are $z = 8 - r^2$ and $z = r^2$, respectively. Hence,

$$\mathcal{W}: 0 \le \theta \le 2\pi,\ 0 \le r \le 2,\ r^2 \le z \le 8 - r^2$$

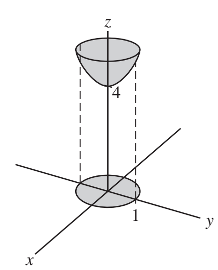
(b) Using change of variables in cylindrical coordinates, we get

$$\text{Volume}(\mathcal{W}) = \iiint_{\mathcal{W}} 1\,dV = \int_0^{2\pi} \int_0^2 \int_{r^2}^{8-r^2} r\,dz\,dr\,d\theta = \int_0^{2\pi} \int_0^2 rz\Big|_{z=r^2}^{8-r^2} dr\,d\theta = \int_0^{2\pi} \int_0^2 r\left(8 - 2r^2\right) dr\,d\theta$$

$$= \int_0^{2\pi} \int_0^2 \left(8r - 2r^3\right) dr\,d\theta = \int_0^{2\pi} 4r^2 - \frac{r^4}{2}\Big|_{r=0}^2 d\theta = \int_0^{2\pi} 8\,d\theta = 16\pi$$

26. Use cylindrical coordinates to calculate the integral of the function $f(x, y, z) = z$ over the region above the disk $x^2 + y^2 = 1$ in the xy-plane and below the surface $z = 4 + x^2 + y^2$.

SOLUTION



The upper boundary is the surface $z = 4 + r^2$, and the lower boundary is the xy-plane $z = 0$. The projection $\mathcal{D}$ onto the xy-plane is the region $x^2 + y^2 \le 1$, having the polar description

$$\mathcal{D}: 0 \le \theta \le 2\pi,\ 0 \le r \le 1$$

Therefore, the inequalities for $\mathcal{W}$ in cylindrical coordinates are

$$\mathcal{W}: 0 \le \theta \le 2\pi,\ 0 \le r \le 1,\ 0 \le z \le 4 + r^2$$

Using cylindrical coordinates we obtain the following integral:

$$\iiint_{\mathcal{W}} z\,dV = \int_0^{2\pi} \int_0^1 \int_0^{4+r^2} zr\,dz\,dr\,d\theta = \int_0^{2\pi} \int_0^1 \frac{z^2 r}{2}\Big|_{z=0}^{4+r^2} dr\,d\theta = \int_0^{2\pi} \int_0^1 \frac{\left(4 + r^2\right)^2 r}{2}\,dr\,d\theta \qquad (1)$$

We compute the inner integral using the substitution $u = 4 + r^2$, $du = 2r\,dr$:

$$\int_0^1 \frac{\left(4 + r^2\right)^2 r}{2}\,dr = \int_4^5 \frac{u^2}{2} \cdot \frac{du}{2} = \int_4^5 \frac{u^2}{4}\,du = \frac{u^3}{12}\Big|_4^5 = \frac{61}{12}.$$

Substituting in (1) gives

$$\iiint_{\mathcal{W}} z\,dV = \int_0^{2\pi} \frac{61}{12}\,d\theta = \frac{61}{12}\theta\Big|_0^{2\pi} = \frac{61}{12} \cdot 2\pi = \frac{61\pi}{6} \approx 31.94$$

In Exercises 27–32, use cylindrical coordinates to calculate $\iiint_{\mathcal{W}} f(x, y, z)\, dV$ *for the given function and region.*

27. $f(x, y, z) = x^2 + y^2;\quad x^2 + y^2 \le 9,\quad 0 \le z \le 5$

SOLUTION The projection of $\mathcal{W}$ onto the xy-plane is the region inside the circle $x^2 + y^2 = 9$. In polar coordinates,

$$\mathcal{D}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le 3$$

The upper and lower boundaries are the planes $z = 5$ and $z = 0$, respectively. Therefore, $\mathcal{W}$ has the following description in cylindrical coordinates:

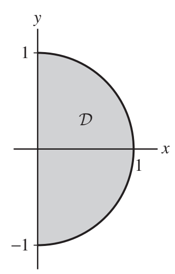
$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le 3,\ 0 \le z \le 5$$

The integral in cylindrical coordinates is thus

$$\iiint_{\mathcal{W}} (x^2 + y^2)\, dV = \int_0^{2\pi}\int_0^3\int_0^5 r^2 \cdot r\, dz\, dr\, d\theta = \int_0^{2\pi}\int_0^3\int_0^5 r^3\, dz\, dr\, d\theta$$
$$= \left(\int_0^{2\pi} 1\, d\theta\right)\left(\int_0^3 r^3\, dr\right)\left(\int_0^5 1\, dz\right) = 2\pi \cdot 5 \cdot \frac{r^4}{4}\bigg|_0^3 = \frac{5 \cdot 3^4 \pi}{2} \approx 636.17$$

28. $f(x, y, z) = xz;\quad x^2 + y^2 \le 1,\quad x \ge 0,\quad 0 \le z \le 2$

SOLUTION



$\mathcal{W}$ projects onto the semicircle $\mathcal{D}$ in the xy-plane of radius 1, where $x \ge 0$. In polar coordinates we have

$$\mathcal{D}:\ -\frac{\pi}{2} \le \theta \le \frac{\pi}{2},\ 0 \le r \le 1$$

The upper and lower boundaries of $\mathcal{W}$ are the planes $z = 2$ and $z = 0$, respectively; therefore, $\mathcal{W}$ has the following description in cylindrical coordinates:

$$\mathcal{W}:\ -\frac{\pi}{2} \le \theta \le \frac{\pi}{2},\ 0 \le r \le 1,\ 0 \le z \le 2$$

The function in cylindrical coordinates is

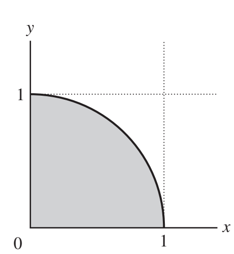
$$f(x, y, z) = xz = (r\cos\theta)z = zr\cos\theta$$

We obtain the following integral:

$$\iiint_{\mathcal{W}} xz\, dV = \int_{-\pi/2}^{\pi/2}\int_0^1\int_0^2 zr\cos\theta \cdot r\, dz\, dr\, d\theta = \int_{-\pi/2}^{\pi/2}\int_0^1\int_0^2 zr^2\cos\theta\, dz\, dr\, d\theta$$
$$= \left(\int_{-\pi/2}^{\pi/2}\cos\theta\, d\theta\right)\left(\int_0^1 r^2\, dr\right)\left(\int_0^2 z\, dz\right) = \left(\sin\theta\bigg|_{-\pi/2}^{\pi/2}\right)\left(\frac{r^3}{3}\bigg|_0^1\right)\left(\frac{z^2}{2}\bigg|_0^2\right) = 2 \cdot \frac{1}{3} \cdot 2 = \frac{4}{3}$$

29. $f(x, y, z) = y;\quad x^2 + y^2 \le 1,\quad x \ge 0,\quad y \ge 0,\quad 0 \le z \le 2$

SOLUTION



The projection of $\mathcal{W}$ onto the xy-plane is the quarter of the unit circle in the first quadrant. It is defined by the following polar equations:

$$\mathcal{D}: 0 \le \theta \le \frac{\pi}{2},\ 0 \le r \le 1$$

The upper and lower boundaries of $\mathcal{W}$ are the planes $z = 2$ and $z = 0$, respectively; hence, $\mathcal{W}$ has the following definition:

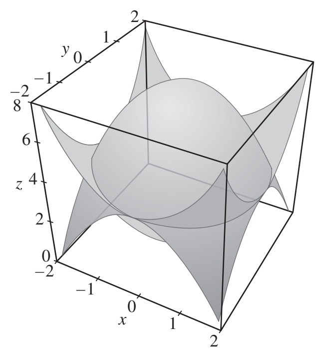
$$\mathcal{W}: 0 \le \theta \le \frac{\pi}{2},\ 0 \le r \le 1,\ 0 \le z \le 2$$

The function is $f(x, y, z) = y = r\sin\theta$. The integral in cylindrical coordinates is thus

$$\iiint_{\mathcal{W}} y\,dV = \int_0^{\pi/2}\int_0^1\int_0^2 (r\sin\theta)r\,dz\,dr\,d\theta = \int_0^{\pi/2}\int_0^1\int_0^2 r^2\sin\theta\,dz\,dr\,d\theta$$
$$= \left(\int_0^{\pi/2}\sin\theta\,d\theta\right)\left(\int_0^1 r^2\,dr\right)\left(\int_0^2 1\,dz\right) = \left(-\cos\theta\Big|_0^{\pi/2}\right)\left(\frac{r^3}{3}\Big|_0^1\right)\left(z\Big|_0^2\right) = 1\cdot\frac{1}{3}\cdot 2 = \frac{2}{3}$$

30. $f(x, y, z) = z\sqrt{x^2 + y^2}$; $\quad x^2 + y^2 \le z \le 8 - (x^2 + y^2)$

SOLUTION

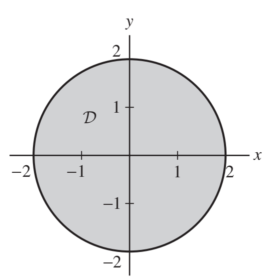


$\mathcal{W}$ is the region enclosed by the upper surface $z = 8 - (x^2 + y^2) = 8 - r^2$ and the lower surface $z = x^2 + y^2 = r^2$, that is, $r^2 \le z \le 8 - r^2$. To find the projection $\mathcal{D}$ of $\mathcal{W}$ onto the xy-plane, we first find the curve of intersection of $z = 8 - r^2$ and $z = r^2$ by solving the equation

$$8 - r^2 = r^2 \quad\Rightarrow\quad 8 = 2r^2 \quad\Rightarrow\quad r^2 = 4 \quad\Rightarrow\quad r = 2$$

We conclude that $\mathcal{D}$ is the region in the xy-plane enclosed by the circle of radius 2:

$$\mathcal{D}: 0 \le \theta \le 2\pi,\ 0 \le r \le 2$$



The inequalities describing $\mathcal{W}$ in cylindrical coordinates are thus

$$\mathcal{W}: 0 \le \theta \le 2\pi,\ 0 \le r \le 2,\ r^2 \le z \le 8 - r^2$$

The function in cylindrical coordinates is

$$f(x, y, z) = z\sqrt{x^2 + y^2} = zr$$

We obtain the following integral:

$$\iiint_{\mathcal{W}} z\sqrt{x^2 + y^2}\,dA = \int_0^{2\pi}\int_0^2\int_{r^2}^{8-r^2} zr\cdot r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^2\int_{r^2}^{8-r^2} zr^2\,dz\,dr\,d\theta$$

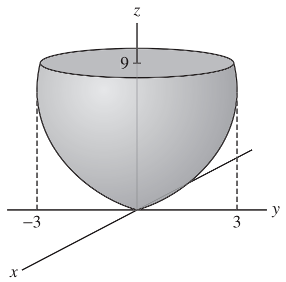
$$= \int_0^{2\pi} \int_0^2 \frac{z^2 r^2}{2}\bigg|_{z=r^2}^{8-r^2} dr\, d\theta = \int_0^{2\pi} \int_0^2 \frac{r^2\left((8-r^2)^2 - r^4\right)}{2}\, dr\, d\theta$$

$$= \int_0^{2\pi} \int_0^2 8r^2(4-r^2)\, dr\, d\theta = \left(\int_0^{2\pi} 8\, d\theta\right)\left(\int_0^2 \left(4r^2 - r^4\right) dr\right)$$

$$= 16\pi \cdot \left(\frac{4r^3}{3} - \frac{r^5}{5}\bigg|_0^2\right) = \frac{1024}{15}\pi \approx 214.47$$

31. $f(x, y, z) = z;\quad x^2 + y^2 \le z \le 9$

SOLUTION



The upper boundary of $\mathcal{W}$ is the plane $z = 9$, and the lower boundary is $z = x^2 + y^2 = r^2$. Therefore, $r^2 \le z \le 9$. The projection $\mathcal{D}$ onto the xy-plane is the circle $x^2 + y^2 = 9$ or $r = 3$. That is,

$$\mathcal{D}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le 3$$

The inequalities defining $\mathcal{W}$ in cylindrical coordinates are thus

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le 3,\ r^2 \le z \le 9$$

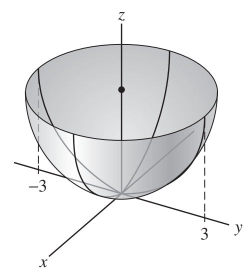
Therefore, we obtain the following integral:

$$\iiint_{\mathcal{W}} z\, dV = \int_0^{2\pi} \int_0^3 \int_{r^2}^9 zr\, dz\, dr\, d\theta = \int_0^{2\pi} \int_0^3 \frac{z^2 r}{2}\bigg|_{z=r^2}^9 dr\, d\theta = \int_0^{2\pi} \int_0^3 \frac{r(81-r^4)}{2}\, dr\, d\theta$$

$$= \int_0^{2\pi} \int_0^3 \frac{81r - r^5}{2}\, dr\, d\theta = \int_0^{2\pi} \frac{81r^2}{4} - \frac{r^6}{12}\bigg|_0^3 d\theta = \int_0^{2\pi} 121.5\, d\theta = 243\pi$$

32. $f(x, y, z) = z;\quad 0 \le z \le x^2 + y^2 \le 9$

SOLUTION

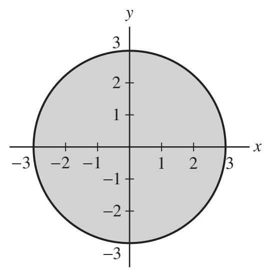


The condition $0 \le z \le x^2 + y^2 = r^2$ tells us that the upper surface is $z = r^2$ and the lower surface is $z = 0$. Also, $x^2 + y^2 \le 9$ or $r \le 3$, hence the projection of $\mathcal{W}$ onto the xy-plane is the region inside the circle $r = 3$. That is,

$$\mathcal{D}: 0 \le \theta \le 2\pi,\ 0 \le r \le 3$$

And $\mathcal{W}$ is determined by

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le 3,\ 0 \le z \le r^2$$



Therefore, we obtain the following integral in cylindrical coordinates:

$$\iiint_{\mathcal{W}} z\,dV = \int_0^{2\pi}\int_0^3\int_0^{r^2} z\cdot r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^3 \frac{z^2 r}{2}\bigg|_{z=0}^{r^2} dr\,d\theta = \int_0^{2\pi}\int_0^3 \frac{r^5}{2}\,dr\,d\theta$$
$$= \int_0^{2\pi} \frac{r^6}{12}\bigg|_0^3 d\theta = \int_0^{2\pi} \frac{729}{12}\,d\theta = \frac{729}{12}\cdot 2\pi = 121.5\pi$$

In Exercises 33–36, express the triple integral in cylindrical coordinates.

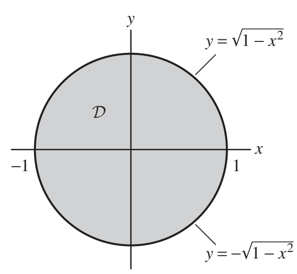
33. $\displaystyle\int_{-1}^{1}\int_{y=-\sqrt{1-x^2}}^{y=\sqrt{1-x^2}}\int_{z=0}^{4} f(x,y,z)\,dz\,dy\,dx$

SOLUTION The region of integration is determined by the limits of integration. That is,

$$\mathcal{W}:\ -1\le x\le 1,\ -\sqrt{1-x^2}\le y\le\sqrt{1-x^2},\ 0\le z\le 4$$

Therefore the projection of $\mathcal{W}$ onto the xy-plane is the disk $x^2+y^2\le 1$. This region has the following definition in polar coordinates:

$$\mathcal{D}:\ 0\le\theta\le 2\pi,\ 0\le r\le 1$$



The upper and lower boundaries of $\mathcal{W}$ are the planes $z=4$ and $z=0$, respectively. Hence,

$$\mathcal{W}:\ 0\le\theta\le 2\pi,\ 0\le r\le 1,\ 0\le z\le 4$$

Using change of variables in cylindrical coordinates, we get the integral

$$\int_0^{2\pi}\int_0^1\int_0^4 f(r\cos\theta, r\sin\theta, z) r\,dz\,dr\,d\theta$$

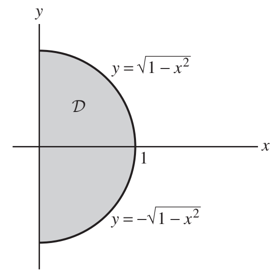
34. $\displaystyle\int_{0}^{1}\int_{y=-\sqrt{1-x^2}}^{y=\sqrt{1-x^2}}\int_{z=0}^{4} f(x,y,z)\,dz\,dy\,dx$

SOLUTION The region of integration is determined by the limits of integration. That is,

$$\mathcal{W}:\ 0\le x\le 1,\ -\sqrt{1-x^2}\le y\le\sqrt{1-x^2},\ 0\le z\le 4$$

Thus, the projection $\mathcal{D}$ of $\mathcal{W}$ onto the xy-plane is the semicircle $x^2+y^2=1$, where $0\le x\le 1$. This region is described by the polar inequalities

$$\mathcal{D}:\ -\frac{\pi}{2}\le\theta\le\frac{\pi}{2},\ 0\le r\le 1$$



The upper and lower boundaries of $\mathcal{W}$ are the planes $z = 4$ and $z = 0$, respectively. Hence,

$$\mathcal{W}: -\frac{\pi}{2} \le \theta \le \frac{\pi}{2},\ 0 \le r \le 1,\ 0 \le z \le 4$$

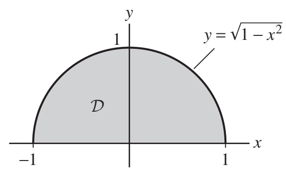
The integral in cylindrical coordinates is thus

$$\int_{-\pi/2}^{\pi/2} \int_0^1 \int_0^4 f(r\cos\theta, r\sin\theta, z) r\, dz\, dr\, d\theta$$

35. $\displaystyle\int_{-1}^{1} \int_{y=0}^{y=\sqrt{1-x^2}} \int_{z=0}^{x^2+y^2} f(x,y,z)\, dz\, dy\, dx$

SOLUTION The inequalities defining the region of integration are

$$\mathcal{W}: -1 \le x \le 1,\ 0 \le y \le \sqrt{1-x^2},\ 0 \le z \le x^2 + y^2$$



The projection of $\mathcal{W}$ onto the xy-plane is the semicircle $x^2 + y^2 = 1$, where $-1 \le x \le 1$. This domain is defined by the polar inequalities

$$\mathcal{D}: 0 \le \theta \le \pi,\ 0 \le r \le 1$$

The lower surface is $z = 0$ and upper surface is $z = x^2 + y^2 = r^2$, hence $\mathcal{W}$ has the following description in cylindrical coordinates:

$$\mathcal{W}: 0 \le \theta \le \pi,\ 0 \le r \le 1,\ 0 \le z \le r^2$$

We obtain the following integral:

$$\int_0^{\pi} \int_0^1 \int_0^{r^2} f(r\cos\theta, r\sin\theta, z) r\, dz\, dr\, d\theta$$

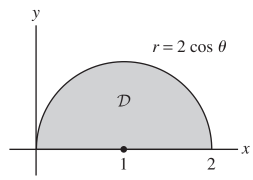
36. $\displaystyle\int_0^2 \int_{y=0}^{y=\sqrt{2x-x^2}} \int_{z=0}^{\sqrt{x^2+y^2}} f(x,y,z)\, dz\, dy\, dx$

SOLUTION The inequalities defining the region of integration are

$$\mathcal{W}: 0 \le x \le 2,\ 0 \le y \le \sqrt{2x-x^2},\ 0 \le z \le \sqrt{x^2+y^2}$$

The curve $y = \sqrt{2x - x^2}$ is the semicircle of radius 1 centered at $(1, 0)$, where $y \ge 0$. We find the polar equation of the semicircle:

$$\begin{aligned} r\sin\theta &= \sqrt{2r\cos\theta - r^2\cos^2\theta} \\ r^2\sin^2\theta &= 2r\cos\theta - r^2\cos^2\theta \\ r^2(\sin^2\theta + \cos^2\theta) &= 2r\cos\theta \\ r^2 &= 2r\cos\theta \quad \Rightarrow \quad r = 2\cos\theta \quad \text{and} \quad 0 \le \theta \le \frac{\pi}{2} \end{aligned}$$



Therefore the projection of $\mathcal{W}$ onto the xy-plane is defined by the polar inequalities

$$\mathcal{D} : 0 \le \theta \le \frac{\pi}{2},\ 0 \le r \le 2\cos\theta$$

The lower boundary of $\mathcal{W}$ is the plane $z = 0$ and the upper boundary is $z = \sqrt{x^2 + y^2} = r$, hence $\mathcal{W}$ has the following cylindrical definition:

$$\mathcal{W} : 0 \le \theta \le \frac{\pi}{2},\ 0 \le r \le 2\cos\theta,\ 0 \le z \le r$$

The integral in cylindrical coordinates is

$$\int_0^{\pi/2} \int_0^{2\cos\theta} \int_0^r f(r\cos\theta, r\sin\theta, z) r\, dz\, dr\, d\theta$$

37. Find the equation of the right-circular cone in Figure 21 in cylindrical coordinates and compute its volume.

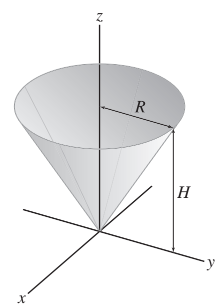


FIGURE 21

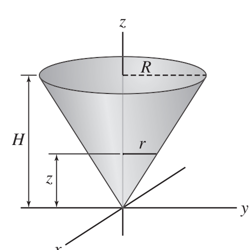
SOLUTION To find the equation of the surface we use proportion in similar triangles.



This gives

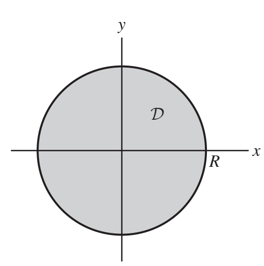
$$\frac{z}{H} = \frac{r}{R} \quad \Rightarrow \quad z = \frac{H}{R} r$$

The volume of the right circular cone is

$$V = \iiint_{\mathcal{W}} 1\, dV$$

The projection of $\mathcal{W}$ onto the xy-plane is the region $x^2 + y^2 \le R^2$, or in polar coordinates,

$$\mathcal{D} : 0 \le \theta \le 2\pi,\ 0 \le r \le R$$



The upper and lower boundaries are the surfaces $z = H$ and $z = \frac{H}{R}r$, respectively. Hence $\mathcal{W}$ is determined by the following cylindrical inequalities:

$$\mathcal{W}: 0 \le \theta \le 2\pi,\ 0 \le r \le R,\ \frac{H}{R}r \le z \le H$$

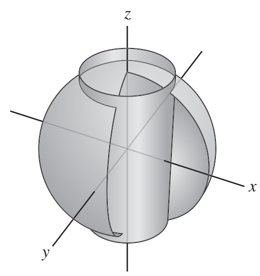
We compute the volume using the following integral:

$$V = \iiint_{\mathcal{W}} 1\,dv = \int_0^{2\pi}\int_0^R\int_{\frac{H}{R}r}^{H} r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^R rz\Big|_{z=\frac{Hr}{R}}^{H} dr\,d\theta = \int_0^{2\pi}\int_0^R r\left(H - \frac{Hr}{R}\right) dr\,d\theta$$

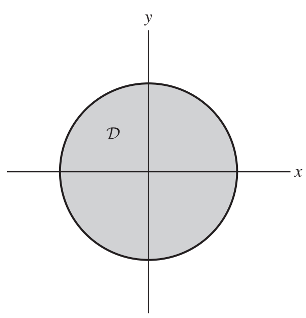
$$= \int_0^{2\pi}\int_0^R \left(rH - \frac{r^2H}{R}\right) dr\,d\theta = \int_0^{2\pi} \frac{r^2H}{2} - \frac{r^3H}{3R}\Big|_{r=0}^{R} d\theta = \int_0^{2\pi} \frac{R^2H}{6}\,d\theta = \frac{R^2H}{6}\cdot 2\pi = \frac{\pi R^2 H}{3}$$

38. Use cylindrical coordinates to integrate $f(x, y, z) = z$ over the intersection of the hemisphere $x^2 + y^2 + z^2 = 4$, $z \ge 0$, and the cylinder $x^2 + y^2 = 1$.

SOLUTION



The region of integration projects onto the circle $\mathcal{D}$ of radius 1 in the xy-plane.



In polar coordinates,

$$\mathcal{D}: 0 \le \theta \le 2\pi,\ 0 \le r \le 1$$

The upper boundary of $\mathcal{W}$ is the sphere

$$x^2 + y^2 + z^2 = 4 \quad \text{or} \quad z = \sqrt{4 - (x^2 + y^2)} = \sqrt{4 - r^2}$$

and the lower boundary is $z = -\sqrt{4 - r^2}$. Therefore,

$$\mathcal{W}: 0 \le \theta \le 2\pi,\ 0 \le r \le 1,\ -\sqrt{4 - r^2} \le z \le \sqrt{4 - r^2}$$

We obtain the following integral in cylindrical coordinates:

$$\iiint_{\mathcal{W}} z\,dV = \int_0^{2\pi}\int_0^1\int_{-\sqrt{4-r^2}}^{\sqrt{4-r^2}} zr\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^1 \frac{z^2r}{2}\Big|_{z=-\sqrt{4-r^2}}^{\sqrt{4-r^2}} dr\,d\theta = \int_0^{2\pi}\int_0^1 0\,dr\,d\theta = 0$$

This should not surprise us since $\mathcal{W}$ is symmetric with respect to $z = 0$ and f is antisymmetric.

39. Use cylindrical coordinates to calculate the volume of the solid obtained by removing a central cylinder of radius b from a sphere of radius a where $b < a$.

SOLUTION Firstly, the equation of the sphere having radius a is

$$x^2 + y^2 + z^2 = a^2 \quad \Rightarrow \quad r^2 + z^2 = a^2$$

in cylindrical coordinates. Next, the equation of the cylinder with radius b that is being removed from the sphere is

$$x^2 + y^2 = b^2 \quad \Rightarrow \quad r^2 = b^2 \quad \Rightarrow \quad r = b$$

in cylindrical coordinates. Thus the region that is remaining can be described by the following inequalities in cylindrical coordinates:

$$0 \le \theta \le 2\pi, \quad 0 \le r \le b, \quad -\sqrt{a^2 - r^2} \le z \le \sqrt{a^2 - r^2}$$

Thus the volume can be computed:

$$\begin{aligned} V &= \iiint_{\mathcal{W}} 1\, dV = \iiint_{\mathcal{W}} r\, dz\, dr\, d\theta \\ &= 2\int_0^{2\pi} \int_b^a \int_0^{\sqrt{a^2-r^2}} r\, dz\, dr\, d\theta \\ &= 2\int_0^{2\pi} \int_b^a rz\Big|_{z=0}^{\sqrt{a^2-r^2}} dr\, d\theta \\ &= 2\int_0^{2} \pi \int_b^a r\sqrt{a^2 - r^2}\, dr\, d\theta \\ &= 2\int_0^{2\pi} -\frac{1}{2} \cdot \frac{2}{3}\left(a^2 - r^2\right)^{3/2}\Big|_{r=b}^{a} d\theta \\ &= \frac{2}{3}\int_0^{2\pi} \left(a^2 - b^2\right)^{3/2} d\theta = \frac{2}{3}\left(a^2 - b^2\right)^{3/2} \cdot \theta\Big|_{\theta=0}^{2\pi} \\ &= \frac{4}{3}\pi\left(a^2 - b^2\right)^{3/2} \end{aligned}$$

40. Find the volume of the region in Figure 22.

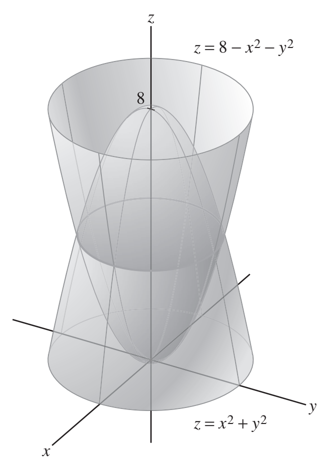


FIGURE 22

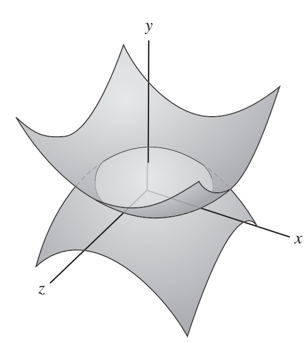
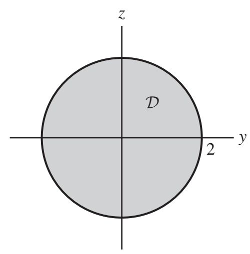
SOLUTION



We first must identify the domain of integration in the xy-plane. To do this we equate the equations of the two surfaces. That is,

$$x^2 + y^2 = 8 - x^2 - y^2 \quad \Rightarrow \quad 2(x^2 + y^2) = 8 \quad \Rightarrow \quad x^2 + y^2 = 4$$



Therefore, the domain of integration is

$$\mathcal{D} = \left\{(x, y); x^2 + y^2 \le 4\right\}$$

The double integrals $\iint_{\mathcal{D}} (x^2 + y^2)\, dA$ and $\iint_{\mathcal{D}} (8 - x^2 - y^2)\, dA$ give the volumes of the regions bounded by the graphs of $z = x^2 + y^2$ and $z = 8 - x^2 - y^2$, respectively, and the xy-plane over the region $\mathcal{D}$. Therefore, the volume of the required region is the difference between these two integrals (see figure). That is,

$$V = \iint_{\mathcal{D}} (8 - x^2 - y^2)\, dA - \iint_{\mathcal{D}} (x^2 + y^2)\, dA = \iint_{\mathcal{D}} \Big((8 - x^2 - y^2) - (x^2 + y^2)\Big)\, dA$$

or

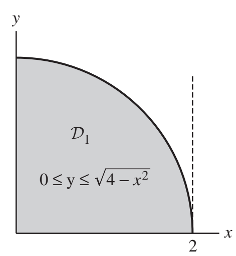
$$V = \iint_{\mathcal{D}} (8 - 2x^2 - 2y^2)\, dA$$

To compute the double integral we first notice that, since the function $f(x, y) = 8 - 2x^2 - 2y^2$ satisfies $f(x, -y) = f(x, y)$ and $f(-x, y) = f(x, y)$, and the circle $\mathcal{D}$ is symmetric with respect to the x and y axes, the double integral over $\mathcal{D}$ is four times the integral over the part $\mathcal{D}_1$ of the circle in the first quadrant. That is,

$$V = 4 \iint_{\mathcal{D}_1} (8 - 2x^2 - 2y^2)\, dA$$

$\mathcal{D}_1$ is the vertically simple region described by the inequalities

$$0 \le x \le 2, \quad 0 \le y \le \sqrt{4 - x^2}$$



Since this is a portion of a circle, using cylindrical coordinates we can write this vertically simple region using the inequalities:

$$0 \le \theta \le \frac{\pi}{2}, \quad 0 \le r \le 2$$

$$V = 4 \iint_{\mathcal{D}_1} (8 - 2x^2 - 2y^2)\, dA = 4 \int_0^{\pi/2} \int_0^2 (8 - 2r^2) r\, dr\, d\theta$$

$$= 4 \int_0^{\pi/2} \int_0^2 8r - 2r^3\, dr\, d\theta = 4 \int_0^{\pi/2} 4r^2 - \frac{1}{2} r^4 \bigg|_0^2 d\theta$$

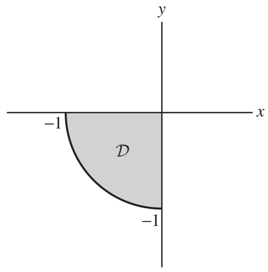
$$= 4 \int_0^{\pi/2} 8\, d\theta = 32 \cdot \frac{\pi}{2} = 16\pi$$

So the volume is 16π.

In Exercises 41–46, use spherical coordinates to calculate the triple integral of $f(x, y, z)$ over the given region.

41. $f(x, y, z) = y; \quad x^2 + y^2 + z^2 \le 1, \quad x, y, z \le 0$

SOLUTION



The region inside the unit sphere in the octant $x, y, z \le 0$ is defined by the inequalities

$$\mathcal{W}: \pi \le \theta \le \frac{3\pi}{2}, \ \frac{\pi}{2} \le \phi \le \pi, \ 0 \le \rho \le 1$$

The function in spherical coordinates is $f(x, y, z) = y = \rho \sin\theta \sin\phi$. Using a triple integral in spherical coordinates, we obtain

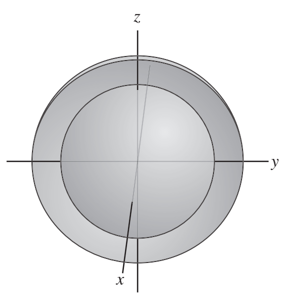
$$\iiint_{\mathcal{W}} y\, dV = \int_{\pi}^{3\pi/2} \int_{\pi/2}^{\pi} \int_0^1 (\rho \sin\theta \sin\phi)\rho^2 \sin\phi\, d\rho\, d\phi\, d\theta = \int_{\pi}^{3\pi/2} \int_{\pi/2}^{\pi} \int_0^1 \rho^3 \sin\theta \sin^2\phi\, d\rho\, d\phi\, d\theta$$

$$= \left(\int_{\pi}^{3\pi/2} \sin\theta\, d\theta\right)\left(\int_{\pi/2}^{\pi} \sin^2\phi\, d\phi\right)\left(\int_0^1 \rho^3 d\rho\right) = \left(-\cos\theta \Big|_{\pi}^{3\pi/2}\right)\left(\frac{\theta}{2} - \frac{\sin 2\theta}{4}\Big|_{\pi/2}^{\pi}\right)\left(\frac{\rho^4}{4}\Big|_0^1\right)$$

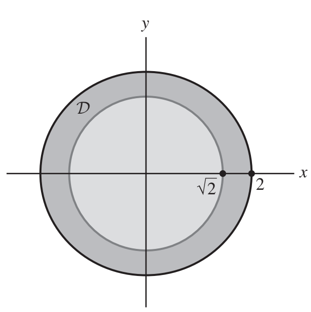
$$= (-1)\cdot\left(\frac{\pi}{2} - \frac{\pi}{4}\right)\cdot\frac{1}{4} = -\frac{\pi}{16}$$

42. $f(x, y, z) = \rho^{-3}; \quad 2 \le x^2 + y^2 + z^2 \le 4$

SOLUTION



The lower and upper boundaries of $\mathcal{W}$ are the spheres $x^2 + y^2 + z^2 = 2$ and $x^2 + y^2 + z^2 = 4$. Therefore, ρ varies from $\sqrt{2}$ to 2, ϕ varies from 0 to π, and θ varies from 0 to 2π.



That is, $\mathcal{W}$ is defined by the inequalities

$$\mathcal{W}: 0 \le \theta \le 2\pi, \ 0 \le \phi \le \pi, \ \sqrt{2} \le \rho \le 2$$

The triple integral in spherical coordinates is thus

$$\iiint_{\mathcal{W}} f(x,y,z)\,dV = \int_0^{2\pi}\int_0^{\pi}\int_{\sqrt{2}}^{2} \rho^{-3}\rho^2 \sin\phi\,d\rho\,d\phi\,d\theta = \int_0^{2\pi}\int_0^{\pi}\int_{\sqrt{2}}^{2} \rho^{-1}\sin\phi\,d\rho\,d\phi\,d\theta$$
$$= \left(\int_0^{2\pi} 1\,d\theta\right)\left(\int_0^{\pi}\sin\phi\,d\phi\right)\left(\int_{\sqrt{2}}^{2}\rho^{-1}\,d\rho\right) = \left(\theta\Big|_0^{2\pi}\right)\left(-\cos\phi\Big|_0^{\pi}\right)\left(\ln\rho\Big|_{\sqrt{2}}^{2}\right)$$
$$= 2\pi\cdot 2\cdot\left(\ln 2 - \frac{1}{2}\ln 2\right) = 2\pi\ln 2$$

43. $f(x,y,z) = x^2+y^2;\quad \rho\le 1$

SOLUTION $\mathcal{W}$ is the region inside the unit sphere, therefore it is described by the following inequalities:

$$\mathcal{W}:\ 0\le\theta\le 2\pi,\ 0\le\phi\le\pi,\ 0\le\rho\le 1$$

The function in spherical coordinates is

$$f(x,y,z) = x^2+y^2 = (\rho\cos\theta\sin\phi)^2 + (\rho\sin\theta\sin\phi)^2$$
$$= \rho^2\sin^2\phi\left(\cos^2\theta+\sin^2\theta\right) = \rho^2\sin^2\phi$$

Using triple integrals in spherical coordinates we get

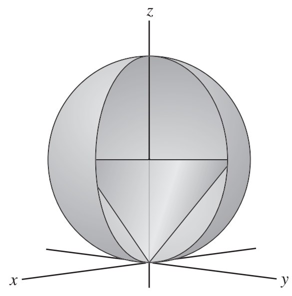
$$\iiint_{\mathcal{W}} (x^2+y^2)\,dV = \int_0^{2\pi}\int_0^{\pi}\int_0^{1} (\rho^2\sin^2\phi)\rho^2\sin\phi\,d\rho\,d\phi\,d\theta$$
$$= \int_0^{2\pi}\int_0^{\pi}\int_0^{1}\rho^4\sin^3\phi\,d\rho\,d\phi\,d\theta = \left(\int_0^{2\pi}1\,d\theta\right)\left(\int_0^{\pi}\sin^3\phi\,d\phi\right)\left(\int_0^1\rho^4 d\rho\right)$$
$$= \left(\theta\Big|_0^{2\pi}\right)\left(-\frac{\sin^2\theta\cos\theta}{3} - \frac{2}{3}\cos\theta\Big|_0^{\pi}\right)\left(\frac{\rho^5}{5}\Big|_0^1\right) = 2\pi\cdot\left(\frac{2}{3}+\frac{2}{3}\right)\cdot\frac{1}{5} = \frac{8\pi}{15}$$

44. $f(x,y,z) = 1;\quad x^2+y^2+z^2\le 4z,\quad z\ge\sqrt{x^2+y^2}$

SOLUTION The inequality $x^2+y^2+z^2\le 4z$ can be rewritten as

$$x^2+y^2+z^2-4z\le 0 \quad\Rightarrow\quad x^2+y^2+(z-2)^2\le 4$$

This inequality defines the region inside the sphere of radius 2 centered at $(0,0,2)$. Therefore, $\mathcal{W}$ is the region inside the sphere, above the cone $z=\sqrt{x^2+y^2}$.



We write the equation of the sphere $x^2+y^2+z^2=4z$ in spherical coordinates:

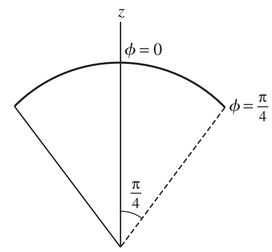
$$(\rho\cos\theta\sin\phi)^2 + (\rho\sin\theta\sin\phi)^2 + (\rho\cos\phi)^2 = 4\rho\cos\phi$$
$$\rho^2\sin^2\phi\left(\cos^2\theta+\sin^2\theta\right) + \rho^2\cos^2\phi = 4\rho\cos\phi$$
$$\rho^2\sin^2\phi + \rho^2\cos^2\phi = 4\rho\cos\phi$$
$$\rho^2 = 4\rho\cos\phi$$
$$\rho = 4\cos\phi$$

We write the equation of the cone $z=\sqrt{x^2+y^2}$ in spherical coordinates:

$$\rho\cos\phi = \sqrt{(\rho\cos\theta\sin\phi)^2+(\rho\sin\theta\sin\phi)^2} = \sqrt{\rho^2\sin^2\phi} = \rho\sin\phi$$

or

$$\tan\phi = 1 \quad \Rightarrow \quad \phi = \frac{\pi}{4}$$



The spherical inequalities for $\mathcal{W}$ are thus

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le \phi \le \frac{\pi}{4},\ 0 \le \rho \le 4\cos\phi$$

We obtain the following integral:

$$\iiint_{\mathcal{W}} 1\,dV = \int_0^{2\pi}\int_0^{\pi/4}\int_0^{4\cos\phi} \rho^2 \sin\phi\,d\rho\,d\phi\,d\theta = \int_0^{2\pi}\int_0^{\pi/4} \left.\frac{\rho^3\sin\phi}{3}\right|_{\rho=0}^{4\cos\phi} d\phi\,d\theta$$

$$= \int_0^{2\pi}\int_0^{\pi/4} \frac{64\cos^3\phi\sin\phi}{3}\,d\phi\,d\theta = \left(\int_0^{2\pi}\frac{64}{3}\,d\theta\right)\left(\int_0^{\pi/4}\cos^3\phi\sin\phi\,d\phi\right)$$

$$= \frac{128\pi}{3}\int_0^{\pi/4}\cos^3\phi\sin\phi\,d\phi$$

We compute the integral using the substitution $u = \cos\phi$, $du = -\sin\phi\,d\phi$:

$$\iiint_{\mathcal{W}} 1\,dV = \frac{128\pi}{3}\int_1^{1/\sqrt{2}} u^3(-du) = \frac{128\pi}{3}\int_{1/\sqrt{2}}^1 u^3\,du = \frac{128\pi}{3}\cdot\left.\frac{u^4}{4}\right|_{1/\sqrt{2}}^1 = 8\pi$$

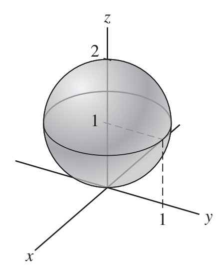
45. $f(x,y,z) = \sqrt{x^2+y^2+z^2}$; $\quad x^2+y^2+z^2 \le 2z$

SOLUTION We rewrite the inequality for the region using spherical coordinates:

$$\rho^2 \le 2\rho\cos\phi \quad \Rightarrow \quad \rho \le 2\cos\phi$$

Completing the square in $x^2+y^2+z^2 = 2z$, we see that this is the equation of the sphere of radius 1 centered at (0, 0, 1). That is,

$$x^2 + y^2 + z - 2z = 0$$
$$x^2 + y^2 + (z-1)^2 = 1$$



$\mathcal{W}$ is the region inside the sphere, hence θ varies from 0 to 2π, and ϕ varies from 0 to $\frac{\pi}{2}$. The inequalities describing $\mathcal{W}$ in spherical coordinates are thus

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le \phi \le \frac{\pi}{2},\ 0 \le \rho \le 2\cos\phi$$

The function in spherical coordinates is

$$f(x,y,z) = \sqrt{x^2+y^2+z^2} = \rho.$$

We obtain the following integral:

$$I = \int_0^{2\pi} \int_0^{\pi/2} \int_0^{2\cos\phi} \rho \cdot \rho^2 \sin\phi \, d\rho \, d\phi \, d\theta = \int_0^{2\pi} \int_0^{\pi/2} \int_0^{2\cos\phi} \rho^3 \sin\phi \, d\rho \, d\phi \, d\theta$$

$$= \int_0^{2\pi} \int_0^{\pi/2} \frac{\rho^4 \sin\phi}{4}\Big|_{\rho=0}^{2\cos\phi} d\phi \, d\theta = \int_0^{2\pi} \int_0^{\pi/2} \frac{16\cos^4\phi \sin\phi}{4} \, d\phi \, d\theta$$

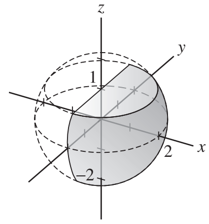
$$= \left(\int_0^{2\pi} 4 \, d\theta\right)\left(\int_0^{\pi/2} \cos^4\phi \sin\phi \, d\phi\right) = 8\pi \int_0^{\pi/2} \cos^4\phi \sin\phi \, d\phi$$

We compute the integral using the substitution $u = \cos\phi$, $du = -\sin\phi \, d\phi$. We obtain

$$I = 8\pi \int_1^0 u^4(-du) = 8\pi \int_0^1 u^4 \, du = 8\pi \frac{u^5}{5}\Big|_0^1 = \frac{8\pi}{5}$$

46. $f(x, y, z) = \rho; \quad x^2 + y^2 + z^2 \le 4, \quad z \le 1, \quad x \ge 0$

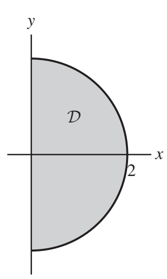
SOLUTION



$\mathcal{W}$ is the region inside the sphere of radius 2, below the plane $z = 1$ and above and below the right xy-plane. The equation of the sphere $x^2 + y^2 + z^2 = 4$ in spherical coordinates is $\rho = 2$, and the equation of the plane $z = 1$ is,

$$\rho\cos\phi = 1 \quad \Rightarrow \quad \rho = \frac{1}{\cos\phi} \tag{1}$$

To evaluate the triple integral we let $\mathcal{W}_1$ be the region inside the sphere above the plane $z = 1$ for $x \ge 0$, and $\mathcal{W}_2$ be the region enclosed by the sphere, for $x \ge 0$.

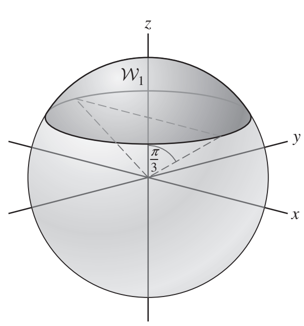


Thus,

$$\iiint_{\mathcal{W}} f(x, y, z) \, dV = \iiint_{\mathcal{W}_2} f(x, y, z) \, dV - \iiint_{\mathcal{W}_1} f(x, y, z) \, dV$$

Setting $\rho = 2$ in (1) gives

$$2 = \frac{1}{\cos\phi} \quad \Rightarrow \quad \cos\phi = \frac{1}{2} \quad \Rightarrow \quad \phi = \frac{\pi}{3}$$



Therefore, we obtain the following definition:

$$\mathcal{W}_1 : -\frac{\pi}{2} \le \theta \le \frac{\pi}{2}, \quad 0 \le \phi \le \frac{\pi}{3}, \quad \frac{1}{\cos\phi} \le \rho \le 2$$
$$\mathcal{W}_2 : -\frac{\pi}{2} \le \theta \le \frac{\pi}{2}, \quad 0 \le \phi \le \pi, \quad 0 \le \rho \le 2$$

We compute the integral over $\mathcal{W}_1$:

$$\begin{aligned}
\iiint_{\mathcal{W}_1} f(x,y,z)\,dV &= \int_{-\pi/2}^{\pi/2}\int_0^{\pi/3}\int_{1/\cos\phi}^{2} \rho\cdot\rho^2\sin\phi\,d\rho\,d\phi\,d\theta = \int_{-\pi/2}^{\pi/2}\int_0^{\pi/3}\int_{1/\cos\phi}^{2} \rho^3\sin\phi\,d\rho\,d\phi\,d\theta \\
&= \int_{-\pi/2}^{\pi/2}\int_0^{\pi/3} \frac{\rho^4\sin\phi}{4}\bigg|_{\rho=\frac{1}{\cos\phi}}^{2} d\phi\,d\theta = \int_{-\pi/2}^{\pi/2}\int_0^{\pi/3}\left(4\sin\phi - \frac{\sin\phi}{4\cos^4\phi}\right)d\phi\,d\theta \\
&= \left(\int_{-\pi/2}^{\pi/2} d\theta\right)\left(\int_0^{\pi/3}\left(4\sin\phi - \frac{\sin\phi}{4\cos^4\phi}\right)\right)d\phi \\
&= \pi\int_0^{\pi/3} 4\sin\phi\,d\phi - \pi\int_0^{\pi/3}\frac{\sin\phi}{4\cos^4\phi}\,d\phi \qquad (2)
\end{aligned}$$

We compute the second integral using the substitution $u = \cos\theta$, $du = -\sin\phi\,d\phi$, and the first using an integration formula. We get

$$\int_0^{\pi/3} 4\,\sin\phi\,d\phi = -4\cos\phi\bigg|_0^{\pi/3} = -4\left(\frac{1}{2}-1\right) = 2$$
$$\int_0^{\pi/3}\frac{\sin\phi}{4\cos^4\phi}d\phi = \int_1^{1/2}\frac{1}{4u^4}(-du) = \int_{1/2}^{1}\frac{u^{-4}}{4}\,du = \frac{u^{-3}}{-12}\bigg|_{1/2}^{1} = \frac{7}{12}$$

Substituting the integrals in (2) we get

$$\iiint_{\mathcal{W}_1} f(x,y,z)\,dV = 2\pi - \frac{7\pi}{12} = \frac{17\pi}{12} \qquad (3)$$

We compute the integral over $\mathcal{W}_2$:

$$\begin{aligned}
\iiint_{\mathcal{W}_2} f(x,y,z)\,dV &= \int_{-\pi/2}^{\pi/2}\int_0^{\pi}\int_0^{2}\rho\cdot\rho^2\sin\phi\,d\rho\,d\phi\,d\theta = \int_{-\pi/2}^{\pi/2}\int_0^{\pi}\int_0^{2}\rho^3\sin\phi\,d\rho\,d\phi\,d\theta \\
&= \left(\int_{-\pi/2}^{\pi/2} 1\,d\theta\right)\left(\int_0^{\pi}\sin\phi\,d\phi\right)\left(\int_0^2\rho^3 d\rho\right) = \pi\cdot\left(-\cos\phi\bigg|_0^{\pi}\right)\left(\frac{\rho^4}{4}\bigg|_0^2\right) \\
&= \pi\cdot 2\cdot 4 = 8\pi \qquad (4)
\end{aligned}$$

We now substitute (3) and (4) in (1) to obtain the following solution:

$$\iiint_{\mathcal{W}} f(x,y,z)\,dV = 8\pi - \frac{17\pi}{12} = \frac{79\pi}{12}$$

47. Use spherical coordinates to evaluate the triple integral of $f(x,y,z) = z$ over the region

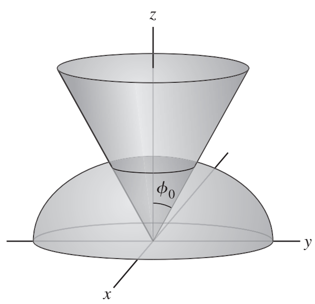
$$0 \le \theta \le \frac{\pi}{3}, \qquad 0 \le \phi \le \frac{\pi}{2}, \qquad 1 \le \rho \le 2$$

SOLUTION The function in spherical coordinates is $f(x,y,z) = z = \rho\cos\phi$. Using triple integral in spherical coordinates gives

$$\begin{aligned}
\iiint_{\mathcal{W}} z\,dV &= \int_0^{\pi/3}\int_0^{\pi/2}\int_1^2(\rho\cos\phi)\rho^2\sin\phi\,d\rho\,d\phi\,d\theta = \int_0^{\pi/3}\int_0^{\pi/2}\int_1^2\rho^3\cos\phi\sin\phi\,d\rho\,d\phi\,d\theta \\
&= \left(\int_0^{\pi/3}1\,d\theta\right)\left(\int_0^{\pi/2}\frac{1}{2}\sin 2\phi\,d\phi\right)\left(\int_1^2\rho^3 d\rho\right) \\
&= \frac{\pi}{3}\cdot\left(-\frac{1}{4}\cos 2\phi\right)\bigg|_0^{\pi/2}\cdot\left(\frac{\rho^4}{4}\bigg|_1^2\right) = \frac{\pi}{3}\cdot\frac{1}{2}\cdot\left(4-\frac{1}{4}\right) = \frac{5}{8}\pi
\end{aligned}$$

48. Find the volume of the region lying above the cone $\phi = \phi_0$ and below the sphere $\rho = R$.

SOLUTION



The region is described by the following inequalities in spherical coordinates:

$$\mathcal{W}: 0 \le \theta \le 2\pi,\ 0 \le \phi \le \phi_0,\ 0 \le \rho \le R$$

We compute the volume V of $\mathcal{W}$ using triple integrals in spherical coordinates:

$$V = \iiint_{\mathcal{W}} 1\,dV = \int_0^{2\pi} \int_0^{\phi_0} \int_0^R \rho^2 \sin\phi\,d\rho\,d\phi\,d\theta = \left(\int_0^{2\pi} 1\,d\theta\right)\left(\int_0^{\phi_0} \sin\phi\,d\phi\right)\left(\int_0^R \rho^2 d\rho\right)$$

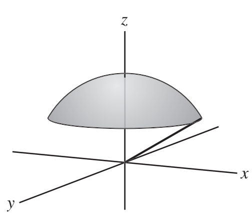
$$= \left(\theta\Big|_0^{2\pi}\right)\left(-\cos\phi\Big|_0^{\phi_0}\right)\left(\frac{\rho^3}{3}\Big|_0^R\right) = 2\pi\,(1-\cos\phi_0)\cdot\frac{R^3}{3} = \frac{2\pi R^3\,(1-\cos\phi_0)}{3}$$

49. Calculate the integral of

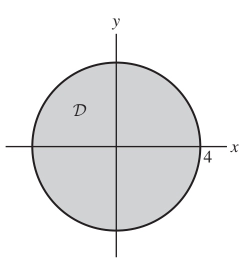
$$f(x, y, z) = z(x^2 + y^2 + z^2)^{-3/2}$$

over the part of the ball $x^2 + y^2 + z^2 \le 16$ defined by $z \ge 2$.

SOLUTION



The equation of the sphere in spherical coordinates is $\rho^2 = 16$ or $\rho = 4$.



We write the equation of the plane $z = 2$ in spherical coordinates:

$$\rho\cos\phi = 2 \quad\Rightarrow\quad \rho = \frac{2}{\cos\phi}$$

To compute the interval of ϕ, we must find the value of ϕ corresponding to $\rho = 4$ on the plane $z = 2$. We get

$$4 = \frac{2}{\cos\phi} \quad\Rightarrow\quad \cos\phi = \frac{1}{2} \quad\Rightarrow\quad \phi = \frac{\pi}{3}$$

Therefore, ϕ is changing from 0 to $\frac{\pi}{3}$, θ is changing from 0 to 2π, and ρ is changing from $\frac{2}{\cos\phi}$ to 4. We obtain the following description for $\mathcal{W}$:

$$\mathcal{W}: 0 \le \theta \le 2\pi,\ 0 \le \phi \le \frac{\pi}{3},\ \frac{2}{\cos\phi} \le \rho \le 4$$

The function is

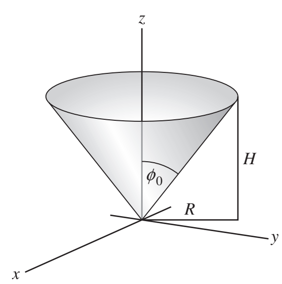
$$f(x, y, z) = z(x^2 + y^2 + z^2)^{-3/2} = \rho \cos\phi \cdot (\rho^2)^{-3/2} = \rho^{-2} \cos\phi$$

We use triple integrals in spherical coordinates to write

$$\begin{aligned}
\iiint_{\mathcal{W}} f(x, y, z)\, dV &= \int_0^{2\pi} \int_0^{\pi/3} \int_{2/\cos\phi}^{4} (\rho^{-2}\cos\phi)\rho^2 \sin\phi \, d\rho\, d\phi\, d\theta = \int_0^{2\pi} \int_0^{\pi/3} \int_{2/\cos\phi}^{4} \frac{\sin 2\phi}{2}\, d\rho\, d\phi\, d\theta \\
&= \int_0^{2\pi} \int_0^{\pi/3} \frac{\sin 2\phi}{2} \rho \Big|_{\rho=\frac{2}{\cos\phi}}^{4} d\phi\, d\theta = \int_0^{2\pi} \int_0^{\pi/3} \left(2\sin 2\phi - \frac{\sin 2\phi}{2} \cdot \frac{2}{\cos\phi}\right) d\phi\, d\theta \\
&= \int_0^{2\pi} \int_0^{\pi/3} (2\sin 2\phi - 2\sin\phi)\, d\phi\, d\theta = 2\pi \cdot \left(-\cos 2\phi + 2\cos\phi \Big|_{\phi=0}^{\pi/3}\right) \\
&= 2\pi \cdot \left(-\cos\frac{2\pi}{3} + 2\cos\frac{\pi}{3} + 1 - 2\right) = \pi
\end{aligned}$$

50. Calculate the volume of the cone in Figure 21 using spherical coordinates.

SOLUTION



First, we write the equation of the upper plane $z = H$ in spherical coordinates:

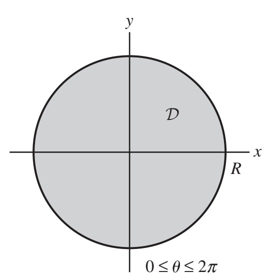
$$\rho\cos\phi = H \quad \Rightarrow \quad \rho = \frac{H}{\cos\phi}$$

To write the equation of the circular cone, we must find the angle ϕ_0 in terms of R and H. That is,

$$\tan\phi_0 = \frac{R}{H} \quad \Rightarrow \quad \phi_0 = \tan^{-1}\frac{R}{H}$$

Therefore, the equation of the lower surface (the circular cone) is $\phi = \tan^{-1}\frac{R}{H}$. We now write the inequalities for the region $\mathcal{W}$:

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le \phi \le \tan^{-1}\frac{R}{H},\ 0 \le \rho \le \frac{H}{\cos\phi}$$



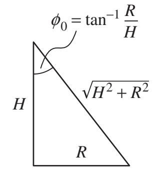
We compute the volume of $\mathcal{W}$ using a triple integral in spherical coordinates. We get

$$\begin{aligned}
V = \iiint_{\mathcal{W}} 1\, dv &= \int_0^{2\pi} \int_0^{\tan^{-1}\frac{R}{H}} \int_0^{H/\cos\phi} \rho^2 \sin\phi\, d\rho\, d\phi\, d\theta = \int_0^{2\pi} \int_0^{\tan^{-1}\frac{R}{H}} \frac{\rho^3 \sin\phi}{3}\Big|_{\rho=0}^{H/\cos\phi} d\phi\, d\theta \\
&= \int_0^{2\pi} \int_0^{\tan^{-1}\frac{R}{H}} \frac{H^3 \sin\phi}{3\cos^3\phi} d\phi\, d\theta = \left(\int_0^{2\pi} \frac{H^3}{3}\, d\theta\right)\left(\int_0^{\tan^{-1}\frac{R}{H}} \frac{\sin\phi}{\cos^3\phi}\, d\phi\right) = \frac{2\pi H^3}{3} \int_0^{\tan^{-1}\frac{R}{H}} \frac{\sin\phi}{\cos^3\phi}\, d\phi
\end{aligned}$$

We compute the integral using the substitution $u = \cos\phi$, $du = -\sin\phi\, d\phi$. We get

$$V = \frac{2\pi H^3}{3}\int_1^{\cos\left(\tan^{-1}\frac{R}{H}\right)} u^{-3}(-du) = \frac{2\pi H^3}{3}\int_{\cos\left(\tan^{-1}\frac{R}{H}\right)}^1 u^{-3}\,du = \frac{2\pi H^3}{3}\left.\frac{u^{-2}}{-2}\right|_{\cos\left(\tan^{-1}\frac{R}{H}\right)}^1$$

$$= \frac{\pi H^3}{3}\left(\frac{1}{\cos^2\left(\tan^{-1}\frac{R}{H}\right)} - 1\right) \tag{1}$$



Using the triangle shown in the figure, we see that

$$\cos\left(\tan^{-1}\frac{R}{H}\right) = \frac{H}{\sqrt{H^2+R^2}} \quad\Rightarrow\quad \cos^2\left(\tan^{-1}\frac{R}{H}\right) = \frac{H^2}{H^2+R^2} \quad\Rightarrow\quad \frac{1}{\cos^2\left(\tan^{-1}\frac{R}{H}\right)} = 1 + \frac{R^2}{H^2}$$

Substituting in (1) gives

$$V = \frac{\pi H^3}{3}\left(1 + \frac{R^2}{H^2} - 1\right) = \frac{\pi H^3}{3}\cdot\frac{R^2}{H^2} = \frac{\pi R^2 H}{3}$$

51. Calculate the volume of the sphere $x^2 + y^2 + z^2 = a^2$, using both spherical and cylindrical coordinates.

SOLUTION Spherical coordinates: In the entire sphere of radius a, we have

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le \phi \le \pi,\ 0 \le \rho \le a$$

Using triple integral in spherical coordinates we get

$$V = \iiint_{\mathcal{W}} 1\,dV = \int_0^{2\pi}\int_0^{\pi}\int_0^a \rho^2 \sin\phi\, d\rho\, d\phi\, d\theta = \left(\int_0^a \rho^2 d\rho\right)\left(\int_0^{\pi}\sin\phi\, d\phi\right)\left(\int_0^{2\pi} 1\, d\theta\right)$$

$$= \left(\left.\frac{\rho^3}{3}\right|_0^a\right)\left(\left.-\cos\phi\right|_0^{\pi}\right)\left(\left.\theta\right|_0^{2\pi}\right) = \frac{a^3}{3}\cdot 2\cdot 2\pi = \frac{4\pi a^3}{3}$$

Cylindrical coordinates: The projection of $\mathcal{W}$ onto the xy-plane is the circle of radius a, that is,

$$\mathcal{D}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le a$$

The upper surface is $z = \sqrt{a^2 - (x^2+y^2)} = \sqrt{a^2 - r^2}$ and the lower surface is $z = -\sqrt{a^2 - r^2}$. Therefore, $\mathcal{W}$ has the following description in cylindrical coordinates:

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le a,\ -\sqrt{a^2-r^2} \le z \le \sqrt{a^2-r^2}$$

We obtain the following integral:

$$V = \int_0^{2\pi}\int_0^a\int_{-\sqrt{a^2-r^2}}^{\sqrt{a^2-r^2}} r\, dz\, dr\, d\theta = \int_0^{2\pi}\int_0^a \left. rz\right|_{z=-\sqrt{a^2-r^2}}^{\sqrt{a^2-r^2}} dr\, d\theta = \int_0^{2\pi}\int_0^a 2r\sqrt{a^2-r^2}\, dr\, d\theta \tag{1}$$

We compute the inner integral using the substitution $u = \sqrt{a^2 - r^2}$, $du = -\frac{r}{u}\,dr$. We get

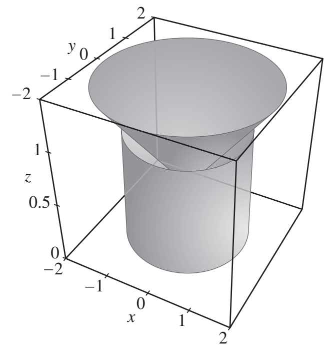
$$\int_0^a 2r\sqrt{a^2-r^2}\, dr = \int_a^0 -2u^2\, du = \int_0^a 2u^2\, du = \left.\frac{2u^3}{3}\right|_0^a = \frac{2a^3}{3}$$

Substituting in (1) gives

$$V = \int_0^{2\pi}\frac{2a^3}{3}\, d\theta = \left.\frac{2a^3}{3}\theta\right|_0^{2\pi} = \frac{2a^3}{3}\cdot 2\pi = \frac{4\pi a^3}{3}.$$

52. Let $\mathcal{W}$ be the region within the cylinder $x^2 + y^2 = 2$ between $z = 0$ and the cone $z = \sqrt{x^2 + y^2}$. Calculate the integral of $f(x, y, z) = x^2 + y^2$ over $\mathcal{W}$, using both spherical and cylindrical coordinates.

SOLUTION Spherical coordinates:



We write the equation of the cylinder $x^2 + y^2 = 2$ in spherical coordinates:

$$2 = (\rho \cos\theta \sin\phi)^2 + (\rho \sin\theta \sin\phi)^2 = \rho^2 \sin^2\phi \left(\cos^2\theta + \sin^2\theta\right)$$

$$2 = \rho^2 \sin^2\phi \quad \Rightarrow \quad \rho = \frac{\sqrt{2}}{\sin\phi}$$

We write the equation of the cone $z = \sqrt{x^2 + y^2}$ in spherical coordinates:

$$\rho\cos\phi = \sqrt{(\rho\cos\theta\sin\phi)^2 + (\rho\sin\theta\sin\phi)^2} = \sqrt{\rho^2\sin^2\phi\left(\cos^2\theta + \sin^2\theta\right)} = \rho\sin\phi$$

or

$$\tan\phi = 1 \quad \Rightarrow \quad \phi = \frac{\pi}{4}$$

Therefore the region $\mathcal{W}$ is described by the following inequalities:

$$0 \le \theta \le 2\pi, \quad \frac{\pi}{4} \le \phi \le \frac{\pi}{2}, \quad 0 \le \rho \le \frac{\sqrt{2}}{\sin\phi}$$

The function is

$$f(x, y, z) = x^2 + y^2 = (\rho\cos\theta\sin\phi)^2 + (\rho\sin\theta\sin\phi)^2 = \rho^2\sin^2\phi$$

We obtain the following integral:

$$\begin{aligned}
\iiint_{\mathcal{W}} (x^2 + y^2)\, dV &= \int_0^{2\pi} \int_{\pi/4}^{\pi/2} \int_0^{\sqrt{2}/\sin\phi} \left(\rho^2 \sin^2\phi\right) \rho^2 \sin\phi \, d\rho\, d\phi\, d\theta \\
&= \int_0^{2\pi} \int_{\pi/4}^{\pi/2} \int_0^{\sqrt{2}/\sin\phi} \rho^4 \sin^3\phi\, d\rho\, d\phi\, d\theta = \int_0^{2\pi} \int_{\pi/4}^{\pi/2} \frac{\rho^5 \sin^3\phi}{5}\bigg|_{\rho=0}^{\sqrt{2}/\sin\phi} d\phi\, d\theta \\
&= \int_0^{2\pi} \int_{\pi/4}^{\pi/2} \frac{\frac{4\sqrt{2}}{\sin^5\phi}\cdot\sin^3\phi}{5}\, d\phi\, d\theta = \int_0^{2\pi} \int_{\pi/4}^{\pi/2} \frac{4\sqrt{2}}{5}\cdot\frac{1}{\sin^2\phi}\, d\phi\, d\theta \\
&= \left(\int_0^{2\pi} \frac{4\sqrt{2}}{5}\, d\theta\right)\left(\int_{\pi/4}^{\pi/2} \frac{1}{\sin^2\phi}\, d\phi\right) = \left(\frac{4\sqrt{2}}{5}\theta\bigg|_0^{2\pi}\right)\left(-\cot\theta\bigg|_{\pi/4}^{\pi/2}\right) \\
&= \frac{4\sqrt{2}}{5}\cdot 2\pi\cdot 1 = \frac{8\pi\sqrt{2}}{5}
\end{aligned}$$

Cylindrical coordinates: The region of integration has the following definition in cylindrical coordinates:

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le \sqrt{2},\ 0 \le z \le \sqrt{x^2 + y^2} = r$$

The function in cylindrical coordinates is $f(x, y, z) = x^2 + y^2 = r^2$. Using triple integrals in cylindrical coordinates, we obtain

$$\iiint_{\mathcal{W}} (x^2 + y^2)\, dV = \int_0^{2\pi} \int_0^{\sqrt{2}} \int_0^r r^2 \cdot r\, dz\, dr\, d\theta = \int_0^{2\pi} \int_0^{\sqrt{2}} \int_0^r r^3\, dz\, dr\, d\theta$$

$$= \int_0^{2\pi} \int_0^{\sqrt{2}} r^3 z\Big|_{z=0}^{r} dr\, d\theta = \int_0^{2\pi} \int_0^{\sqrt{2}} r^4\, dr\, d\theta = \left(\int_0^{2\pi} 1\, d\theta\right)\left(\int_0^{\sqrt{2}} r^4\, dr\right)$$

$$= \left(\theta\Big|_0^{2\pi}\right)\left(\frac{r^5}{5}\Big|_0^{\sqrt{2}}\right) = 2\pi \cdot \frac{4\sqrt{2}}{5} = \frac{8\sqrt{2}\pi}{5}$$

53. Bell-Shaped Curve One of the key results in calculus is the computation of the area under the bell-shaped curve (Figure 23):

$$I = \int_{-\infty}^{\infty} e^{-x^2}\, dx$$

This integral appears throughout engineering, physics, and statistics, and although e^{-x^2} does not have an elementary antiderivative, we can compute I using multiple integration.

(a) Show that $I^2 = J$, where J is the improper double integral

$$J = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-x^2-y^2}\, dx\, dy$$

Hint: Use Fubini's Theorem and $e^{-x^2-y^2} = e^{-x^2}e^{-y^2}$.

(b) Evaluate J in polar coordinates.

(c) Prove that $I = \sqrt{\pi}$.

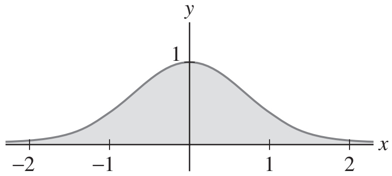


FIGURE 23 The bell-shaped curve $y = e^{-x^2}$.

SOLUTION

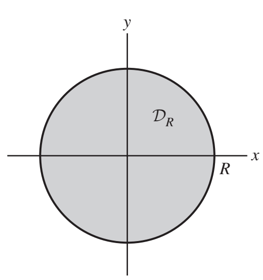
(a) We must show that $I^2 = J$. Firstly, consider the following:

$$I^2 = I \cdot I = \int_{-\infty}^{\infty} e^{-x^2}\, dx \cdot \int_{-\infty}^{\infty} e^{-y^2}\, dy = \int_{-\infty}^{\infty} e^{-x^2} \cdot e^{-y^2}\, dx\, dy = \int_{-\infty}^{\infty} e^{-x^2-y^2}\, dx\, dy$$

This works because each integral after the first equals sign is independent of the other.

(b) The improper integral over the xy-plane can be computed as the limit as $\mathcal{R} \to \infty$ of the double integrals over the disk. $\mathcal{D}_{\mathcal{R}}$ is defined by

$$\mathcal{D}_{\mathcal{R}} : 0 \le \theta \le 2\pi,\ 0 \le r \le \mathcal{R}$$



That is,

$$J = \lim_{\mathcal{R}\to\infty} \iint_{\mathcal{D}_{\mathcal{R}}} e^{-(x^2+y^2)}\, dx\, dy \tag{1}$$

We compute the double integral using polar coordinates. The function is $f(x, y) = e^{-(x^2+y^2)} = e^{-r^2}$, hence

$$\iint_{\mathcal{D}_{\mathcal{R}}} e^{-(x^2+y^2)}\, dx\, dy = \int_0^{2\pi} \int_0^{\mathcal{R}} e^{-r^2} r\, dr\, d\theta = \left(\int_0^{2\pi} 1\, d\theta\right)\left(\int_0^{\mathcal{R}} e^{-r^2} r\, dr\right) = 2\pi \int_0^{\mathcal{R}} e^{-r^2} r\, dr$$

We compute the integral using the substitution $u = r^2$, $du = 2r\,dr$. We get

$$\iint_{\mathcal{D}_{\mathcal{R}}} e^{-(x^2+y^2)}\,dx\,dy = 2\pi \int_0^{\mathcal{R}^2} e^{-u}\frac{du}{2} = \pi \int_0^{\mathcal{R}^2} e^{-u}\,du = \pi(-e^{-u})\Big|_0^{R^2} = \pi(1-e^{-R^2}) \qquad (2)$$

Combining (1) and (2), we get

$$J = \lim_{\mathcal{R}\to\infty}\left(\pi\left(1-e^{-R^2}\right)\right) = \pi$$

On the other hand, using the Iterated Integral of a Product Function, we get

$$\begin{aligned}\pi = J &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{-x^2-y^2}\,dx\,dy = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{-x^2}\cdot e^{-y^2}\,dx\,dy\\ &= \left(\int_{-\infty}^{\infty} e^{-x^2}\,dx\right)\left(\int_{-\infty}^{\infty} e^{-y^2}\,dy\right) = I^2\end{aligned}$$

(c) That is,

$$I^2 = \pi \quad\Rightarrow\quad I = \sqrt{\pi}$$

Further Insights and Challenges

54. An Improper Multiple Integral Show that a triple integral of $(x^2+y^2+z^2+1)^{-2}$ over all of $\mathbf{R}^3$ is equal to π^2. This is an improper integral, so integrate first over $\rho \le R$ and let $R \to \infty$.

SOLUTION The triple integral I over $\mathbf{R}^3$ can be computed as the limit as $R \to \infty$ of the triple integral over the balls of radius R. These balls have the following definition in spherical coordinates:

$$\mathcal{D}_R:\ 0 \le \theta \le 2\pi,\ 0 \le \phi \le \pi,\ 0 \le \rho \le R$$

The function in spherical coordinates is $f(x,y,z) = (x^2+y^2+z^2+1)^{-2} = (\rho^2+1)^{-2}$. We obtain the following integral:

$$\begin{aligned}I_R &= \iiint_{\mathcal{W}_R} (x^2+y^2+z^2+1)^{-2}\,dV = \int_0^{2\pi}\int_0^{\pi}\int_0^R (1+\rho^2)^{-2}\cdot\rho^2\sin\phi\,d\rho\,d\phi\,d\theta\\ &= \left(\int_0^{2\pi} 1\,d\theta\right)\left(\int_0^{\pi}\sin\phi\,d\phi\right)\left(\int_0^R (1+\rho^2)^{-2}\rho^2 d\rho\right) = 2\pi\cdot\left(-\cos\phi\Big|_0^{\pi}\right)\int_0^R (1+\rho^2)^{-2}\rho^2 d\rho\\ &= 4\pi\int_0^R (1+\rho^2)^{-2}\rho^2 d\rho\end{aligned}$$

We compute the integral using the trigonometric substitution $\rho = \tan u$, $d\rho = \frac{1}{\cos^2 u}\,du$. Therefore, $1+\rho^2 = 1+\tan^2 u = \frac{1}{\cos^2 u}$, and we obtain

$$\begin{aligned}I_R &= 4\pi\int_0^{\tan^{-1}R}\left(\frac{1}{\cos^2 u}\right)^{-2}\tan^2 u\cdot\frac{1}{\cos^2 u}\,du = 4\pi\int_0^{\tan^{-1}R}\tan^2 u\,\cos^2 u\,du\\ &= 4\pi\int_0^{\tan^{-1}R}\sin^2 u\,du = 4\pi\left(\frac{u}{2}-\frac{\sin 2u}{4}\Big|_0^{\tan^{-1}R}\right) = 4\pi\left(\frac{\tan^{-1}R}{2}-\frac{\sin 2(\tan^{-1}R)}{4}\right)\end{aligned}$$

We now let $R \to \infty$. Using the limit $\lim_{R\to\infty}\tan^{-1}R = \frac{\pi}{2}$, we obtain

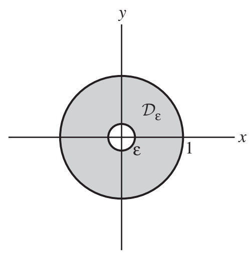
$$I_R = 4\pi\lim_{R\to\infty}\left(\frac{\tan^{-1}R}{2}-\frac{\sin 2(\tan^{-1}R)}{4}\right) = 4\pi\left(\frac{\pi}{4}-\frac{\sin\left(2\cdot\frac{\pi}{2}\right)}{4}\right) = 4\pi\left(\frac{\pi}{4}-0\right) = \pi^2$$

55. Prove the formula

$$\iint_{\mathcal{D}} \ln r\,dA = -\frac{\pi}{2}$$

swhere $r = \sqrt{x^2+y^2}$ and $\mathcal{D}$ is the unit disk $x^2+y^2 \le 1$. This is an improper integral since $\ln r$ is not defined at $(0,0)$, so integrate first over the annulus $a \le r \le 1$ where $0 < a < 1$, and let $a \to 0$.

SOLUTION



The improper integral I is computed by the limit as $a \to 0^+$ of the integrals over the annulus $\mathcal{D}_a$ defined by

$$\mathcal{D}_a : 0 \le \theta \le 2\pi,\ a \le r \le 1$$

Using double integrals in polar coordinates and integration by parts, we get

$$I_a = \int_0^{2\pi} \int_a^1 (\ln r) \cdot r\,dr\,d\theta = 2\pi \int_a^1 r \ln r\,dr = 2\pi \left(\frac{r^2 \ln r}{2} - \frac{r^2}{4} \bigg|_a^1 \right)$$
$$= 2\pi \left(\frac{\ln 1}{2} - \frac{1}{4} - \frac{a^2 \ln a}{2} + \frac{a^2}{4} \right) = \frac{\pi}{2} \left(a^2 - 2a^2 \ln a - 1 \right)$$

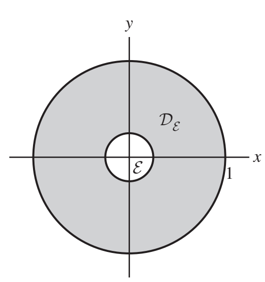
We now compute the limit of I_a as $a \to 0^+$. We use L'Hôpital's rule to obtain

$$I = \lim_{a\to 0^+} \frac{\pi}{2}(a^2 - 2a^2 \ln a - 1) = -\frac{\pi}{2} - \pi \lim_{a\to 0^+} a^2 \ln a = -\frac{\pi}{2} - \pi \lim_{a\to 0^+} \frac{\ln a}{a^{-2}}$$
$$= -\frac{\pi}{2} - \pi \lim_{a\to 0^+} \frac{a^{-1}}{-2a^{-3}} = -\frac{\pi}{2} + \frac{\pi}{2} \lim_{a\to 0^+} a^2 = -\frac{\pi}{2}$$

56. Recall that the improper integral $\int_0^1 x^{-a}\,dx$ converges if and only if $a < 1$. For which values of a does $\iint_{\mathcal{D}} r^{-a}\,dA$ converge, where $r = \sqrt{x^2 + y^2}$ and $\mathcal{D}$ is the unit disk $x^2 + y^2 \le 1$?

SOLUTION The improper integral $I = \iint_{\mathcal{D}} r^{-a}\,dA$ is computed as the limit $\epsilon \to 0^+$ of the double integrals over the annulus $\mathcal{D}_\epsilon$ defined by

$$\mathcal{D}_\epsilon : 0 \le \theta \le 2\pi,\ \epsilon \le r \le 1$$



We compute the integral over $\mathcal{D}_a$ using double integral in polar coordinates. We obtain

$$\iint_{\mathcal{D}_\epsilon} \left(\sqrt{x^2 + y^2} \right)^{-a} dA = \int_0^{2\pi} \int_\epsilon^1 r^{-a} \cdot r\,dr\,d\theta = 2\pi \int_\epsilon^1 r^{1-a}\,dr$$

Therefore,

$$I = \lim_{\epsilon\to 0^+} 2\pi \int_\epsilon^1 r^{1-a}\,dr = 2\pi \int_0^1 r^{1-a}\,dr = 2\pi \int_0^1 r^{-(a-1)}\,dr$$

This integral converges only if $a - 1 < 1$, or $a < 2$.

15.5 Applications of Multiple Integrals (LT Section 16.5)

Preliminary Questions

1. What is the mass density $\rho(x, y, z)$ of a solid of volume 5 m^3 with uniform mass density and total mass 25 kg?

SOLUTION Here, recall that

$$\text{total mass} = \iiint_{\mathcal{W}} \rho(x, y, z)\, dV$$

Since we are told that the solid has volume 5, and $\rho(x, y, z)$ is uniform (i.e. constant, let $\rho(x, y, z) = \rho$), we can write:

$$25 = \iiint_{\mathcal{W}} \rho(x, y, z)\, dV = \rho \cdot V(\mathcal{W}) = 5\rho, \quad \Rightarrow \quad \rho = 5 \text{ kg/m}^3$$

2. A domain $\mathcal{D}$ in $\mathbf{R}^2$ with uniform mass density is symmetric with respect to the y-axis. Which of the following are true?

(a) $x_{\text{CM}} = 0$ **(b)** $y_{\text{CM}} = 0$ **(c)** $I_x = 0$ **(d)** $I_y = 0$

SOLUTION Here, the x-coordinate of the center of mass, $x_{\text{CM}} = 0$ (a) since $x_{\text{CM}} = \frac{M_y}{M}$ and $M_y = \iint_{\mathcal{D}} x\rho(x, y)\, dA$. Since $\rho(x, y) = \rho(-x, y)$, then we see that $(-x)\rho(-x, y) = -x\rho(x, y)$ and M_y is an integral of an odd function over a symmetric region, hence $M_y = 0$.

3. If $p(x, y)$ is the joint probability density function of random variables X and Y, what does the double integral of $p(x, y)$ over $[0, 1] \times [0, 1]$ represent? What does the integral of $p(x, y)$ over the triangle bounded by $x = 0$, $y = 0$, and $x + y = 1$ represent?

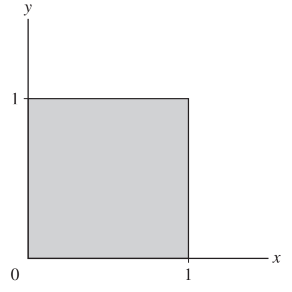
SOLUTION The double integral of $p(x, y)$ over $[0, 1] \times [0, 1]$ represents the probability that both X and Y are between 0 and 1. The integral of $p(x, y)$ over the triangle bounded by $x = 0$, $y = 0$, and $x + y = 1$ represents the probability that both X and Y are nonnegative and $X + Y \le 1$.

Exercises

1. Find the total mass of the square $0 \le x \le 1$, $0 \le y \le 1$ assuming a mass density of

$$\rho(x, y) = x^2 + y^2$$

SOLUTION



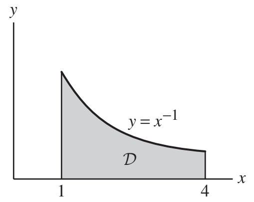
The total mass M is obtained by integrating the mass density $\rho(x, y) = x^2 + y^2$ over the square $\mathcal{D}$ in the xy-plane. This gives

$$M = \iint_{\mathcal{D}} \rho(x, y)\, dA = \int_0^1 \int_0^1 \left(x^2 + y^2\right) dx\, dy = \int_0^1 \frac{x^3}{3} + y^2 x \Big|_{x=0}^{1} dy$$

$$= \int_0^1 \left(\frac{1}{3} + y^2 - 0\right) dy = \int_0^1 \left(\frac{1}{3} + y^2\right) dy = \frac{y}{3} + \frac{y^3}{3}\Big|_0^1 = \frac{1}{3} + \frac{1}{3} = \frac{2}{3}$$

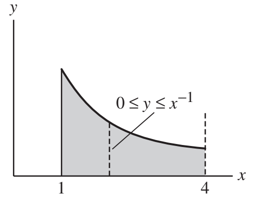
2. Calculate the total mass of a plate bounded by $y = 0$ and $y = x^{-1}$ for $1 \le x \le 4$ (in meters) assuming a mass density of $\rho(x, y) = y/x$ kg/m^2.

SOLUTION The total mass M of the plate is obtained by computing the double integral of mass density $\rho(x, y) = \frac{y}{x}$ over the region $\mathcal{D}$ shown in the figure.



$\mathcal{D}$ is a vertically simple region defined by the following inequalities:

$$1 \le x \le 4, \quad 0 \le y \le x^{-1}$$



We compute the double integral using Theorem 2. That is,

$$M = \iint_{\mathcal{D}} \rho(x, y)\, dA = \int_1^4 \int_0^{x^{-1}} \frac{y}{x}\, dy\, dx = \int_1^4 \frac{y^2}{2x}\bigg|_{y=0}^{x^{-1}} dx = \int_1^4 \frac{\left(x^{-1}\right)^2 - 0^2}{2x}\, dx = \int_1^4 \frac{1}{2} x^{-3}\, dx$$
$$= -\frac{1}{4} x^{-2}\bigg|_{x=1}^{4} = -\frac{1}{4}(4^{-2} - 1^{-2}) = \frac{15}{64}$$

3. Find the total charge in the region under the graph of $y = 4e^{-x^2/2}$ for $0 \le x \le 10$ (in centimeters) assuming a charge density of $\rho(x, y) = 10^{-6} xy$ coulombs per square centimeter.

SOLUTION The total charge C of the region is obtained by computing the double integral of charge density $\rho(x, y) = 10^{-6} xy$ over the region defined by the inequalities

$$0 \le x \le 10, \quad 0 \le y \le 4e^{-x^2/2}$$

Therefore, we compute the double integral

$$C = \iint_{\mathcal{D}} \rho(x, y)\, dA = \int_0^{10} \int_0^{4e^{-x^2/2}} 10^{-6} xy\, dy\, dx = 10^{-6} \int_0^{10} \left(\frac{1}{2} xy^2 \bigg|_{y=0}^{4e^{-x^2/2}} \right) dx$$
$$= \frac{1}{2} \cdot 10^{-6} \int_0^{10} 16xe^{-x^2}\, dx = -4 \cdot 10^{-6} \int_0^{10} e^{-x^2} (-2x\, dx) = -4 \cdot 10^{-6} \left(e^{-x^2} \bigg|_0^{10} \right)$$
$$= -4 \cdot 10^{-6} \left(e^{-10^2} - 1 \right) = \frac{1}{250{,}000} \left(1 - e^{-100} \right)$$

4. Find the total population within a 4-kilometer radius of the city center (located at the origin) assuming a population density of $\rho(x, y) = 2000(x^2 + y^2)^{-0.2}$ people per square kilometer.

SOLUTION The total population P of the region is obtained by computing the double integral of population density $\rho(x, y) = 2000(x^2 + y^2)^{-0.2}$ over the region defined by the inequalities:

$$0 \le x^2 + y^2 \le 16$$

We can think of this region with polar coordinates and write:

$$x = 4\cos\theta, \quad y = 4\sin\theta, \quad 0 \le r \le 4, 0 \le \theta \le 2\pi$$

Transforming with this information we compute the double integral:

$$\iint_{\mathcal{D}} \rho(x, y)\, dA = \iint_{\mathcal{D}} 2000(x^2 + y^2)^{-0.2}\, dA = \int_0^{2\pi} \int_0^4 2000(r^2)^{-0.2} \cdot r\, dr\, d\theta$$
$$= 2000 \int_0^{2\pi} \int_0^4 r^{0.6}\, dr\, d\theta = 2000 \int_0^{2\pi} \frac{1}{1.6} r^{1.6} \bigg|_0^4 d\theta$$

$$= \frac{2000}{1.6} \cdot 4^{1.6} \int_0^{2\pi} 1\, d\theta = 2500\pi \cdot 4^{1.6} \approx 72{,}175$$

5. Find the total population within the sector $2|x| \le y \le 8$ assuming a population density of $\rho(x, y) = 100e^{-0.1y}$ people per square kilometer.

SOLUTION The total population P of the region is obtained by computing the double integral of population density $\rho(x, y) = 100e^{-0.1y}$ over the region defined by the inequality $2|x| \le y \le 8$. This means the region can be split into two vertically simple regions described by the inequalities:

$$0 \le x \le 4, \quad 2x \le y \le 8$$

and

$$-4 \le x \le 4, \quad -2x \le y \le 8$$

Now to compute the double integral:

$$\iint_{\mathcal{D}} \rho(x, y)\, dA = \iint_{\mathcal{D}_1} \rho(x, y)\, dA + \iint_{\mathcal{D}_2} \rho(x, y)\, dA$$

$$\begin{aligned}
\iint_{\mathcal{D}_1} \rho(x, y)\, dA + \iint_{\mathcal{D}_2} \rho(x, y)\, dA &= \int_0^4 \int_{2x}^8 100e^{-0.1y}\, dy\, dx + \int_{-4}^0 \int_{-2x}^8 100e^{-0.1y}\, dy\, dx \\
&= \int_0^4 \frac{100}{-0.1} e^{-0.1y}\Big|_{y=2x}^{8} dx + \int_{-4}^0 \frac{100}{-0.1} e^{-0.1y}\Big|_{y=-2x}^{8} dx \\
&= -1000 \int_0^4 e^{-0.8} - e^{-0.2x}\, dx - 1000 \int_{-4}^0 e^{-0.8} - e^{0.2x}\, dx \\
&= -1000 \left(e^{-0.8}x + 5e^{-0.2x}\Big|_0^4 \right) - 1000 \left(e^{-0.8}x - 5e^{0.2x}\Big|_{-4}^0 \right) \\
&= -1000 \left(4e^{-0.8} + 5e^{-0.8} - 5 \right) - 1000 \left(-5 + 4e^{-0.8} + 5e^{-0.8} \right) \\
&= -1000 \left(18e^{-0.8} - 10 \right) \approx 1912
\end{aligned}$$

6. Find the total mass of the solid region $\mathcal{W}$ defined by $x \ge 0$, $y \ge 0$, $x^2 + y^2 \le 4$, and $x \le z \le 32 - x$ (in centimeters) assuming a mass density of $\rho(x, y, z) = 6y$ g/cm^3.

SOLUTION To find the total mass of this solid region, we will think of it using cylindrical coordinates:

$$0 \le r \le 2, \quad r\cos\theta \le z \le 32 - r\cos\theta$$

and the mass density is:

$$\rho(x, y, z) = 6y \quad \Rightarrow \quad \rho(r\cos\theta, r\sin\theta, z) = 6r\sin\theta$$

Since we are given $x \ge 0$ and $y \ge 0$, then we know

$$0 \le \theta \le \frac{\pi}{2}$$

Therefore, the total mass can be computed:

$$\begin{aligned}
\iiint_{\mathcal{W}} \rho(r\cos\theta, r\sin\theta, z)\, dV &= \int_{\theta=0}^{\pi/2} \int_{r=0}^{2} \int_{z=r\cos\theta}^{z=32-r\cos\theta} (6r\sin\theta) r\, dz\, dr\, d\theta \\
&= 6 \int_0^{\pi/2} \int_0^2 \int_{r\cos\theta}^{32-r\cos\theta} r^2 \sin\theta\, dz\, dr\, d\theta \\
&= 6 \int_0^{\pi/2} \int_0^2 r^2 \sin\theta \left(z\Big|_{r\cos\theta}^{32-r\cos\theta} \right) dr\, d\theta \\
&= 6 \int_0^{\pi/2} \int_0^2 r^2 \sin\theta\, (32 - 2r\cos\theta)\; dr\, d\theta \\
&= 6 \int_0^{\pi/2} \int_0^2 32r^2 \sin\theta - 2r^3 \sin\theta\cos\theta\, dr\, d\theta
\end{aligned}$$

$$= 6 \int_0^{\pi/2} \frac{32}{3} r^3 \sin\theta - \frac{1}{2} r^4 \sin\theta\cos\theta \Big|_0^2 \, d\theta$$

$$= 6 \int_0^{\pi/2} \frac{256}{3} \sin\theta - 8\sin\theta\cos\theta \, d\theta$$

$$= 6 \left(-\frac{256}{3}\cos\theta - 4\sin^2\theta \right) \Big|_0^{\pi/2}$$

$$= 6 \left(-4 + \frac{256}{3} \right) = 488$$

7. Calculate the total charge of the solid ball $x^2 + y^2 + z^2 \le 5$ (in centimeters) assuming a charge density (in coulombs per cubic centimeter) of

$$\rho(x, y, z) = (3 \cdot 10^{-8})(x^2 + y^2 + z^2)^{1/2}$$

SOLUTION To calculate total charge, first we consider the solid ball in spherical coordinates:

$$x^2 + y^2 + z^2 \le 5 \quad \Rightarrow \quad 0 \le \rho \le \sqrt{5}, \quad 0 \le \theta \le 2\pi, \quad 0 \le \phi \le \pi$$

And the charge density function too, let us rename it $R(x, y, z)$:

$$R(x, y, z) = (3 \cdot 10^{-8})(x^2 + y^2 + z^2)^{1/2} \quad \Rightarrow \quad R(\rho\sin\phi\cos\theta, \rho\sin\phi\sin\theta, \rho\cos\phi) = (3 \cdot 10^{-8})\rho$$

Then integrating to compute the total charge we have:

$$\int_0^{2\pi}\int_0^{\pi}\int_0^{\sqrt{5}} (3 \cdot 10^{-8})\rho \cdot \rho^2 \sin\phi \, d\rho \, d\phi \, d\theta = 3 \cdot 10^{-8} \int_0^{2\pi}\int_0^{\pi}\int_0^{\sqrt{5}} \rho^3 \sin\phi \, d\rho \, d\phi \, d\theta$$

$$= 3 \cdot 10^{-8} \int_0^{2\pi}\int_0^{\pi} \sin\phi \left(\frac{1}{4}\rho^4 \Big|_0^{\sqrt{5}} \right) d\phi \, d\theta = 3 \cdot 10^{-8} \cdot \frac{25}{4} \int_0^{2\pi}\int_0^{\pi} \sin\phi \, d\phi \, d\theta$$

$$= 3 \cdot 10^{-8} \cdot \frac{25}{4} \int_0^{2\pi} -\cos\phi \Big|_0^{\pi} d\theta = 3 \cdot 10^{-8} \cdot \frac{25}{4} \int_0^{2\pi} 2 \, d\theta = 3 \cdot 10^{-8} \cdot 25\pi$$

$$\approx 2.356 \cdot 10^{-6}$$

8. Compute the total mass of the plate in Figure 10 assuming a mass density of $f(x, y) = x^2/(x^2 + y^2)$ g/cm^2.

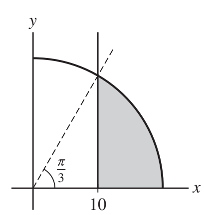


FIGURE 10

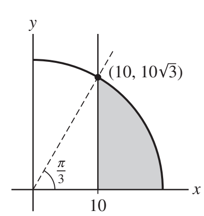
SOLUTION The total mass of the plate is

$$M = \iint_{\mathcal{D}} \frac{x^2}{x^2 + y^2} \, dA$$

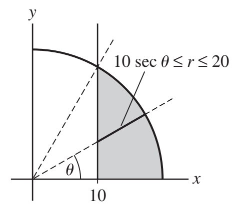
We compute the integral using polar coordinates.

Step 1. Describe $\mathcal{D}$ and f in polar coordinates. The region $\mathcal{D}$ lies in the angular sector $0 \le \theta \le \frac{\pi}{3}$.



The vertical line $x = 10$ has polar equation $r\cos\theta = 10$ or $r = 10\sec\theta$. The circle is of radius $r = \sqrt{10^2 + (10\sqrt{3})^2} = 20$, hence its polar equation is $r = 20$. A ray of angle θ intersects $\mathcal{D}$ for r between $10\sec\theta$ and 20. Therefore, $\mathcal{D}$ has the following description in polar coordinates:

$$0 \le \theta \le \frac{\pi}{3}, \quad 10\sec\theta \le r \le 20$$



The function f can be rewritten as

$$f(x, y) = \frac{x^2}{x^2 + y^2} = \frac{r^2\cos^2\theta}{r^2} = \cos^2\theta$$

Step 2. Change variables in the integral and evaluate. The Change of Variables Formula gives

$$\begin{aligned} M &= \iint_{\mathcal{D}} \frac{x^2}{x^2+y^2}\,dA = \int_0^{\pi/3}\int_{10\sec\theta}^{20} \cos^2\theta \cdot r\,dr\,d\theta = \int_0^{\pi/3} \frac{r^2\cos^2\theta}{2}\bigg|_{r=10\sec\theta}^{20} d\theta \\ &= \int_0^{\pi/3} \frac{\cos^2\theta}{2}\left(400 - 100\sec^2\theta\right) d\theta = \int_0^{\pi/3} 200\cos^2\theta - 50\,d\theta \\ &= 100\int_0^{\pi/3} 1 + \cos 2\theta\,d\theta - 50\int_0^{\pi/3} d\theta = 100\left(\theta + \frac{1}{2}\sin 2\theta\bigg|_0^{\pi/3}\right) - \frac{50\pi}{3} \\ &= 100\left(\frac{\pi}{3} + \frac{1}{2}\sin\frac{2\pi}{3}\right) - \frac{50\pi}{3} = \frac{50\pi}{3} + 25\sqrt{3} \approx 95.661 \end{aligned}$$

9. Assume that the density of the atmosphere as a function of altitude h (in km) above sea level is $\rho(h) = ae^{-bh}$ kg/km^3, where $a = 1.225 \times 10^9$ and $b = 0.13$. Calculate the total mass of the atmosphere contained in the cone-shaped region $\sqrt{x^2 + y^2} \le h \le 3$.

SOLUTION First we must consider the given cone in cylindrical coordinates:

$$\sqrt{x^2 + y^2} \le z \le 3 \quad \Rightarrow \quad r \le z \le 3$$

while

$$0 \le r \le 3, \quad 0 \le \theta \le 2\pi$$

And the density function as well:

$$\rho(x, y, z) = ae^{-bz} \quad \Rightarrow \quad \rho(r\cos\theta, r\sin\theta, z) = ae^{-bz}$$

Now to compute the total mass of the atmosphere in question:

$$\begin{aligned} \int_0^{\theta=2\pi}\int_{r=0}^3\int_{z=r}^3 ae^{-bz}\cdot r\,dz\,dr\,d\theta &= \int_0^{2\pi}\int_0^3\int_r^3 r(ae^{-bz})\,dz\,dr\,d\theta \\ &= \int_0^{2\pi}\int_0^3 r\left(-\frac{1}{b}ae^{-bz}\bigg|_{z=r}^3\right) dr\,d\theta \\ &= -\frac{a}{b}\int_0^{2\pi}\int_0^3 re^{-3b} - re^{-br}\,dr\,d\theta \\ &= -\frac{a}{b}\int_0^{2\pi} \frac{1}{2}r^2e^{-3b}\bigg|_0^3 - \left(-\frac{1}{b}re^{-br} - \frac{1}{b^2}e^{-br}\bigg|_0^3\right) d\theta \\ &= -\frac{a}{b}\cdot 2\pi\left(\frac{9}{2}e^{-3b} + \frac{3}{b}e^{-3b} + \frac{1}{b^2}e^{-3b} - \frac{1}{b^2}\right) \end{aligned}$$

Now, since $a = 1.225 \times 10^9$ and $b = 0.13$ we have that the total mass is

$$-\frac{a}{b} \cdot 2\pi \left(\frac{9}{2}e^{-3b} + \frac{3}{b}e^{-3b} + \frac{1}{b^2}e^{-3b} - \frac{1}{b^2}\right) \approx 2.593 \times 10^{10}$$

10. Calculate the total charge on a plate $\mathcal{D}$ in the shape of the ellipse with the polar equation

$$r^2 = \left(\frac{1}{6}\sin^2\theta + \frac{1}{9}\cos^2\theta\right)^{-1}$$

with the disk $x^2 + y^2 \le 1$ removed (Figure 11) assuming a charge density of $\rho(r,\theta) = 3r^{-4}$ C/cm^2.

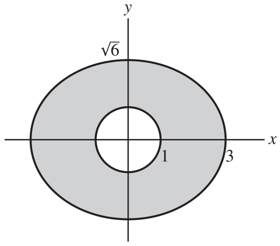


FIGURE 11

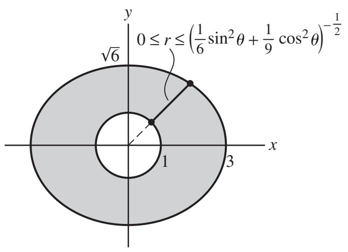
SOLUTION We first describe the region in polar coordinates. The circle $x^2 + y^2 = 1$ has the polar equation $r = 1$, and the ellipse has the polar equation $r = \left(\frac{1}{6}\sin^2\theta + \frac{1}{9}\cos^2\theta\right)^{-1/2}$.



The angle θ is changing between 0 and 2π, therefore the polar inequalities for the region are

$$\mathcal{D}: \ 0 \le \theta \le 2\pi, \ 1 \le r \le \left(\frac{1}{6}\sin^2\theta + \frac{1}{9}\cos^2\theta\right)^{-1/2}$$

Using the Double Integral in Polar Coordinates, we obtain the following iterated integral for the total charge on the plate:

$$\begin{aligned}
Q &= \int_0^{2\pi}\int_1^{\left(\frac{\sin^2\theta}{6}+\frac{\cos^2\theta}{9}\right)^{-1/2}} 3r^{-4}\cdot r\,dr\,d\theta = \int_0^{2\pi}\int_1^{\left(\frac{\sin^2\theta}{6}+\frac{\cos^2\theta}{9}\right)^{-1/2}} 3r^{-3}\,dr\,d\theta \\
&= \int_0^{2\pi} \left.\frac{-3r^{-2}}{2}\right|_{r=1}^{\left(\frac{\sin^2\theta}{6}+\frac{\cos^2\theta}{9}\right)^{-1/2}} d\theta = \int_0^{2\pi} -\frac{3}{2}\left(\frac{\sin^2\theta}{6} + \frac{\cos^2\theta}{9} - 1\right) d\theta \\
&= -\frac{3}{2}\int_0^{2\pi} \frac{2+\sin^2\theta}{18} - 1\,d\theta = -\frac{3}{2}\int_0^{2\pi} \frac{1}{18}\sin^2\theta - \frac{8}{9}\,d\theta \\
&= -\frac{3}{2}\left(\frac{1}{36}\theta - \frac{1}{36}\sin\theta\cos\theta - \frac{8}{9}\theta\right)\Bigg|_0^{2\pi} \\
&= -\frac{3}{2}\left(\frac{\pi}{18} - \frac{16\pi}{9}\right) = \frac{3}{2}\cdot\frac{31}{18}\pi = \frac{31}{12}\pi
\end{aligned}$$

In Exercises 11–14, find the centroid of the given region.

11. Region bounded by $y = 1 - x^2$ and $y = 0$

SOLUTION First we will compute the area of the region:

$$\text{Area}(\mathcal{D}) = \int_{-1}^{1}\int_0^{1-x^2} dy\,dx = \int_{-1}^{1} 1 - x^2\,dx = x - \frac{1}{3}x^3\Big|_{-1}^{1} = 1 - \frac{1}{3} - \left(-1 + \frac{1}{3}\right) = \frac{4}{3}$$

It is clear from symmetry that $\overline{x} = 0$, and

$$\begin{aligned}
\overline{y} &= \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} y\, dA = \frac{3}{4} \int_{-1}^{1} \int_{0}^{1-x^2} y\, dy\, dx \\
&= \frac{3}{4} \int_{-1}^{1} \frac{1}{2} y^2 \Big|_0^{1-x^2} dx = \frac{3}{8} \int_{-1}^{1} (1-x^2)^2\, dx \\
&= \frac{3}{8} \int_{-1}^{1} 1 - 2x^2 + x^4\, dx = \frac{3}{8} \left(x - \frac{2}{3}x^3 + \frac{1}{5}x^5 \right) \Big|_{-1}^{1} \\
&= \frac{3}{8} \left(1 - \frac{2}{3} + \frac{1}{5} \right) - \frac{3}{8} \left(-1 + \frac{2}{3} - \frac{1}{5} \right) = \frac{2}{5}
\end{aligned}$$

The centroid has coordinates $(\overline{x}, \overline{y}) = \left(0, \frac{2}{5}\right)$.

12. Region bounded by $y^2 = x + 4$ and $x = 4$

SOLUTION First we compute the area of the region. Note that when $x = 4$, $y = \pm\sqrt{8} = \pm 2\sqrt{2}$, so that

$$\text{Area}(\mathcal{D}) = \int_{-2\sqrt{2}}^{2\sqrt{2}} \int_{y^2-4}^{4} 1\, dx\, dy = \int_{-2\sqrt{2}}^{2\sqrt{2}} 8 - y^2\, dy = \left(8y - \frac{1}{3}y^3 \right) \Big|_{-2\sqrt{2}}^{2\sqrt{2}} = \frac{64}{3}\sqrt{2}$$

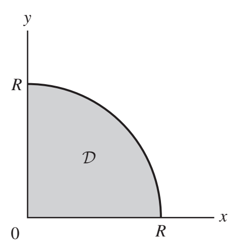
Since the region is symmetric around the x-axis, it is clear that $\overline{y} = 0$, and

$$\begin{aligned}
\overline{x} &= \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} x\, dA = \frac{3}{64\sqrt{2}} \int_{-2\sqrt{2}}^{2\sqrt{2}} \int_{y^2-4}^{4} x\, dx\, dy \\
&= \frac{3}{64\sqrt{2}} \int_{-2\sqrt{2}}^{2\sqrt{2}} \frac{1}{2} x^2 \Big|_{y^2-4}^{4} dy = \frac{3}{64\sqrt{2}} \cdot \frac{1}{2} \int_{-2\sqrt{2}}^{2\sqrt{2}} 16 - (y^2 - 4)^2\, dy \\
&= \frac{3}{128\sqrt{2}} \int_{-2\sqrt{2}}^{2\sqrt{2}} 8y^2 - y^4\, dy = \frac{3}{128\sqrt{2}} \left(\frac{8}{3}y^3 - \frac{1}{5}y^5 \Big|_{-2\sqrt{2}}^{2\sqrt{2}} \right) \\
&= \frac{3}{128\sqrt{2}} \left(\frac{128\sqrt{2}}{3} - \frac{128\sqrt{2}}{5} + \frac{128\sqrt{2}}{3} - \frac{128\sqrt{2}}{5} \right) \\
&= \frac{3}{128\sqrt{2}} \cdot \frac{512\sqrt{2}}{15} = \frac{4}{5}
\end{aligned}$$

The centroid has coordinates $(\overline{x}, \overline{y}) = \left(\frac{4}{5}, 0\right)$.

13. Quarter circle $x^2 + y^2 \le R^2$, $x \ge 0$, $y \ge 0$

SOLUTION



The centroid $P = (\overline{x}, \overline{y})$ has the following coordinates:

$$\begin{aligned}
\overline{x} &= \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} x\, dA = \frac{4}{\pi R^2} \iint_{\mathcal{D}} x\, dA \\
\overline{y} &= \frac{1}{\text{Area}(\mathcal{D})} \iint_{\mathcal{D}} y\, dA = \frac{4}{\pi R^2} \iint_{\mathcal{D}} y\, dA
\end{aligned}$$

We compute the integrals using polar coordinates. The domain $\mathcal{D}$ is described in polar coordinates by the inequalities

$$\mathcal{D}: 0 \le \theta \le \frac{\pi}{2},\ 0 \le r \le R$$

The functions are $x = r\cos\theta$ and $y = r\sin\theta$, respectively. Using the Change of Variables Formula gives

$$\begin{aligned}\overline{x} &= \frac{4}{\pi R^2}\int_0^{\pi/2}\int_0^R r\cos\theta\cdot r\,dr\,d\theta = \frac{4}{\pi R^2}\int_0^{\pi/2}\int_0^R r^2\cos\theta\,dr\,d\theta = \frac{4}{\pi R^2}\int_0^{\pi/2}\frac{r^3\cos\theta}{3}\bigg|_{r=0}^R d\theta \\ &= \frac{4}{\pi R^2}\int_0^{\pi/2}\frac{R^3\cos\theta}{3}\,d\theta = \frac{4R}{3\pi}\sin\theta\bigg|_0^{\pi/2} = \frac{4R}{3\pi}\left(\sin\frac{\pi}{2} - \sin 0\right) = \frac{4R}{3\pi}\end{aligned}$$

And,

$$\begin{aligned}\overline{y} &= \frac{4}{\pi R^2}\int_0^{\pi/2}\int_0^R r\sin\theta\cdot r\,dr\,d\theta = \frac{4}{\pi R^2}\int_0^{\pi/2}\int_0^R r^2\sin\theta\,dr\,d\theta = \frac{4}{\pi R^2}\int_0^{\pi/2}\frac{r^3\sin\theta}{3}\bigg|_{r=0}^R d\theta \\ &= \frac{4}{\pi R^2}\int_0^{\pi/2}\frac{R^3\sin\theta}{3}\,d\theta = \frac{4R}{3\pi}(-\cos\theta)\bigg|_0^{\pi/2} = \frac{4R}{3\pi}\left(-\cos\frac{\pi}{2} + \cos 0\right) = \frac{4R}{3\pi}\end{aligned}$$

Notice that we can use the symmetry of $\mathcal{D}$ with respect to x and y to conclude that $\overline{y} = \overline{x}$, and save the computation of $\overline{y}$. We obtain the centroid $P = \left(\frac{4R}{3\pi}, \frac{4R}{3\pi}\right)$.

14. Infinite lamina bounded by the x- and y-axes and the graph of $y = e^{-x}$

SOLUTION The area of this region is

$$A = \int_0^\infty e^{-x}\,dx = \left(-e^{-x}\right)\bigg|_0^\infty = 1$$

Using integration by parts, we have

$$\begin{aligned}\overline{x} &= \frac{1}{A}\iint_{\mathcal{D}} x\,dA = \int_0^\infty\int_0^{e^{-x}} x\,dy\,dx = \int_0^\infty xe^{-x}\,dx = \left(-xe^{-x}\right)\bigg|_0^\infty + \int_0^\infty e^{-x}\,dx \\ &= 0 - \left(-e^{-x}\bigg|_0^\infty\right) = 1\end{aligned}$$

and

$$\begin{aligned}\overline{y} &= \frac{1}{A}\iint_{\mathcal{D}} y\,dA = \int_0^\infty\int_0^{e^{-x}} y\,dy\,dx = \int_0^\infty\left(\frac{1}{2}y^2\right)\bigg|_0^{e^{-x}} dx \\ &= \int_0^\infty \frac{1}{2}e^{-2x}\,dx = \left(-\frac{1}{4}e^{-2x}\right)\bigg|_0^\infty = \frac{1}{4}\end{aligned}$$

and therefore the centroid is $(\overline{x}, \overline{y}) = \left(1, \dfrac{1}{4}\right)$.

15. CAS Use a computer algebra system to compute numerically the centroid of the shaded region in Figure 12 bounded by $r^2 = \cos 2\theta$ for $x \geq 0$.

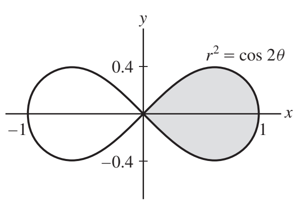


FIGURE 12

SOLUTION Using symmetry, it is easy to see $\overline{y} = 0$. Also, computing the area of the region,

$$\text{Area} = 2\cdot\frac{1}{2}\int_{-\pi/4}^{\pi/4} r^2\,d\theta = \int_{-\pi/4}^{\pi/4}\cos 2\theta\,d\theta = \frac{1}{2}\sin 2\theta\bigg|_{-\pi/4}^{\pi/4} = 1$$

and we will compute $\overline{x}$ as

$$\overline{x} = \frac{1}{A}\iint_{\mathcal{D}} x\,dA = \int_{\theta=-\pi/4}^{\pi/4}\int_{r=0}^{\sqrt{\cos 2\theta}} r\cos\theta\cdot r\,dr\,d\theta = \frac{\sqrt{2}}{16}\pi \approx 0.278$$

Therefore, we have that the centroid is $(\overline{x}, \overline{y}) = (\sqrt{2}\pi/16, 0)$.

16. Show that the centroid of the sector in Figure 13 has y-coordinate

$$\overline{y} = \left(\frac{2R}{3}\right)\left(\frac{\sin\theta}{\theta}\right)$$

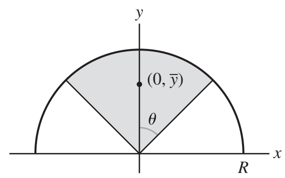

FIGURE 13

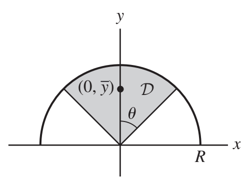
SOLUTION



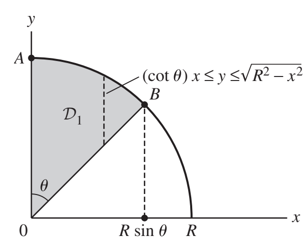
The y-coordinate of the centroid of the sector $\mathcal{D}$ is the average value of the y-coordinate of a point in the sector. That is,

$$\overline{y} = \frac{1}{\text{Area}(\mathcal{D})}\iint_{\mathcal{D}} y\,dA$$

The sector is symmetric with respect to the y-axis, and the integrand $f(x, y) = y$ satisfies $f(-x, y) = f(x, y)$, hence the double integral over $\mathcal{D}$ is twice the integral over the right half $\mathcal{D}_1$ of the sector. Also $\text{Area}(\mathcal{D}) = 2\text{Area}\,(\mathcal{D}_1)$, therefore

$$\overline{y} = \frac{1}{\text{Area}\,(\mathcal{D}_1)}\iint_{\mathcal{D}_1} y\,dA \tag{1}$$

We now find the inequalities describing $\mathcal{D}_1$ as a vertically simple region.



The circle bounding the region has the equation $y = \sqrt{R^2 - x^2}$ and the line OB has the equation $y = (\cot\theta)x$. We obtain the following inequalities for $\mathcal{D}_1$:

$$0 \le x \le R\sin\theta, \quad (\cot\theta)x \le y \le \sqrt{R^2 - x^2}$$

Hence,

$$\iint_{\mathcal{D}_1} y\,dA = \int_0^{R\sin\theta}\int_{(\cot\theta)x}^{\sqrt{R^2-x^2}} y\,dy\,dx = \int_0^{R\sin\theta} \frac{y^2}{2}\bigg|_{y=(\cot\theta)x}^{\sqrt{R^2-x^2}} dx = \int_0^{R\sin\theta} \frac{R^2 - x^2 - (\cot\theta)^2x^2}{2}\,dx$$

$$= \int_0^{R\sin\theta}\left(\frac{R^2}{2} - \frac{x^2}{2\sin^2\theta}\right)dx = \frac{R^2}{2}x - \frac{x^3}{6\sin^2\theta}\bigg|_{x=0}^{R\sin\theta} = \frac{R^3\sin\theta}{2} - \frac{R^3\sin^3\theta}{6\sin^2\theta} = \frac{R^3\sin\theta}{3} \tag{2}$$

The area of the sector $\mathcal{D}_1$ is

$$\text{Area}\,(\mathcal{D}_1) = \frac{R^2\theta}{2} \tag{3}$$

Substituting (2) and (3) in (1), we obtain the following solution:

$$\overline{y} = \frac{1}{\frac{R^2\theta}{2}} \cdot \frac{R^3\sin\theta}{3} = \frac{2R^3\sin\theta}{3R^2\theta} = \left(\frac{2R}{3}\right)\left(\frac{\sin\theta}{\theta}\right)$$

In Exercises 17–19, find the centroid of the given solid region.

17. Hemisphere $x^2 + y^2 + z^2 \le R^2, z \ge 0$

SOLUTION First we need to find the volume of the solid in question. It is a hemisphere, so using geometry, we have

$$\text{Volume} = \frac{1}{2} \cdot \frac{4}{3}\pi R^3 = \frac{2\pi R^3}{3}$$

The centroid is the point P with the following coordinates:

$$\overline{x} = \frac{1}{V}\iiint_{\mathcal{W}} x\,dV, \quad \overline{y} = \frac{1}{V}\iiint_{\mathcal{W}} y\,dV, \quad \overline{z} = \frac{1}{V}\iiint_{\mathcal{W}} z\,dV$$

By symmetry, it is clear that $\overline{x} = \overline{y} = 0$, and using spherical coordinates,

$$\begin{aligned}
\overline{z} &= \frac{1}{V}\iiint_{region} z\,dV = \frac{3}{2\pi R^3}\int_0^{2\pi}\int_0^{\pi/2}\int_0^R \rho\cos\phi \cdot \rho^2 \sin\phi\,d\rho\,d\phi\,d\theta \\
&= \frac{3}{2\pi R^3}\int_0^{2\pi}\int_0^{\pi/2}\int_0^R \rho^3 \cos\phi\sin\phi\,d\rho\,d\phi\,d\theta \\
&= \frac{3}{2\pi R^3}\int_0^{2\pi} 1\,d\theta \cdot \int_0^{\pi/2}\cos\phi\sin\phi\,d\phi \cdot \int_0^R \rho^3\,d\rho \\
&= \frac{3}{2\pi R^3}\cdot 2\pi\left(\frac{1}{2}\sin^2\phi\Big|_0^{\pi/2}\right)\left(\frac{1}{4}\rho^4\Big|_0^R\right) = \frac{3}{2\pi R^3}\cdot 2\pi \cdot \frac{1}{2}\cdot\frac{1}{4}R^4 = \frac{3R}{8}
\end{aligned}$$

Therefore, the coordinates of the centroid of a hemisphere having radius R, are $(0, 0, 3R/8)$.

18. Region bounded by the xy-plane, the cylinder $x^2 + y^2 = R^2$, and the plane $x/R + z/H = 1$, where $R > 0$ and $H > 0$

SOLUTION First to find the volume of this solid. The first equation lends itself well to cylindrical coordinates:

$$x^2 + y^2 = R^2 \quad \Rightarrow \quad r = R, 0 \le \theta \le 2\pi$$

and

$$\frac{x}{R} + \frac{z}{H} = 1 \quad \Rightarrow \quad z = H\left(1 - \frac{x}{R}\right) = H\left(1 - \frac{r\cos\theta}{R}\right)$$

The volume is:

$$\begin{aligned}
V &= \int_0^{2\pi}\int_0^R\int_0^{H(1-r\cos\theta/R)} 1\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^R H\left(1 - \frac{r\cos\theta}{R}\right)dr\,d\theta \\
&= H\int_0^{2\pi} r - \frac{1}{2}\cdot\frac{r^2\cos\theta}{R}\Big|_{r=0}^R d\theta = H\int_0^{2\pi} R - \frac{1}{2}R\cos\theta\,d\theta \\
&= H\left(R\theta - \frac{1}{2}R\sin\theta\Big|_0^{2\pi}\right) = 2\pi HR
\end{aligned}$$

Now to compute the coordinates of the centroid:

$$\begin{aligned}
\overline{x} &= \frac{1}{V}\iiint_{\mathcal{W}} x\,dV = \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R\int_0^{H(1-r\cos\theta/R)} r\cos\theta\,dz\,dr\,d\theta \\
&= \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R r\cos\theta\cdot z\Big|_0^{H(1-r\cos\theta/R)} dr\,d\theta = \frac{H}{2\pi HR}\int_0^{2\pi}\int_0^R r\cos\theta\left(1 - \frac{r\cos\theta}{R}\right)dr\,d\theta \\
&= \frac{1}{2\pi R}\int_0^{2\pi}\int_0^R r\cos\theta - \frac{1}{R}r^2\cos^2\theta\,dr\,d\theta = \frac{1}{2\pi R}\int_0^{2\pi}\frac{1}{2}r^2\cos\theta - \frac{1}{3R}r^3\cos^2\theta\Big|_0^R d\theta \\
&= \frac{1}{2\pi R}\int_0^{2\pi}\frac{1}{2}R^2\cos\theta - \frac{R^2}{6}(1+\cos 2\theta)\,d\theta \\
&= \frac{1}{2\pi R}\left(\frac{1}{2}R^2\sin\theta - \frac{R^2}{6}\left(\theta + \frac{1}{2}\sin 2\theta\right)\Big|_0^{2\pi}\right) = \frac{1}{2\pi R}\cdot -\frac{R^2}{6}(2\pi) = -\frac{R}{6}
\end{aligned}$$

$$\begin{aligned}
\overline{y} &= \frac{1}{V}\iiint_{\mathcal{W}} y\,dV = \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R\int_0^{H(1-r\cos\theta/R)} r\sin\theta\,dz\,dr\,d\theta\\
&= \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R r\sin\theta\cdot z\Big|_0^{H(1-r\cos\theta/R)} dr\,d\theta = \frac{H}{2\pi HR}\int_0^{2\pi}\int_0^R r\sin\theta\left(1-\frac{r\cos\theta}{R}\right)dr\,d\theta\\
&= \frac{1}{2\pi R}\int_0^{2\pi}\int_0^R r\sin\theta - \frac{1}{R}r^2\sin\theta\cos\theta\,dr\,d\theta = \frac{1}{2\pi R}\int_0^{2\pi}\frac{1}{2}r^2\sin\theta - \frac{1}{3R}r^3\sin\theta\cos\theta\Big|_0^R d\theta\\
&= \frac{1}{2\pi R}\int_0^{2\pi}\frac{1}{2}R^2\sin\theta - \frac{R^2}{3}\sin\theta\cos\theta\,d\theta = \frac{1}{2\pi R}\left(-\frac{1}{2}R^2\cos\theta - \frac{R^2}{6}\sin^2\theta\Big|_0^{2\pi}\right) = 0
\end{aligned}$$

$$\begin{aligned}
\overline{z} &= \frac{1}{V}\iiint_{\mathcal{W}} z\,dV = \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R\int_0^{H(1-r\cos\theta/R)} z\,dz\,dr\,d\theta\\
&= \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R \frac{1}{2}z^2\Big|_0^{H(1-r\cos\theta/R)} dr\,d\theta = \frac{H^2}{4\pi HR}\int_0^{2\pi}\int_0^R\left(1-\frac{r\cos\theta}{R}\right)^2 dr\,d\theta\\
&= \frac{H}{4\pi R}\int_0^{2\pi}\int_0^R 1 - \frac{2r\cos\theta}{R} + \frac{r^2\cos^2\theta}{R^2}\,dr\,d\theta = \frac{H}{4\pi R}\int_0^{2\pi} r - \frac{r^2\cos\theta}{R} + \frac{r^3\cos^2\theta}{3R^2}\Big|_0^R d\theta\\
&= \frac{H}{4\pi R}\int_0^{2\pi} R - R\cos\theta + \frac{1}{6}R(1+\cos 2\theta)\,d\theta = \frac{H}{4\pi R}\left(R\theta - R\sin\theta + \frac{1}{6}R\left(\theta + \frac{1}{2}\sin 2\theta\right)\Big|_0^{2\pi}\right)\\
&= \frac{H}{4\pi R}\left(2\pi R + \frac{1}{3}\pi R\right)\\
&= \frac{H}{4\pi R}\cdot\frac{7\pi R}{3} = \frac{7}{12}H
\end{aligned}$$

The coordinates of the centroid are $(-R/6, 0, 7H/12)$.

19. The "ice cream cone" region $\mathcal{W}$ bounded, in spherical coordinates, by the cone $\phi = \pi/3$ and the sphere $\rho = 2$

SOLUTION First we must find the volume of this solid:

$$\begin{aligned}
V &= \int_{\theta=0}^{2\pi}\int_{\phi=0}^{\pi/3}\int_{\rho=0}^{2}\rho^2\sin\phi\,d\rho\,d\phi\,d\theta\\
&= 2\pi\left(\int_0^{\pi/3}\sin\phi\,d\phi\right)\left(\int_0^2\rho^2\,d\rho\right) = 2\pi\cdot\frac{8}{3}\left(-\cos\phi\Big|_0^{\pi/3}\right)\\
&= \frac{16\pi}{3}\cdot\frac{1}{2} = \frac{8\pi}{3}
\end{aligned}$$

And now compute the coordinates of the centroid. By symmetry, it is clear that $\overline{x} = \overline{y} = 0$.

$$\begin{aligned}
\overline{z} &= \frac{1}{V}\iiint_{\mathcal{W}} z\,dV = \frac{3}{8\pi}\int_{\theta=0}^{2\pi}\int_{\phi=0}^{\pi/3}\int_{\rho=0}^{2}\rho\cos\phi\cdot\rho^2\sin\phi\,d\rho\,d\phi\,d\theta\\
&= \frac{3}{8\pi}\int_0^{2\pi}d\theta\cdot\int_0^{\pi/3}\cos\phi\sin\phi\,d\phi\cdot\int_0^2\rho^3\,d\rho\\
&= \frac{3}{8\pi}\cdot 2\pi\cdot\left(\frac{1}{2}\sin^2\phi\Big|_0^{\pi/3}\right)\left(\frac{1}{4}\rho^4\Big|_0^2\right) = \frac{3}{4}\left(\frac{1}{2}\cdot\frac{3}{4}\right)(4) = \frac{9}{8}
\end{aligned}$$

The coordinates of the centroid are $(0, 0, 9/8)$.

20. Show that the z-coordinate of the centroid of the tetrahedron bounded by the coordinate planes and the plane

$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$$

in Figure 14 is $\overline{z} = c/4$. Conclude by symmetry that the centroid is $(a/4, b/4, c/4)$.

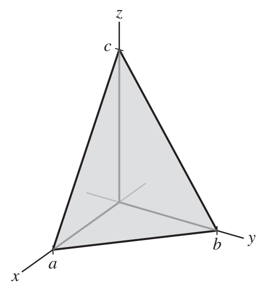


FIGURE 14

SOLUTION First we must find the volume of the tetrahedron. Solving the equation of the plane for z we get:

$$z = c - \frac{c}{a}x - \frac{c}{b}y$$

and the projection into the xy-plane is:

$$y = b - \frac{b}{a}x$$

Hence, volume can be computed:

$$\begin{aligned}
Volume &= \iiint_{\mathcal{W}} 1\, dV = \int_{x=0}^{a}\int_{y=0}^{b-\frac{b}{a}x}\int_{z=0}^{c-\frac{c}{a}x-\frac{c}{b}y} 1\, dz\, dy\, dx \\
&= \int_0^a \int_0^{b-\frac{b}{a}x} z\Big|_0^{c-\frac{c}{a}x-\frac{c}{b}y} dy\, dx = \int_0^a\int_0^{b-\frac{b}{a}x} c - \frac{c}{a}x - \frac{c}{b}y\, dy\, dx \\
&= \int_0^a cy - \frac{c}{a}xy - \frac{c}{2b}y^2\Big|_0^{b-\frac{b}{a}x} dx \\
&= \int_0^a c\left(b - \frac{b}{a}x\right) - \frac{c}{a}x\left(b - \frac{b}{a}x\right) - \frac{c}{2b}\left(b - \frac{b}{a}x\right)^2 dx \\
&= \int_0^a \frac{bc}{2} - \frac{bc}{a}x + \frac{bc}{2a^2}x^2\, dx \\
&= \frac{bc}{2}x - \frac{bc}{2a}x^2 + \frac{bc}{6a^2}x^3\Big|_0^a = \frac{abc}{2} - \frac{abc}{2} + \frac{abc}{6} = \frac{abc}{6}
\end{aligned}$$

Now to find $\overline{z}$, the z-coordinate of the centroid:

$$\begin{aligned}
\overline{z} &= \frac{1}{V}\iiint_{\mathcal{W}} 1\, dV = \frac{6}{abc}\int_{x=0}^{a}\int_{y=0}^{b-\frac{b}{a}x}\int_{z=0}^{c-\frac{c}{a}x-\frac{c}{b}y} z\, dz\, dy\, dx \\
&= \frac{3}{abc}\int_{x=0}^{a}\int_{y=0}^{b-\frac{b}{a}x} z^2\Big|_{z=0}^{c-\frac{c}{a}x-\frac{c}{b}y} dy\, dx \\
&= \frac{3}{abc}\int_0^a\int_0^{b-\frac{b}{a}x}\left(c - \frac{c}{a}x - \frac{c}{b}y\right)^2 dy\, dx \\
&= \frac{3}{abc}\int_0^a\int_0^{b-\frac{b}{a}x} c^2 - \frac{2c^2}{a}x - \frac{2c^2}{b}y + \frac{2c^2}{ab}xy + \frac{c^2}{a^2}x^2 + \frac{c^2}{b^2}y^2\, dy\, dx \\
&= \frac{3}{abc}\int_0^a c^2y - \frac{2c^2}{a}xy - \frac{c^2}{b}y^2 + \frac{c^2}{ab}xy^2 + \frac{c^2}{a^2}x^2y + \frac{c^2}{3b^2}y^3\Big|_0^{b-\frac{b}{a}x} dx \\
&= \frac{3}{abc}\int_0^a c^2\left(b - \frac{b}{a}x\right) - \frac{2c^2}{a}x\left(b - \frac{b}{a}x\right) - \frac{c^2}{b}\left(b - \frac{b}{a}x\right)^2 \\
&\qquad + \frac{c^2}{ab}x\left(b - \frac{b}{a}x\right)^2 + \frac{c^2}{a^2}x^2\left(b - \frac{b}{a}x\right) + \frac{c^2}{3b^2}\left(b - \frac{b}{a}x\right)^3 dx
\end{aligned}$$

$$= \frac{3}{abc}\int_0^a \frac{bc^2}{3} - \frac{bc^2}{a}x + \frac{bc^2}{a^2}x^2 - \frac{bc^2}{3a^3}x^3\,dx$$
$$= \frac{3}{abc}\left(\frac{bc^2}{3}x - \frac{bc^2}{2a}x^2 + \frac{bc^2}{3a^2}x^3 - \frac{bc^2}{12a^3}x^4\Big|_0^a\right)$$
$$= \frac{3}{abc}\left(\frac{abc^2}{3} - \frac{abc^2}{2} + \frac{abc^2}{3} - \frac{abc^2}{12}\right)$$
$$= \frac{3}{abc}\cdot\frac{abc^2}{12} = \frac{c}{4}$$

Then, using symmetry, we can conclude $\overline{x} = a/4$ and $\overline{y} = b/4$, therefore, the coordinates of the centroid are $(a/4, b/4, c/4)$.

21. Find the centroid of the region $\mathcal{W}$ lying above the sphere $x^2 + y^2 + z^2 = 6$ and below the paraboloid $z = 4 - x^2 - y^2$ (Figure 15).

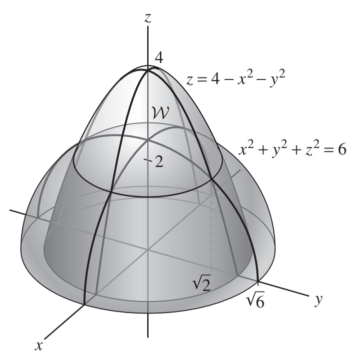

FIGURE 15

SOLUTION The centroid is the point P with the following coordinates:

$$\overline{x} = \frac{1}{V}\iiint_{\mathcal{W}} x\,dV,\quad \overline{y} = \frac{1}{V}\iiint_{\mathcal{W}} y\,dV,\quad \overline{z} = \frac{1}{V}\iiint_{\mathcal{W}} z\,dV$$

In a previous section we showed that the volume of the region is $V = 1.54\pi$. We also showed that $\mathcal{D}$ has the following definition in cylindrical coordinates:

$$0 \le \theta \le 2\pi,\quad 0 \le r \le \sqrt{2},\quad \sqrt{6 - r^2} \le z \le 4 - r^2$$

Using this information we compute the coordinates of the centroid by the following integrals:

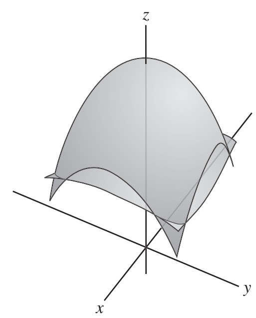
$$\overline{x} = \frac{1}{1.54\pi}\int_0^{2\pi}\int_0^{\sqrt{2}}\int_{\sqrt{6-r^2}}^{4-r^2}(r\cos\theta)r\,dz\,dr\,d\theta = \frac{1}{1.54\pi}\int_0^{2\pi}\int_0^{\sqrt{2}} r^2\cos\theta z\Big|_{z=\sqrt{6-r^2}}^{4-r^2}dr\,d\theta$$
$$= \frac{1}{1.54\pi}\int_0^{2\pi}\int_0^{\sqrt{2}} r^2\cos\theta\left(4 - r^2 - \sqrt{6-r^2}\right)dr\,d\theta$$
$$= \frac{1}{1.54\pi}\int_0^{2\pi}\cos\theta\int_0^{\sqrt{2}}\left(4r^2 - r^4 - r^2\sqrt{6-r^2}\right)dr\,d\theta \tag{1}$$

We denote the inner integral by a and compute the second integral to obtain

$$\overline{x} = \frac{1}{1.54\pi}\int_0^{2\pi}\cos\theta\cdot a\,d\theta = \frac{1}{1.54\pi}a\sin\theta\Big|_0^{2\pi} = 0$$

The value $\overline{x} = 0$ is the result of the symmetry of $\mathcal{W}$ with respect to the yz-plane. Similarly, since $\mathcal{W}$ is symmetric with respect to the xz-plane, the average value of the y-coordinate is zero.

$\overline{y} = 0$:



We compute the z-coordinate of the centroid:

$$\overline{z} = \frac{1}{1.54\pi}\int_0^{2\pi}\int_0^{\sqrt{2}}\int_{\sqrt{6-r^2}}^{4-r^2} zr\,dz\,dr\,d\theta = \frac{1}{1.54\pi}\int_0^{2\pi}\int_0^{\sqrt{2}} \frac{z^2 r}{2}\bigg|_{z=\sqrt{6-r^2}}^{4-r^2} dr\,d\theta$$

$$= \frac{1}{1.54\pi}\int_0^{2\pi}\int_0^{\sqrt{2}} \frac{r}{2}\left((4-r^2)^2 - \left(\sqrt{6-r^2}\right)^2\right) dr\,d\theta$$

$$= \frac{1}{2\cdot 1.54\pi}\int_0^{2\pi}\int_0^{\sqrt{2}} (r^5 - 7r^3 + 10r)\,dr\,d\theta$$

$$= \frac{1}{3.08\pi}\int_0^{2\pi} \frac{r^6}{6} - \frac{7r^4}{4} + 5r^2\bigg|_{r=0}^{\sqrt{2}} d\theta = \frac{1}{3.08\pi}\cdot\frac{13}{3}\cdot 2\pi \approx 2.81$$

Therefore the centroid of $\mathcal{W}$ is

$$P = (0, 0, 2.81).$$

22. Let $R > 0$ and $H > 0$, and let $\mathcal{W}$ be the upper half of the ellipsoid $x^2 + y^2 + (Rz/H)^2 = R^2$ where $z \geq 0$ (Figure 16). Find the centroid of $\mathcal{W}$ and show that it depends on the height H but not on the radius R.

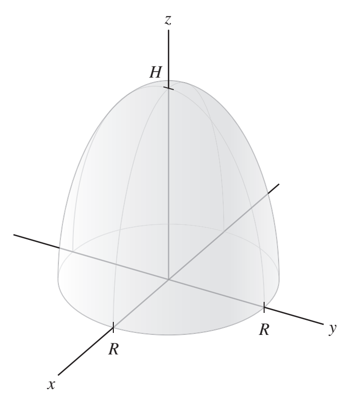


FIGURE 16 Upper half of ellipsoid $x^2 + y^2 + (Rz/H)^2 = R^2$, $z \geq 0$.

SOLUTION By symmetry, it is clear that the x and y-coordinates of the centroid are both zero. To find the z-coordinate, we first compute the volume. Using cylindrical coordinates, the equation of the ellipsoid is

$$z = \sqrt{\frac{H^2}{R^2}(R^2 - x^2 - y^2)} = \frac{H}{R}\sqrt{R^2 - r^2}$$

so that

$$M = \int_0^{2\pi}\int_0^R\int_0^{\frac{H}{R}\sqrt{R^2-r^2}} r\,dz\,dr\,d\theta = 2\pi\frac{H}{R}\int_0^R r\sqrt{R^2-r^2}\,dr$$

$$= 2\pi\frac{H}{R}\cdot\left(-\frac{1}{3}(R^2-r^2)^{3/2}\right)\bigg|_0^R = 2\pi\frac{H}{R}\cdot\left(\frac{1}{3}R^3\right) = \frac{2}{3}\pi H R^2$$

and the z-moment is

$$M_{xy} = \iiint_E z\,dV = \int_0^{2\pi} \int_0^R \int_0^{\frac{H}{R}\sqrt{R^2-r^2}} zr\,dz\,dr\,d\theta = 2\pi \int_0^R \frac{1}{2} r z^2 \Big|_0^{\frac{H}{R}\sqrt{R^2-r^2}} dr$$
$$= \pi \frac{H^2}{R^2} \int_0^R R^2 r - r^3\,dr = \pi \frac{H^2}{R^2} \left(\frac{1}{2} R^2 r^2 - \frac{1}{4} r^4 \right) \Big|_0^R = \pi \frac{H^2}{R^2} \left(\frac{1}{2} R^4 - \frac{1}{4} R^4 \right)$$
$$= \frac{1}{4} \pi H^2 R^2$$

Thus the z-coordinate of the centroid is

$$\frac{M_{xy}}{M} = \frac{1}{4} \pi H^2 R^2 \cdot \frac{3}{2\pi H R^2} = \frac{3}{8} H$$

which depends on H but not on R.

In Exercises 23–26, find the center of mass of the region with the given mass density ρ.

23. Region bounded by $y = 4 - x$, $x = 0$, $y = 0$; $\rho(x, y) = x$

SOLUTION The mass of the region is

$$M = \int_0^4 \int_0^{4-x} x\,dy\,dx = \int_0^4 xy \Big|_0^{4-x} dx = \int_0^4 4x - x^2\,dx = 2x^2 - \frac{1}{3} x^3 \Big|_0^4 = 32 - \frac{64}{3} = \frac{32}{3}$$

and we have

$$M_x = \int_0^4 \int_0^{4-x} yx\,dy\,dx = \int_0^4 \frac{1}{2} x y^2 \Big|_0^{4-x} dx = \frac{1}{2} \int_0^4 16x - 8x^2 + x^3\,dx$$
$$= \frac{1}{2} \left(8x^2 - \frac{8}{3} x^3 + \frac{1}{4} x^4 \right) \Big|_0^4 = \frac{1}{2} \left(128 - \frac{512}{3} + 64 \right) = \frac{32}{3}$$

and

$$M_y = \int_0^4 \int_0^{4-x} x^2\,dy\,dx = \int_0^4 x^2 y \Big|_0^{4-x} dx = \int_0^4 4x^2 - x^3\,dx$$
$$= \left(\frac{4}{3} x^3 - \frac{1}{4} x^4 \right) \Big|_0^4 = \frac{256}{3} - 64 = \frac{64}{3}$$

and thus the center of mass is

$$\left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{64}{3} \cdot \frac{3}{32}, \frac{32}{3} \cdot \frac{3}{32} \right) = (2, 1)$$

24. Region bounded by $y^2 = x + 4$ and $x = 0$; $\rho(x, y) = |y|$

SOLUTION Solving for x gives $x = y^2 - 4$. Now, the mass of the region is

$$M = \int_{-2}^2 \int_{y^2-4}^0 |y|\,dx\,dy = 2 \int_0^2 \int_{y^2-4}^0 y\,dx\,dy = 2 \int_0^2 yx \Big|_{y^2-4}^0 dy$$
$$= 2 \int_0^2 4y - y^3\,dy = 2 \left(2y^2 - \frac{1}{4} y^4 \right) \Big|_0^2 = 2(8 - 4) = 8$$

and

$$M_y = \iint_{\mathcal{D}} x\rho(x, y)\,dA = \int_{-2}^2 \int_{y^2-4}^0 x|y|\,dx\,dy = 2 \int_0^2 \int_{y^2-4}^0 xy\,dx\,dy$$
$$= 2 \int_0^2 y \cdot \frac{1}{2} x^2 \Big|_{y^2-4}^0 dy = - \int_0^2 y(y^2 - 4)^2\,dy$$
$$= -\frac{1}{2} \int_{-4}^0 u^2\,du = -\frac{1}{6} u^3 \Big|_{-4}^0 = \frac{-32}{3}$$

Clearly $M_x = 0$ by symmetry, since both the region and the density are symmetric around the x-axis. Thus the center of mass is

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(-\frac{32}{3} \cdot \frac{1}{8}, 0\right) = \left(-\frac{4}{3}, 0\right)$$

25. Region $|x| + |y| \leq 1$; $\quad \rho(x, y) = (x+1)(y+1)$

SOLUTION For $x \leq 0$, the region is defined by $-1 \leq x \leq 0$ and $-1 - x \leq y \leq 1 + x$; for $x \geq 0$, it is parameterized by $0 \leq x \leq 1$ and $-1 + x \leq y \leq 1 - x$. The mass of the region is thus

$$\begin{aligned}
M &= \int_{-1}^{0} \int_{-1-x}^{1+x} (x+1)(y+1)\, dy\, dx + \int_{0}^{1} \int_{x-1}^{1-x} (x+1)(y+1)\, dy\, dx \\
&= \frac{1}{2}\left(\int_{-1}^{0} (x+1)(y+1)^2 \Big|_{y=-1-x}^{1+x} dx + \int_{0}^{1} (x+1)(y+1)^2 \Big|_{y=x-1}^{1-x} dx\right) \\
&= \frac{1}{2}\left(\int_{-1}^{0} (x+1)((x+2)^2 - (-x)^2)\, dx + \int_{0}^{1} (x+1)((2-x)^2 - x^2)\, dx\right) \\
&= \frac{1}{2}\left(\int_{-1}^{0} 4(x+1)^2\, dx + \int_{0}^{1} 4(1-x^2)\, dx\right) \\
&= 2\left(\left(\frac{1}{3}(x+1)^3\right)\Big|_{-1}^{0} + \left(x - \frac{1}{3}x^3\right)\Big|_{0}^{1}\right) = 2\left(\frac{1}{3} + \left(1 - \frac{1}{3}\right)\right) = 2
\end{aligned}$$

We have

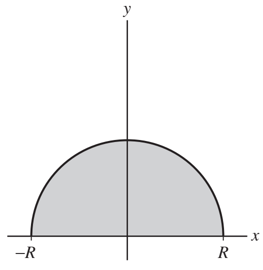
$$\begin{aligned}
M_x &= \int_{-1}^{0} \int_{-1-x}^{1+x} y(x+1)(y+1)\, dy\, dx + \int_{0}^{1} \int_{x-1}^{1-x} y(x+1)(y+1)\, dy\, dx \\
&= \int_{-1}^{0} \int_{-1-x}^{1+x} (x+1)(y^2+y)\, dy\, dx + \int_{0}^{1} \int_{x-1}^{1-x} (x+1)(y^2+y)\, dy\, dx \\
&= \int_{-1}^{0} (x+1)\left(\frac{1}{3}y^3 + \frac{1}{2}y^2\right)\Big|_{y=-1-x}^{1+x} dx + \int_{0}^{1} (x+1)\left(\frac{1}{3}y^3 + \frac{1}{2}y^2\right)\Big|_{y=x-1}^{1-x} dx \\
&= \int_{-1}^{0} (x+1)\left(\frac{2}{3} + 2x + 2x^2 + \frac{2}{3}x^3\right) dx + \int_{0}^{1} (x+1)\left(\frac{2}{3} - 2x + 2x^2 - \frac{2}{3}x^3\right) dx \\
&= \int_{-1}^{0} \frac{2}{3}x^4 + \frac{8}{3}x^3 + 4x^2 + \frac{8}{3}x + \frac{2}{3}\, dx + \int_{0}^{1} -\frac{2}{3}x^4 + \frac{4}{3}x^3 - \frac{4}{3}x + \frac{2}{3}\, dx \\
&= \left(\frac{2}{15}x^5 + \frac{2}{3}x^4 + \frac{4}{3}x^3 + \frac{4}{3}x^2 + \frac{2}{3}x\right)\Big|_{-1}^{0} + \left(-\frac{2}{15}x^5 + \frac{1}{3}x^4 - \frac{2}{3}x^3 + \frac{2}{3}x\right)\Big|_{0}^{1} \\
&= \frac{2}{15} + \frac{1}{5} = \frac{1}{3}
\end{aligned}$$

Since the region and the density function are symmetric in x and y, we must have also $M_y = M_x = \frac{1}{3}$. Then the center of mass is

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(\frac{1}{3} \cdot \frac{1}{2}, \frac{1}{3} \cdot \frac{1}{2}\right) = \left(\frac{1}{6}, \frac{1}{6}\right)$$

26. Semicircle $x^2 + y^2 \leq R^2$, $y \geq 0$; $\quad \rho(x, y) = y$

SOLUTION



The center of mass has the following coordinates:

$$x_{\text{CM}} = \frac{1}{M}\iint_{\mathcal{D}} x\rho\, dA = \frac{1}{M}\iint_{\mathcal{D}} xy\, dA$$
$$y_{\text{CM}} = \frac{1}{M}\iint_{\mathcal{D}} y\rho\, dA = \frac{1}{M}\iint_{\mathcal{D}} y^2\, dA$$

We compute the integrals using polar coordinates. The semicircle $\mathcal{D}$ has the following description:

$$0 \le \theta \le \pi, \quad 0 \le r \le R$$

We first compute the total mass M. Using the Change of Variables Formula we get

$$M = \iint_{\mathcal{D}} \rho(x, y, z)\, dA = \iint_{\mathcal{D}} y\, dA = \int_0^{\pi}\int_0^R r\sin\theta \cdot r\, dr\, d\theta = \int_0^{\pi}\int_0^R r^2 \sin\theta\, dr\, d\theta$$
$$= \int_0^{\pi} \left.\frac{r^3\sin\theta}{3}\right|_{r=0}^{R} d\theta = \int_0^{\pi} \frac{R^3\sin\theta}{3}\, d\theta = -\left.\frac{R^3\cos\theta}{3}\right|_0^{\pi} = -\frac{R^3}{3}(\cos\pi - \cos 0) = \frac{2R^3}{3}$$

We compute x_{CM}:

$$x_{\text{CM}} = \frac{1}{M}\iint_{\mathcal{D}} xy\, dA = \frac{3}{2R^3}\int_0^{\pi}\int_0^R (r\cos\theta)(r\sin\theta)\cdot r\, dr\, d\theta = \frac{3}{2R^3}\int_0^{\pi}\int_0^R \frac{r^3\sin 2\theta}{2}\, dr\, d\theta$$
$$= \frac{3}{2R^3}\int_0^{\pi} \left.\frac{r^4\sin 2\theta}{8}\right|_{r=0}^{R} d\theta = \frac{3}{2R^3}\cdot\frac{R^4}{8}\int_0^{\pi}\sin 2\theta\, d\theta = \frac{3R}{16}\cdot \left.\frac{-\cos 2\theta}{2}\right|_{\theta=0}^{\pi}$$
$$= -\frac{3R}{32}(\cos 2\pi - \cos 0) = 0$$

We compute y_{CM}:

$$y_{\text{CM}} = \frac{1}{M}\iint_{\mathcal{D}} y^2\, dA = \frac{3}{2R^3}\int_0^{\pi}\int_0^R r^2\sin^2\theta\cdot r\, dr\, d\theta = \frac{3}{2R^3}\int_0^{\pi}\int_0^R r^3\sin^2\theta\, dr\, d\theta$$
$$= \frac{3}{2R^3}\int_0^{\pi}\left.\frac{r^4\sin^2\theta}{4}\right|_{r=0}^{R} d\theta = \frac{3}{2R^3}\cdot\frac{R^4}{4}\int_0^{\pi}\sin^2\theta\, d\theta = \frac{3R}{8}\left.\left(\frac{\theta}{2} - \frac{\sin 2\theta}{4}\right)\right|_0^{\pi} = \frac{3R}{8}\cdot\frac{\pi}{2} = \frac{3\pi R}{16}$$

We obtain the following center of mass:

$$\left(0, \frac{3\pi R}{16}\right)$$

27. Find the z-coordinate of the center of mass of the first octant of the unit sphere with mass density $\rho(x, y, z) = y$ (Figure 17).

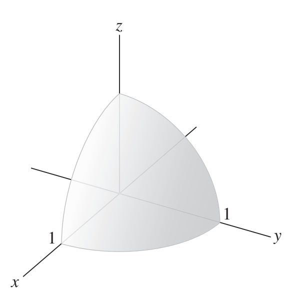


FIGURE 17

SOLUTION We use spherical coordinates:

$$x = \rho\cos\theta\sin\phi, \; y = \rho\sin\theta\sin\phi, \; z = \rho\cos\phi$$

$$dV = \rho^2 \sin\phi\, d\rho\, d\phi\, d\theta$$

The octant $\mathcal{W}$ is defined by $0 \le \theta \le \frac{\pi}{2}$, $0 \le \phi \le \frac{\pi}{2}$, $0 \le \rho \le 1$, so we have

$$M_{xy} = \iiint_{\mathcal{W}} z\,\rho(x, y, z)\, dV = \int_{\theta=0}^{\pi/2}\int_{\phi=0}^{\pi/2}\int_{\rho=0}^{1} (\rho\cos\phi)(\rho\sin\theta\sin\phi)\,\rho^2\sin\phi\, d\rho\, d\phi\, d\theta$$

$$= \left(\int_{\theta=0}^{\pi/2} \sin\theta \, d\theta \right) \left(\int_{\phi=0}^{\pi/2} \cos\phi \sin^2\phi \, d\phi \right) \left(\int_{\rho=0}^{1} \rho^4 \, d\rho \right)$$

$$= (1) \left(\frac{1}{3} \sin^3\phi \Big|_0^{\pi/2} \right) \left(\frac{1}{5} \right) = \frac{1}{15}$$

The total mass M of $\mathcal{W}$ is equal to the integral of the mass density $\rho(x, y, z)$:

$$M = \iiint_{\mathcal{W}} \rho(x, y, z)\, dV = \int_{\theta=0}^{\pi/2} \int_{\phi=0}^{\pi/2} \int_{\rho=0}^{1} (\rho \sin\theta \sin\phi)\, \rho^2 \sin\phi \, d\rho \, d\phi \, d\theta$$

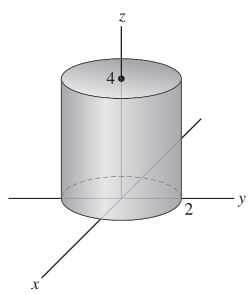
$$= \left(\int_{\theta=0}^{\pi/2} \sin\theta \, d\theta \right) \left(\int_{\phi=0}^{\pi/2} \sin^2\phi \, d\phi \right) \left(\int_{\rho=0}^{1} \rho^3 \, d\rho \right) = (1) \left(\frac{\pi}{4} \right) \left(\frac{1}{4} \right) = \frac{\pi}{16}$$

We conclude that

$$z_{\rm CM} = \frac{1}{M} \iiint_{\mathcal{W}} z\, \rho(x, y, z)\, dV = \frac{1/15}{\pi/16} = \frac{16}{15\pi} \approx 0.34$$

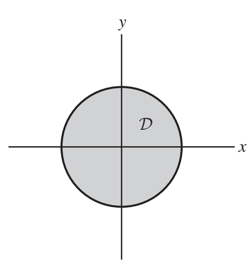
28. Find the center of mass of a cylinder of radius 2 and height 4 and mass density e^{-z}, where z is the height above the base.

SOLUTION



The center of mass is the point with the following coordinates:

$$x_{\rm CM} = \frac{1}{M} \iiint_{\mathcal{W}} x e^{-z}\, dV, \quad y_{\rm CM} = \frac{1}{M} \iiint_{\mathcal{W}} y e^{-z}\, dV, \quad z_{\rm CM} = \frac{1}{M} \iiint_{\mathcal{W}} z e^{-z}\, dV$$



Since $\mathcal{W}$ is symmetric with respect to the z axis, and the functions xe^{-z} and ye^{-z} are odd with respect to the variables x and y, respectively, we have

$$x_{\rm CM} = y_{\rm CM} = 0$$

We need only to find $z_{\rm CM}$. We first compute the mass M by the triple integral

$$M = \iiint_{\mathcal{W}} e^{-z}\, dV$$

To evaluate the integral we use cylindrical coordinates. The region $\mathcal{W}$ is described by the inequalities

$$\mathcal{W}: \; 0 \le \theta \le 2\pi, \; 0 \le r \le 2, \; 0 \le z \le 4$$

Using triple integrals in cylindrical coordinates, we obtain

$$M = \int_0^{2\pi} \int_0^2 \int_0^4 e^{-z} r \, dz \, dr \, d\theta = \left(\int_0^{2\pi} 1 \, d\theta \right) \left(\int_0^2 r \, dr \right) \left(\int_0^4 e^{-z} \, dz \right)$$

$$= 2\pi \cdot \left(\frac{r^2}{2} \Big|_0^2 \right) \left(-e^{-z} \Big|_0^4 \right) = 2\pi \cdot 2 \cdot (1 - e^{-4}) = 4\pi (1 - e^{-4}) \approx 12.34$$

We compute z_{CM}:

$$z_{CM} = \frac{1}{12.34}\int_0^{2\pi}\int_0^2\int_0^4 ze^{-z} r\,dz\,dr\,d\theta = 0.08\left(\int_0^{2\pi} d\theta\right)\left(\int_0^2 r\,dr\right)\left(\int_0^4 ze^{-z}\,dz\right)$$
$$= 0.08\cdot 2\pi\cdot 2\int_0^4 ze^{-z}\,dz = 0.32\pi\int_0^4 ze^{-z}\,dz$$

We compute the integral using integration by parts:

$$z_{CM} = 0.32\pi\left(-ze^{-z}\Big|_0^4 - e^{-z}\Big|_0^4\right) = -0.32\pi e^{-z}(1+z)\Big|_0^4 = 0.32\pi(1-5e^{-4}) = 0.91$$

The center of mass is the point $(0, 0, 0.91)$.

29. Let $\mathcal{R}$ be the rectangle $[-a, a]\times[b, -b]$ with uniform density and total mass M. Calculate:

(a) The mass density ρ of $\mathcal{R}$

(b) I_x and I_0

(c) The radius of gyration about the x-axis

SOLUTION

(a) The mass density is simply the mass per unit area since the density is uniform; this is

$$\frac{M}{4ab}$$

(b) We have

$$I_x = \iint_{\mathcal{R}} y^2\rho(x,y)\,dA = \frac{M}{4ab}\int_{-a}^{a}\int_{-b}^{b} y^2\,dy\,dx = \frac{2aM}{4ab}\int_{-b}^{b} y^2\,dy$$
$$= \frac{M}{2b}\cdot\frac{1}{3}y^3\Big|_{-b}^{b} = \frac{1}{3}Mb^2$$

and

$$I_0 = \iint_{\mathcal{R}}(x^2+y^2)\rho(x,y)\,dA = \frac{M}{4ab}\int_{-a}^{a}\int_{-b}^{b} x^2+y^2\,dy\,dx = \frac{M}{4ab}\int_{-a}^{a} x^2y+\frac{1}{3}y^3\Big|_{-b}^{b}\,dx$$
$$= \frac{2M}{4ab}\int_{-a}^{a} x^2b+\frac{1}{3}b^3\,dx = \frac{M}{2ab}\left(\frac{b}{3}x^3+\frac{b^3}{3}x\right)\Big|_{-a}^{a}$$
$$= \frac{M}{2ab}\left(\frac{2}{3}ba^3+\frac{2}{3}b^3a\right) = \frac{1}{3}M(a^2+b^2)$$

(c) The radius of gyration about the x-axis is defined to be

$$\sqrt{\frac{I_x}{M}} = \sqrt{\frac{Mb^2}{3}\cdot\frac{1}{M}} = \frac{b}{\sqrt{3}}$$

30. Calculate I_x and I_0 for the rectangle in Exercise 29 assuming a mass density of $\rho(x,y)=x$.

SOLUTION

$$I_x = \iint_{\mathcal{R}} y^2\rho(x,y)\,dA = \int_{-b}^{b}\int_{-a}^{a} xy^2\,dx\,dy = \left(\int_{-b}^{b} y^2\,dy\right)\cdot\left(\int_{-a}^{a} x\,dx\right) = 0$$

since x is an odd function. Also

$$I_0 = \iint_{\mathcal{R}}(x^2+y^2)\rho(x,y)\,dA = \int_{-b}^{b}\int_{-a}^{a} x^3+y^2x\,dx\,dy = 0$$

since the integrand is an odd function of x.

31. Calculate I_0 and I_x for the disk $\mathcal{D}$ defined by $x^2 + y^2 \le 16$ (in meters), with total mass 1000 kg and uniform mass density. *Hint:* Calculate I_0 first and observe that $I_0 = 2I_x$. Express your answer in the correct units.

SOLUTION Note that the area of the disk is $\pi r^2 = 16\pi$ so that the mass density is

$$\rho(x, y) = \frac{1000}{16\pi} = \frac{125}{2\pi}$$

Then using polar coordinates we have

$$I_0 = \iint_{\mathcal{D}} (x^2 + y^2)\frac{125}{2\pi}\, dA = \frac{125}{2\pi}\int_0^4 \int_0^{2\pi} r^2 \cdot r\, d\theta\, dr = 125 \cdot \frac{1}{4}r^4\Big|_0^4 = 125 \cdot 64 = 8000 \text{ kg-m}^2$$

Since both the region and the mass density are symmetric in x and y, we have $I_x = I_y$. But then $I_0 = I_x + I_y = 2I_x$ so that

$$I_x = 4000 \text{ kg-m}^2$$

32. Calculate I_x and I_y for the half-disk $x^2 + y^2 \le R^2$, $x \ge 0$ (in meters), of total mass M kg and uniform mass density.

SOLUTION This is quite similar to the preceding exercise. The area of the disk is πR^2, so that its mass density is

$$\rho(x, y) = \frac{M}{\pi R^2}$$

Using polar coordinates,

$$I_0 = \iint_{\mathcal{D}} (x^2 + y^2)\rho(x, y)\, dA = \frac{M}{\pi R^2}\int_0^R \int_0^{2\pi} r^2 \cdot r\, d\theta\, dr = \frac{M}{\pi R^2} \cdot 2\pi \int_0^R r^3\, dr = \frac{2M}{R^2} \cdot \frac{1}{4}r^4\Big|_0^R$$
$$= \frac{1}{2}MR^2$$

Since both the region and the mass density are symmetric in x and y, we have $I_x = I_y$. But then $I_0 = I_x + I_y = 2I_x$, so that

$$I_x = \frac{1}{4}MR^2$$

In Exercises 33–36, let $\mathcal{D}$ be the triangular domain bounded by the coordinate axes and the line $y = 3 - x$, with mass density $\rho(x, y) = y$. Compute the given quantities.

33. Total mass

SOLUTION The total mass is simply

$$\iint_{\mathcal{D}} \rho(x, y)\, dA = \int_0^3 \int_0^{3-x} y\, dy\, dx = \frac{1}{2}\int_0^3 y^2\Big|_0^{3-x} dx = \frac{1}{2}\int_0^3 (3 - x)^2\, dx = -\frac{1}{6}(3 - x)^3\Big|_0^3 = \frac{27}{6} = \frac{9}{2}$$

34. Center of Mass

SOLUTION We have

$$M_x = \iint_{\mathcal{D}} y\rho(x, y)\, dA = \int_0^3 \int_0^{3-x} y^2\, dy\, dx = \frac{1}{3}\int_0^3 (3 - x)^3\, dx = -\frac{1}{12}(3 - x)^4\Big|_0^3$$
$$= \frac{1}{12} \cdot 81 = \frac{27}{4}$$

and

$$M_y = \iint_{\mathcal{D}} x\rho(x, y)\, dA = \int_0^3 \int_0^{3-x} xy\, dy\, dx = \frac{1}{2}\int_0^3 xy^2\Big|_0^{3-x} dx$$
$$= \frac{1}{2}\int_0^3 9x - 6x^2 + x^3\, dx = \frac{1}{2}\left(\frac{9}{2}x^2 - 2x^3 + \frac{1}{4}x^4\right)\Big|_0^3 = \frac{1}{2}\left(\frac{81}{2} - 54 + \frac{81}{4}\right) = \frac{27}{8}$$

so that the center of mass is

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(\frac{27}{8} \cdot \frac{2}{9}, \frac{27}{4} \cdot \frac{2}{9}\right) = \left(\frac{3}{4}, \frac{3}{2}\right)$$

35. I_x

SOLUTION

$$I_x = \iint_{\mathcal{D}} y^2 \rho(x, y)\, dA = \int_0^3 \int_0^{3-x} y^3\, dy\, dx = \frac{1}{4} \int_0^3 (3-x)^4\, dx$$
$$= -\frac{1}{20}(3-x)^5 \Big|_0^3 = \frac{1}{20} 3^5 = \frac{243}{20}$$

36. I_0

SOLUTION

$$I_0 = \iint_{\mathcal{D}} (x^2 + y^2)\rho(x, y)\, dA = \int_0^3 \int_0^{3-x} (x^2 + y^2) y\, dy\, dx$$
$$= \int_0^3 \int_0^{3-x} x^2 y + y^3\, dy\, dx = \int_0^3 \frac{1}{2} x^2 y^2 + \frac{1}{4} y^4 \Big|_0^{3-x} dx$$
$$= \int_0^3 \frac{1}{2} x^2 (3-x)^2 + \frac{1}{4}(3-x)^4\, dx$$
$$= \int_0^3 \frac{9}{2} x^2 - 3x^3 + \frac{1}{2} x^4 + \frac{1}{4}(3-x)^4\, dx$$
$$= \left(\frac{3}{2} x^3 - \frac{3}{4} x^4 + \frac{1}{10} x^5 - \frac{1}{20}(3-x)^5 \right) \Big|_0^3$$
$$= \frac{81}{5}$$

In Exercises 37–40, let $\mathcal{D}$ be the domain between the line $y = bx/a$ and the parabola $y = bx^2/a^2$ where $a, b > 0$. Assume the mass density is $\rho(x, y) = xy$. Compute the given quantities.

37. Centroid

SOLUTION The curves intersect at $x = 0$ and at $x = a$. The area is

$$A = \iint_{\mathcal{D}} 1\, dA = \int_0^a \int_{bx^2/a^2}^{bx/a} 1\, dy\, dx = \int_0^a \frac{bx}{a} - \frac{bx^2}{a^2}\, dx$$
$$= \left(\frac{bx^2}{2a} - \frac{bx^3}{3a^2} \right) \Big|_0^a = \frac{ab}{2} - \frac{ab}{3} = \frac{ab}{6}$$

Then

$$\overline{x} = \frac{1}{A} \iint_{\mathcal{D}} x\, dA = \frac{6}{ab} \int_0^a \int_{bx^2/a^2}^{bx/a} x\, dy\, dx = \frac{6}{ab} \int_0^a x \left(\frac{bx}{a} - \frac{bx^2}{a^2} \right) dx$$
$$= \frac{6}{ab} \int_0^a \frac{b}{a} x^2 - \frac{b}{a^2} x^3\, dx = \frac{6}{ab} \left(\frac{b}{3a} a^3 - \frac{b}{4a^2} a^4 \right)$$
$$= \frac{6}{ab} \left(\frac{a^2 b}{3} - \frac{a^2 b}{4} \right) = \frac{a}{2}$$

and

$$\overline{y} = \frac{1}{A} \iint_{\mathcal{D}} y\, dA = \frac{6}{ab} \int_0^a \int_{bx^2/a^2}^{bx/a} y\, dy\, dx = \frac{6}{2ab} \int_0^a y^2 \Big|_{bx^2/a^2}^{bx/a} dx$$
$$= \frac{3}{ab} \int_0^a \frac{b^2}{a^2} x^2 - \frac{b^2}{a^4} x^4\, dx = \frac{3}{ab} \left(\frac{b^2}{3a^2} x^3 - \frac{b^2}{5a^4} x^5 \right) \Big|_0^a$$
$$= \frac{3}{ab} \left(\frac{ab^2}{3} - \frac{ab^2}{5} \right) = \frac{2b}{5}$$

38. Center of Mass

SOLUTION The curves intersect at $x = 0$ and at $x = a$, so the mass is

$$M = \iint_{\mathcal{D}} \rho(x, y)\, dA = \int_0^a \int_{bx^2/a^2}^{bx/a} xy\, dy\, dx = \frac{1}{2}\int_0^a xy^2\Big|_{bx^2/a^2}^{bx/a} dx$$

$$= \frac{1}{2}\int_0^a x\left(\frac{b^2x^2}{a^2} - \frac{b^2x^4}{a^4}\right) dx = \frac{b^2}{2a^4}\int_0^a a^2x^3 - x^5\, dx$$

$$= \frac{b^2}{2a^4}\left(\frac{a^2}{4}x^4 - \frac{1}{6}x^6\right)\Big|_0^a = \frac{b^2}{2a^4}\left(\frac{a^6}{3} - \frac{a^6}{4}\right) = \frac{a^2b^2}{24}$$

We also have

$$M_x = \iint_{\mathcal{D}} y\rho(x, y)\, dA = \int_0^a \int_{bx^2/a^2}^{bx/a} xy^2\, dy\, dx = \frac{1}{3}\int_0^a xy^3\Big|_{bx^2/a^2}^{bx/a} dx$$

$$= \frac{1}{3}\int_0^a x\left(\frac{b^3x^3}{a^3} - \frac{b^3x^6}{a^6}\right) dx = \frac{b^3}{3a^6}\int_0^a a^3x^4 - x^7\, dx$$

$$= \frac{b^3}{3a^6}\left(\frac{a^3}{5}x^5 - \frac{1}{8}x^8\right)\Big|_0^a = \frac{b^3}{3a^6}\left(\frac{a^8}{5} - \frac{a^8}{8}\right) = \frac{a^2b^3}{40}$$

and

$$M_y = \iint_{\mathcal{D}} x\rho(x, y)\, dA = \int_0^a \int_{bx^2/a^2}^{bx/a} x^2y\, dy\, dx = \frac{1}{2}\int_0^a x^2y^2\Big|_{bx^2/a^2}^{bx/a} dx$$

$$= \frac{1}{2}\int_0^a x^2\left(\frac{b^2x^2}{a^2} - \frac{b^2x^4}{a^4}\right) dx = \frac{b^2}{2a^4}\int_0^a a^2x^4 - x^6\, dx$$

$$= \frac{b^2}{2a^4}\left(\frac{a^2}{5}x^5 - \frac{1}{7}x^7\right)\Big|_0^a = \frac{b^2}{2a^4}\left(\frac{a^7}{5} - \frac{a^7}{7}\right) = \frac{a^3b^2}{35}$$

so that the center of mass is at

$$\left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \left(\frac{a^3b^2}{35}\cdot\frac{24}{a^2b^2}, \frac{a^2b^3}{40}\cdot\frac{24}{a^2b^2}\right) = \left(\frac{24}{35}a, \frac{3}{5}b\right)$$

39. I_x

SOLUTION The curves intersect at $x = 0$ and at $x = a$, so

$$I_x = \iint_{\mathcal{D}} y^2\rho(x, y)\, dA = \int_0^a \int_{bx^2/a^2}^{bx/a} xy^3\, dy\, dx = \frac{1}{4}\int_0^a xy^4\Big|_{bx^2/a^2}^{bx/a} dx$$

$$= \frac{1}{4}\int_0^a x\left(\frac{b^4}{a^4}x^4 - \frac{b^4}{a^8}x^8\right) dx = \frac{b^4}{4a^8}\int_0^a a^4x^5 - x^9\, dx$$

$$= \frac{b^4}{4a^8}\left(\frac{a^4}{6}x^6 - \frac{1}{10}x^10\right)\Big|_0^a = \frac{b^4}{4a^8}\left(\frac{a^{10}}{6} - \frac{a^{10}}{10}\right) = \frac{a^2b^4}{60}$$

40. I_0

SOLUTION The curves intersect at $x = 0$ and at $x = a$. We computed I_x in the previous exercise, so we will compute I_y and add the two to get I_0:

$$I_y = \iint_{\mathcal{D}} x^2\rho(x, y)\, dA = \int_0^a \int_{bx^2/a^2}^{bx/a} x^3y\, dy\, dx = \frac{1}{2}\int_0^a x^3y^2\Big|_{bx^2/a^2}^{bx/a} dx$$

$$= \frac{1}{2}\int_0^a x^3\left(\frac{b^2}{a^2}x^2 - \frac{b^2}{a^4}x^4\right) dx = \frac{b^2}{2a^4}\int_0^a a^2x^5 - x^7\, dx$$

$$= \frac{b^2}{2a^4}\left(\frac{a^2}{6}x^6 - \frac{1}{8}x^8\right)\Big|_0^a$$

$$= \frac{b^2}{2a^4}\left(\frac{a^8}{6} - \frac{a^8}{8}\right) = \frac{a^4b^2}{48}$$

Thus

$$I_0 = I_x + I_y = \frac{a^2 b^4}{60} + \frac{a^4 b^2}{48} = a^2 b^2 \frac{5a^2 + 4b^2}{240}$$

41. Calculate the moment of inertia I_x of the disk $\mathcal{D}$ defined by $x^2 + y^2 \le R^2$ (in meters) with total mass M kg. How much kinetic energy (in joules) is required to rotate the disk about the x-axis with angular velocity 10 rad/s?

SOLUTION The area of the disk is πR^2, so its mass density is

$$\rho(x, y) = \frac{M}{\pi R^2}$$

We compute I_x using polar coordinates:

$$\begin{aligned} I_x &= \iint_{\mathcal{D}} y^2 \rho(x, y)\, dA = \frac{M}{\pi R^2} \int_0^{2\pi} \int_0^R (r \sin\theta)^2 r\, dr\, d\theta = \frac{M}{\pi R^2} \int_0^{2\pi} \int_0^R r^3 \sin^2\theta\, dr\, d\theta \\ &= \frac{M}{\pi R^2} \left(\int_0^{2\pi} \sin^2\theta\, d\theta \right) \left(\int_0^R r^3\, dr \right) \\ &= \frac{M}{\pi R^2} \cdot \pi \cdot \frac{R^4}{4} = \frac{1}{4} M R^2 \end{aligned}$$

It follows that the kinetic energy required to rotate the disk about the x-axis with angular velocity 10 rad/s is

$$\frac{1}{2} I_x \omega^2 = \frac{1}{8} M R^2 \cdot 100 = \frac{25}{2} M R^2 \text{ joules}$$

42. Calculate the moment of inertia I_z of the box $\mathcal{W} = [-a, a] \times [-a, a] \times [0, H]$ assuming that $\mathcal{W}$ has total mass M.

SOLUTION The volume of the region is $2a \cdot 2a \cdot H = 4a^2 H$, so that the mass density is

$$\rho = \rho(x, y, z) = \frac{M}{4a^2 H}$$

Then

$$\begin{aligned} I_z &= \iint_{\mathcal{W}} (x^2 + y^2) \rho(x, y, z)\, dA = \frac{M}{4a^2 H} \int_{-a}^{a} \int_{-a}^{a} \int_0^H x^2 + y^2\, dz\, dy\, dx \\ &= \frac{M}{4a^2 H} H \int_{-a}^{a} \int_{-a}^{a} x^2 + y^2\, dy\, dx = \frac{M}{4a^2} \int_{-a}^{a} \left(x^2 y + \frac{1}{3} y^3 \right) \Big|_{-a}^{a} dx \\ &= \frac{2M}{4a^2} \int_{-a}^{a} a x^2 + \frac{a^3}{3}\, dx = \frac{M}{2a^2} \left(\frac{a}{3} x^3 + \frac{a^3}{3} x \right) \Big|_{-a}^{a} \\ &= \frac{M}{2a^2} \left(\frac{2a^4}{3} + \frac{2a^4}{3} \right) = \frac{2}{3} M a^2 \end{aligned}$$

43. Show that the moment of inertia of a sphere of radius R of total mass M with uniform mass density about any axis passing through the center of the sphere is $\frac{2}{5} M R^2$. Note that the mass density of the sphere is $\rho = M / \left(\frac{4}{3}\pi R^3\right)$.

SOLUTION Since the sphere is symmetric under an arbitrary rotation, and since the mass density is uniform, it follows that the moments of inertia of the sphere about all axes passing through its center are equal. Thus it suffices to prove the result for an arbitrary axis; we choose the z-axis. Then, using spherical coordinates, we have

$$\begin{aligned} I_z &= \iiint_{\mathcal{S}} (x^2 + y^2) \rho(x, y, z)\, dA \\ &= \frac{3M}{4\pi R^3} \int_0^{2\pi} \int_0^{\pi} \int_0^R ((r \cos\theta \sin\phi)^2 + (r \sin\theta \sin\phi)^2) r^2 \sin\phi\, dr\, d\theta\, d\phi \\ &= \frac{3M}{4\pi R^3} \int_0^{2\pi} \int_0^{\pi} \int_0^R r^4 \sin^3\phi\, dr\, d\theta\, d\phi = \frac{3M}{4\pi R^3} \cdot 2\pi \left(\int_0^{\pi} \sin^3\phi\, d\phi \right) \left(\int_0^R r^4\, dr \right) \\ &= \frac{3M}{2R^3} \cdot \frac{4}{3} \cdot \frac{1}{5} R^5 = \frac{2}{5} M R^2 \end{aligned}$$

44. Use the result of Exercise 43 to calculate the radius of gyration of a uniform sphere of radius R about any axis through the center of the sphere.

SOLUTION From the referenced exercise, we know that the moment of inertia of the sphere around the given axis a is

$$I_a = \frac{2}{5}MR^2$$

so that the radius of gyration about a is

$$r_g = \sqrt{\frac{I_a}{M}} = \sqrt{\frac{2}{5}MR^2 \cdot \frac{1}{M}} = \frac{\sqrt{10}}{5}R$$

In Exercises 45 and 46, prove the formula for the right circular cylinder in Figure 18.

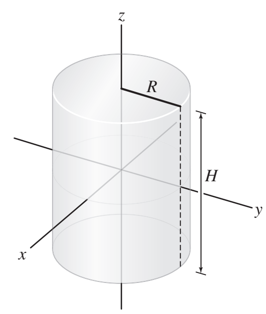


FIGURE 18

45. $I_z = \frac{1}{2}MR^2$

SOLUTION Assuming the cylinder has uniform mass density 1, and using cylindrical coordinates, we have

$$I_z = \iiint_C (x^2+y^2)\rho(x,y,z)\,dA = \int_0^R \int_0^{2\pi} \int_{-H/2}^{H/2} r^2 \cdot r\,dz\,d\theta\,dr$$
$$= 2\pi H \int_0^R r^3\,dr = \frac{1}{2}\pi R^4 H$$

But the volume of the cylinder, which is equal to its mass, is $\pi R^2 H$, so that

$$I_z = \frac{1}{2}\pi R^4 H = \frac{1}{2}MR^2$$

46. $I_x = \frac{1}{4}MR^2 + \frac{1}{12}MH^2$

SOLUTION Assuming the cylinder has uniform mass density 1, and using cylindrical coordinates, we have

$$I_x = \iiint_C (y^2+z^2)\rho(x,y,z)\,dA = \int_0^R \int_0^{2\pi} \int_{-H/2}^{H/2} (r^2\sin^2\theta + z^2)r\,dz\,d\theta\,dr$$
$$= \int_0^R \int_0^{2\pi} \left(r^3 z\sin^2\theta + \frac{1}{3}rz^3\right)\Big|_{-H/2}^{H/2} d\theta\,dr = \int_0^R \int_0^{2\pi} Hr^3\sin^2\theta + \frac{1}{12}H^3 r\,d\theta\,dr$$
$$= \int_0^R \pi Hr^3 + \frac{2\pi}{12}H^3 r\,dr = \frac{1}{4}\pi HR^4 + \frac{1}{12}\pi H^3 R^2$$

The volume of the cylinder, which is equal to its mass, is $\pi R^2 H$; substituting, we get

$$I_x = \frac{1}{4}\pi HR^4 + \frac{1}{12}\pi H^3 R^2 = \frac{1}{4}MR^2 + \frac{1}{12}MH^2$$

47. The yo-yo in Figure 19 is made up of two disks of radius $r = 3$ cm and an axle of radius $b = 1$ cm. Each disk has mass $M_1 = 20$ g, and the axle has mass $M_2 = 5$ g.

(a) Use the result of Exercise 45 to calculate the moment of inertia I of the yo-yo with respect to the axis of symmetry. Note that I is the sum of the moments of the three components of the yo-yo.

(b) The yo-yo is released and falls to the end of a 100-cm string, where it spins with angular velocity ω. The total mass of the yo-yo is $m = 45$ g, so the potential energy lost is $\mathrm{PE} = mgh = (45)(980)100$ g-cm^2/s^2. Find ω under the assumption that one-third of this potential energy is converted into rotational kinetic energy.

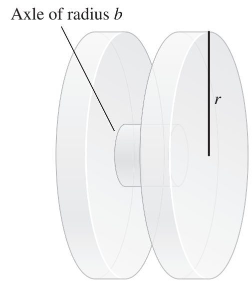

FIGURE 19

SOLUTION

(a) If the figure is rotated by 90°, it looks like three right circular cylinders oriented as in Exercise 45. The moment of inertia of each of the disks around the axis of rotation is thus

$$\frac{1}{2}MR^2 = \frac{1}{2} \cdot 20 \cdot 3^2 = 90 \text{ g-cm}^2$$

and the moment of inertia of the axle around the axis of rotation is

$$\frac{1}{2}MR^2 = \frac{1}{2} \cdot 5 \cdot 1^2 = \frac{5}{2} \text{ g-cm}^2$$

Thus the total moment of inertia of the yo-yo around its axis of rotation is

$$2 \cdot 90 + \frac{5}{2} = 182.5 \text{ g-cm}^2$$

(b) If one third of the potential energy is converted to kinetic energy, then

$$\frac{1}{3} \cdot 45 \cdot 980 \cdot 100 = \frac{1}{2} \cdot 182.5 \cdot \omega^2 \text{ g-cm}^2$$

so that

$$\omega = \sqrt{\frac{2}{3} \cdot \frac{45 \cdot 980 \cdot 100}{182.5}} \approx 127 \text{ radians/sec} = \frac{127}{2\pi} \approx 20.2 \text{ rotations/sec}$$

48. Calculate I_z for the solid region $\mathcal{W}$ inside the hyperboloid $x^2 + y^2 = z^2 + 1$ between $z = 0$ and $z = 1$.

SOLUTION We have

$$\begin{aligned} I_z &= \iiint_{\mathcal{W}} (x^2 + y^2)\rho(x, y, z)\, dA = \int_0^1 \int_0^{2\pi} \int_0^{\sqrt{z^2+1}} r^3\, dr\, d\theta\, dz = \frac{1}{4} \int_0^1 \int_0^{2\pi} r^4 \Big|_0^{\sqrt{z^2+1}} d\theta\, dz \\ &= \frac{1}{4} \int_0^1 \int_0^{2\pi} (z^2 + 1)^2\, d\theta\, dz = \frac{\pi}{2} \int_0^1 z^4 + 2z^2 + 1\, dz \\ &= \frac{\pi}{2} \left(\frac{1}{5} z^5 + \frac{2}{3} z^2 + z \right) \Big|_0^1 = \frac{14}{15}\pi \end{aligned}$$

49. Calculate $P(0 \le X \le 2; 1 \le Y \le 2)$, where X and Y have joint probability density function

$$p(x, y) = \begin{cases} \frac{1}{72}(2xy + 2x + y) & \text{if } 0 \le x \le 4 \text{ and } 0 \le y \le 2 \\ 0 & \text{otherwise} \end{cases}$$

SOLUTION The region $0 \le X \le 2; 1 \le Y \le 2$ falls into the region where $p(x, y)$ is defined by the first line of the given formula, so that

$$\begin{aligned} P(0 \le X \le 2; 1 \le Y \le 2) &= \int_0^2 \int_1^2 \frac{1}{72}(2xy + 2x + y)\, dy\, dx = \frac{1}{72} \int_0^2 \left(xy^2 + 2xy + \frac{1}{2}y^2 \right) \Big|_1^2 dx \\ &= \frac{1}{72} \int_0^2 5x + \frac{3}{2}\, dx = \frac{1}{72} \left(\frac{5}{2}x^2 + \frac{3}{2}x \right) \Big|_0^2 = \frac{1}{72} \cdot 13 = \frac{13}{72} \approx 0.18 \end{aligned}$$

50. Calculate the probability that $X + Y \le 2$ for random variables with joint probability density function as in Exercise 49.

SOLUTION Note that $p(x, y) = 0$ if either x or y is negative, so that $X + Y \le 2$ corresponds to the region of integration $0 \le x \le 2$ and $0 \le y \le 2 - x$. Thus

$$\begin{aligned}
P(X + Y \le 2) &= \int_0^2 \int_0^{2-x} \frac{1}{72}(2xy + 2x + y)\,dy\,dx = \frac{1}{72}\int_0^2 \left(xy^2 + 2xy + \frac{1}{2}y^2\right)\Big|_0^{2-x} dx \\
&= \frac{1}{72}\int_0^2 x(2-x)^2 + 2x(2-x) + \frac{1}{2}(2-x)^2\,dx \\
&= \frac{1}{72}\int_0^2 x^3 - 4x^2 + 4x + 4x - 2x^2 + 2 - 2x + \frac{1}{2}x^2\,dx \\
&= \frac{1}{72}\int_0^2 x^3 - \frac{11}{2}x^2 + 6x + 2\,dx = \frac{1}{72}\left(\frac{1}{4}x^4 - \frac{11}{6}x^3 + 3x^2 + 2x\right)\Big|_0^2 \\
&= \frac{1}{72}\left(4 - \frac{11}{6}\cdot 8 + 12 + 4\right) = \frac{2}{27} \approx 0.074
\end{aligned}$$

51. The lifetime (in months) of two components in a certain device are random variables X and Y that have joint probability distribution function

$$p(x, y) = \begin{cases} \frac{1}{9216}(48 - 2x - y) & \text{if } x \ge 0,\ y \ge 0,\ 2x + y \le 48 \\ 0 & \text{otherwise} \end{cases}$$

Calculate the probability that both components function for at least 12 months without failing. Note that $p(x, y)$ is nonzero only within the triangle bounded by the coordinate axes and the line $2x + y = 48$ shown in Figure 20.

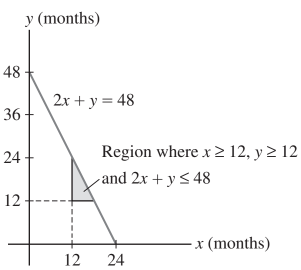

FIGURE 20

SOLUTION Both components function for at least 12 months without failing if $X + Y \ge 12$; however, we must also have $2X + Y \le 48$. Then the region of integration is the shaded triangle in the figure; the lower left corner of that triangle is (12, 12). One of the remaining vertices is the intersection of $x = 12$ and $2x + y = 48$; solving for y we have $y = 24$, so the point is (12, 24). The other vertex is the intersection of $y = 12$ and $2x + y = 48$; solving for x gives $x = 18$, so the point is (18, 12). The region of integration is then $12 \le x \le 18$ and $12 \le y \le 48 - 2x$. Thus the probability is

$$\begin{aligned}
P(X \ge 12, Y \ge 12) &= \int_{12}^{18} \int_{12}^{48-2x} \frac{1}{9216}(48 - 2x - y)\,dy\,dx \\
&= \frac{1}{9216}\int_{12}^{18} \left(48y - 2xy - \frac{1}{2}y^2\right)\Big|_{12}^{48-2x} dx \\
&= \frac{1}{9216}\int_{12}^{18} 1800 - 96x - 2x(36 - 2x) - \frac{1}{2}(48 - 2x)^2\,dx \\
&= \frac{1}{9216}\left(1800x - 48x^2 - 36x^2 + \frac{4}{3}x^3 + \frac{1}{12}(48 - 2x)^3\right)\Big|_{12}^{18} \\
&= \frac{144}{9216} = \frac{1}{64} = .015625
\end{aligned}$$

52. Find a constant C such that

$$p(x, y) = \begin{cases} Cxy & \text{if } 0 \le x \text{ and } 0 \le y \le 1 - x \\ 0 & \text{otherwise} \end{cases}$$

is a joint probability density function. Then calculate

(a) $P\left(X \le \frac{1}{2}; Y \le \frac{1}{4}\right)$

(b) $P(X \ge Y)$

SOLUTION In order for $p(x, y)$ to be a joint probability density function, we must have

$$1 = \int_0^1 \int_0^{1-x} p(x, y) = \int_0^1 \int_0^{1-x} Cxy\,dy\,dx = \frac{C}{2} \int_0^1 xy^2 \Big|_0^{1-x} dx$$
$$= \frac{C}{2} \int_0^1 x(1-x)^2\,dx = \frac{C}{2} \int_0^1 x - 2x^2 + x^3\,dx = \frac{C}{2}\left(\frac{1}{2} - \frac{2}{3} + \frac{1}{4}\right) = \frac{C}{24}$$

so that $C = 24$.

(a)

$$P\left(X \le \frac{1}{2}; Y \le \frac{1}{4}\right) = \int_0^{1/2} \int_0^{1/4} 24xy\,dy\,dx = 24\left(\int_0^{1/2} x\,dx\right)\left(\int_0^{1/4} y\,dy\right)$$
$$= 24 \cdot \frac{1}{8} \cdot \frac{1}{32} = \frac{3}{32} = 0.09375$$

(b) The probability density function is nonzero only for $0 \le y \le 1 - x$; in addition, $X \ge Y$ means that $y \le x$. The region of integration is then the region below both the lines $y = x$ and $y = 1 - x$ for $y \ge 0$; this is the triangle with vertices $(0, 0)$, $(1, 0)$, and $(1/2, 1/2)$. Integrating first in the x direction gives:

$$P(X \ge Y) = \int_0^{1/2} \int_y^{1-y} 24xy\,dx\,dy = \int_0^{1/2} 12x^2 y \Big|_{x=y}^{1-y} dy$$
$$= \int_0^{1/2} 12y((1-y)^2 - y^2)\,dy = \int_0^{1/2} 12y - 24y^2\,dy = (6y^2 - 8y^3)\Big|_0^{1/2}$$
$$= \frac{3}{2} - 1 = \frac{1}{2}$$

53. Find a constant C such that

$$p(x, y) = \begin{cases} Cy & \text{if } 0 \le x \le 1 \text{ and } x^2 \le y \le x \\ 0 & \text{otherwise} \end{cases}$$

is a joint probability density function. Then calculate the probability that $Y \ge X^{3/2}$.

SOLUTION $p(x, y)$ is a joint probability density function if

$$1 = \int_0^1 \int_{x^2}^x p(x, y)\,dy\,dx = \int_0^1 \int_{x^2}^x Cy\,dy\,dx$$
$$= \frac{C}{2} \int_0^1 y^2 \Big|_{x^2}^x dx = \frac{C}{2} \int_0^1 x^2 - x^4\,dx = \frac{C}{15}$$

so that we must have $C = 15$. Now, for $0 \le x \le 1$ we have $x^2 \le x^{3/2} \le x$, so that

$$P(Y \ge X^{3/2}) = \int_0^1 \int_{x^{3/2}}^x 15y\,dy\,dx = \frac{15}{2} \int_0^1 y^2 \Big|_{x^{3/2}}^x dx$$
$$= \frac{15}{2} \int_0^1 x^2 - x^3\,dx = \frac{15}{2}\left(\frac{1}{3} - \frac{1}{4}\right) = \frac{15}{24} = \frac{5}{8} = 0.375$$

54. Numbers X and Y between 0 and 1 are chosen randomly. The joint probability density is $p(x, y) = 1$ if $0 \le x \le 1$ and $0 \le y \le 1$, and $p(x, y) = 0$ otherwise. Calculate the probability P that the product XY is at least $\frac{1}{2}$.

SOLUTION Since the probability density function is 1, the probability P is the integral of 1 over the region $\mathcal{W} = \{(x, y) : 0 \le x \le 1, 0 \le y \le 1, xy \ge \frac{1}{2}\}$, which is just the area of $\mathcal{W}$. Now, $\mathcal{W}$ is the area bounded the curves $y = \frac{1}{2x}$ and $y = 1$ for $0 \le x \le 1$. Since these curves cross at $x = \frac{1}{2}$, the area is simply

$$P = \int_{1/2}^1 1 - \frac{1}{2x}\,dx = \left(x - \frac{1}{2}\ln x\right)\Big|_{1/2}^1 = 1 - \frac{1}{2} + \frac{1}{2}\ln\frac{1}{2} = \frac{1}{2}(1 - \ln 2)$$

55. According to quantum mechanics, the x- and y-coordinates of a particle confined to the region $\mathcal{R} = [0, 1] \times [0, 1]$ are random variables with joint probability density function

$$p(x, y) = \begin{cases} C\sin^2(2\pi\ell x)\sin^2(2\pi ny) & \text{if } (x, y) \in \mathcal{R} \\ 0 & \text{otherwise} \end{cases}$$

The integers ℓ and n determine the energy of the particle, and C is a constant.

(a) Find the constant C.
(b) Calculate the probability that a particle with $\ell = 2$, $n = 3$ lies in the region $\left[0, \frac{1}{4}\right] \times \left[0, \frac{1}{8}\right]$.

SOLUTION
(a) We have

$$\int_0^1 \int_0^1 C \sin^2(2\pi \ell x) \sin^2(2\pi n y)\, dx\, dy = C \left(\int_0^1 \sin^2(2\pi \ell x)^2\, dx\right)\left(\int_0^1 \sin^2(2\pi n y)^2\, dy\right)$$

Now, since ℓ is an integer, using the substitution $u = 2\pi\ell x$, $du = 2\pi\ell\, dx$, we have

$$\int_0^1 \sin^2(2\pi\ell x)\, dx = \frac{1}{2\pi\ell}\int_0^{2\pi\ell} \sin^2 u\, du = \frac{1}{2\pi\ell}\left(\frac{1}{2}u - \frac{1}{2}\sin u \cos u\right)\Big|_0^{2\pi\ell}$$
$$= \frac{1}{2\pi\ell}\left(\pi\ell - \frac{1}{2}\sin(2\pi\ell)\cos(2\pi\ell) + \frac{1}{2}\sin 0 \cos 0\right) = \frac{1}{2}$$

and the same is true of $\int_0^1 \sin^2(2\pi n y)\, dy$. Thus the value of the entire integral is $C\frac{1}{2} \cdot \frac{1}{2} = \frac{C}{4}$. In order for this to be a joint probability density function, then, we must have $C = 4$.
(b) We compute

$$\int_0^{1/4}\int_0^{1/8} 4\sin^2(2\pi \cdot 2x)\sin^2(2\pi \cdot 3y)\, dy\, dx = 4\left(\int_0^{1/4}\sin^2(4\pi x)\, dx\right)\left(\int_0^{1/8}\sin^2(6\pi y)\, dy\right)$$
$$= 4\left(\frac{1}{4\pi}\int_0^{\pi}\sin^2 u\, du\right)\left(\frac{1}{6\pi}\int_0^{3\pi/4}\sin^2 v\, dv\right)$$
$$= 4\left(\frac{1}{4\pi}\cdot\frac{\pi}{2}\right)\left(\frac{1}{6\pi}\cdot\left(\frac{3\pi}{8} + \frac{1}{4}\right)\right)$$
$$= 4\left(\frac{1}{8}\right)\left(\frac{1}{16} + \frac{1}{24\pi}\right) = \frac{1}{32} + \frac{1}{48\pi} \approx 0.03788$$

56. The wave function for the 1s state of an electron in the hydrogen atom is

$$\psi_{1s}(\rho) = \frac{1}{\sqrt{\pi a_0^3}} e^{-\rho/a_0}$$

where a_0 is the Bohr radius. The probability of finding the electron in a region $\mathcal{W}$ of $\mathbf{R}^3$ is equal to

$$\iiint_{\mathcal{W}} p(x, y, z)\, dV$$

where, in spherical coordinates,

$$p(\rho) = |\psi_{1s}(\rho)|^2$$

Use integration in spherical coordinates to show that the probability of finding the electron at a distance greater than the Bohr radius is equal to $5/e^2 \approx 0.677$. The Bohr radius is $a_0 = 5.3 \times 10^{-11}$ m, but this value is not needed.

SOLUTION According to the problem statement, the probability of finding the electron at a distance greater than the Bohr radius is the probability of finding it in the region $\mathcal{W}$ of $\mathbf{R}^3$ with $\rho \geq a_0$ in spherical coordinates. This probability is

$$\iiint_{\mathcal{W}} p(x, y, z)\, dV = \int_{a_0}^{\infty}\int_0^{2\pi}\int_0^{\pi}\left(\frac{1}{\sqrt{\pi a_0^3}}e^{-\rho/a_0}\right)^2 \cdot \rho^2 \sin\phi\, d\phi\, d\theta\, d\rho$$
$$= \int_{a_0}^{\infty}\int_0^{2\pi}\left(\frac{1}{\sqrt{\pi a_0^3}}e^{-\rho/a_0}\right)^2 \cdot \rho^2 \cdot (-\cos\phi)\Big|_0^{\pi} d\theta\, d\rho$$
$$= 2\int_{a_0}^{\infty}\int_0^{2\pi}\left(\frac{1}{\sqrt{\pi a_0^3}}e^{-\rho/a_0}\right)^2 \cdot \rho^2\, d\theta\, d\rho$$
$$= 4\pi \cdot \frac{1}{\pi a_0^3}\int_{a_0}^{\infty}\rho^2 e^{-2\rho/a_0}\, d\rho$$

Using integration by parts twice, we continue

$$\iiint_{\mathcal{W}} p(x, y, z)\,dV = \frac{4}{a_0^3}\left(-\frac{a_0}{2}\rho^2 e^{-2\rho/a_0}\Big|_{a_0}^{\infty} + a_0\int_{a_0}^{\infty} \rho e^{-2\rho/a_0}\,d\rho\right)$$

$$= \frac{4}{a_0^3}\left(\frac{a_0^3}{2}e^{-2} + a_0\left(-\frac{a_0}{2}\rho e^{-2\rho/a_0}\Big|_{a_0}^{\infty} + a_0\int_{a_0}^{\infty} e^{-2\rho/a_0}\,d\rho\right)\right)$$

$$= \frac{4}{a_0^3}\left(\frac{a_0^3}{2}e^{-2} + \frac{a_0^3}{2}e^{-2} - a_0\left(\frac{a_0^2}{4}e^{-2\rho/a_0}\right)\Big|_{a_0}^{\infty}\right)$$

$$= \frac{4}{a_0^3}\left(a_0^3 e^{-2} + \frac{a_0^3}{4}e^{-2}\right) = \frac{4}{a_0^3}\left(\frac{5}{4}a_0^3 e^{-2}\right) = 5e^{-2} \approx 0.68$$

57. According to Coulomb's Law, the force between two electric charges of magnitude q_1 and q_2 separated by a distance r is kq_1q_2/r^2 (k is a negative constant). Let F be the net force on a charged particle P of charge Q coulombs located d centimeters above the center of a circular disk of radius R with a uniform charge distribution of density ρ C/m^2 (Figure 21). By symmetry, F acts in the vertical direction.

(a) Let $\mathcal{R}$ be a small polar rectangle of size $\Delta r \times \Delta\theta$ located at distance r. Show that $\mathcal{R}$ exerts a force on P whose vertical component is

$$\left(\frac{k\rho Q d}{(r^2 + d^2)^{3/2}}\right) r\,\Delta r\,\Delta\theta$$

(b) Explain why F is equal to the following double integral, and evaluate:

$$F = k\rho Q d\int_0^{2\pi}\int_0^R \frac{r\,dr\,d\theta}{(r^2 + d^2)^{3/2}}$$

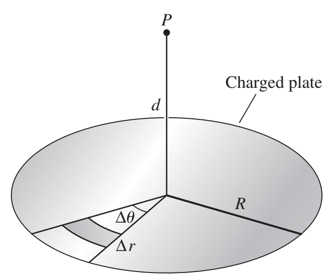

FIGURE 21

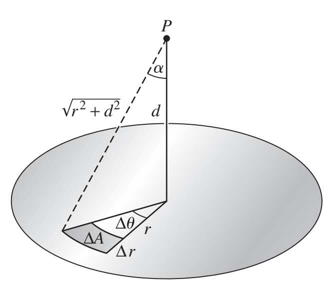
SOLUTION

(a) The area of the small polar rectangle $\mathcal{R}$ is

$$\Delta A = \frac{1}{2}(r + \Delta r)^2\Delta\theta - \frac{1}{2}r^2\Delta\theta = r(\Delta r\,\Delta\theta) + \frac{1}{2}\Delta r^2\Delta\theta \approx r(\Delta r\,\Delta\theta)$$

Therefore, the charge on $\mathcal{R}$ is $q_1 = \rho r(\Delta r\,\Delta\theta)$. The distance between P and $\mathcal{R}$ is, by the Pythagorean Law, $\sqrt{r^2 + d^2}$.



Therefore, the magnitude of the force between P and $\mathcal{R}$ is

$$\frac{kq_1q_2}{\left(\sqrt{r^2 + d^2}\right)^2} = \frac{k\,(\rho r\,\Delta r\,\Delta\theta)\,Q}{r^2 + d^2} = \frac{k\rho Q}{r^2 + d^2} r\,\Delta r\,\Delta\theta$$

The vertical component of this force is obtained by multiplying the force by $\cos\alpha = \frac{d}{\sqrt{r^2+d^2}}$. That is,

$$F_{\text{vert}} = \frac{k\rho Q}{r^2+d^2} \cdot \frac{d}{\sqrt{r^2+d^2}} r\,\Delta r\,\Delta\theta = \frac{k\rho Q d}{(r^2+d^2)^{3/2}} r\,\Delta r\,\Delta\theta$$

(b) Since F acts in the vertical direction, it is approximated by the Riemann sum of the forces F_{vert} in part (a), over the polar rectangles. This Riemann sum approximates F in higher precision if we let $\Delta\theta \to 0$ and $\Delta r \to 0$. The result is the double integral of $\frac{k\rho Q d}{(r^2+d^2)^{3/2}}$ over the disk. The disk is determined by $0 \le \theta \le 2\pi$ and $0 \le r \le R$. Therefore we get

$$F = \int_0^R \int_0^{2\pi} \frac{k\rho Q d}{(r^2+d^2)^{3/2}} r\,dr\,d\theta = 2\pi k\rho Q d \int_0^R \int_0^{2\pi} \frac{r\,dr\,d\theta}{(r^2+d^2)^{3/2}}$$

Using the u-substitution of $u = r^2 + d^2$, $du = 2r\,dr$, we continue

$$F = 2\pi k\rho Q d \int_0^R \frac{r\,dr}{(r^2+d^2)^{3/2}} = 2\pi k\rho Q d \cdot \frac{1}{2} \int_{d^2}^{R^2+d^2} u^{-3/2}\,du = -\pi k\rho Q d u^{-1/2}\Big|_{d^2}^{R^2+d^2}$$

$$= \pi k\rho Q d \left(\frac{1}{d} - \frac{1}{\sqrt{R^2+d^2}}\right)$$

58. Let $\mathcal{D}$ be the annular region

$$-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}, \quad a \le r \le b$$

where $b > a > 0$. Assume that $\mathcal{D}$ has a uniform charge distribution of ρ C/m^2. Let F be the net force on a charged particle of charge Q coulombs located at the origin (by symmetry, F acts along the x-axis).

(a) Argue as in Exercise 57 to show that

$$F = k\rho Q \int_{\theta=-\pi/2}^{\pi/2} \int_{r=a}^{b} \left(\frac{\cos\theta}{r^2}\right) r\,dr\,d\theta$$

(b) Compute F.

SOLUTION As in Exercise 57, let $\mathcal{R}$ be a small polar rectangle of size $\Delta r \times \Delta\theta$ located at distance r ($a \le r \le b$) from the origin and at an angle θ to the x-axis. As before, its area is approximately $r\,\Delta r\,\Delta\theta$, so the charge on $\mathcal{R}$ is $q_1 = \rho r\,\Delta r\,\Delta\theta$. The distance between P, at the origin, and $\mathcal{R}$ is r, so the magnitude of the force between P and $\mathcal{R}$ is

$$F = \frac{kq_1q_2}{r^2} = \frac{k\rho Q}{r^2} r\,\Delta r\,\Delta\theta = \frac{k\rho Q}{r^2} r\,\Delta r\,\Delta\theta$$

Now, since the force acts along the x-axis, we want the horizontal component of F; this is just

$$F_{\text{horiz}} = F\cos\theta = k\rho Q \frac{\cos\theta}{r^2} r\,\Delta r\,\Delta\theta$$

Then F is approximated by the Riemann sum of the forces F_{horiz} over the polar rectangles. As $\Delta r \to 0$, $\Delta\theta \to 0$, this becomes the double integral of $k\rho Q \frac{\cos\theta}{r^2} r$ over the half-annulus. Since the region is determined by $a \le r \le b$ and $-\pi/2 \le \theta \le \pi/2$, we hve

$$F = k\rho Q \int_a^b \int_{-\pi/2}^{\pi/2} \frac{\cos\theta}{r^2} r\,d\theta\,dr = 2k\rho Q \int_a^b \frac{1}{r}\,dr = 2k\rho Q \ln\left(\frac{b}{a}\right)$$

Further Insights and Challenges

59. Let $\mathcal{D}$ be the domain in Figure 22. Assume that $\mathcal{D}$ is symmetric with respect to the y-axis; that is, both $g_1(x)$ and $g_2(x)$ are even functions.

(a) Prove that the centroid lies on the y-axis—that is, that $\bar{x} = 0$.

(b) Show that if the mass density satisfies $\rho(-x, y) = \rho(x, y)$, then $M_y = 0$ and $x_{\text{CM}} = 0$.

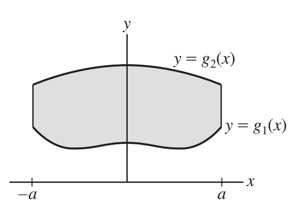


FIGURE 22

SOLUTION

(a) Assume $\mathcal{D}$ has area A. Then the x coordinate of the centroid is

$$\overline{x} = \frac{1}{A}\iint_{\mathcal{D}} x\,dA = \frac{1}{A}\int_{-a}^{a}\int_{g_1(x)}^{g_2(x)} x\,dy\,dx = \frac{1}{A}\int_{-a}^{a} x(g_2(x) - g_1(x))\,dx$$

Since g_1 and g_2 are both even functions, $x(g_2(x) - g_1(x))$ is an odd function, so its integral over a region symmetric about the x-axis is zero. Thus $\overline{x} = 0$.

(b) Let $R(x, y)$ be an antiderivative of $\rho(x, y)$ with respect to y, i.e. $R(x, y) = \int \rho(x, y)\,dy$. Note that

$$R(-x, y) = \int \rho(-x, y)\,dy = \int \rho(x, y)\,dy = R(x, y)$$

so that R is an even function with respect to x. Now, we have

$$M_y \iint_{\mathcal{D}} x\rho(x, y)\,dA = \int_{-a}^{a}\int_{g_1(x)}^{g_2(x)} x\rho(x, y)\,dy\,dx = \int_{-a}^{a} x(R(x, g_2(x)) - R(x, g_1(x))\,dx$$

Since g_1, g_2, and R are all even functions of x, we have

$$R(-x, g_2(-x)) - R(-x, g_1(-x)) = R(-x, g_2(x)) - R(-x, g_1(x)) = R(x, g_2(x)) - R(x, g_1(x))$$

so that the second factor in the integrand is an even function of x. But x is an odd function of x, so their product is odd. It follows that the integral over the range $-a \le x \le a$ is zero. Thus $M_y = x_{\mathrm{CM}} = 0$.

60. Pappus's Theorem Let A be the area of the region $\mathcal{D}$ between two graphs $y = g_1(x)$ and $y = g_2(x)$ over the interval $[a, b]$, where $g_2(x) \ge g_1(x) \ge 0$. Prove Pappus's Theorem: The volume of the solid obtained by revolving $\mathcal{D}$ about the x-axis is $V = 2\pi A\overline{y}$, where $\overline{y}$ is the y-coordinate of the centroid of $\mathcal{D}$ (the average of the y-coordinate). *Hint:* Show that

$$A\overline{y} = \int_{x=a}^{b}\int_{y=g_1(x)}^{g_2(x)} y\,dy\,dx$$

SOLUTION Using the washer method, the volume of the solid of revolution about the x axis is

$$V = \int_{a}^{b} \pi(g_2(x)^2 - g_1(x)^2)\,dx$$

Now, we have by definition

$$A\overline{y} = \iint_{\mathcal{D}} y\,dA = \int_{a}^{b}\int_{g_1(x)}^{g_2(x)} y\,dy\,dx = \frac{1}{2}\int_{a}^{b} y^2\Big|_{g_1(x)}^{g_2(x)}\,dx = \frac{1}{2}\int_{a}^{b} g_2(x)^2 - g_1(x)^2\,dx$$

so that

$$2\pi A\overline{y} = 2\pi\cdot\frac{1}{2}\int_{a}^{b} g_2(x)^2 - g_1(x)^2\,dx = \int_{a}^{b}\pi(g_2(x)^2 - g_1(x)^2)\,dx = V$$

61. Use Pappus's Theorem in Exercise 60 to show that the torus obtained by revolving a circle of radius b centered at $(0, a)$ about the x-axis (where $b < a$) has volume $V = 2\pi^2 ab^2$.

SOLUTION The centroid of the circle is obviously at the center, $(0, a)$, and the area of the circle is πb^2, so that by Pappus' theorem,

$$V = 2\pi\pi b^2 a = 2\pi ab^2$$

62. Use Pappus's Theorem to compute $\overline{y}$ for the upper half of the disk $x^2 + y^2 \le a^2$, $y \ge 0$. *Hint:* The disk revolved about the x-axis is a sphere.

SOLUTION Since the disk revolved about the x-axis is a sphere of radius a, it has volume $\frac{4}{3}\pi a^3$. The area of the upper half of the disk is $\frac{1}{2}\pi a^2$. Thus by Pappus' theorem,

$$\frac{4}{3}\pi a^3 = 2\pi\cdot\frac{1}{2}\pi a^2\cdot\overline{y}$$

Solving for $\overline{y}$ gives

$$\overline{y} = \frac{4a}{3\pi}$$

63. Parallel-Axis Theorem Let $\mathcal{W}$ be a region in $\mathbf{R}^3$ with center of mass at the origin. Let I_z be the moment of inertia of $\mathcal{W}$ about the z-axis, and let I_h be the moment of inertia about the vertical axis through a point $P = (a, b, 0)$, where $h = \sqrt{a^2 + b^2}$. By definition,

$$I_h = \iiint_{\mathcal{W}} ((x-a)^2 + (y-b)^2)\rho(x, y, z)\,dV$$

Prove the Parallel-Axis Theorem: $I_h = I_z + Mh^2$.

SOLUTION We have

$$\begin{aligned}
I_h - I_z &= \iiint_{\mathcal{W}} ((x-a)^2 + (y-b)^2)\rho(x, y, z)\,dV - \iiint_{\mathcal{W}} (x^2 + y^2)\rho(x, y, z)\,dV \\
&= \iiint_{\mathcal{W}} (-2ax + a^2 - 2by + b^2)\rho(x, y, z)\,dV \\
&= (a^2 + b^2)\iiint_{\mathcal{W}} \rho(x, y, z)\,dV - 2a\iiint_{\mathcal{W}} x\rho(x, y, z)\,dV - 2b\iiint_{\mathcal{W}} y\rho(x, y, z)\,dV \\
&= (a^2 + b^2)M - 2aM_{yz} - 2bM_{xz} = Mh^2
\end{aligned}$$

since the last two terms are zero because the center of mass of $\mathcal{W}$ is at the origin.

64. Let $\mathcal{W}$ be a cylinder of radius 10 cm and height 20 cm, with total mass $M = 500$ g. Use the Parallel-Axis Theorem (Exercise 63) and the result of Exercise 45 to calculate the moment of inertia of $\mathcal{W}$ about an axis that is parallel to and at a distance of 30 cm from the cylinder's axis of symmetry.

SOLUTION For this cylinder, using Exercise 45, we see that the moment of inertia about the cylinder's axis of symmetry is

$$I_{\text{symm}} = \frac{1}{2}MR^2 = \frac{1}{2}\cdot 500 \cdot 100 = 25{,}000 \text{ g-cm}^2$$

Since the axis we are considering is at a distance of 30 cm from the axis of symmetry, the Parallel-Axis theorem tells us that

$$I = I_{\text{symm}} + Mh^2 = 25000 + 500 \cdot 900 = 475{,}000 \text{ g-cm}^2$$

15.6 Change of Variables (LT Section 16.6)

Preliminary Questions

1. Which of the following maps is linear?

(a) (uv, v) **(b)** $(u + v, u)$ **(c)** $(3, e^u)$

SOLUTION

(a) This map is not linear since it does not satisfy the linearity property:

$$\Phi(2u, 2v) = (2u \cdot 2v, 2v) = (4uv, 2v) = 2(2uv, v)$$
$$2\Phi(u, v) = 2(uv, v) \quad \Rightarrow \quad \Phi(2u, 2v) \neq 2\Phi(u, v)$$

(b) This map is linear since it has the form $\Phi(u, v) = (Au + Cv, Bu + Dv)$ where $A = C = 1$, $B = 1$, $D = 0$.

(c) This map is not linear since it does not satisfy the linearity properties. For example,

$$\left.\begin{aligned}\Phi(2u, 2v) &= (3, e^{2u}) \\ 2\Phi(u, v) &= 2(3, e^u)\end{aligned}\right. \quad \Rightarrow \quad \Phi(2u, 2v) \neq 2\Phi(u, v)$$

2. Suppose that Φ is a linear map such that $\Phi(2, 0) = (4, 0)$ and $\Phi(0, 3) = (-3, 9)$. Find the images of:

(a) $\Phi(1, 0)$ **(b)** $\Phi(1, 1)$ **(c)** $\Phi(2, 1)$

SOLUTION We denote the linear map by $\Phi(u, v) = (Au + Cv, Bu + Dv)$. By the given information we have

$$\Phi(2, 0) = (A \cdot 2 + C \cdot 0, B \cdot 2 + D \cdot 0) = (2A, 2B) = (4, 0)$$
$$\Phi(0, 3) = (A \cdot 0 + C \cdot 3, B \cdot 0 + D \cdot 3) = (3C, 3D) = (-3, 9)$$

Therefore,

$$\begin{aligned} 2A &= 4 \\ 2B &= 0 \\ 3C &= -3 \\ 3D &= 9 \end{aligned} \quad \Rightarrow \quad A = 2, \quad B = 0, \quad C = -1, \quad D = 3$$

The linear map is thus

$$\Phi(u, v) = (2u - v, 3v)$$

We now compute the images:

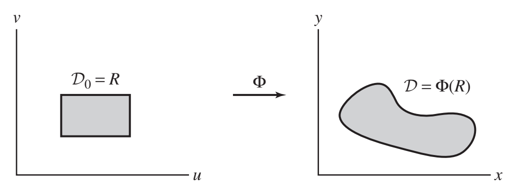
(a) $\Phi(1, 0) = (2 \cdot 1 - 0, 3 \cdot 0) = (2, 0)$

(b) $\Phi(1, 1) = (2 \cdot 1 - 1, 3 \cdot 1) = (1, 3)$

(c) $\Phi(2, 1) = (2 \cdot 2 - 1, 3 \cdot 1) = (3, 3)$

3. What is the area of $\Phi(\mathcal{R})$ if $\mathcal{R}$ is a rectangle of area 9 and Φ is a mapping whose Jacobian has constant value 4?

SOLUTION



The areas of $\mathcal{D}_0 = \Phi(\mathcal{R})$ and $\mathcal{D} = \mathcal{R}$ are the following integrals:

$$\text{Area}(\mathcal{R}) = 9 = \iint_{\mathcal{D}_0} 1\, du\, dv$$

$$\text{Area}(\Phi(\mathcal{R})) = \iint_{\mathcal{D}} 1\, dx\, dy$$

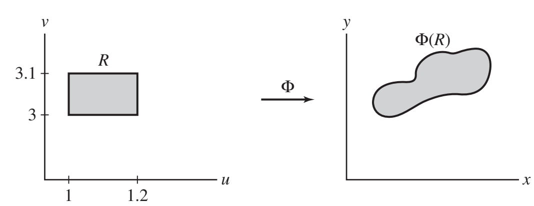
Using the Change of Variables Formula, we have

$$\text{Area}\,(\Phi(\mathcal{R})) = \iint_{\mathcal{D}} 1\, dx\, dy = \iint_{\mathcal{D}_0} 1|\text{Jac}\Phi|\, du\, dv = \iint_{\mathcal{D}_0} 4\, du\, dv = 4 \iint_{\mathcal{D}_0} 1\, du\, dv = 4 \cdot 9 = 36$$

The area of $\Phi(\mathcal{R})$ is 36.

4. Estimate the area of $\Phi(\mathcal{R})$, where $\mathcal{R} = [1, 1.2] \times [3, 3.1]$ and Φ is a mapping such that $\text{Jac}(\Phi)(1, 3) = 3$.

SOLUTION



We use the following estimation:

$$\text{Area}\,(\Phi(\mathcal{R})) \approx |\text{Jac}\,(\Phi)\,(P)|\text{Area}(\mathcal{R})$$

The area of the rectangle $\mathcal{R}$ is

$$\text{Area}(\mathcal{R}) = 0.2 \cdot 0.1 = 0.02$$

We choose the sample point $P = (1, 3)$ in $\mathcal{R}$ to obtain the following estimation:

$$\text{Area}\,(\Phi(\mathcal{R})) \approx |\text{Jac}\,(\Phi)\,(1, 3)|\text{Area}(\mathcal{R}) = 3 \cdot 0.02 = 0.06$$

Exercises

1. Determine the image under $\Phi(u, v) = (2u, u + v)$ of the following sets:

(a) The u- and v-axes

(b) The rectangle $\mathcal{R} = [0, 5] \times [0, 7]$

(c) The line segment joining $(1, 2)$ and $(5, 3)$

(d) The triangle with vertices $(0, 1)$, $(1, 0)$, and $(1, 1)$

SOLUTION

(a) The image of the u-axis is obtained by substituting $v = 0$ in $\Phi(u, v) = (2u, u + v)$. That is,

$$\Phi(u, 0) = (2u, u + 0) = (2u, u).$$

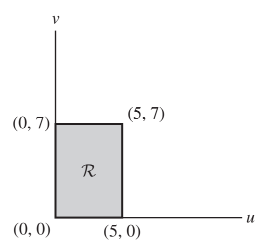
The image of the u-axis is the set of points $(x, y) = (2u, u)$, which is the line $y = \frac{1}{2}x$ in the xy-plane. The image of the v-axis is obtained by substituting $u = 0$ in $\Phi(u, v) = (2u, u + v)$. That is,

$$\Phi(0, v) = (0, 0 + v) = (0, v).$$

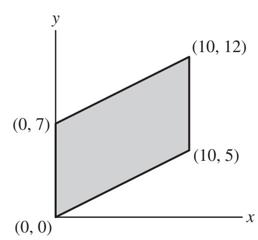
Therefore, the image of the v-axis is the set $(x, y) = (0, v)$, which is the vertical line $x = 0$ (the y-axis).

(b) Since Φ is a linear map, the segment through points P and Q is mapped to the segment through $\Phi(P)$ and $\Phi(Q)$. We thus must find the images of the vertices of $\mathcal{R}$:

$$\Phi(0, 0) = (2 \cdot 0, 0 + 0) = (0, 0)$$
$$\Phi(5, 0) = (2 \cdot 5, 5 + 0) = (10, 5)$$
$$\Phi(5, 7) = (2 \cdot 5, 5 + 7) = (10, 12)$$
$$\Phi(0, 7) = (2 \cdot 0, 0 + 7) = (0, 7)$$

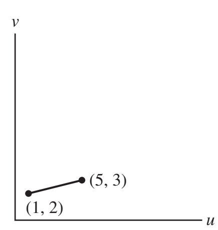


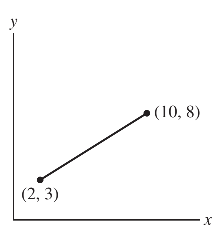
The image of $\mathcal{R}$ is the parallelogram with vertices $(0, 0)$, $(10, 5)$, $(10, 12)$, and $(0, 7)$ in the xy-plane.



(c) We compute the images of the endpoints of the segment:

$$\Phi(1, 2) = (2 \cdot 1, 1 + 2) = (2, 3)$$
$$\Phi(5, 3) = (2 \cdot 5, 5 + 3) = (10, 8)$$





The image is the segment in the xy-plane joining the points $(2, 3)$ and $(10, 8)$.

(d) Since Φ is linear, the image of the triangle is the triangle whose vertices are the images of the vertices of the triangle. We compute these images:

$$\Phi(0, 1) = (2 \cdot 0, 0 + 1) = (0, 1)$$
$$\Phi(1, 0) = (2 \cdot 1, 1 + 0) = (2, 1)$$
$$\Phi(1, 1) = (2 \cdot 1, 1 + 1) = (2, 2)$$

Therefore the image is the triangle in the xy-plane whose vertices are at the points $(0, 1)$, $(2, 1)$, and $(2, 2)$.

2. Describe [in the form $y = f(x)$] the images of the lines $u = c$ and $v = c$ under the mapping $\Phi(u, v) = (u/v, u^2 - v^2)$.

SOLUTION The image of the vertical line $u = c$ is the set of points

$$(x, y) = \Phi(c, v) = \left(\frac{c}{v}, c^2 - v^2\right).$$

That is, $x = \frac{c}{v}$ and $y = c^2 - v^2$. We substitute $v = \frac{c}{x}$ in the equation for y to obtain

$$y = c^2 - \frac{c^2}{x^2} = c^2\left(1 - \frac{1}{x^2}\right)$$

The image of the horizontal line $v = c$ is the set of points

$$(x, y) = \Phi(u, c) = \left(\frac{u}{c}, u^2 - c^2\right).$$

That is, $x = \frac{u}{c}$ and $y = u^2 - c^2$. Substituting $u = cx$ in the equation for y gives the parabola

$$y = c^2x^2 - c^2 = c^2(x^2 - 1).$$

3. Let $\Phi(u, v) = (u^2, v)$. Is Φ one-to-one? If not, determine a domain on which Φ is one-to-one. Find the image under Φ of:

(a) The u- and v-axes
(b) The rectangle $\mathcal{R} = [-1, 1] \times [-1, 1]$
(c) The line segment joining $(0, 0)$ and $(1, 1)$
(d) The triangle with vertices $(0, 0)$, $(0, 1)$, and $(1, 1)$

SOLUTION Φ is not one-to-one since for any $u \neq 0$, (u, v) and $(-u, v)$ are two different points with the same image. However, Φ is one-to-one on the domain $\{(u, v) : u \geq 0\}$ and on the domain $\{(u, v) : u \leq 0\}$.

(a) The image of the u-axis is the set of the points

$$(x, y) = \Phi(u, 0) = (u^2, 0) \quad \Rightarrow \quad x = u^2, \quad y = 0$$

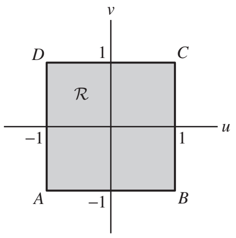
That is, the positive x-axis, including the origin. The image of the v-axis is the set of the following points:

$$(x, y) = \Phi(0, v) = (0^2, v) = (0, v) \quad \Rightarrow \quad x = 0, \quad y = v$$

That is, the line $x = 0$, which is the y-axis.

(b) The rectangle $\mathcal{R}$ is defined by

$$|u| \leq 1, \quad |v| \leq 1$$



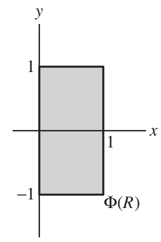
Since $x = u^2$ and $y = v$, we have $u = \pm\sqrt{x}$ and $v = y$ (depending on our choice of domain). Therefore, the inequalities for x and y are

$$|\pm\sqrt{x}| \leq 1, \quad |y| \leq 1$$

or

$$0 \leq x \leq 1 \quad \text{and} \quad -1 \leq y \leq 1.$$

We conclude that the image of $\mathcal{R}$ in the xy-plane is the rectangle $[0, 1] \times [-1, 1]$.



(c) The line segment joining the points (0, 0) and (1, 1) in the uv-plane is defined by

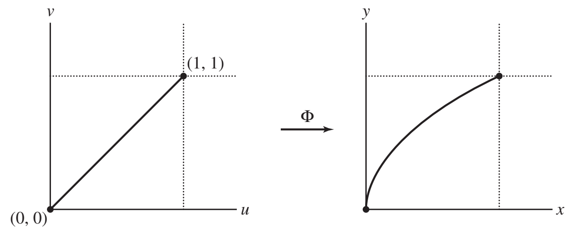
$$0 \le u \le 1, \quad v = u.$$

Substituting $u = \sqrt{x}$ and $v = y$, we get

$$0 \le \sqrt{x} \le 1, \quad y = \sqrt{x}$$

or

$$0 \le x \le 1, \quad y = \sqrt{x}$$



The image is the curve $y = \sqrt{x}$ for $0 \le x \le 1$.

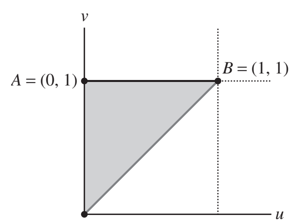
(d) We identify the image of the sides of the triangle OAB.

The image of $\overline{OA}$: This segment is defined by $u = 0$ and $0 \le v \le 1$. That is,

$$\pm\sqrt{x} = 0 \quad \text{and} \quad 0 \le y \le 1$$

or

$$x = 0, \quad 0 \le y \le 1.$$



This is the segment joining the points (0, 0) and (0, 1) in the xy-plane.

The image of $\overline{AB}$: This segment is defined by $0 \le u \le 1$ and $v = 1$. That is,

$$0 \le \sqrt{x} \le 1, \quad y = 1$$

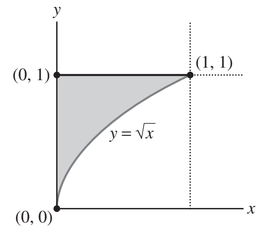
or

$$0 \le x \le 1, \quad y = 1.$$

This is the segment joining the points (0, 1) and (1, 1) in the xy-plane.

The image of $\overline{OB}$: In part (c) we showed that the image of the segment is the curve $y = \sqrt{x}$, $0 \le x \le 1$.

Therefore, the image of the triangle is the region shown in the figure:



4. Let $\Phi(u, v) = (e^u, e^{u+v})$.

(a) Is Φ one-to-one? What is the image of Φ?

(b) Describe the images of the vertical lines $u = c$ and the horizontal lines $v = c$.

SOLUTION

(a) Suppose that $\Phi(u_1, v_1) = \Phi(u_2, v_2)$. We show that $(u_1, v_1) = (u_2, v_2)$, hence Φ is one-to-one. We have

$$\left(e^{u_1}, e^{u_1+v_1}\right) = \left(e^{u_2}, e^{u_2+v_2}\right) \quad \Rightarrow \quad e^{u_1} = e^{u_2} \quad \Rightarrow \quad u_1 = u_2$$

and

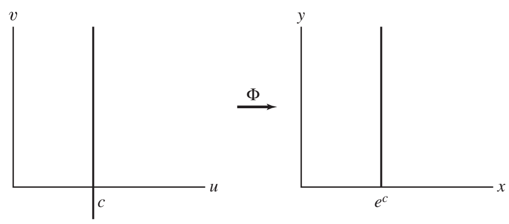
$$e^{u_1+v_1} = e^{u_2+v_2} \quad \Rightarrow \quad u_1 + v_1 = u_2 + v_2 \quad \Rightarrow \quad v_1 = v_2$$

We find the image of Φ. The image of the exponent function is $(0, \infty)$. Since u and v can take any value, the points (e^u, e^{u+v}) are all the points (x, y) where $x > 0$ and $y > 0$; that is, the image of Φ is the first quadrant of the xy-plane, with the axes excluded.

(b) The image of the vertical line $u = c$ is the set of the following points:

$$(x, y) = \Phi(c, v) = (e^c, e^{c+v}) \quad \Rightarrow \quad x = e^c, \quad y = e^v x \quad \Rightarrow \quad x = e^c, \quad y > 0$$

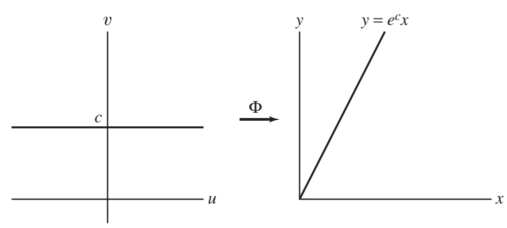
That is, the image is the ray $x = e^c$, $y > 0$ in the xy-plane.



The image of the horizontal line $v = c$ is the set of the points

$$(x, y) = \Phi(u, c) = (e^u, e^{u+c}) \quad \Rightarrow \quad x = e^u, \quad y = e^c x \quad \Rightarrow \quad y = e^c x, \quad x > 0$$

Since u can take any value, x can take any positive value, and hence the image is the ray $y = e^c x$, $x > 0$.



In Exercises 5–12, let $\Phi(u, v) = (2u + v, 5u + 3v)$ be a map from the uv-plane to the xy-plane.

5. Show that the image of the horizontal line $v = c$ is the line $y = \frac{5}{2}x + \frac{1}{2}c$. What is the image (in slope-intercept form) of the vertical line $u = c$?

SOLUTION The image of the horizontal line $v = c$ is the set of the following points:

$$(x, y) = \Phi(u, c) = (2u + c, 5u + 3c) \quad \Rightarrow \quad x = 2u + c, \quad y = 5u + 3c$$

The first equation implies $u = \frac{x-c}{2}$. Substituting in the second equation gives

$$y = 5\frac{(x - c)}{2} + 3c = \frac{5x}{2} + \frac{c}{2}$$

Therefore, the image of the line $v = c$ is the line $y = \frac{5x}{2} + \frac{c}{2}$ in the xy-plane.

The image of the vertical line $u = c$ is the set of the following points:

$$(x, y) = \Phi(c, v) = (2c + v, 5c + 3v) \quad \Rightarrow \quad x = 2c + v, \quad y = 5c + 3v$$

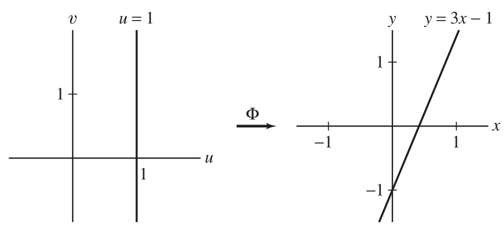
By the first equation, $v = x - 2c$. Substituting in the second equation gives

$$y = 5c + 3(x - 2c) = 5c + 3x - 6c = 3x - c$$

Therefore, the image of the line $u = c$ is the line $y = 3x - c$ in the xy-plane.

6. Describe the image of the line through the points $(u, v) = (1, 1)$ and $(u, v) = (1, -1)$ under Φ in slope-intercept form.

SOLUTION



The line is the vertical line $u = 1$ in the uv-plane. The image of the line under the linear map $\Phi(u, v) = (2u + v, 5u + 3v)$ is the line through the images of the points $(u, v) = (1, 1)$ and $(u, v) = (1, -1)$. We find these images:

$$\Phi(1, 1) = (2 \cdot 1 + 1, 5 \cdot 1 + 3 \cdot 1) = (3, 8)$$
$$\Phi(1, -1) = (2 \cdot 1 - 1, 5 \cdot 1 - 3) = (1, 2)$$

We find the slope-intercept form of the equation of the line in the xy-plane, through the points $(3, 8)$ and $(1, 2)$:

$$y - 2 = \frac{8 - 2}{3 - 1}(x - 1) = 3(x - 1) \quad \Rightarrow \quad y = 3x - 1$$

7. Describe the image of the line $v = 4u$ under Φ in slope-intercept form.

SOLUTION We choose any two points on the line $v = 4u$, for example $(u, v) = (1, 4)$ and $(u, v) = (0, 0)$. By a property of linear maps, the image of the line $v = 4u$ under the linear map $\Phi(u, v) = (2u + v, 5u + 3v)$ is the line in the xy-plane through the points $\Phi(1, 4)$ and $\Phi(0, 0)$. We find these points:

$$\Phi(0, 0) = (2 \cdot 0 + 0, 5 \cdot 0 + 3 \cdot 0) = (0, 0)$$
$$\Phi(1, 4) = (2 \cdot 1 + 4, 5 \cdot 1 + 3 \cdot 4) = (6, 17)$$

We now find the slope-intercept equation of the line in the xy-plane through the points $(0, 0)$ and $(6, 17)$:

$$y - 0 = \frac{17 - 0}{6 - 0}(x - 0) \quad \Rightarrow \quad y = \frac{17}{6}x$$

8. Show that Φ maps the line $v = mu$ to the line of slope $(5 + 3m)/(2 + m)$ through the origin in the xy-plane.

SOLUTION The points $(0, 0)$ and $(1, m)$ lie on the line $v = mu$. The images of these points under the map $\Phi(u, v) = (2u + v, 5u + 3v)$ are

$$\Phi(0, 0) = (2 \cdot 0 + 0, 5 \cdot 0 + 3 \cdot 0) = (0, 0)$$
$$\Phi(1, m) = (2 \cdot 1 + m, 5 \cdot 1 + 3m) = (2 + m, 5 + 3m)$$

By properties of linear maps, the image of the line $v = mu$ under the linear map Φ is a line through the points $(0, 0)$ and $(2 + m, 5 + 3m)$. The slope of this line is

$$\frac{(5 + 3m) - 0}{(2 + m) - 0} = \frac{5 + 3m}{2 + m}.$$

9. Show that the inverse of Φ is

$$\Phi^{-1}(x, y) = (3x - y, -5x + 2y)$$

Hint: Show that $\Phi(\Phi^{-1}(x, y)) = (x, y)$ and $\Phi^{-1}(\Phi(u, v)) = (u, v)$.

SOLUTION By the definition of the inverse map, we must show that the given maps $\Phi^{-1}(x, y) = (3x - y, -5x + 2y)$ and $\Phi(u, v) = (2u + v, 5u + 3v)$ satisfy $\Phi\left(\Phi^{-1}(x, y)\right) = (x, y)$ and $\Phi^{-1}(\Phi(u, v)) = (u, v)$. We have

$$\Phi\left(\Phi^{-1}(x, y)\right) = \Phi(3x - y, -5x + 2y) = (2(3x - y) + (-5x + 2y), 5(3x - y) + 3(-5x + 2y)) = (x, y)$$
$$\Phi^{-1}(\Phi(u, v)) = \Phi^{-1}(2u + v, 5u + 3v) = (3(2u + v) - (5u + 3v), -5(2u + v) + 2(5u + 3v)) = (u, v)$$

We conclude that Φ^{-1} is the inverse of Φ.

10. Use the inverse in Exercise 9 to find:

(a) A point in the uv-plane mapping to $(2, 1)$

(b) A segment in the uv-plane mapping to the segment joining $(-2, 1)$ and $(3, 4)$

SOLUTION

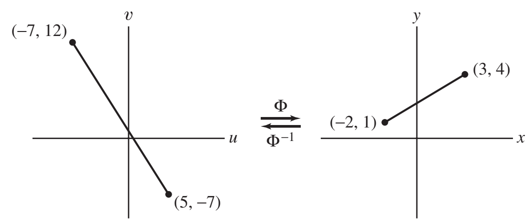
(a) The inverse of $\Phi(u, v)$ is $\Phi^{-1}(x, y) = (3x - y, -5x + 2y)$. Therefore, the point in the uv-plane mapping to $(2, 1)$ in the xy-plane is $\Phi^{-1}(2, 1)$. We find it:

$$(u, v) = \Phi^{-1}(2, 1) = (3 \cdot 2 - 1, -5 \cdot 2 + 2 \cdot 1) = (5, -8)$$

(b) The segment we need to find is the image of the segment joining the points $(-2, 1)$ and $(3, 4)$ in the xy-plane, under the inverse map $\Phi^{-1}(x, y) = (3x - y, -5x + 2y)$. By properties of linear maps, this image is the segment in the uv-plane joining the points $\Phi^{-1}(-2, 1)$ and $\Phi^{-1}(3, 4)$. We find these points:

$$\Phi^{-1}(-2, 1) = (3 \cdot (-2) - 1, -5 \cdot (-2) + 2 \cdot 1) = (-7, 12)$$
$$\Phi^{-1}(3, 4) = (3 \cdot 3 - 4, -5 \cdot 3 + 2 \cdot 4) = (5, -7)$$

Therefore, the segment in the uv-plane mapping to the given segment under Φ is the segment joining the points $(-7, 12)$ and $(5, -7)$ in the uv-plane.



11. Calculate $\text{Jac}(\Phi) = \dfrac{\partial(x, y)}{\partial(u, v)}$.

SOLUTION The Jacobian of the linear mapping $\Phi(u, v) = (2u + v, 5u + 3v)$ is the following determinant:

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} 2 & 1 \\ 5 & 3 \end{vmatrix} = 2 \cdot 3 - 5 \cdot 1 = 1$$

12. Calculate $\text{Jac}(\Phi^{-1}) = \dfrac{\partial(u, v)}{\partial(x, y)}$.

SOLUTION We use the formula for the Jacobian of the inverse map, and the result of Exercise 11 to obtain

$$\text{Jac}(\Phi^{-1}) = \left(\text{Jac}(\Phi)^{-1}\right) = 1^{-1} = 1$$

In Exercises 13–18, compute the Jacobian (at the point, if indicated).

13. $\Phi(u, v) = (3u + 4v, u - 2v)$

SOLUTION Using the Jacobian of linear mappings we get

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} 3 & 4 \\ 1 & -2 \end{vmatrix} = 3 \cdot (-2) - 1 \cdot 4 = -10$$

14. $\Phi(r, s) = (rs, r + s)$

SOLUTION We have $x = rs$ and $y = r + s$, therefore,

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(r, s)} = \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial s} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial s} \end{vmatrix} = \begin{vmatrix} s & r \\ 1 & 1 \end{vmatrix} = s \cdot 1 - r \cdot 1 = s - r$$

15. $\Phi(r, t) = (r \sin t, r - \cos t), \quad (r, t) = (1, \pi)$

SOLUTION We have $x = r \sin t$ and $y = r - \cos t$. Therefore,

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(r, t)} = \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial t} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial t} \end{vmatrix} = \begin{vmatrix} \sin t & r \cos t \\ 1 & \sin t \end{vmatrix} = \sin^2 t - r \cos t$$

At the point $(r, t) = (1, \pi)$ we get

$$\text{Jac}(\Phi)(1, \pi) = \sin^2 \pi - 1 \cdot \cos \pi = 0 - 1 \cdot (-1) = 1$$

16. $\Phi(u, v) = (v \ln u, u^2 v^{-1})$, $\quad (u, v) = (1, 2)$

SOLUTION We have $x = v \ln u$ and $y = u^2 v^{-1}$. Therefore,

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{v}{u} & \ln u \\ \frac{2u}{v} & \frac{-u^2}{v^2} \end{vmatrix} = -\frac{u}{v} - \frac{2u}{v} \ln u = -\frac{u}{v}(1 + 2 \ln u)$$

At the point $(u, v) = (1, 2)$ we get:

$$\text{Jac}(\Phi)(1, 2) = -\frac{1}{2}(1 + 2 \ln 1) = -\frac{1}{2}$$

17. $\Phi(r, \theta) = (r \cos\theta, r \sin\theta)$, $\quad (r, \theta) = \left(4, \frac{\pi}{6}\right)$

SOLUTION Since $x = r \cos\theta$ and $y = r \sin\theta$, the Jacobian of Φ is the following determinant:

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(r, \theta)} = \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} \end{vmatrix} = \begin{vmatrix} \cos\theta & -r\sin\theta \\ \sin\theta & r\cos\theta \end{vmatrix}$$
$$= r\cos^2\theta + r\sin^2\theta = r(\cos^2\theta + \sin^2\theta) = r \cdot 1 = r$$

At the point $(r, \theta) = (4, \pi/6)$ we get:

$$\text{Jac}(\Phi)(4, \pi/6) = 4$$

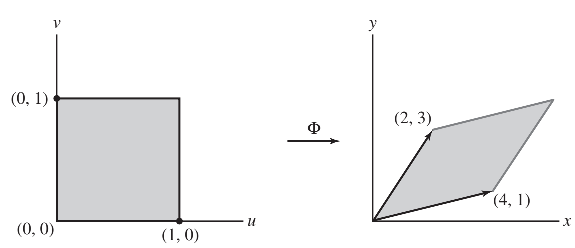
18. $\Phi(u, v) = (ue^v, e^u)$

SOLUTION We have $x = ue^v$ and $y = e^u$, hence the Jacobian of Φ is the following determinant:

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} e^v & ue^v \\ e^u & 0 \end{vmatrix} = e^v \cdot 0 - ue^v \cdot e^u = -ue^{u+v}$$

19. Find a linear mapping Φ that maps $[0, 1] \times [0, 1]$ to the parallelogram in the xy-plane spanned by the vectors $\langle 2, 3\rangle$ and $\langle 4, 1\rangle$.

SOLUTION



We denote the linear map by

$$\Phi(u, v) = (Au + Cv, Bu + Dv) \tag{1}$$

The image of the unit square $\mathcal{R} = [0, 1] \times [0, 1]$ under the linear map is the parallelogram whose vertices are the images of the vertices of $\mathcal{R}$. Two of vertices of the given parallelogram are $(2, 3)$ and $(4, 1)$. To find A, B, C, and D it suffices to determine four equations. Therefore, we ask that (notice that for linear maps $\Phi(0, 0) = (0, 0)$)

$$\Phi(0, 1) = (2, 3), \quad \Phi(1, 0) = (4, 1)$$

We substitute in (1) and solve for A, B, C, and D:

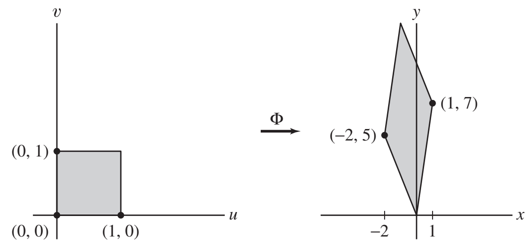
$$\begin{matrix} (A \cdot 0 + C \cdot 1, B \cdot 0 + D \cdot 1) = (C, D) = (2, 3) \\ (A \cdot 1 + C \cdot 0, B \cdot 1 + D \cdot 0) = (A, B) = (4, 1) \end{matrix} \quad \Rightarrow \quad \begin{matrix} C = 2, \quad D = 3 \\ A = 4, \quad B = 1 \end{matrix}$$

Substituting in (1) we obtain the following map:

$$\Phi(u, v) = (4u + 2v, u + 3v).$$

20. Find a linear mapping Φ that maps $[0,1] \times [0,1]$ to the parallelogram in the xy-plane spanned by the vectors $\langle -2, 5\rangle$ and $\langle 1, 7\rangle$.

SOLUTION



We denote the linear map by

$$\Phi(u, v) = (Au + Cv, Bu + Dv) \tag{1}$$

By properties of linear mapping, the images of the vertices of the unit square in the uv-plane are the vertices of the parallelogram in the xy-plane. Since we need four equations to determine A, B, C, and D, we ask that (notice that for any linear map, $\Phi(0,0) = (0,0)$)

$$\Phi(0,1) = (-2, 5), \quad \Phi(1,0) = (1,7)$$

We substitute in (1) and solve for A, B, C, and D:

$$\Phi(0,1) = (A\cdot 0 + C\cdot 1, B\cdot 0 + D\cdot 1) = (C, D) = (-2, 5) \quad \Rightarrow \quad C = -2, \quad D = 5$$
$$\Phi(1,0) = (A\cdot 1 + C\cdot 0, B\cdot 1 + D\cdot 0) = (A, B) = (1, 7) \quad \Rightarrow \quad A = 1, \quad B = 7$$

We substitute in (1) to obtain the following map:

$$\Phi(u, v) = (u - 2v, 7u + 5v)$$

21. Let $\mathcal{D}$ be the parallelogram in Figure 13. Apply the Change of Variables Formula to the map $\Phi(u, v) = (5u + 3v, u + 4v)$ to evaluate $\iint_{\mathcal{D}} xy\,dx\,dy$ as an integral over $\mathcal{D}_0 = [0,1] \times [0,1]$.

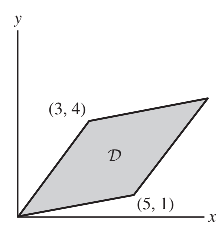


FIGURE 13

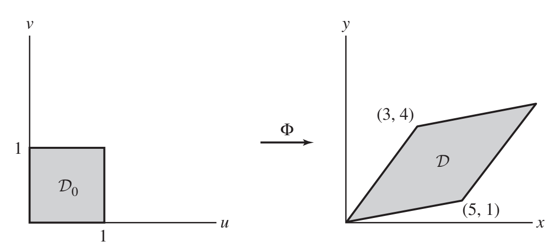
SOLUTION



We express $f(x, y) = xy$ in terms of u and v. Since $x = 5u + 3v$ and $y = u + 4v$, we have

$$f(x, y) = xy = (5u + 3v)(u + 4v) = 5u^2 + 12v^2 + 23uv$$

The Jacobian of the linear map $\Phi(u, v) = (5u + 3v, u + 4v)$ is

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} 5 & 3 \\ 1 & 4 \end{vmatrix} = 20 - 3 = 17$$

Applying the Change of Variables Formula we get

$$\iint_{\mathcal{D}} xy\,dA = \iint_{\mathcal{D}_0} f(x,y)\left|\frac{\partial(x,y)}{\partial(u,v)}\right| du\,dv = \int_0^1\int_0^1 (5u^2+12v^2+23uv)\cdot 17\,du\,dv$$

$$= 17\int_0^1 \frac{5u^3}{3}+12v^2u+\frac{23u^2v}{2}\bigg|_{u=0}^{1} dv = 17\int_0^1\left(\frac{5}{3}+12v^2+\frac{23v}{2}\right)dv$$

$$= 17\left(\frac{5v}{3}+4v^3+\frac{23v^2}{4}\bigg|_0^1\right) = 17\left(\frac{5}{3}+4+\frac{23}{4}\right) = \frac{2329}{12} \approx 194.08$$

22. Let $\Phi(u,v)=(u-uv,uv)$.

(a) Show that the image of the horizontal line $v=c$ is $y=\dfrac{c}{1-c}x$ if $c\neq 1$, and is the y-axis if $c=1$.

(b) Determine the images of vertical lines in the uv-plane.

(c) Compute the Jacobian of Φ.

(d) Observe that by the formula for the area of a triangle, the region $\mathcal{D}$ in Figure 14 has area $\frac{1}{2}(b^2-a^2)$. Compute this area again, using the Change of Variables Formula applied to Φ.

(e) Calculate $\iint_{\mathcal{D}} xy\,dx\,dy$.

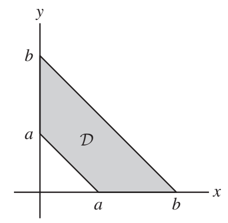


FIGURE 14

SOLUTION

(a) The image of the horizontal line $v=c$ in the (u,v)-plane is the set of the following points:

$$(x,y)=\Phi(u,c)=(u-uc,uc) \quad\Rightarrow\quad x=u-uc,\quad y=uc$$

Substituting $u=\frac{y}{c}$ (for $c\neq 0$) in $x=u-uc$ gives $x=\frac{y}{c}-\frac{y}{c}\cdot c$, $x=\frac{y}{c}-y$, or $y=\frac{cx}{1-c}$ (for $c\neq 1$). The image of $v=0$ (the u-axis) is

$$(x,y)=\Phi(u,0)=(u,0) \quad\Rightarrow\quad y=0$$

The image of $v=1$ is

$$(x,y)=\Phi(u,1)=(0,u) \quad\Rightarrow\quad x=0$$

We conclude that

The image of the line $v=c$ is the line $y=\frac{cx}{1-c}$ for $c\neq 1$, and the image of the line $v=1$ is the y-axis.
The image of the vertical line $u=c$ is the set of the following points:

$$(x,y)=\Phi(c,v)=(c-cv,cv) \quad\Rightarrow\quad x=c-cv,\quad y=cv$$

Therefore, for $c\neq 0$ we have $v=\frac{y}{c}$ and $x=c-c\cdot\frac{y}{c}=c-y$ or $y=c-x$.

The image of the vertical line $u=0$ (the v-axis) is

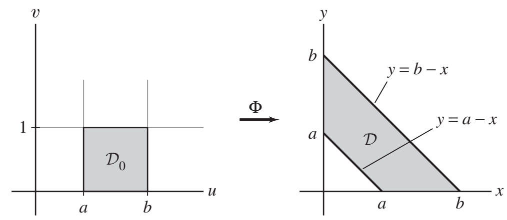
$$(x,y)=\Phi(0,v)=(0,0)$$

We conclude that the image of the line $u=c$ is the line $y=c-x$ if $c\neq 0$, and the image of the line $u=0$ is the point at the origin of the xy-plane.

(b) Since $x=u-uv$ and $y=uv$, the Jacobian of Φ is the following determinant:

$$\operatorname{Jac}(\Phi)=\frac{\partial(x,y)}{\partial(u,v)}=\begin{vmatrix}\frac{\partial x}{\partial u} & \frac{\partial x}{\partial v}\\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v}\end{vmatrix}=\begin{vmatrix}1-v & -u\\ v & u\end{vmatrix}=(1-v)u+uv=u$$

(c)



The area of $\mathcal{D}$ is the following determinant:

$$\text{Area}(\mathcal{D}) = \iint_{\mathcal{D}} 1\, dA \tag{1}$$

We compute this integral using the Change of Variables Formula with the mapping $\Phi(u, v) = (u - uv, uv)$. By part (a) the lines $y = b - x$ and $y = a - x$ are the images of the lines $u = b$ and $u = a$, respectively, in the uv-plane. Also the lines $y = 0$ and $x = 0$ are the images of the lines $v = 0$ and $v = 1$, respectively. Therefore, $\mathcal{D}$ is the image of the rectangle $\mathcal{D}_0$ in the uv-plane shown in the figure. We compute the integral (1) using the Change of Variables Formula and the Jacobian computed in part (b). We get

$$\text{Area}(\mathcal{D}) = \iint_{\mathcal{D}} 1\, dA = \iint_{\mathcal{D}_0} 1|\text{Jac}\Phi|\, du\, dv = \int_a^b \int_0^1 u\, dv\, du = \left(\int_a^b u\, du\right)\left(\int_0^1 dv\right) = \left(\frac{u^2}{2}\Big|_a^b\right) = \frac{b^2 - a^2}{2}$$

(d) The function expressed in the new variables u and v is

$$f(x, y) = xy = (u - uv)uv = u^2 v - u^2 v^2$$

Using the Change of Variables Formula and the Jacobian obtained in part (b) we get

$$\iint_{\mathcal{D}} xy\, dA = \iint_{\mathcal{D}_0} (u^2 v - u^2 v^2) u\, du\, dv = \int_a^b \int_0^1 (u^3 v - u^3 v^2)\, dv\, du = \int_a^b \frac{u^3 v^2}{2} - \frac{u^3 v^3}{3}\Big|_{v=0}^1 du$$

$$= \int_a^b \left(\frac{u^3}{2} - \frac{u^3}{3}\right) du = \int_a^b \frac{u^3}{6}\, du = \frac{u^4}{24}\Big|_a^b = \frac{b^4 - a^4}{24}$$

23. Let $\Phi(u, v) = (3u + v, u - 2v)$. Use the Jacobian to determine the area of $\Phi(\mathcal{R})$ for:
(a) $\mathcal{R} = [0, 3] \times [0, 5]$ **(b)** $\mathcal{R} = [2, 5] \times [1, 7]$

SOLUTION The Jacobian of the linear map $\Phi(u, v) = (3u + v, u - 2v)$ is the following determinant:

$$\text{Jac}\Phi = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} 3 & 1 \\ 1 & -2 \end{vmatrix} = -6 - 1 = -7$$

By properties of linear maps, we have

$$\text{Area}\,(\Phi(\mathcal{R})) = |\text{Jac}\Phi|\text{Area}(\mathcal{R}) = 7 \cdot \text{Area}(\mathcal{R})$$

(a) The area of the rectangle $R = [0, 3] \times [0, 5]$ is $3 \cdot 5 = 15$, therefore the area of $\Phi(\mathcal{R})$ is

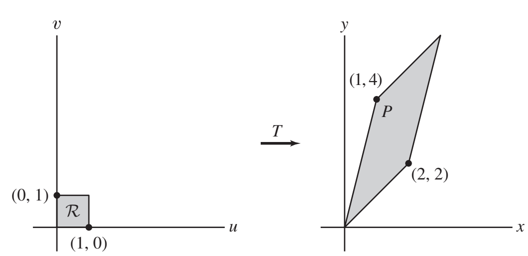
$$\text{Area}\,(\Phi(\mathcal{R})) = 7 \cdot 15 = 105$$

(b) The area of the rectangle $\mathcal{R} = [2, 5] \times [1, 7]$ is $3 \cdot 6 = 18$ hence the area of $\Phi(\mathcal{R})$ is

$$\text{Area}\,(\Phi(\mathcal{R})) = 7 \cdot 18 = 126.$$

24. Find a linear map T that maps $[0, 1] \times [0, 1]$ to the parallelogram $\mathcal{P}$ in the xy-plane with vertices $(0, 0)$, $(2, 2)$, $(1, 4)$, $(3, 6)$. Then calculate the double integral of e^{2x-y} over $\mathcal{P}$ via change of variables.

SOLUTION



By properties of linear maps, the vertices of the square $\mathcal{R} = [0, 1] \times [0, 1]$ are mapped to the vertices of the parallelogram $\mathcal{P}$. Denoting the linear map by $T(u, v) = (Au + Cv, Bu + Dv)$, we ask that

$$T(0, 1) = (1, 4), \quad T(1, 0) = (2, 2)$$

We substitute the points in $T(u, v)$ and solve for A, B, C, D to obtain

$$T(0, 1) = (A \cdot 0 + C \cdot 1, B \cdot 0 + D \cdot 1) = (C, D) = (1, 4) \quad \Rightarrow \quad C = 1, \quad D = 4$$
$$T(1, 0) = (A \cdot 1 + C \cdot 0, B \cdot 1 + D \cdot 0) = (A, B) = (2, 2) \quad \Rightarrow \quad A = 2, \quad B = 2$$

We obtain the following map:

$$T(u, v) = (2u + v, 2u + 4v)$$

We now compute the integral $\iint_{\mathcal{P}} e^{2x-y}\, dA$ using change of variables. We express $f(x, y) = e^{2x-y}$ in terms of the new variables u and v. Since $x = 2u + v$ and $y = 2u + 4v$, we obtain

$$f(x, y) = e^{2(2u+v)-(2u+4v)} = e^{2u-2v}$$

The Jacobian of linear map T is

$$\text{Jac}(T) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} 2 & 1 \\ 2 & 4 \end{vmatrix} = 2 \cdot 4 - 2 \cdot 1 = 6$$

Using the Change of Variables Formula, we get

$$\begin{aligned}
\iint_{\mathcal{P}} e^{2x-y}\, dA &= \iint_{\mathcal{R}} e^{2u-2v} |\text{Jac}(T)|\, du\, dv = \int_0^1 \int_0^1 e^{2u-2v} \cdot 6\, du\, dv = 6 \int_0^1 \int_0^1 e^{2u} \cdot e^{-2v}\, du\, dv \\
&= 6 \left(\int_0^1 e^{2u}\, du \right) \left(\int_0^1 e^{-2v}\, dv \right) = 6 \left(\frac{e^{2u}}{2} \bigg|_0^1 \right) \cdot \left(\frac{e^{-2v}}{-2} \bigg|_0^1 \right) \\
&= -\frac{3}{2}(e^2 - 1)(e^{-2} - 1) = \frac{3}{2}(e^2 - 1)(1 - e^{-2}) = \frac{3}{2}(e^2 + e^{-2} - 2)
\end{aligned}$$

25. With Φ as in Example 3, use the Change of Variables Formula to compute the area of the image of $[1, 4] \times [1, 4]$.

SOLUTION Let $\mathcal{R}$ represent the rectangle $[1, 4] \times [1, 4]$. We proceed as follows. $\text{Jac}(\Phi)$ is easily calculated as

$$\text{Jac}(T) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} 1/v & -u/v^2 \\ v & u \end{vmatrix} = 2u/v$$

Now, the area is given by the Change of Variables Formula as

$$\begin{aligned}
\iint_{\Phi(\mathcal{R})} 1\, dA &= \iint_{\mathcal{R}} 1 |\text{Jac}(\Phi)|\, du\, dv = \iint_{\mathcal{R}} 1 |2u/v|\, du\, dv = \int_1^4 \int_1^4 2u/v\, du\, dv \\
&= \int_1^4 2u\, du \cdot \int_1^4 \frac{1}{v}\, dv = (16 - 1)(\ln 4 - \ln 1) = 15 \ln 4
\end{aligned}$$

In Exercises 26–28, let $\mathcal{R}_0 = [0, 1] \times [0, 1]$ be the unit square. The translate of a map $\Phi_0(u, v) = (\phi(u, v), \psi(u, v))$ is a map

$$\Phi(u, v) = (a + \phi(u, v), b + \psi(u, v))$$

where a, b are constants. Observe that the map Φ_0 in Figure 15 maps $\mathcal{R}_0$ to the parallelogram $\mathcal{P}_0$ and that the translate

$$\Phi_1(u, v) = (2 + 4u + 2v, 1 + u + 3v)$$

maps $\mathcal{R}_0$ to $\mathcal{P}_1$.

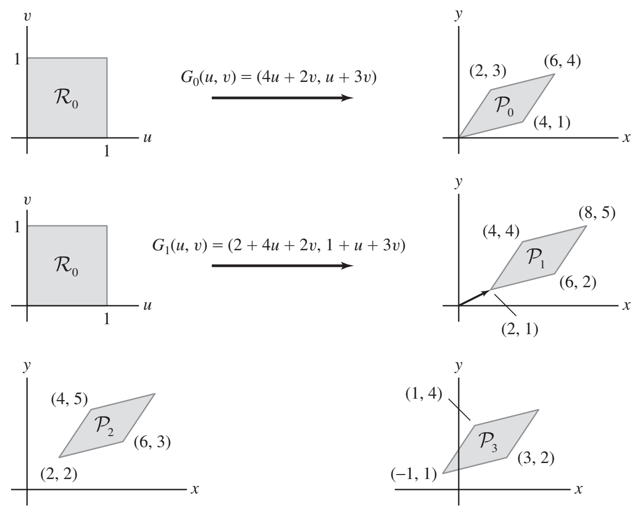


FIGURE 15

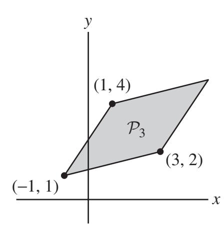
26. Find translates Φ_2 and Φ_3 of the mapping Φ_0 in Figure 15 that map the unit square $\mathcal{R}_0$ to the parallelograms $\mathcal{P}_2$ and $\mathcal{P}_3$.

SOLUTION The parallelogram $\mathcal{P}_2$ is obtained by translating $\mathcal{P}_0$ two units upward and two units to the left. Therefore the translate that maps the unit square $\mathcal{R}_0$ to $\mathcal{P}_2$ is

$$\Phi_2(u, v) = (2 + 4u + 2v, 2 + u + 3v)$$

The parallelogram $\mathcal{P}_3$ is obtained by translating $\mathcal{P}_0$ one unit upward and one unit to the left.

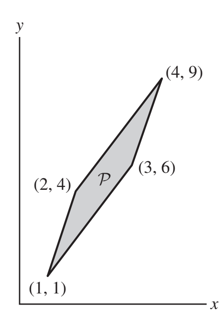


Therefore, the translate that maps $\mathcal{R}_0$ to $\mathcal{P}_2$ is

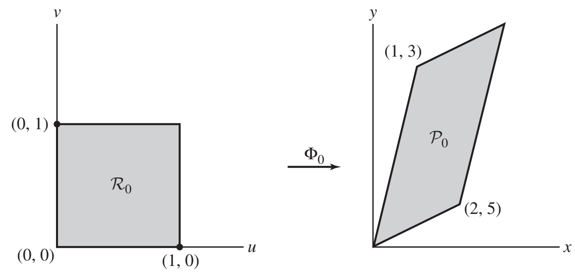
$$\Phi_3(u, v) = (-1 + 4u + 2v, 1 + u + 3v)$$

27. Sketch the parallelogram $\mathcal{P}$ with vertices (1, 1), (2, 4), (3, 6), (4, 9) and find the translate of a linear mapping that maps $\mathcal{R}_0$ to $\mathcal{P}$.

SOLUTION The parallelogram $\mathcal{P}$ is shown in the figure:



We first translate the parallelogram $\mathcal{P}$ one unit to the left and one unit downward to obtain a parallelogram $\mathcal{P}_0$ with a vertex at the origin.



We find a linear map $\Phi_0(u, v) = (Au + Cv, Bu + Dv)$ that maps $\mathcal{R}_0$ to $\mathcal{P}_0$:

$$\Phi_0(0, 1) = (1, 3) \quad \Rightarrow \quad (C, D) = (1, 3) \quad \Rightarrow \quad C = 1, \quad D = 3$$
$$\Phi_0(1, 0) = (2, 5) \quad \Rightarrow \quad (A, B) = (2, 5) \quad \Rightarrow \quad A = 2, \quad B = 5$$

Therefore,

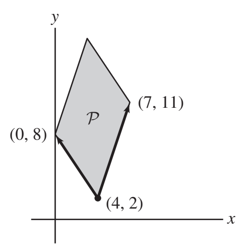
$$\Phi_0(u, v) = (2u + v, 5u + 3v)$$

Now we can determine the translate Φ of Φ_0 that maps $\mathcal{R}_0$ to $\mathcal{P}$. Since $\mathcal{P}$ is obtained by translating $\mathcal{P}_0$ one unit upward and one unit to the right, the map Φ is the following translate of Φ_0:

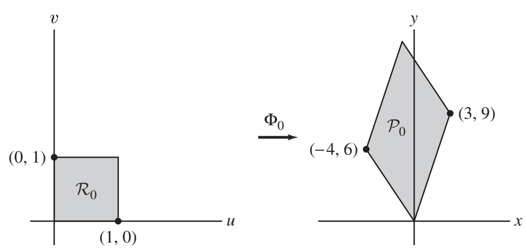
$$\Phi(u, v) = (1 + 2u + v, 1 + 5u + 3v)$$

28. Find the translate of a linear mapping that maps $\mathcal{R}_0$ to the parallelogram spanned by the vectors $\langle 3, 9\rangle$ and $\langle -4, 6\rangle$ based at $(4, 2)$.

SOLUTION The parallelogram $\mathcal{P}$ spanned by $\langle 3, 9\rangle$ and $\langle -4, 6\rangle$ based at $(4, 2)$ is shown in the figure:



We first translate $\mathcal{P}$ four units to the left and two units downward, so that the base $(4, 2)$ is moved to the origin. The translated parallelogram $\mathcal{P}_0$ is shown in the figure:



We find a linear map $\Phi_0(u, v) = (Au + Cv, Bu + Dv)$ that maps $\mathcal{R}_0$ to $\mathcal{P}_0$. We demand that

$$\Phi(1, 0) = (A, B) = (3, 9) \quad \Rightarrow \quad A = 3, \quad B = 9$$
$$\Phi(0, 1) = (C, D) = (-4, 6) \quad \Rightarrow \quad C = -4, \quad D = 6$$

Therefore,

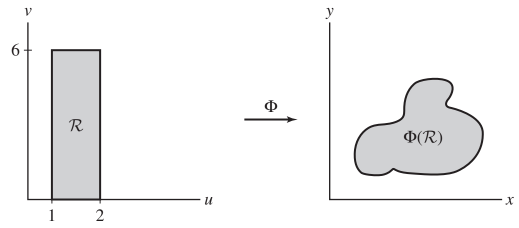
$$\Phi_0(u, v) = (3u - 4v, 9u + 6v)$$

Since $\mathcal{P}$ is obtained by translating $\mathcal{P}_0$ four units to the right and two units upward, the translate of Φ_0 that maps $\mathcal{R}_0$ to $\mathcal{P}$ is

$$\Phi(u, v) = (4 + 3u - 4v, 2 + 9u + 6v)$$

29. Let $\mathcal{D} = \Phi(\mathcal{R})$, where $\Phi(u, v) = (u^2, u + v)$ and $\mathcal{R} = [1, 2] \times [0, 6]$. Calculate $\iint_{\mathcal{D}} y\,dx\,dy$. *Note:* It is not necessary to describe $\mathcal{D}$.

SOLUTION



Changing variables, we have

$$\iint_{\mathcal{D}} y\,dA = \iint_{\mathcal{R}} (u + v) \left| \frac{\partial(x, y)}{\partial(u, v)} \right| du\,dv \tag{1}$$

We compute the Jacobian of Φ. Since $x = u^2$ and $y = u + v$, we have

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 2u & 0 \\ 1 & 1 \end{vmatrix} = 2u$$

We substitute in (1) and compute the resulting integral:

$$\iint_{\mathcal{D}} y\,dA = \int_0^6 \int_1^2 (u + v) \cdot 2u\,du\,dv = \int_0^6 \int_1^2 (2u^2 + 2uv)\,du\,dv = \int_0^6 \frac{2u^3}{3} + u^2 v \Big|_{u=1}^{2} dv$$
$$= \int_0^6 \left(\left(\frac{16}{3} + 4v \right) - \left(\frac{2}{3} + v \right) \right) dv = \int_0^6 \left(3v + \frac{14}{3} \right) dv = \frac{3}{2} v^2 + \frac{14}{3} v \Big|_0^6 = 82$$

30. Let $\mathcal{D}$ be the image of $\mathcal{R} = [1, 4] \times [1, 4]$ under the map $\Phi(u, v) = (u^2/v, v^2/u)$.

(a) Compute $\mathrm{Jac}(\Phi)$.

(b) Sketch $\mathcal{D}$.

(c) Use the Change of Variables Formula to compute $\mathrm{Area}(\mathcal{D})$ and $\iint_{\mathcal{D}} f(x, y)\,dx\,dy$, where $f(x, y) = x + y$.

SOLUTION

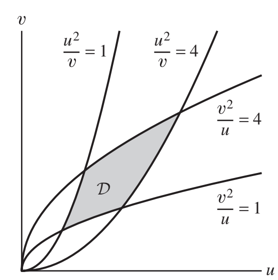
(a) Since $x = \frac{u^2}{v}$ and $y = \frac{v^2}{u}$, the Jacobian of Φ is the following determinant:

$$\mathrm{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{2u}{v} & -\frac{u^2}{v^2} \\ -\frac{v^2}{u^2} & \frac{2v}{u} \end{vmatrix} = \frac{2u}{v} \cdot \frac{2v}{u} - \frac{u^2}{v^2} \cdot \frac{v^2}{u^2} = 3$$

(b) In the rectangle $\mathcal{R}$, we have $1 \le x \le 4$ and $1 \le y \le 4$. Therefore, the image $\mathcal{D}$ is defined by the following inequalities:

$$\mathcal{D}: 1 \le \frac{u^2}{v} \le 4 \quad \text{and} \quad 1 \le \frac{v^2}{u} \le 4$$

The domain $\mathcal{D}$ is shown in the figure:



(c) Since $x = \frac{u^2}{v}$ and $y = \frac{v^2}{u}$, the function in the new variables is

$$f(x,y) = \left(\frac{u^2}{v}\right)^2 + \left(\frac{v^2}{u}\right)^2 = \frac{u^4}{v^2} + \frac{v^4}{u^2}$$

Using change of variables, we get

$$\iint_{\mathcal{D}} f(x,y)\,dA = \iint_{\mathcal{R}} \left(\frac{u^4}{v^2} + \frac{v^4}{u^2}\right)\left|\frac{\partial(x,y)}{\partial(u,v)}\right| du\,dv = \int_1^4\int_1^4 \left(\frac{u^4}{v^2} + \frac{v^4}{u^2}\right)\cdot 3\,du\,dv = 3\int_1^4 \left(\frac{u^5}{5v^2} - \frac{v^4}{u}\right)\Bigg|_{u=1}^4 dv$$

$$= 3\int_1^4 \left(\left(\frac{1024}{5v^2} - \frac{v^4}{4}\right) - \left(\frac{1}{5v^2} - v^4\right)\right) dv = 3\int_1^4 \left(\frac{1023}{5v^2} + \frac{3v^4}{4}\right) dv$$

$$= \frac{3069}{5}\left(-\frac{1}{v}\right) + \frac{9v^5}{20}\Bigg|_1^4 = \left(-\frac{3069}{20} + \frac{2304}{5}\right) - \left(-\frac{3069}{5} + \frac{9}{20}\right) = 920.7$$

31. Compute $\iint_{\mathcal{D}} (x+3y)\,dx\,dy$, where $\mathcal{D}$ is the shaded region in Figure 16. *Hint:* Use the map $\Phi(u,v) = (u-2v, v)$.

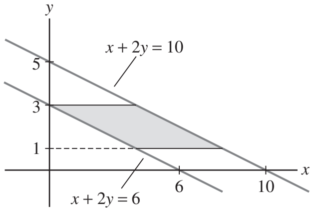


FIGURE 16

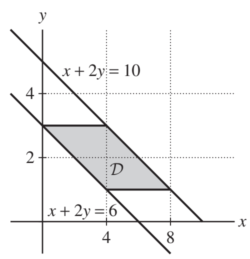
SOLUTION The boundary of $\mathcal{D}$ is defined by the lines $x+2y=6$, $x+2y=10$, $y=1$, and $y=3$.



Therefore, $\mathcal{D}$ is mapped to a rectangle $\mathcal{D}_0$ in the uv-plane under the map

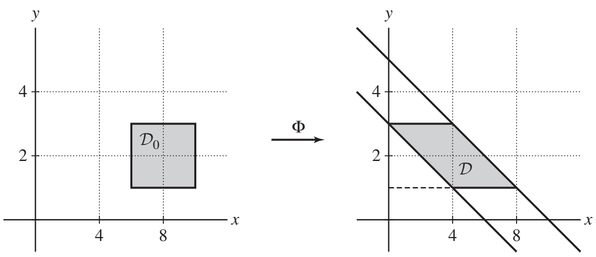
$$u = x + 2y, \quad v = y \tag{1}$$

or

$$(u,v) = \Phi^{-1}(x,y) = (x+2y, y)$$

Since $\mathcal{D}$ is defined by the inequalities $6 \le x+2y \le 10$ and $1 \le y \le 3$, the corresponding domain in the uv-plane is the rectangle

$$\mathcal{D}_0:\ 6 \le u \le 10,\ 1 \le v \le 3$$



To find $\Phi(u, v)$ we must solve the equations (1) for x and y in terms of u and v. We obtain

$$\begin{array}{l} u = x + 2y \\ v = y \end{array} \quad \Rightarrow \quad \begin{array}{l} x = u - 2v \\ y = v \end{array} \quad \Rightarrow \quad \Phi(u, v) = (u - 2v, v)$$

We compute the Jacobian of the linear mapping Φ:

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} 1 & -2 \\ 0 & 1 \end{vmatrix} = 1 \cdot 1 + 2 \cdot 0 = 1$$

The function $f(x, y) = x + 3y$ expressed in terms of the new variables u and v is

$$f(x, y) = u - 2v + 3v = u + v$$

We now use the Change of Variables Formula to compute the required integral. We get

$$\begin{aligned} \iint_{\mathcal{D}} f(x, y)\, dx\, dy &= \iint_{\mathcal{D}_0} (u + v) \left| \frac{\partial(x, y)}{\partial(u, v)} \right| du\, dv = \int_1^3 \int_6^{10} (u + v) \cdot 1\, du\, dv \\ &= \int_1^3 \frac{u^2}{2} + vu \Big|_{u=6}^{10} dv = \int_1^3 ((50 + 10v) - (18 + 6v))\ dv \\ &= \int_1^3 (32 + 4v)\, dv = 32v + 2v^2 \Big|_1^3 = (96 + 18) - (32 + 2) = 80 \end{aligned}$$

32. Use the map $\Phi(u, v) = \left(\frac{u}{v + 1}, \frac{uv}{v + 1} \right)$ to compute

$$\iint_{\mathcal{D}} (x + y)\, dx\, dy$$

where $\mathcal{D}$ is the shaded region in Figure 17.

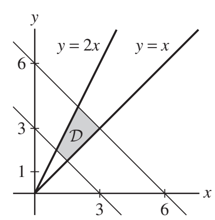


FIGURE 17

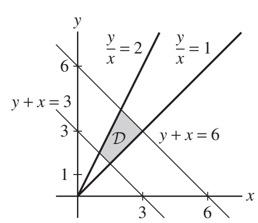
SOLUTION



We first identify the region $\mathcal{D}_0$ in the uv-plane, mapped to $\mathcal{D}$ under Φ. The equations of the lines defining the boundary of $\mathcal{D}$ can be rewritten as

$$\frac{y}{x} = 2, \quad \frac{y}{x} = 1, \quad y + x = 3, \quad y + x = 6.$$

Therefore, $\mathcal{D}$ is defined by the inequalities

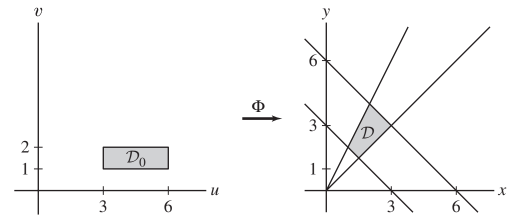
$$1 \le \frac{y}{x} \le 2, \quad 3 \le y + x \le 6$$

Since $x = \frac{u}{v+1}$ and $y = \frac{uv}{v+1}$, we have

$$\frac{y}{x} = \frac{\frac{uv}{v+1}}{\frac{u}{v+1}} = v \quad \text{and} \quad y + x = \frac{uv}{v + 1} + \frac{u}{v + 1} = \frac{u(v + 1)}{v + 1} = u$$

Therefore, the corresponding domain $\mathcal{D}_0$ in the uv-plane is the rectangle

$$\mathcal{D}_0 : 1 \le v \le 2,\ 3 \le u \le 6$$



We express the function $f(x, y) = x + y$ in terms of u and v:

$$f(x, y) = \frac{uv}{v+1} + \frac{u}{v+1} = \frac{uv+u}{v+1} = \frac{u(v+1)}{v+1} = u$$

We compute the Jacobian of Φ. Since $x = \frac{u}{v+1}$ and $y = \frac{uv}{v+1}$, we have

$$\frac{\partial x}{\partial u} = \frac{1}{v+1}, \quad \frac{\partial x}{\partial v} = -\frac{u}{(v+1)^2}, \quad \frac{\partial y}{\partial u} = \frac{v}{v+1},$$
$$\frac{\partial y}{\partial v} = \frac{u(v+1) - uv \cdot 1}{(v+1)^2} = \frac{u}{(v+1)^2}$$

Therefore,

$$\text{Jac}(\Phi) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{1}{v+1} & -\frac{u}{(v+1)^2} \\ \frac{v}{v+1} & \frac{u}{(v+1)^2} \end{vmatrix} = \frac{1}{v+1} \cdot \frac{u}{(v+1)^2} + \frac{u}{(v+1)^2} \cdot \frac{v}{v+1}$$
$$= \frac{u+uv}{(v+1)^3} = \frac{u(1+v)}{(v+1)^3} = \frac{u}{(1+v)^2}$$

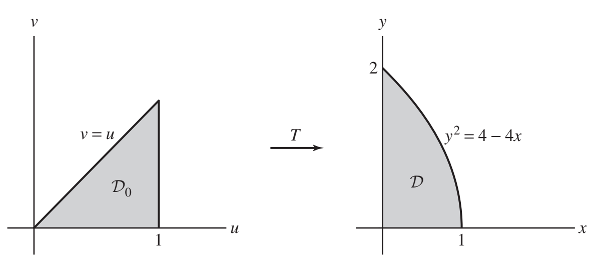
Now we can apply the Change of Variables Formula to compute the integral:

$$\iint_{\mathcal{D}} (x+y)\, dx\, dy = \iint_{\mathcal{D}_0} u \cdot \frac{u}{(1+v)^2}\, du\, dv = \int_1^2 \int_3^6 u^2 \cdot \frac{1}{(1+v)^2}\, du\, dv$$
$$= \left(\int_1^2 \frac{1}{(1+v)^2}\, dv \right) \left(\int_3^6 u^2\, du \right) = \left(-\frac{1}{1+v}\Big|_1^2 \right) \left(\frac{u^3}{3}\Big|_3^6 \right)$$
$$= \left(-\frac{1}{3} + \frac{1}{2} \right) \left(\frac{216}{3} - \frac{27}{3} \right) = \frac{63}{6} = 10.5$$

33. Show that $T(u, v) = (u^2 - v^2, 2uv)$ maps the triangle $\mathcal{D}_0 = \{(u, v) : 0 \le v \le u \le 1\}$ to the domain $\mathcal{D}$ bounded by $x = 0$, $y = 0$, and $y^2 = 4 - 4x$. Use T to evaluate

$$\iint_{\mathcal{D}} \sqrt{x^2 + y^2}\, dx\, dy$$

SOLUTION We show that the boundary of $\mathcal{D}_0$ is mapped to the boundary of $\mathcal{D}$.



We have

$$x = u^2 - v^2 \quad \text{and} \quad y = 2uv$$

The line $v = u$ is mapped to the following set:

$$(x, y) = (u^2 - u^2, 2u^2) = (0, 2u^2) \quad \Rightarrow \quad x = 0, \quad y \ge 0$$

That is, the image of the line $u = v$ is the positive y-axis. The line $v = 0$ is mapped to the following set:

$$(x, y) = (u^2, 0) \quad \Rightarrow \quad x = u^2, \quad y = 0 \quad \Rightarrow \quad y = 0, \quad x \geq 0$$

Thus, the line $v = 0$ is mapped to the positive x-axis. We now show that the vertical line $u = 1$ is mapped to the curve $y^2 + 4x = 4$. The image of the line $u = 1$ is the following set:

$$(x, y) = (1 - v^2, 2v) \quad \Rightarrow \quad x = 1 - v^2, \quad y = 2v$$

We substitute $v = \frac{y}{2}$ in the equation $x = 1 - v^2$ to obtain

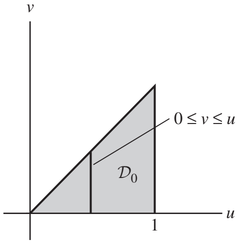
$$x = 1 - \left(\frac{y}{2}\right)^2 = 1 - \frac{y^2}{4} \quad \Rightarrow \quad 4x = 4 - y^2 \quad \Rightarrow \quad y^2 + 4x = 4$$

Since the boundary of $\mathcal{D}_0$ is mapped to the boundary of $\mathcal{D}$, we conclude that the domain $\mathcal{D}_0$ is mapped by T to the domain $\mathcal{D}$ in the xy-plane. We now compute the integral $\iint_{\mathcal{D}} \sqrt{x^2 + y^2}\, dx\, dy$. We express the function $f(x, y) = \sqrt{x^2 + y^2}$ in terms of the new variables u and v:

$$\begin{aligned} f(x, y) &= \sqrt{(u^2 - v^2)^2 + (2uv)^2} = \sqrt{u^4 - 2u^2v^2 + v^4 + 4u^2v^2} \\ &= \sqrt{u^4 + 2u^2v^2 + v^4} = \sqrt{(u^2 + v^2)^2} = u^2 + v^2 \end{aligned}$$

We compute the Jacobian of T:

$$\operatorname{Jac}(T) = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 2u & -2v \\ 2v & 2u \end{vmatrix} = 4u^2 + 4v^2 = 4(u^2 + v^2)$$



Using the Change of Variables Formula gives

$$\begin{aligned} \iint_{\mathcal{D}} \sqrt{x^2 + y^2}\, dx\, dy &= \iint_{\mathcal{D}_0} (u^2 + v^2) \cdot 4(u^2 + v^2)\, du\, dv = 4 \int_0^1 \int_0^u (u^4 + 2u^2v^2 + v^4)\, dv\, du \\ &= 4 \int_0^1 u^4 v + \frac{2}{3}u^2v^3 + \frac{v^5}{5} \bigg|_{v=0}^{u} du = 4 \int_0^1 \left(u^5 + \frac{2}{3}u^5 + \frac{u^5}{5}\right) du \\ &= 4 \int_0^1 \frac{28}{15} u^5\, du = \frac{112}{15} \cdot \frac{u^6}{6} \bigg|_0^1 = \frac{56}{45} \end{aligned}$$

34. Find a mapping Φ that maps the disk $u^2 + v^2 \leq 1$ onto the interior of the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 \leq 1$. Then use the Change of Variables Formula to prove that the area of the ellipse is πab.

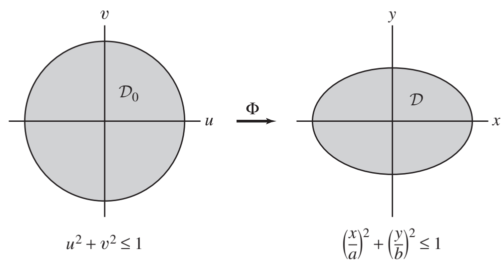
SOLUTION We define the following mapping:

$$x = au, \quad y = bv$$

or

$$(x, y) = \Phi(u, v) = (au, bv)$$

Then, $u^2 + v^2 \leq 1$ if and only if $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 \leq 1$. Hence Φ maps the disk $u^2 + v^2 \leq 1$ onto the interior of the ellipse $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 \leq 1$.



We find the Jacobian of Φ:

$$\text{Jac}(\Phi) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} a & 0 \\ 0 & b \end{vmatrix} = ab$$

We compute the area of $\mathcal{D}$ using the Change of Variables Formula (notice the area of the disk $\mathcal{D}_0$ is π):

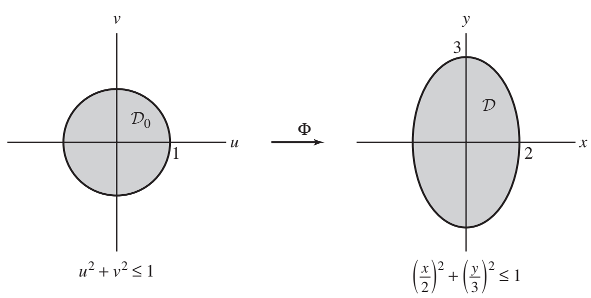
$$\text{Area}(\mathcal{D}) = \iint_{\mathcal{D}} 1\,dx\,dy = \iint_{\mathcal{D}_0} 1 \cdot \left|\frac{\partial(x,y)}{\partial(u,v)}\right| du\,dv = \iint_{\mathcal{D}_0} ab\,du\,dv$$
$$= ab\iint_{\mathcal{D}_0} 1\,du\,dv = ab\text{Area}\,(\mathcal{D}_0) = ab\pi$$

35. Calculate $\iint_{\mathcal{D}} e^{9x^2+4y^2}\,dx\,dy$, where $\mathcal{D}$ is the interior of the ellipse $\left(\frac{x}{2}\right)^2 + \left(\frac{y}{3}\right)^2 \le 1$.

SOLUTION We define a map that maps the unit disk $u^2+v^2 \le 1$ onto the interior of the ellipse. That is,

$$x = 2u, \quad y = 3v \quad \Rightarrow \quad \Phi(u,v) = (2u, 3v)$$

Since $\left(\frac{x}{2}\right)^2 + \left(\frac{y}{3}\right)^2 \le 1$ if and only if $u^2+v^2 \le 1$, Φ is the map we need.



We express the function $f(x,y) = e^{9x^2+4y^2}$ in terms of u and v:

$$f(x,y) = e^{9(2u)^2+4(3v)^2} = e^{36u^2+36v^2} = e^{36(u^2+v^2)}$$

We compute the Jacobian of Φ:

$$\text{Jac}(\Phi) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 2 & 0 \\ 0 & 3 \end{vmatrix} = 6$$

Using the Change of Variables Formula gives

$$\iint_{\mathcal{D}} e^{9x^2+4y^2}\,dA = \iint_{\mathcal{D}_0} e^{36(u^2+v^2)} \cdot 6\,du\,dv$$

We compute the integral using polar coordinates $u = r\cos\theta$, $v = r\sin\theta$:

$$\iint_{\mathcal{D}} e^{9x^2+4y^2}\,dA = \int_0^{2\pi}\int_0^1 6e^{36r^2}\cdot r\,dr\,d\theta = \left(6\int_0^{2\pi} d\theta\right)\left(\int_0^1 e^{36r^2} r\,dr\right)$$
$$= 12\pi \left.\frac{e^{36r^2}}{72}\right|_{r=0}^{1} = \frac{12\pi(e^{36}-1)}{72} = \frac{\pi(e^{36}-1)}{6}$$

36. Compute the area of the region enclosed by the ellipse $x^2 + 2xy + 2y^2 - 4y = 8$ as an integral in the variables $u = x + y$, $v = y - 2$.

SOLUTION We complete the square to rewrite the equation of the boundary of the region as follows:

$$x^2 + 2xy + 2y^2 - 4y = (x^2 + 2xy + y^2) + y^2 - 4y = (x + y)^2 + (y - 2)^2 - 4 = 8$$
$$\Rightarrow \quad (x + y)^2 + (y - 2)^2 = 12$$

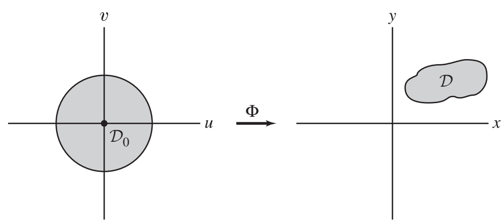
We use the following mapping:

$$u = x + y, \quad v = y - 2 \quad \Rightarrow \quad x = u - v - 2, \quad y = v + 2$$

or

$$\Phi(u, v) = (u - v - 2, v + 2)$$

Then $(x + y)^2 + (y - 2)^2 \le 12$ if and only if $u^2 + v^2 \le 12$, hence Φ maps the disc of radius $\sqrt{12}$ centered at $(0, 0)$ in the uv-plane to the given region $\mathcal{D}$.



The Jacobian of Φ is

$$\text{Jac}(\Phi) = \begin{vmatrix} 1 & -1 \\ 0 & 1 \end{vmatrix} = 1$$

Using the Change of Variables Formula and the area of the disk, Area $(\mathcal{D}_0) = 12\pi$, we get

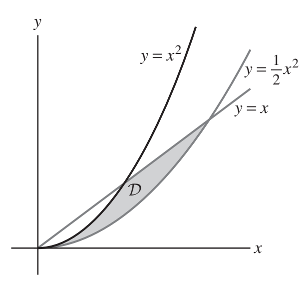
$$\text{Area}(\mathcal{D}) = \iint_{\mathcal{D}} 1\, dx\, dy = \iint_{\mathcal{D}_0} 1 \cdot |\text{Jac}\Phi|\, du\, dv = \iint_{\mathcal{D}_0} du\, dv = \text{Area}\,(\mathcal{D}_0) = 12\pi$$

37. Sketch the domain $\mathcal{D}$ bounded by $y = x^2$, $y = \frac{1}{2}x^2$, and $y = x$. Use a change of variables with the map $x = uv$, $y = u^2$ to calculate

$$\iint_{\mathcal{D}} y^{-1}\, dx\, dy$$

This is an improper integral since $f(x, y) = y^{-1}$ is undefined at $(0, 0)$, but it becomes proper after changing variables.

SOLUTION The domain $\mathcal{D}$ is shown in the figure.



We must identify the domain $\mathcal{D}_0$ in the uv-plane. Notice that Φ is one-to-one, where $u \ge 0$ (or $u \le 0$), since in $\mathcal{D}$, $x \ge 0$, so it also follows by $x = uv$ that $v \ge 0$. Therefore, we search the domain $\mathcal{D}_0$ in the first quadrant of the uv-plane. To do this, we examine the curves that are mapped to the curves defining the boundary of $\mathcal{D}$. We examine each curve separately.

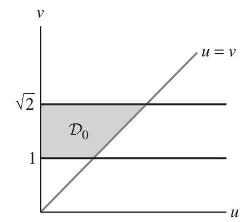
$y = x^2$: Since $x = uv$ and $y = u^2$ we get

$$u^2 = (uv)^2 \quad \Rightarrow \quad 1 = v^2 \quad \Rightarrow \quad v = 1$$

$y = \frac{1}{2}x^2$:

$$u^2 = \frac{1}{2}(uv)^2 \quad \Rightarrow \quad 1 = \frac{1}{2}v^2 \quad \Rightarrow \quad v^2 = 2 \quad \Rightarrow \quad v = \sqrt{2}$$

$y = x$: $u^2 = uv \quad \Rightarrow \quad v = u$. The region $\mathcal{D}_0$ is the region in the first quadrant of the uv-plane enclosed by the curves $v = 1$, $v = \sqrt{2}$, and $v = u$.



We now use change of variables to compute the integral $\iint_{\mathcal{D}} y^{-1}\,dx\,dy$. The function in terms of the new variables is $f(x, y) = u^{-2}$. We compute the Jacobian of $\Phi(u, v) = (x, y) = (uv, u^2)$:

$$\operatorname{Jac}(\Phi) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} v & u \\ 2u & 0 \end{vmatrix} = -2u^2$$

Using the Change of Variables Formula gives

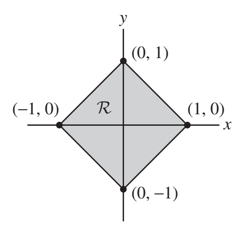
$$\iint_{\mathcal{D}} y^{-1}\,dx\,dy = \iint_{\mathcal{D}_0} u^{-2} \cdot 2u^2\,du\,dv = \int_1^{\sqrt{2}} \int_0^v 2\,du\,dv = \int_1^{\sqrt{2}} 2u\Big|_{u=0}^{v}\,dv = \int_1^{\sqrt{2}} 2v\,dv = v^2\Big|_1^{\sqrt{2}} = 2 - 1 = 1$$

38. Find an appropriate change of variables to evaluate

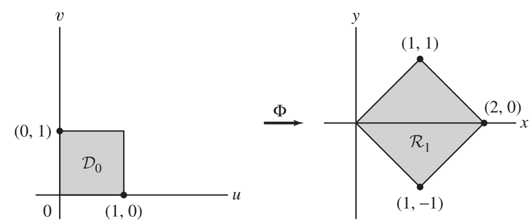
$$\iint_{\mathcal{R}} (x + y)^2 e^{x^2 - y^2}\,dx\,dy$$

where $\mathcal{R}$ is the square with vertices $(1, 0)$, $(0, 1)$, $(-1, 0)$, $(0, -1)$.

SOLUTION



We first find a linear map $\Phi(u, v)$ that maps the unit square $\mathcal{D}_0$ in the uv-plane to the square $\mathcal{R}_1$ in the xy-plane, obtained by translating $\mathcal{R}$ one unit to the right.



Let us use $u = x + y$ and $v = x - y$ then

$$x = \frac{u + v}{2}, \quad y = \frac{u - v}{2}$$

Therefore, $\Phi(u, v) = (x + y, x - y) = \left(\frac{u + v}{2}, \frac{u - v}{2}\right)$. This transformation maps the square $\mathcal{R}_1$ to the square defined by $u = \pm 1$ and $v = \pm 1$.

We use the change of variables $x = \frac{u + v}{2}$, $y = \frac{u - v}{2}$ to compute the integral $\iint_{\mathcal{R}} (x + y)^2 e^{x^2 - y^2}\,dx\,dy$. The function expressed in the new variables u and v is

$$f(u, v) = \left(\frac{u + v}{2} + \frac{u - v}{2}\right)^2 e^{1/4((u+v)^2 - (u-v)^2)} = u^2 e^{uv}$$

We compute the Jacobian of Φ:

$$\mathrm{Jac}(\Phi) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 1/2 & 1/2 \\ 1/2 & -1/2 \end{vmatrix} = -\frac{1}{2}$$

Using the Change of Variables Formula gives

$$\begin{aligned} I &= \iint_{\mathcal{R}} (x+y)^2 e^{x^2-y^2}\,dx\,dy = \iint_{\mathcal{D}_0} u^2 e^{uv}\cdot\frac{1}{2}\,dv\,du \\ &= \frac{1}{2}\int_{-1}^{1}\int_{-1}^{1} u^2 e^{uv}\,dv\,du = \frac{1}{2}\int_{-1}^{1} u^2\cdot\frac{1}{u}e^{uv}\bigg|_{v=-1}^{1}\,du \\ &= \frac{1}{2}\int_{-1}^{1} ue^u - ue^{-u}\,du = \frac{1}{2}\int_{-1}^{1} ue^u\,du - \frac{1}{2}\int_{-1}^{1} ue^{-u}\,du \\ &= \frac{1}{2}\left(ue^u - e^u\bigg|_{-1}^{1}\right) - \frac{1}{2}\left(-ue^{-u} - e^{-u}\bigg|_{-1}^{1}\right) \\ &= \frac{1}{2}(e-e) - \frac{1}{2}(-e^{-1}-e^{-1}) - \left[\frac{1}{2}(-e^{-1}-e^{-1}) - \frac{1}{2}(e-e)\right] \\ &= \frac{1}{e} + \frac{1}{e} = \frac{2}{e} \end{aligned}$$

39. Let Φ be the inverse of the map $F(x, y) = (xy, x^2 y)$ from the xy-plane to the uv-plane. Let $\mathcal{D}$ be the domain in Figure 18. Show, by applying the Change of Variables Formula to the inverse $\Phi = F^{-1}$, that

$$\iint_{\mathcal{D}} e^{xy}\,dx\,dy = \int_{10}^{20}\int_{20}^{40} e^u v^{-1}\,dv\,du$$

and evaluate this result. *Hint:* See Example 8.

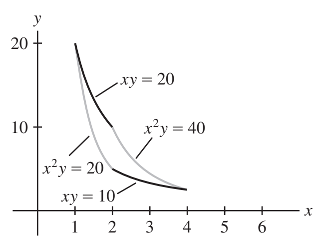


FIGURE 18

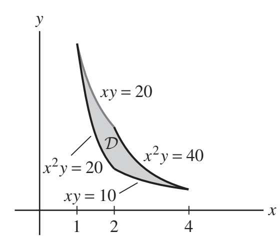
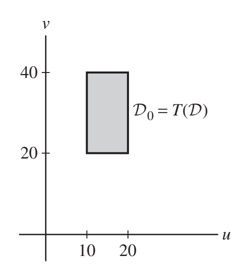
SOLUTION The domain $\mathcal{D}$ is defined by the inequalities

$$\mathcal{D}:\ 10 \le xy \le 20,\ 20 \le x^2 y \le 40$$



Since $u = xy$ and $v = x^2 y$, the image $\mathcal{D}_0$ of $\mathcal{D}$ (in the uv-plane) under F is the rectangle

$$\mathcal{D}_0:\ 10 \le u \le 20,\ 20 \le v \le 40$$



The function expressed in the new variables is

$$f(x, y) = e^{xy} = e^u$$

To find the Jacobian of the inverse Φ of F, we use the formula for the Jacobian of the inverse mapping. That is,

$$\frac{\partial(x, y)}{\partial(u, v)} = \left(\frac{\partial(u, v)}{\partial(x, y)}\right)^{-1}$$

We find the Jacobian of F. Since $u = xy$ and $v = x^2 y$, we have

$$\text{Jac}(F) = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix} = \begin{vmatrix} y & x \\ 2xy & x^2 \end{vmatrix} = yx^2 - 2x^2 y = -x^2 y$$

Hence,

$$\text{Jac}(\Phi) = -\frac{1}{x^2 y}$$

We now compute the double integral $\iint_{\mathcal{D}} e^{xy}\, dA$ using the Change of Variables Formula. Since $y > 0$ in $\mathcal{D}$, we have $|\text{Jac}(\Phi)| = |-\frac{1}{x^2 y}| = \frac{1}{x^2 y} = v^{-1}$. Therefore,

$$\iint_{\mathcal{D}} e^{xy}\, dA = \iint_{\mathcal{D}_0} e^u v^{-1}\, dv\, du = \int_{10}^{20} \int_{20}^{40} e^u v^{-1}\, dv\, du = \left(\int_{10}^{20} e^u\, du\right)\left(\int_{20}^{40} v^{-1}\, dv\right)$$

$$= e^u \Big|_{10}^{20} \cdot \ln v \Big|_{20}^{40} = (e^{20} - e^{10})(\ln(40) - \ln(20)) = (e^{20} - e^{10}) \ln 2$$

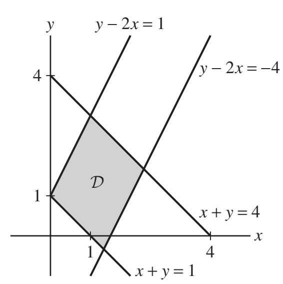
40. Sketch the domain

$$\mathcal{D} = \{(x, y) : 1 \le x + y \le 4,\ -4 \le y - 2x \le 1\}$$

(a) Let F be the map $u = x + y$, $v = y - 2x$ from the xy-plane to the uv-plane, and let Φ be its inverse. Use Eq. (14) to compute $\text{Jac}(\Phi)$.

(b) Compute $\iint_{\mathcal{D}} e^{x+y}\, dx\, dy$ using the Change of Variables Formula with the map Φ. *Hint:* It is not necessary to solve for Φ explicitly.

SOLUTION The domain $\mathcal{D} = \{(x, y) : 1 \le x + y \le 4, -4 \le y - 2x \le 1\}$ is shown in the figure.



(a) By Eq. (**??**), the Jacobian of the inverse map Φ is the reciprocal of the Jacobian of F. We compute the Jacobian of the linear mapping F:

$$\text{Jac}(F) = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ -2 & 1 \end{vmatrix} = 1 + 2 = 3$$

Therefore,

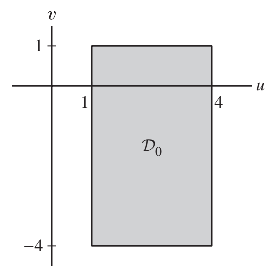
$$\text{Jac}(\Phi) = (\text{Jac}(F))^{-1} = \frac{1}{3}$$

(b) We first must identify the region of integration $\mathcal{D}_0$ in the uv-plane. The region $\mathcal{D}$ is defined by the inequalities

$$\mathcal{D}: \ 1 \le x + y \le 4, \ -4 \le y - 2x \le 1$$

Since $u = x + y$ and $v = y - 2x$, the image of $\mathcal{D}$ under F is the following rectangle:

$$\mathcal{D}_0: \ 1 \le u \le 4, \ -4 \le v \le 1$$



The function expressed in the new variables is $f(x, y) = e^{x+y} = e^u$. We now compute the integral $\iint_{\mathcal{D}} e^{x+y}\, dA$ using change of variables with the map Φ. We obtain

$$\iint_{\mathcal{D}} e^{x+y}\, dA = \iint_{\mathcal{D}_0} e^u |\mathrm{Jac}(\Phi)|\, du\, dv = \int_{-4}^{1}\int_{1}^{4} e^u \cdot \frac{1}{3}\, du\, dv = \left(\int_{-4}^{1} \frac{1}{3}\, dv\right)\left(\int_{1}^{4} e^u\, du\right)$$
$$= \left(\frac{1}{3}v\Big|_{-4}^{1}\right)\left(e^u\Big|_{1}^{4}\right) = \frac{5}{3}(e^4 - e)$$

41. Let $I = \iint_{\mathcal{D}} (x^2 - y^2)\, dx\, dy$, where

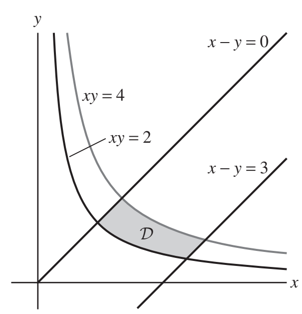
$$\mathcal{D} = \{(x, y) : 2 \le xy \le 4, 0 \le x - y \le 3, x \ge 0, y \ge 0\}$$

(a) Show that the mapping $u = xy$, $v = x - y$ maps $\mathcal{D}$ to the rectangle $\mathcal{R} = [2, 4] \times [0, 3]$.
(b) Compute $\partial(x, y)/\partial(u, v)$ by first computing $\partial(u, v)/\partial(x, y)$.
(c) Use the Change of Variables Formula to show that I is equal to the integral of $f(u, v) = v$ over $\mathcal{R}$ and evaluate.

SOLUTION

(a) The domain $\mathcal{D}$ is defined by the inequalities

$$\mathcal{D}: \ 2 \le xy \le 4, \ 0 \le x - y \le 3, \ x \ge 0, \ y \ge 0$$



Since $u = xy$ and $v = x - y$, the image of $\mathcal{D}$ under this mapping is the rectangle defined by

$$\mathcal{D}_0: \ 2 \le u \le 4, \ 0 \le v \le 3$$

That is, $\mathcal{D}_0 = [2, 4] \times [0, 3]$.

(b) We compute the Jacobian $\frac{\partial(u,v)}{\partial(x,y)}$ and then use the formula for the Jacobian of the inverse mapping to compute $\frac{\partial(x,y)}{\partial(u,v)}$. Since $u = xy$ and $v = x - y$, we have

$$\frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix} = \begin{vmatrix} y & x \\ 1 & -1 \end{vmatrix} = -y - x = -(x + y)$$

Therefore,

$$\frac{\partial(x,y)}{\partial(u,v)} = \left(\frac{\partial(u,v)}{\partial(x,y)}\right)^{-1} = -\frac{1}{x+y}$$

(c) In $\mathcal{D}$, $x \ge 0$ and $y \ge 0$, hence $\left|\frac{\partial(x,y)}{\partial(u,v)}\right| = \frac{1}{x+y}$. Using the change of variable formula gives:

$$I = \iint_{\mathcal{D}_0} (x^2 - y^2) \cdot \frac{1}{x+y}\, du\, dv = \iint_{\mathcal{D}_0} (x-y)\, du\, dv = \int_0^3 \int_2^4 v\, du\, dv$$
$$= \left(\int_0^3 v\, dv\right)\left(\int_2^4 du\right) = \left(\frac{v^2}{2}\Big|_0^3\right)\left(u\Big|_2^4\right) = \frac{9}{2} \cdot 2 = 9$$

42. Derive formula (5) in Section 15.4 for integration in cylindrical coordinates from the general Change of Variables Formula.

SOLUTION The cylindrical coordinates are

$$x = r\cos\theta, \quad y = r\sin\theta, \quad z = z$$

Suppose that a region $\mathcal{W}$ in the (x, y, z)-space is the image of a region $\mathcal{W}_0$ in the (θ, r, z)-space defined by

$$\mathcal{W}_0 : \theta_1 \le \theta \le \theta_2,\ \alpha(\theta) \le r \le \beta(\theta),\ z_1(r,\theta) \le z \le z_2(r,\theta)$$

Then by the change of variables formula, we have

$$\iiint_{\mathcal{W}} f(x,y,z)\, dV = \iiint_{\mathcal{W}_0} f(r\cos\theta, r\sin\theta, z) \left|\frac{\partial(x,y,z)}{\partial(r,\theta,z)}\right| dz\, dr\, d\theta$$

We compute the Jacobian:

$$\frac{\partial(x,y,z)}{\partial(r,\theta,z)} = \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} & \frac{\partial x}{\partial z} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} & \frac{\partial y}{\partial z} \\ \frac{\partial z}{\partial r} & \frac{\partial z}{\partial \theta} & \frac{\partial z}{\partial z} \end{vmatrix} = \begin{vmatrix} \cos\theta & -r\sin\theta & 0 \\ \sin\theta & r\cos\theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = \cos\theta \begin{vmatrix} r\cos\theta & 0 \\ 0 & 1 \end{vmatrix} + r\sin\theta \begin{vmatrix} \sin\theta & 0 \\ 0 & 1 \end{vmatrix} + 0$$
$$= \cos\theta(r\cos\theta - 0) + r\sin\theta(\sin\theta - 0) = r\cos^2\theta + r\sin^2\theta = r$$

Thus,

$$\iiint_{\mathcal{W}} f(x,y,z)\, dv = \int_{\theta_1}^{\theta_2} \int_{\alpha(\theta)}^{\beta(\theta)} \int_{z_1(r,\theta)}^{z_2(r,\theta)} f(r\cos\theta, r\sin\theta, z) \cdot r\, dz\, dr\, d\theta$$

43. Derive formula (9) in Section 15.4 for integration in spherical coordinates from the general Change of Variables Formula.

SOLUTION The spherical coordinates are

$$x = \rho\cos\theta\sin\phi, \quad y = \rho\sin\theta\sin\phi, \quad z = \rho\cos\phi$$

Suppose that a region $\mathcal{W}$ in the (x, y, z)-plane is the image of a region $\mathcal{W}_0$ in the (θ, ϕ, ρ)-space defined by:

$$\mathcal{W}_0 : \theta_1 \le \theta \le \theta_2,\ \phi_1 \le \phi \le \phi_2, \quad \rho_1(\theta,\phi) \le \rho \le \rho_2(\theta,\phi) \tag{1}$$

Then, by the Change of Variables Formula, we have

$$\iiint_{\mathcal{W}} f(x,y,z) = \iiint_{\mathcal{W}_0} f(\rho\cos\theta\sin\phi, \rho\sin\theta\sin\phi, \rho\cos\phi) = \left|\frac{\partial(x,y,z)}{\partial(\theta,\phi,\rho)}\right| d\rho\, d\phi\, d\theta \tag{2}$$

We compute the Jacobian:

$$\frac{\partial(x,y,z)}{\partial(\theta,\phi,\rho)} = \begin{vmatrix} \frac{\partial x}{\partial\theta} & \frac{\partial x}{\partial\phi} & \frac{\partial x}{\partial\rho} \\ \frac{\partial y}{\partial\theta} & \frac{\partial y}{\partial\phi} & \frac{\partial y}{\partial\rho} \\ \frac{\partial z}{\partial\theta} & \frac{\partial z}{\partial\phi} & \frac{\partial z}{\partial\rho} \end{vmatrix} = \begin{vmatrix} -\rho\sin\theta\sin\phi & \rho\cos\theta\cos\phi & \cos\theta\sin\phi \\ \rho\cos\theta\sin\phi & \rho\sin\theta\cos\phi & \sin\theta\sin\phi \\ 0 & -\rho\sin\phi & \cos\phi \end{vmatrix}$$

$$\begin{aligned}
&= -\rho\sin\theta\sin\phi \begin{vmatrix} \rho\sin\theta\cos\phi & \sin\theta\sin\phi \\ -\rho\sin\phi & \cos\phi \end{vmatrix} - \rho\cos\theta\cos\phi \begin{vmatrix} \rho\cos\theta\sin\phi & \sin\theta\sin\phi \\ 0 & \cos\phi \end{vmatrix} \\
&\quad + \cos\theta\sin\phi \begin{vmatrix} \rho\cos\theta\sin\phi & \rho\sin\theta\cos\phi \\ 0 & -\rho\sin\phi \end{vmatrix} \\
&= -\rho\sin\theta\sin\phi(\rho\sin\theta\cos^2\phi + \rho\sin\theta\sin^2\phi) - \rho\cos\theta\cos\phi(\rho\cos\theta\cos\phi\sin\phi - 0) \\
&\quad + \cos\theta\sin\phi(-\rho^2\cos\theta\sin^2\phi - 0) \\
&= -\rho^2\sin^2\theta\sin\phi(\cos^2\phi + \sin^2\phi) - \rho^2\cos^2\theta\cos^2\phi\sin\phi - \rho^2\cos^2\theta\sin^3\phi \\
&= -\rho^2\sin^2\theta\sin\phi - \rho^2\cos^2\theta\cos^2\phi\sin\phi - \rho^2\cos^2\theta\sin^3\phi \\
&= -\rho^2\sin\phi(\sin^2\theta + \cos^2\theta\cos^2\phi + \cos^2\theta\sin^2\phi) \\
&= -\rho^2\sin\phi\left(\sin^2\theta + \cos^2\theta(\cos^2\phi + \sin^2\phi)\right) \\
&= -\rho^2\sin\phi(\sin^2\theta + \cos^2\theta) = -\rho^2\sin\phi
\end{aligned}$$

Since $0 \le \phi \le \pi$, we have $\sin\phi \ge 0$. Therefore,

$$\left|\frac{\partial(x,y,z)}{\partial(\theta,\phi,\rho)}\right| = \rho^2\sin\phi \tag{3}$$

Combining (1), (2), and (3) gives

$$\iiint_{\mathcal{W}} f(x,y,z)\,dv = \int_{\theta_1}^{\theta_2}\int_{\phi_1}^{\phi_2}\int_{\rho_1(\theta,\phi)}^{\rho_2(\theta,\phi)} f(\rho\cos\theta\sin\phi, \rho\sin\theta\sin\phi, \rho\cos\phi)\rho^2\sin\phi\,d\rho\,d\phi\,d\theta$$

44. Use the Change of Variables Formula in three variables to prove that the volume of the ellipsoid $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 = 1$ is equal to $abc \times$ the volume of the unit sphere.

SOLUTION We define a map $\Phi(u,v,w)$ that maps the interior of the unit ball $\mathcal{W}_0$ in the (u,v,w)-space onto the interior of the ellipsoid $\mathcal{W}$. We define

$$\begin{aligned} x &= au \\ y &= bv \quad \Rightarrow \quad \Phi(u,v,w) = (au, bv, cw) \\ z &= cw \end{aligned}$$

Then, $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 \le 1$ if and only if $u^2 + v^2 + w^2 \le 1$. Therefore, Φ is the map we need. Using the Change of Variables Formula gives

$$\text{Volume}(\mathcal{W}) = \iiint_{\mathcal{W}} 1\,dv = \iiint_{\mathcal{W}_0} 1\left|\frac{\partial(x,y,z)}{\partial(u,v,w)}\right| du\,dv\,dw \tag{1}$$

We compute the Jacobian:

$$\frac{\partial(x,y,z)}{\partial(u,v,w)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{vmatrix} = a\begin{vmatrix} b & 0 \\ 0 & c \end{vmatrix} + 0 + 0 = abc$$

We substitute in (1) and compute the integral:

$$\text{Volume}(\mathcal{W}) = \iiint_{\mathcal{W}_0} abc\,du\,dv\,dw = abc\iiint_{\mathcal{W}_0} du\,dv\,dw = abc \cdot \frac{4}{3}\pi.$$

Further Insights and Challenges

45. Use the map

$$x = \frac{\sin u}{\cos v}, \qquad y = \frac{\sin v}{\cos u}$$

to evaluate the integral

$$\int_0^1 \int_0^1 \frac{dx\,dy}{1 - x^2y^2}$$

This is an improper integral since the integrand is infinite if $x = \pm 1$, $y = \pm 1$, but applying the Change of Variables Formula shows that the result is finite.

SOLUTION We express the function $f(x, y) = \frac{1}{1-x^2y^2}$ in terms of the new variables u and v:

$$1 - x^2y^2 = 1 - \frac{\sin^2 u}{\cos^2 v}\frac{\sin^2 v}{\cos^2 u} = 1 - \left(\frac{\sin u}{\cos u}\right)^2 \cdot \left(\frac{\sin v}{\cos v}\right)^2 = 1 - \tan^2 u \tan^2 v$$

Hence,

$$f(x, y) = \frac{1}{1 - \tan^2 u \tan^2 v}$$

We compute the Jacobian of the mapping:

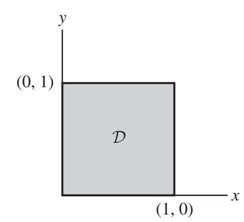
$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{\cos u}{\cos v} & \frac{\sin u \sin v}{\cos^2 v} \\ \frac{\sin v \sin u}{\cos^2 u} & \frac{\cos v}{\cos u} \end{vmatrix} = \frac{\cos u}{\cos v} \cdot \frac{\cos v}{\cos u} - \frac{\sin u \sin v}{\cos^2 v} \cdot \frac{\sin v \sin u}{\cos^2 u}$$

$$= 1 - \frac{\sin^2 u}{\cos^2 u} \cdot \frac{\sin^2 v}{\cos^2 v} = 1 - \tan^2 u \tan^2 v$$

Now, since $0 \le x \le 1$ and $0 \le y \le 1$, we have $0 \le \frac{\sin u}{\cos v} \cdot \frac{\sin v}{\cos u} \le 1$ or $0 \le \tan u \tan v \le 1$. Therefore, $0 \le \tan^2 u \, \tan^2 v \le 1$, hence

$$\left|\frac{\partial(x, y)}{\partial(u, v)}\right| = 1 - \tan^2 u \tan^2 v$$

We now identify a domain $\mathcal{D}_0$ in the uv-plane that is mapped by Φ onto $\mathcal{D}$ and Φ is one-to-one on $\mathcal{D}_0$.



We examine each segment on the boundary of $\mathcal{D}$ separately.

$y = 0$:

$$\frac{\sin v}{\cos u} = 0 \quad \Rightarrow \quad \sin v = 0 \quad \Rightarrow \quad v = \pi k$$

$x = 0$:

$$\frac{\sin u}{\cos v} = 0 \quad \Rightarrow \quad \sin u = 0 \quad \Rightarrow \quad u = \pi k$$

$y = 1$:

$$\frac{\sin v}{\cos u} = 1 \quad \Rightarrow \quad \sin v = \cos u \quad \Rightarrow \quad v + u = \frac{\pi}{2} + 2\pi k \quad \text{or} \quad v - u = \frac{\pi}{2} + 2\pi k \tag{1}$$

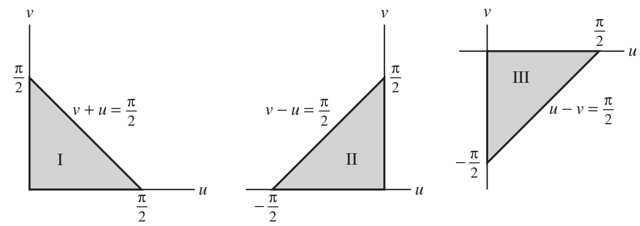
$x = 1$:

$$\frac{\sin u}{\cos v} = 1 \quad \Rightarrow \quad \sin u = \cos v \quad \Rightarrow \quad v + u = \frac{\pi}{2} + 2\pi k \quad \text{or} \quad u - v = \frac{\pi}{2} + 2\pi k \tag{2}$$

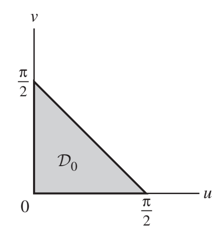
One of the possible regions $\mathcal{D}_0$ is obtained by choosing $k = 0$ in all solutions. We get

$$v = 0, \quad u = 0, \quad \left(v + u = \frac{\pi}{2} \text{ or } v - u = \frac{\pi}{2}\right), \quad \left(u + v = \frac{\pi}{2} \text{ or } u - v = \frac{\pi}{2}\right)$$

The corresponding regions are:



In II, $x = \frac{\sin u}{\cos v} < 0$ and in III $y = \frac{\sin v}{\cos u} < 0$, therefore these regions are not mapped to the unit square in the xy-plane. The appropriate region is I.



We now use the Change of Variables Formula and the result obtained previously to obtain the following integral:

$$\int_0^1 \int_0^1 \frac{dx\,dy}{1 - x^2 y^2} = \iint_{\mathcal{D}_0} \frac{1}{1 - \tan^2 u \tan^2 v} \cdot (1 - \tan^2 u \tan^2 v)\,du\,dv$$
$$= \iint_{\mathcal{D}_0} 1\,du\,dv = \text{Area}(\mathcal{D}_0) = \frac{\frac{\pi}{2} \cdot \frac{\pi}{2}}{2} = \frac{\pi^2}{8}$$

46. Verify properties (1) and (2) for linear functions and show that any map satisfying these two properties is linear.

SOLUTION Let $\Phi(u, v) = (Au + Cv, Bu + Dv)$ be a linear function. We show that property (1) is satisfied:

$$\begin{aligned}\Phi(u + u', v + v') &= \big(A(u + u') + C(v + v'), B(u + u') + D(v + v')\big)\\ &= \big((Au + Cv) + (Au' + Cv'), (Bu + Dv) + (Bu' + Dv')\big)\\ &= (Au + Cv, Bu + Dv) + (Au' + Cv', Bu' + Dv')\\ &= \Phi(u, v) + \Phi(u', v')\end{aligned}$$

We now verify property (2):

$$\begin{aligned}\Phi(cu, cv) &= (A(cu) + C(cv), B(cu) + D(cv)) = (cAu + cCv, cBu + cDv)\\ &= c(Au + Cv, Bu + Dv) = c\Phi(u, v)\end{aligned}$$

We now suppose that $\Phi(u, v)$ is defined for all u and v and satisfies properties (1) and (2). We show that Φ is linear. We denote the following values:

$$\Phi(1, 0) = (A, B), \quad \Phi(0, 1) = (C, D) \tag{1}$$

We write

$$(u, v) = (u \cdot 1 + v \cdot 0, u \cdot 0 + v \cdot 1)$$

Using property (1) gives

$$\Phi(u, v) = \phi(u \cdot 1 + v \cdot 0, u \cdot 0 + v \cdot 1) = \phi(u \cdot 1, u \cdot 0) + \phi(v \cdot 0, v \cdot 1)$$

We now use property (2) and equation (3) to write

$$\Phi(u, v) = u\phi(1, 0) + v\phi(0, 1) = u(A, B) + v(C, D) = (Au, Bu) + (Cv, Dv) = (Au + Cv, Bu + Dv)$$

Hence Φ is linear.

47. Let P and Q be points in $\mathbf{R}^2$. Show that a linear map $\Phi(u, v) = (Au + Cv, Bu + Dv)$ maps the segment joining P and Q to the segment joining $\Phi(P)$ to $\Phi(Q)$. *Hint:* The segment joining P and Q has parametrization

$$(1-t)\overrightarrow{OP} + t\overrightarrow{OQ} \quad \text{for} \quad 0 \le t \le 1$$

SOLUTION First let $P(x_0, y_0)$ and $Q(x_1, y_1)$ so that we see if

$$\mathbf{r}(0) = \overrightarrow{OP} = (x_0, y_0), \quad \mathbf{r}(1) = \overrightarrow{OQ} = (x_1, y_1)$$

Then using the linear map we see:

$$\Phi(x_0, y_0) = (Ax_0 + Cy_0, Bx_0 + Dy_0) = \Phi(P)$$

and

$$\Phi(x_1, y_1) = (Ax_1 + Cy_1, Bx_1 + Dy_1) = \Phi(Q)$$

Hence this linear map take the endpoints P and Q to the new endpoints $\Phi(P)$ and $\Phi(Q)$. Now to determine the line segment mapping, consider the following:

$$\begin{aligned}
\Phi(\mathbf{r}(t)) &= \Phi((1-t)\overrightarrow{OP} + t\overrightarrow{OQ}) = \Phi((1-t)x_0 + tx_1, (1-t)y_0 + ty_1) \\
&= (A((1-t)x_0 + tx_1) + C((1-t)y_0 + ty_1), B((1-t)x_0 + tx_1 + D((1-t)y_0 + ty_1)) \\
&= ((1-t)Ax_0 + t(Ax_1) + (1-t)Cy_0 + t(Cy_1), (1-t)Bx_0 + t(Bx_1) + (1-t)Dy_0 + t(Dy_1)) \\
&= ((1-t)(Ax_0 + Cy_0) + t(Ax_1 + Cy_1), (1-t)(Bx_0 + Dy_0) + t(Bx_1 + Dy_1)) \\
&= (1-t)(Ax_0 + Cy_0, Bx_0 + Dy_0) + t(Ax_1 + Cy_1, Bx_1 + Dy_1) \\
&= (1-t)\Phi(P) + t\Phi(Q)
\end{aligned}$$

This is a parameterization for the line segment joining $\Phi(P)$ and $\Phi(Q)$. Therefore, the linear map maps the line segment joining P and Q to the line segment joining $\Phi(P)$ and $\Phi(Q)$.

48. Let Φ be a linear map. Prove Eq. (6) in the following steps.

(a) For any set $\mathcal{D}$ in the uv-plane and any vector $\mathbf{u}$, let $\mathcal{D} + \mathbf{u}$ be the set obtained by translating all points in $\mathcal{D}$ by $\mathbf{u}$. By linearity, Φ maps $\mathcal{D} + \mathbf{u}$ to the translate $\Phi(\mathcal{D}) + \Phi(\mathbf{u})$ [Figure 19(C)]. Therefore, if Eq. (6) holds for $\mathcal{D}$, it also holds for $\mathcal{D} + \mathbf{u}$.

(b) In the text, we verified Eq. (6) for the unit rectangle. Use linearity to show that Eq. (6) also holds for all rectangles with vertex at the origin and sides parallel to the axes. Then argue that it also holds for each triangular half of such a rectangle, as in Figure 19(A).

(c) Figure 19(B) shows that the area of a parallelogram is a difference of the areas of rectangles and triangles covered by steps (a) and (b). Use this to prove Eq. (6) for arbitrary parallelograms.

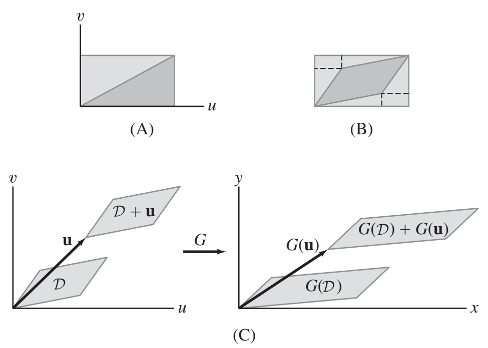


FIGURE 19

SOLUTION We must show that if Φ is a linear map, then

$$\text{Area}\,(\Phi(\mathcal{D})) = |\text{Jac}\,(\Phi)\,|\text{Area}(\mathcal{D}) \tag{1}$$

(a) For any vector $\mathbf{v} \in \mathcal{D}$, $\mathbf{v} + \mathbf{u}$ is in $\mathcal{D} + \mathbf{u}$. We show that $\Phi(\mathbf{v} + \mathbf{u})$ is in $\Phi(\mathcal{D}) + \Phi(\mathbf{u})$. By linearity, we have

$$\Phi(\mathbf{v} + \mathbf{u}) = \Phi(\mathbf{v}) + \Phi(\mathbf{u})$$

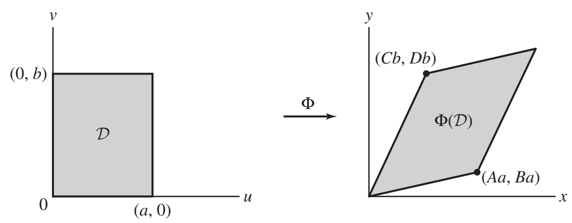
Since $\mathbf{v} \in \mathcal{D}$, $\Phi(\mathbf{v}) \in \Phi(\mathcal{D})$, hence $\Phi(\mathbf{v}) + \Phi(\mathbf{u}) \in \Phi(\mathcal{D}) + \Phi(\mathbf{u})$. Therefore, Φ maps $\mathcal{D} + \mathbf{u}$ to $\Phi(\mathcal{D}) + \Phi(\mathbf{u})$.

(b) Let $\mathcal{D}$ be the rectangle $\mathcal{D} = [0, a] \times [0, b]$ in the uv-plane, and $\Phi(\mathcal{D})$ be the image of $\mathcal{D}$ under the linear mapping Φ:

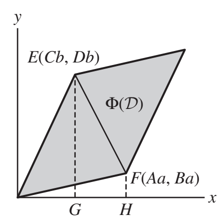
$$\Phi(u, v) = (Au + Cv, Bu + Dv)$$

Suppose that $a > 0$, $b > 0$, and $AD > BC$. For other cases, the proof is similar. To determine $\Phi(\mathcal{D})$, we compute the images of the vertices $(0, b)$ and $(a, 0)$ of $\mathcal{D}$:

$$\Phi(0, b) = (A \cdot 0 + Cb, B \cdot 0 + Db) = (Cb, Db)$$
$$\Phi(a, 0) = (Aa + C \cdot 0, B \cdot a + D \cdot 0) = (Aa, Ba)$$



Therefore, $\Phi(\mathcal{D})$ is the parallelogram spanned by the vectors $\langle Cb, Db\rangle$ and $\langle Aa, Ba\rangle$.



The area of the parallelogram is

$$\begin{aligned} 2\left(S_{\text{tri}(OEG)} + S_{\text{tra}(GEFH)} - S_{\text{tri}(OFH)}\right) &= 2\left(\frac{EG \cdot OG}{2} + \frac{(EG + FH)GH}{2} - \frac{FH \cdot OH}{2}\right) \\ &= 2\left(\frac{Db \cdot Cb}{2} + \frac{(Db + Ba)(Aa - Cb)}{2} - \frac{Ba \cdot Aa}{2}\right) \\ &= DCb^2 + ADab - DCb^2 + ABa^2 - BCab - ABa^2 \\ &= ab(AD - BC) \end{aligned}$$

That is,

$$\text{Area}\,(\Phi(\mathcal{D})) = (AD - BC)ab$$

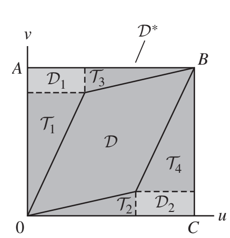
Since $|\text{Jac}(\Phi)| = AD - BC$ and $\text{Area}(\mathcal{D}) = ab$, we get

$$\text{Area}\,(\Phi(\mathcal{D})) = |\text{Jac}\,(\Phi)\,|\text{Area}(\mathcal{D}).$$

Now, let $\mathcal{D}_1$ be a triangular half of the parallelogram $\mathcal{D}$. Then, $\Phi(\mathcal{D}_1)$ is a triangular half of the parallelogram $\Phi(\mathcal{D})$. Using the result above, we have

$$\text{Area}\Phi(\mathcal{D}_1) = \frac{1}{2}\text{Area}\Phi(\mathcal{D}) = \frac{1}{2} \cdot |\text{Jac}(\Phi)|\text{Area}(\mathcal{D}) = |\text{Jac}(\Phi)|\frac{\text{Area}(\mathcal{D})}{2} = |\text{Jac}(\Phi)|\text{Area}(\mathcal{D}_1)$$

(c) By part (a), if we show that Eq. (4) holds for parallelograms with vertex at the origin, it holds for all other parallelograms (since each parallelogram can be translated to a parallelogram with a vertex at the origin). We consider a parallelogram with a vertex at the origin, and inscribe it in a rectangle $\mathcal{D}^*$; as shown in the figure:



We denote the triangles and rectangles as shown in the figure. By parts (a) and (b), it follows that Eq. (4) holds for each one of the rectangles and triangles. That is,

$$\begin{aligned}\text{Area}\,\Phi(\mathcal{D}^*) &= |\text{Jac}(\Phi)|\text{Area}(\mathcal{D}^*)\\ \text{Area}\,\Phi(\mathcal{D}_i) &= |\text{Jac}(\Phi)|\text{Area}(\mathcal{D}_i), \quad i = 1, 2\\ \text{Area}\,\Phi(T_i) &= |\text{Jac}(\Phi)|\text{Area}(T_i), \quad i = 1, 2, 3, 4 \end{aligned} \tag{2}$$

Since

$$\sum_{i=1}^{2} \text{Area}\,\Phi(\mathcal{D}_i) + \sum_{i=1}^{4} \text{Area}\,\Phi(T_i) + \text{Area}\,\Phi(\mathcal{D}) = \text{Area}\,\Phi(\mathcal{D}^*)$$

we have by (1),

$$|\text{Jac}(\Phi)| \left(\sum_{i=1}^{2} \text{Area}\,(\mathcal{D}_i) + \sum_{i=1}^{4} \text{Area}(T_i) \right) + \text{Area}\,\Phi(\mathcal{D}) = |\text{Jac}\,\Phi|\text{Area}(\mathcal{D}^*)$$

Translating sides gives

$$|\text{Jac}(\Phi)| \left(\text{Area}(\mathcal{D}^*) - \sum_{i=1}^{2} \text{Area}(\mathcal{D}_i) - \sum_{i=1}^{4} \text{Area}(T_i) \right) = \text{Area}\,\Phi(\mathcal{D})$$

But the difference in the brackets on the left-hand side is the area of the parallelogram $\mathcal{D}$. Therefore, we get

$$|\text{Jac}(\Phi)|\text{Area}(\mathcal{D}) = \text{Area}\,\Phi(\mathcal{D})$$

We thus showed that Eq. (4) holds for $\mathcal{D}$.

49. The product of 2×2 matrices A and B is the matrix AB defined by

$$\underbrace{\begin{pmatrix} a & b \\ c & d \end{pmatrix}}_{A} \underbrace{\begin{pmatrix} a' & b' \\ c' & d' \end{pmatrix}}_{B} = \underbrace{\begin{pmatrix} aa' + bc' & ab' + bd' \\ ca' + dc' & cb' + dd' \end{pmatrix}}_{AB}$$

The (i, j)-entry of A is the **dot product** of the ith row of A and the jth column of B. Prove that $\det(AB) = \det(A)\det(B)$.

SOLUTION The determinants of A and B are

$$\begin{aligned}\det(A) &= \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc,\\ \det(B) &= \begin{vmatrix} a' & b' \\ c' & d' \end{vmatrix} = a'd' - b'c' \end{aligned} \tag{1}$$

We now compute the determinant of AB:

$$\begin{aligned}\det(AB) = \begin{vmatrix} aa' + bc' & ab' + bd' \\ ca' + dc' & cb' + dd' \end{vmatrix} &= (aa' + bc')(cb' + dd') - (ab' + bd')(ca' + dc')\\ &= aa'cb' + aa'dd' + bc'cb' + bc'dd' - ab'ca' - ab'dc' - bd'ca' - bd'dc'\\ &= (aa'dd' - bd'ca') + (bc'cb' - ab'dc') = a'd'(ad - bc) - b'c'(ad - bc)\\ &= (ad - bc)(a'd' - b'c') \end{aligned} \tag{2}$$

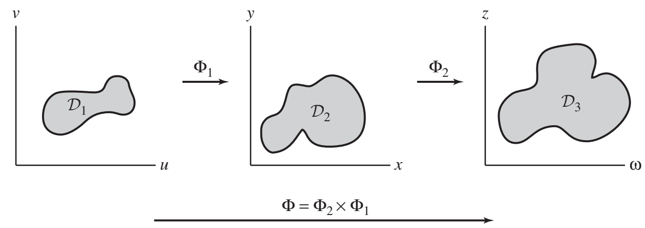
We combine (1) and (2) to conclude

$$\det(AB) = \det(A)\det(B).$$

50. Let $\Phi_1 : \mathcal{D}_1 \to \mathcal{D}_2$ and $\Phi_2 : \mathcal{D}_2 \to \mathcal{D}_3$ be C^1 maps, and let $\Phi_2 \circ \Phi_1 : \mathcal{D}_1 \to \mathcal{D}_3$ be the composite map. Use the Multivariable Chain Rule and Exercise 49 to show that

$$\text{Jac}(\Phi_2 \circ \Phi_1) = \text{Jac}(\Phi_2)\text{Jac}(\Phi_1)$$

SOLUTION



Let $\Phi = \Phi_2 \circ \Phi_1$. We have

$$\operatorname{Jac}(\Phi_1) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} \tag{1}$$

$$\operatorname{Jac}(\Phi_2) = \begin{vmatrix} \frac{\partial \omega}{\partial x} & \frac{\partial \omega}{\partial y} \\ \frac{\partial z}{\partial x} & \frac{\partial z}{\partial y} \end{vmatrix} \tag{2}$$

$$\operatorname{Jac}(\Phi) = \begin{vmatrix} \frac{\partial \omega}{\partial u} & \frac{\partial \omega}{\partial v} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} \end{vmatrix} \tag{3}$$

We use the multivariable Chain Rule to write

$$\frac{\partial \omega}{\partial u} = \frac{\partial \omega}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial \omega}{\partial y}\frac{\partial y}{\partial u}, \qquad \frac{\partial z}{\partial u} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial u}$$

$$\frac{\partial \omega}{\partial v} = \frac{\partial \omega}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial \omega}{\partial y}\frac{\partial y}{\partial v}, \qquad \frac{\partial z}{\partial v} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial v}$$

Substituting in (3) we obtain

$$\operatorname{Jac}(\Phi) = \begin{vmatrix} \frac{\partial \omega}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial \omega}{\partial y}\frac{\partial y}{\partial u} & \frac{\partial \omega}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial \omega}{\partial y}\frac{\partial y}{\partial v} \\ \frac{\partial z}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial u} & \frac{\partial z}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial v} \end{vmatrix}$$

We now use the definition of the product of two matrices, given in Exercise 49, equalities (1) and (2), and the equality proved in Exercise 49, to write

$$\operatorname{Jac}(\Phi) = \left| \begin{pmatrix} \frac{\partial \omega}{\partial x} & \frac{\partial \omega}{\partial y} \\ \frac{\partial z}{\partial x} & \frac{\partial z}{\partial y} \end{pmatrix} \begin{pmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{pmatrix} \right| = \begin{vmatrix} \frac{\partial \omega}{\partial x} & \frac{\partial \omega}{\partial y} \\ \frac{\partial z}{\partial x} & \frac{\partial z}{\partial y} \end{vmatrix} \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \operatorname{Jac}(\Phi_2)\operatorname{Jac}(\Phi_1)$$

That is,

$$\operatorname{Jac}(\Phi_2 \circ \Phi_1) = \operatorname{Jac}(\Phi_2)\operatorname{Jac}(\Phi_1)$$

51. Use Exercise 50 to prove that

$$\operatorname{Jac}(\Phi^{-1}) = \operatorname{Jac}(\Phi)^{-1}$$

Hint: Verify that $\operatorname{Jac}(I) = 1$, where I is the identity map $I(u, v) = (u, v)$.

SOLUTION Since $\Phi^{-1}(\Phi(u, v)) = (u, v)$, we have $(\Phi^{-1} \circ \Phi)(u, v) = (u, v)$. Therefore, $\Phi^{-1} \circ \Phi = I$. Using Exercise 50, we have

$$\operatorname{Jac}(I) = \operatorname{Jac}(\Phi^{-1} \circ \Phi) = \operatorname{Jac}(\Phi^{-1})\operatorname{Jac}(\Phi) \tag{1}$$

The Jacobian of the linear map $I(u, v) = (u, v) = (1 \cdot u + 0 \cdot v, 0 \cdot u + 1 \cdot v)$ is

$$\operatorname{Jac}(I) = \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix} = 1 \cdot 1 - 0 \cdot 0 = 1$$

Substituting in (1) gives

$$1 = \text{Jac}(\Phi^{-1})\text{Jac}(\Phi)$$

or

$$\text{Jac}(\Phi^{-1}) = (\text{Jac}(\Phi))^{-1}.$$

52. Let $(\overline{x}, \overline{y})$ be the centroid of a domain $\mathcal{D}$. For $\lambda > 0$, let $\lambda\mathcal{D}$ be the **dilate** of $\mathcal{D}$, defined by

$$\lambda\mathcal{D} = \{(\lambda x, \lambda y) : (x, y) \in \mathcal{D}\}$$

Use the Change of Variables Formula to prove that the centroid of $\lambda\mathcal{D}$ is $(\lambda\overline{x}, \lambda\overline{y})$.

SOLUTION The centroid of $\mathcal{D}$ has the following coordinates, where $S = \text{Area}(\mathcal{D})$:

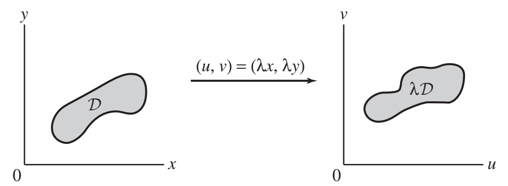
$$\overline{x} = \frac{1}{S}\iint_{\mathcal{D}} x\,dx\,dy, \quad \overline{y} = \frac{1}{S}\iint_{\mathcal{D}} y\,dx\,dy \tag{1}$$

The centroid of $\lambda\mathcal{D}$ is the following point:

$$\overline{u} = \frac{1}{\text{Area}(\lambda\mathcal{D})}\iint_{\lambda\mathcal{D}} u\,du\,dv, \quad \overline{v} = \frac{1}{\text{Area}(\lambda\mathcal{D})}\iint_{\lambda\mathcal{D}} v\,du\,dv \tag{2}$$

We compute the double integrals in (2) using change of variables with the following mapping:

$$u = \lambda x, \quad v = \lambda y$$



Therefore $(u, v) \in \lambda\mathcal{D}$ if and only if $(x, y) \in \mathcal{D}$, hence the image of $\lambda\mathcal{D}$ under this mapping is the domain $\mathcal{D}$ in the xy-plane. The Jacobian of the linear mapping $(u, v) = (\lambda x + 0y, 0x + \lambda y)$ is

$$\frac{\partial(u, v)}{\partial(x, y)} = \begin{vmatrix} \lambda & 0 \\ 0 & \lambda \end{vmatrix} = \lambda^2$$

We compute the integrals:

$$\iint_{\lambda\mathcal{D}} u\,du\,dv = \iint_{\mathcal{D}} \lambda x \cdot \lambda^2\,dx\,dy = \lambda^3\iint_{\mathcal{D}} x\,dx\,dy = \lambda^3 S\overline{x}$$
$$\iint_{\lambda\mathcal{D}} v\,du\,dv = \iint_{\mathcal{D}} \lambda y \cdot \lambda^2\,dx\,dy = \lambda^3\iint_{\mathcal{D}} y\,dx\,dy = \lambda^3 S\overline{y}$$

Substituting in (2) gives

$$\overline{u} = \frac{\lambda^3 S}{\text{Area}(\lambda\mathcal{D})}\overline{x}, \quad \overline{v} = \frac{\lambda^3 S}{\text{Area}(\lambda\mathcal{D})}\overline{y} \tag{3}$$

We now compute the area of $\lambda\mathcal{D}$ using the same mapping:

$$\text{Area}(\lambda\mathcal{D}) = \iint_{\lambda\mathcal{D}} 1\,du\,dv = \iint_{\mathcal{D}} \lambda^2\,dx\,dy = \lambda^2\iint_{\mathcal{D}} dx\,dy = \lambda^2\text{Area}(\mathcal{D}) = \lambda^2 S$$

Substituting in (3), we obtain the following centroid of $\lambda\mathcal{D}$:

$$\overline{u} = \frac{\lambda^3 S\overline{x}}{\lambda^2 S} = \lambda\overline{x}, \quad \overline{v} = \frac{\lambda^3 S\overline{y}}{\lambda^2 S} = \lambda\overline{y}$$

The centroid of $\lambda\mathcal{D}$ is $(\lambda\overline{x}, \lambda\overline{y})$.

CHAPTER REVIEW EXERCISES

1. Calculate the Riemann sum $S_{2,3}$ for $\int_1^4 \int_2^6 x^2 y \, dx \, dy$ using two choices of sample points:

(a) Lower-left vertex

(b) Midpoint of rectangle

Then calculate the exact value of the double integral.

SOLUTION

(a) The rectangle $[2, 6] \times [1, 3]$ is divided into 2×3 subrectangles. The lower-left vertices of the subrectangles are

$$\begin{array}{lll} P_{11} = (2, 1) & P_{21} = (2, 2) & P_{31} = (2, 3) \\ P_{12} = (3, 1) & P_{22} = (3, 2) & P_{32} = (3, 3) \end{array}$$

Also $\Delta x = \frac{6-2}{2} = 2$, $\Delta y = \frac{4-1}{3} = 1$, hence $\Delta A = 2 \cdot 1 = 2$. The Riemann sum $S_{3,4}$ is the following sum:

$$\begin{aligned} S_{2,3} &= 2\left(2^2 \cdot 1 + 2^2 \cdot 2 + 2^2 \cdot 3 + 3^2 \cdot 1 + 3^2 \cdot 2 + 3^2 \cdot 3\right) \\ &= 2\,(4 + 8 + 12 + 9 + 18 + 27) = 156 \end{aligned}$$

(b) The midpoints of the subrectangles are

$$\begin{array}{lll} P_{11} = (3, 3/2) & P_{21} = (3, 5/2) & P_{31} = (3, 7/2) \\ P_{12} = (5, 3/2) & P_{22} = (5, 5/2) & P_{32} = (5, 7/2) \end{array}$$

Also $\Delta x = 2$, $\Delta y = 1$, hence $\Delta A = 2 \cdot 1 = 2$. The Riemann sum $S_{2,3}$ is

$$\begin{aligned} S_{2,3} &= 2\left(3^2 \cdot \frac{3}{2} + 3^2 \cdot \frac{5}{2} + 3^2 \cdot \frac{7}{2} + 5^2 \cdot \frac{3}{2} + 5^2 \cdot \frac{5}{2} + 5^2 \cdot \frac{7}{2}\right) \\ &= 2\left(\frac{27}{2} + \frac{45}{2} + \frac{63}{2} + \frac{75}{2} + \frac{125}{2} + \frac{175}{2}\right) \\ &= 510 \end{aligned}$$

We compute the exact value of the double integral, using an iterated integral of a product function. We get

$$\begin{aligned} \int_1^4 \int_2^6 x^2 y \, dx \, dy &= \left(\int_1^4 y \, dy\right)\left(\int_2^6 x^2 \, dx\right) = \left(\frac{y^2}{2}\Big|_1^4\right)\left(\frac{x^3}{3}\Big|_2^6\right) \\ &= \frac{16-1}{2} \cdot \frac{216-8}{3} = \frac{3120}{6} = 520 \end{aligned}$$

2. Let $S_{N,N}$ be the Riemann sum for $\int_0^1 \int_0^1 \cos(xy) \, dx \, dy$ using midpoints as sample points.

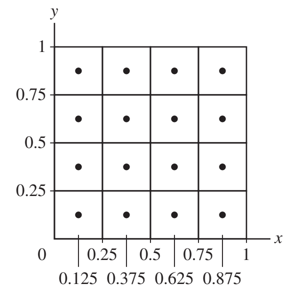
(a) Calculate $S_{4,4}$.

(b) CAS Use a computer algebra system to calculate $S_{N,N}$ for $N = 10, 50, 100$.

SOLUTION

(a) The midpoints of the 16 subrectangles are

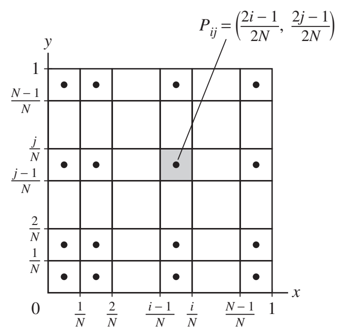
$$\begin{array}{ll} P_{11} = (0.125, 0.125) & P_{21} = (0.375, 0.125) \\ P_{31} = (0.625, 0.125) & P_{41} = (0.875, 0.125) \\ P_{12} = (0.125, 0.375) & P_{22} = (0.375, 0.375) \\ P_{32} = (0.625, 0.375) & P_{42} = (0.875, 0.375) \\ P_{13} = (0.125, 0.625) & P_{23} = (0.375, 0.625) \\ P_{33} = (0.625, 0.625) & P_{43} = (0.875, 0.625) \\ P_{14} = (0.125, 0.875) & P_{24} = (0.375, 0.875) \\ P_{34} = (0.625, 0.875) & P_{44} = (0.875, 0.875) \end{array}$$



Also $\Delta x = \Delta y = 0.25$, hence $\Delta A = 0.0625$. The Riemann Sum $S_{4,4}$ is

$$\begin{aligned} S_{4,4} = 0.0625 \cdot \Big(&\cos 0.125^2 + 2\cos(0.125 \cdot 0.375) + 2\cos(0.125 \cdot 0.625) + 2\cos(0.125 \cdot 0.875) \\ &+ \cos(0.375^2) + 2\cos(0.375 \cdot 0.625) + 2\cos(0.375 \cdot 0.875) + \cos(0.625^2) \\ &+ 2\cos(0.625 \cdot 0.875) + \cos(0.875^2)\Big) \\ = 0.947644& \end{aligned}$$

(b) The subrectangles on the rectangle $[0, 1] \times [0, 1]$ have sides of length $\Delta x = \Delta y = \frac{1}{N}$ and area $\Delta A = \frac{1}{N^2}$.



The midpoints are $P_{ij} = \left(\frac{2i-1}{2N}, \frac{2j-1}{2N}\right)$ for $i, j = 1, \ldots, N$. The corresponding Riemann sum is

$$S_{N,N} = \frac{1}{N^2} \sum_{i=1}^{N} \sum_{j=1}^{N} \cos\left(\frac{2i-1}{2N} \cdot \frac{2j-1}{2N}\right)$$

We compute the sums for $N = 10$, 50, and 100 using a CAS:

$$S_{10,10} = 0.946334, \quad S_{50,50} = 0.946093, \quad S_{100,100} = 0.946086$$

3. Let $\mathcal{D}$ be the shaded domain in Figure 1.

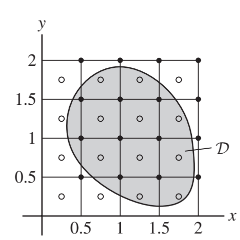


FIGURE 1

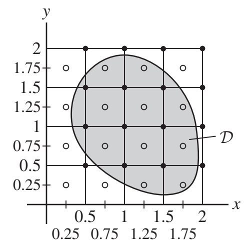
Estimate $\iint_{\mathcal{D}} xy\, dA$ by the Riemann sum whose sample points are the midpoints of the squares in the grid.

SOLUTION The subrectangles have sides of length $\Delta x = \Delta y = 0.5$ and area $\Delta A = 0.5^2 = 0.25$. Of sixteen sample points only ten lie in $\mathcal{D}$. The sample points that lie in $\mathcal{D}$ are

$$(0.75, 0.75),\ (0.75, 1.25),\ (0.75, 1.75),\ (1.25, 0.25),\ (1.25, 0.75),$$
$$(1.25, 1.25),\ (1.25, 1.75),\ (1.75, 0.25),\ (1.75, 0.75),\ (1.75, 1.25)$$



The Riemann sum S_{44} is thus

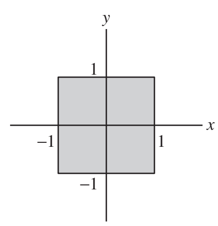
$$\begin{aligned}
S_{44} &= 0.25\,(f(0.75,0.75)+f(0.75,1.25)+f(0.75,1.75)+f(1.25,0.25)+f(1.25,0.75)\\
&\quad + f(1.25,1.25)+f(1.25,1.75)+f(1.75,0.25)+f(1.75,0.75)+f(1.75,1.25))\\
&= 0.25\left(0.75^2+0.75\cdot 1.25+0.75\cdot 1.75+1.25\cdot 0.25+1.25\cdot 0.75+1.25^2\right.\\
&\quad \left.+\,1.25\cdot 1.75+1.75\cdot 0.25+1.75\cdot 0.75+1.75\cdot 1.25\right)\\
&= 0.25\cdot 11.75 = 2.9375
\end{aligned}$$

4. Explain the following:

(a) $\int_{-1}^{1}\int_{-1}^{1}\sin(xy)\,dx\,dy = 0$ **(b)** $\int_{-1}^{1}\int_{-1}^{1}\cos(xy)\,dx\,dy > 0$

SOLUTION

(a) The double integral is the signed volume of the region between the graph of $f(x, y)$ and the xy-plane.



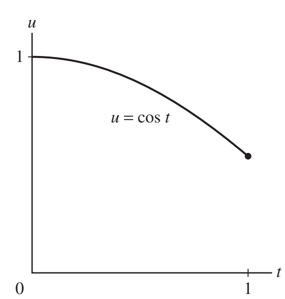
Region of integration

The function $f(x, y) = \sin(xy)$ satisfies $f(-x, y) = \sin(-xy) = -\sin(xy) = -f(x, y)$, hence the region left of the y-axis cancels with the region to the right of the y-axis. Therefore the double integral is zero.

(b) The function $f(x, y) = \cos(xy)$ satisfies $f(-x, y) = f(x, -y) = f(-x, -y) = f(x, y)$, hence

$$\int_{-1}^{1}\int_{-1}^{1}\cos(xy)\,dx = 4\int_{0}^{1}\int_{0}^{1}\cos(xy)\,dx.$$

Since $0 \le xy \le 1$ for the square $[0, 1] \times [0, 1]$, we have $\cos xy > 0$, and the double integral is positive.



$u = \cos t$

In Exercises 5–8, evaluate the iterated integral.

5. $\int_{0}^{2}\int_{3}^{5} y(x-y)\,dx\,dy$

SOLUTION First we evaluate the inner integral treating y as a constant:

$$\int_{3}^{5} y(x-y)\,dx = y\left(\frac{x^2}{2}-yx\right)\Big|_{x=3}^{5} = y\left(\left(\frac{25}{2}-5y\right)-\left(\frac{9}{2}-3y\right)\right) = y(8-2y) = 8y-2y^2$$

Now we integrate this result with respect to y:

$$\int_0^2 (8y - 2y^2)\,dy = 4y^2 - \frac{2}{3}y^3\Big|_0^2 = 16 - \frac{16}{3} = \frac{32}{3}$$

Therefore,

$$\int_0^2 \int_3^5 y(x-y)\,dx\,dy = \frac{32}{3}.$$

6. $\displaystyle\int_{1/2}^0 \int_0^{\pi/6} e^{2y} \sin 3x\,dx\,dy$

SOLUTION We use an iterated integral of a product function to compute the double integral as the product of two single integrals. That is,

$$\int_{1/2}^0 \int_0^{\pi/6} e^{2y}\sin 3x\,dx\,dy = \left(\int_{1/2}^0 e^{2y}\,dy\right)\left(\int_0^{\pi/6}\sin 3x\,dx\right) = \left(\frac{1}{2}e^{2y}\Big|_{1/2}^0\right)\left(-\frac{1}{3}\cos 3x\Big|_0^{\pi/6}\right)$$

$$= \frac{1}{2}(1-e)\cdot\left(-\frac{1}{3}\right)\left(\cos\frac{\pi}{2} - \cos 0\right) = \frac{1}{6}(1-e)$$

7. $\displaystyle\int_0^{\pi/3} \int_0^{\pi/6} \sin(x+y)\,dx\,dy$

SOLUTION We compute the inner integral treating y as a constant:

$$\int_0^{\pi/6}\sin(x+y)\,dx = -\cos(x+y)\Big|_{x=0}^{\pi/6} = -\cos\left(\frac{\pi}{6}+y\right) + \cos y = \cos y - \cos\left(y + \frac{\pi}{6}\right)$$

We now integrate the result with respect to y:

$$\int_0^{\pi/3}\int_0^{\pi/6}\sin(x+y)\,dx\,dy = \int_0^{\pi/3}\left(\cos y - \cos\left(y+\frac{\pi}{6}\right)\right)dy = \sin y - \sin\left(y + \frac{\pi}{6}\right)\Big|_0^{\pi/3}$$

$$= \sin\frac{\pi}{3} - \sin\left(\frac{\pi}{3}+\frac{\pi}{6}\right) - \left(\sin 0 - \sin\frac{\pi}{6}\right) = \frac{\sqrt{3}}{2} - 1 + \frac{1}{2} = \frac{\sqrt{3}-1}{2}$$

8. $\displaystyle\int_1^2 \int_1^2 \frac{y\,dx\,dy}{x+y^2}$

SOLUTION We compute the inner integral with respect to x, then compute the outer integral of the result with respect to y. We obtain

$$\int_1^2 \frac{y}{x+y^2}\,dx = y\ln(x+y^2)\Big|_{x=1}^2 = y\ln(2+y^2) - y\ln(1+y^2)$$

$$\int_1^2\int_1^2 \frac{y}{x+y^2}\,dx\,dy = \int_1^2\left(y\ln(2+y^2) - y\ln(1+y^2)\right)dy = \int_1^2 y\ln(2+y^2)\,dy - \int_1^2 y\ln(1+y^2)\,dy$$

We compute the integrals using the substitutions $u = 2+y^2$, $du = 2y\,dy$, and $V = 1+y^2$, $dV = 2y\,dy$, respectively. We get

$$\int_1^2\int_1^2 \frac{y}{x+y^2}\,dx\,dy = \frac{1}{2}\int_3^6 \ln u\,du - \frac{1}{2}\int_2^5 \ln V\,dV = \frac{1}{2}u(\ln u - 1)\Big|_3^6 - \frac{1}{2}V(\ln V - 1)\Big|_2^5$$

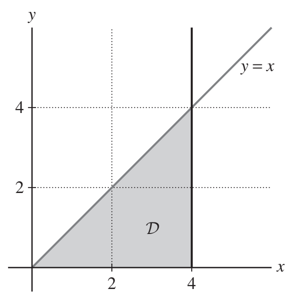
$$= \frac{1}{2}\cdot 6(\ln 6 - 1) - \frac{1}{2}\cdot 3(\ln 3 - 1) - \frac{1}{2}\cdot 5(\ln 5 - 1) + \frac{1}{2}\cdot 2(\ln 2 - 1)$$

$$= 3\ln 6 - \frac{3}{2}\ln 3 - \frac{5}{2}\ln 5 + \ln 2 \approx 0.396912$$

In Exercises 9–14, sketch the domain $\mathcal{D}$ and calculate $\displaystyle\iint_{\mathcal{D}} f(x,y)\,dA$.

9. $\mathcal{D} = \{0 \le x \le 4,\ 0 \le y \le x\}$, $\quad f(x,y) = \cos y$

SOLUTION The domain $\mathcal{D}$ is shown in the figure:



We compute the double integral, considering $\mathcal{D}$ as a vertically simple region. We describe $\mathcal{D}$ by the inequalities

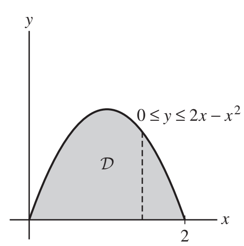
$$0 \le x \le 4, \quad 0 \le y \le x.$$

We now write the double integral as an iterated integral and compute:

$$\iint_{\mathcal{D}} \cos y \, dA = \int_0^4 \int_0^x \cos y \, dy \, dx = \int_0^4 \sin y \Big|_{y=0}^{x} dx$$
$$= \int_0^4 (\sin x - \sin 0) dx = \int_0^4 \sin x \, dx = -\cos x \Big|_0^4 = 1 - \cos 4$$

10. $\mathcal{D} = \{0 \le x \le 2, \; 0 \le y \le 2x - x^2\}, \quad f(x, y) = \sqrt{x}y$

SOLUTION The limits of the inner integral are $0 \le y \le 2x - x^2$, and the limits of outer integral are $0 \le x \le 2$.

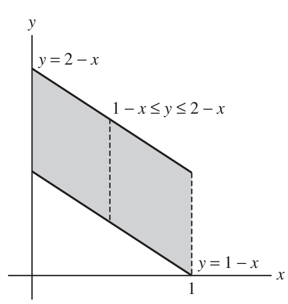


The region is vertically simple and the double integral is computed by the following iterated integral:

$$\iint_{\mathcal{D}} \sqrt{x} y \, dA = \int_0^2 \int_0^{2x-x^2} \sqrt{x} y \, dy \, dx = \int_0^2 \frac{\sqrt{x} y^2}{2} \Big|_{y=0}^{2x-x^2} dx = \int_0^2 \frac{\sqrt{x}(2x - x^2)^2}{2} \, dx$$
$$= \int_0^2 \left(2x^{5/2} - 2x^{7/2} + \frac{1}{2} x^{9/2} \right) dx = \frac{4}{7} x^{7/2} - \frac{4}{9} x^{9/2} + \frac{1}{11} x^{11/2} \Big|_0^2$$
$$= \frac{4}{7} \cdot 2^{7/2} - \frac{4}{9} \cdot 2^{9/2} + \frac{1}{11} \cdot 2^{11/2} = \frac{256\sqrt{2}}{693}$$

11. $\mathcal{D} = \{0 \le x \le 1, \; 1 - x \le y \le 2 - x\}, \quad f(x, y) = e^{x+2y}$

SOLUTION



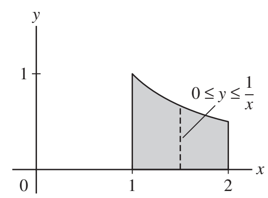
$\mathcal{D}$ is a vertically simple region, hence the double integral over $\mathcal{D}$ is the following iterated integral:

$$\iint_{\mathcal{D}} e^{x+2y} \, dA = \int_0^1 \int_{1-x}^{2-x} e^{x+2y} \, dy \, dx = \int_0^1 \frac{1}{2} e^{x+2y} \Big|_{y=1-x}^{2-x} dx = \int_0^1 \left(\frac{1}{2} e^{x+2(2-x)} - \frac{1}{2} e^{x+2(1-x)} \right) dx$$

$$= \int_0^1 \left(\frac{1}{2}e^{4-x} - \frac{1}{2}e^{2-x}\right) dx = -\frac{1}{2}e^{4-x} + \frac{1}{2}e^{2-x}\Big|_0^1 = -\frac{1}{2}e^3 + \frac{1}{2}e + \frac{1}{2}e^4 - \frac{1}{2}e^2$$
$$= \frac{1}{2}e(e^3 - e^2 - e + 1) = \frac{1}{2}e(e+1)(e-1)^2$$

12. $\mathcal{D} = \{1 \le x \le 2,\ 0 \le y \le 1/x\}, \quad f(x, y) = \cos(xy)$

SOLUTION

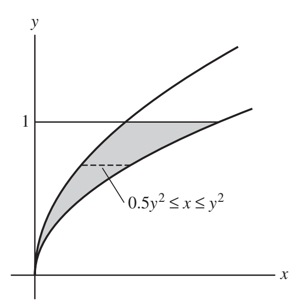


The region is vertically simple, hence the double integral is computed by the following iterated integral:

$$\iint_{\mathcal{D}} \cos(xy)\, dA = \int_1^2 \int_0^{1/x} \cos(xy)\, dy\, dx = \int_1^2 \frac{1}{x} \sin(xy)\Big|_{y=0}^{1/x} dx = \int_1^2 \frac{1}{x}\left(\sin\left(x \cdot \frac{1}{x}\right) - \sin 0\right) dx$$
$$= \int_1^2 \frac{1}{x} \sin 1\, dx = (\sin 1) \ln x\Big|_1^2 = (\sin 1)(\ln 2 - \ln 1) = (\sin 1) \ln 2$$

13. $\mathcal{D} = \{0 \le y \le 1,\ 0.5y^2 \le x \le y^2\}, \quad f(x, y) = ye^{1+x}$

SOLUTION



The region is horizontally simple, hence the double integral is equal to the following iterated integral:

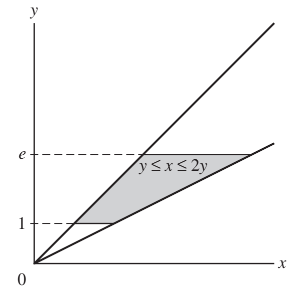
$$\iint_{\mathcal{D}} ye^{1+x}\, dA = \int_0^1 \int_{0.5y^2}^{y^2} ye^{1+x}\, dx\, dy = \int_0^1 ye^{1+x}\Big|_{x=0.5y^2}^{y^2} dy$$
$$= \int_0^1 y\left(e^{1+y^2} - e^{1+0.5y^2}\right) dy = \int_0^1 ye^{1+y^2}\, dy - \int_0^1 ye^{1+0.5y^2}\, dy$$

We compute the integrals using the substitutions $u = 1 + y^2$, $du = 2y\, dy$, and $v = 1 + 0.5y^2$, $dv = y\, dy$, respectively. We get

$$\iint_{\mathcal{D}} ye^{1+x}\, dA = \frac{1}{2}\int_1^2 e^u\, du - \int_1^{1.5} e^v dv = \frac{1}{2}e^u\Big|_1^2 - e^v\Big|_1^{1.5} = \frac{1}{2}(e^2 - e) - (e^{3/2} - e)$$
$$= \frac{1}{2}e^2 + \frac{1}{2}e - e^{3/2} = 0.5(e^2 - 2e^{1.5} + e)$$

14. $\mathcal{D} = \{1 \le y \le e,\ y \le x \le 2y\}, \quad f(x, y) = \ln(x + y)$

SOLUTION



The region is horizontally simple. We compute the double integral by the following iterated integral:

$$\begin{aligned}
\iint_{\mathcal{D}} \ln(x+y)\,dA &= \int_1^e \int_y^{2y} \ln(x+y)\,dx\,dy = \int_1^e (x+y)\left(\ln(x+y)-1\right)\Big|_{x=y}^{2y} dy \\
&= \int_1^e \left(3y(\ln 3y - 1) - 2y(\ln 2y - 1)\right)\,dy = \int_1^e (3y\ln 3y - 2y\ln 2y - y)\,dy \\
&= \int_1^e y\ln\frac{27y^3}{4y^2}\,dy - \int_1^e y\,dy = \int_1^e y\ln\frac{27y}{4}\,dy - \frac{y^2}{2}\Big|_1^e \\
&= \int_1^e y\ln\frac{27y}{4}\,dy - 0.5(e^2-1) \qquad (1)
\end{aligned}$$

We compute the integral using the substitution $u = \frac{27y}{4}$, $du = \frac{27}{4}\,dy$ and the integration formula:

$$\int u\ln u\,du = \frac{u^2}{2}\left(\ln u - \frac{1}{2}\right) + C$$

We get

$$\begin{aligned}
\int_1^e y\ln\frac{27y}{4}\,dy &= \int_{27/4}^{27e/4} \frac{4}{27}u\ln u \cdot \frac{4}{27}\,du = \left(\frac{4}{27}\right)^2 \int_{27/4}^{27e/4} u\ln u\,du = \left(\frac{4}{27}\right)^2 \cdot \frac{1}{2}u^2\left(\ln u - \frac{1}{2}\right)\Big|_{27/4}^{27e/4} \\
&= \left(\frac{4}{27}\right)^2 \cdot \frac{1}{2}\left(\left(\frac{27}{4}\right)^2 e^2\left(\ln\frac{27e}{4} - \frac{1}{2}\right) - \left(\frac{27}{4}\right)^2\left(\ln\frac{27}{4} - \frac{1}{2}\right)\right) \\
&= \frac{1}{2}\left(e^2\left(\ln\frac{27}{4} + \frac{1}{2}\right) - \left(\ln\frac{27}{4} - \frac{1}{2}\right)\right)
\end{aligned}$$

Substituting in (1) we obtain the following solution:

$$\begin{aligned}
\iint_{\mathcal{D}} \ln(x+y)\,dA &= 0.5\left(e^2\left(\ln\frac{27}{4} + \frac{1}{2}\right) - \left(\ln\frac{27}{4} - \frac{1}{2}\right) - (e^2-1)\right) \\
&= 0.5\left(\left(\ln\left(\frac{27}{4}\right) - 0.5\right)e^2 - \left(\ln\left(\frac{27}{4}\right) - 1.5\right)\right) \approx 5
\end{aligned}$$

15. Express $\int_{-3}^{3}\int_0^{9-x^2} f(x, y)\,dy\,dx$ as an iterated integral in the order $dx\,dy$.

SOLUTION The limits of integration correspond to the inequalities describing the domain $\mathcal{D}$:

$$-3 \le x \le 3, \quad 0 \le y \le 9 - x^2.$$

A quick sketch verifies that this is the region under the upper part of the parabola $y = 9 - x^2$, that is, the part that is above the x-axis. Therefore, the double integral can be rewritten as the following sum:

$$\int_{-3}^{3}\int_0^{9-x^2} f(x, y)\,dy\,dx = \int_0^9 \int_{-\sqrt{9-y}}^{\sqrt{9-y}} f(x, y)\,dx\,dy$$

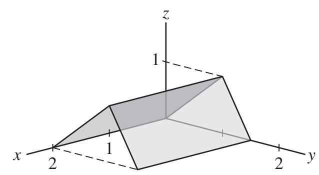
16. Let $\mathcal{W}$ be the region bounded by the planes $y = z$, $2y + z = 3$, and $z = 0$ for $0 \le x \le 4$.

(a) Express the triple integral $\iiint_{\mathcal{W}} f(x, y, z)\, dV$ as an iterated integral in the order $dy\, dz\, dx$ (project $\mathcal{W}$ onto the yz-plane).

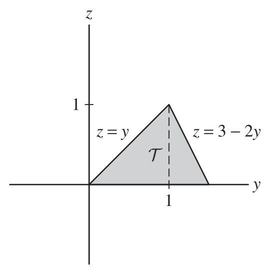
(b) Evaluate the triple integral for $f(x, y, z) = 1$.

(c) Compute the volume of $\mathcal{W}$ using geometry and check that the result coincides with the answer to (b).

SOLUTION The region $\mathcal{W}$ is the prism shown in the figure:



The projection of $\mathcal{W}$ onto the yz-plane is the triangle determined by the lines $z = y$, $2y + z = 3$ (or $z = 3 - 2y$), and the y-axis.



(a) First to express this triple integral as an iterated integral in the order $dy\, dz\, dx$:

$$\iiint_{\mathcal{W}} f(x, y, z)\, dV = \int_{x=0}^{4} \int_{z=0}^{1} \int_{y=z}^{3/2-1/2z} f(x, y, z)\, dy\, dz\, dx$$

(b) Now evaluate this integral for $f(x, y, z) = 1$:

$$\begin{aligned}
\int_{x=0}^{4} \int_{z=0}^{1} \int_{y=z}^{3/2-1/2z} 1\, dy\, dz\, dx &= \int_{0}^{4} \int_{0}^{1} y \Big|_{y=z}^{3/2-1/2z} dz\, dx \\
&= \int_{0}^{4} \int_{0}^{1} \frac{3}{2} - \frac{1}{2}z - z\, dz\, dx \\
&= \int_{0}^{4} \int_{0}^{1} \frac{3}{2} - \frac{3}{2}z\, dz\, dx \\
&= \int_{0}^{4} \frac{3}{2}z - \frac{3}{4}z^2 \Big|_{0}^{1} dx \\
&= \int_{0}^{4} \left(\frac{3}{2} - \frac{3}{4}\right) dx \\
&= \frac{3}{4} \int_{0}^{4} dx = 3
\end{aligned}$$

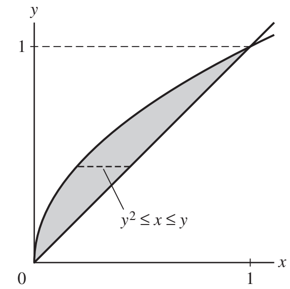
17. Let $\mathcal{D}$ be the domain between $y = x$ and $y = \sqrt{x}$. Calculate $\iint_{\mathcal{D}} xy\, dA$ as an iterated integral in the order $dx\, dy$ and $dy\, dx$.

SOLUTION In the order $dx\, dy$: The inequalities describing $\mathcal{D}$ as a horizontally simple region are obtained by first rewriting the equations of the curves with x as a function of y, that is, $x = y$ and $x = y^2$, respectively. The points of intersection are found solving the equation

$$y = y^2 \quad \Rightarrow \quad y(1 - y) = 0 \quad \Rightarrow \quad y = 0, \quad y = 1$$

We obtain the following inequalities for $\mathcal{D}$ (see figure):

$$\mathcal{D} : 0 \le y \le 1,\ y^2 \le x \le y$$



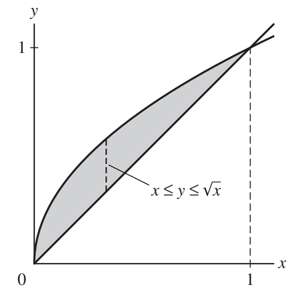
We now compute the double integral as the following iterated integral:

$$\iint_{\mathcal{D}} xy\,dA = \int_0^1 \int_{y^2}^{y} xy\,dx\,dy = \int_0^1 \frac{x^2y}{2}\bigg|_{x=y^2}^{x=y} dy = \int_0^1 \left(\frac{y\cdot y^2}{2} - \frac{y^4\cdot y}{2}\right) dy$$

$$= \int_0^1 \left(\frac{y^3}{2} - \frac{y^5}{2}\right) dy = \frac{y^4}{8} - \frac{y^6}{12}\bigg|_0^1 = \frac{1}{8} - \frac{1}{12} = \frac{1}{24}$$

In the order $dy\,dx$: $\mathcal{D}$ is described as a vertically simple region by the following inequalities (see figure):

$$\mathcal{D}:\ 0 \le x \le 1,\ x \le y \le \sqrt{x}$$



The corresponding iterated integral is

$$\iint_{\mathcal{D}} xy\,dA = \int_0^1 \int_x^{\sqrt{x}} xy\,dy\,dx = \int_0^1 \frac{xy^2}{2}\bigg|_{y=x}^{\sqrt{x}} dx = \int_0^1 \left(\frac{x\cdot x}{2} - \frac{x\cdot x^2}{2}\right) dx$$

$$= \int_0^1 \left(\frac{x^2}{2} - \frac{x^3}{2}\right) dx = \frac{x^3}{6} - \frac{x^4}{8}\bigg|_0^1 = \frac{1}{6} - \frac{1}{8} = \frac{1}{24}$$

18. Find the double integral of $f(x, y) = x^3y$ over the region between the curves $y = x^2$ and $y = x(1-x)$.

SOLUTION The region $\mathcal{D}$ is a vertically simple region defined by the inequalities

$$0 \le x \le \frac{1}{2}, \quad x^2 \le y \le x(1-x)$$

We obtain the following integral:

$$\int_0^{1/2} \int_{x^2}^{x(1-x)} x^3y\,dy\,dx = \int_0^{1/2} \frac{x^3y^2}{2}\bigg|_{y=x^2}^{x(1-x)} dx = \int_0^{1/2} \left(\frac{x^3\cdot x^2(1-x)^2}{2} - \frac{x^3\cdot x^4}{2}\right) dx$$

$$= \int_0^{1/2} \left(\frac{x^5}{2} - x^6\right) dx = \frac{x^6}{12} - \frac{x^7}{7}\bigg|_0^{1/2} = \frac{\left(\frac{1}{2}\right)^6}{12} - \frac{\left(\frac{1}{2}\right)^7}{7} = \frac{1}{42}\cdot\left(\frac{1}{2}\right)^7 = \frac{1}{5376}$$

19. Change the order of integration and evaluate $\displaystyle\int_0^9 \int_0^{\sqrt{y}} \frac{x\,dx\,dy}{(x^2+y)^{1/2}}$.

SOLUTION The region here is described by the inequalities:

$$0 \le x \le \sqrt{y}, \quad 0 \le y \le 9$$

This region can also be described by writing these inequalities:

$$0 \le x \le 3, \quad x^2 \le y \le 9$$

Hence, changing the order of integration and evaluating we get:

$$\int_0^9 \int_0^{\sqrt{y}} \frac{x}{\sqrt{x^2+y}}\,dx\,dy = \int_0^3 \int_{x^2}^9 \frac{x}{\sqrt{x^2+y}}\,dy\,dx = \int_0^3 x\left(2\sqrt{x^2+y}\Big|_{x^2}^{9}\right)dx$$

$$= 2\int_0^3 x\sqrt{x^2+9} - x\sqrt{x^2+x^2}\,dx = 2\int_0^3 x\sqrt{x^2+9} - x^2\sqrt{2}\,dx$$

$$= 2\left(\frac{1}{3}(x^2+9)^{3/2} - \frac{\sqrt{2}}{3}x^3\Big|_0^3\right)$$

$$= \frac{2}{3}\cdot 18^{3/2} - \frac{2\sqrt{2}}{3}\cdot 27 - 2\cdot\frac{1}{3}\cdot 9^{3/2}$$

$$= 36\sqrt{2} - 18\sqrt{2} - 18 = 18\sqrt{2} - 18$$

20. Verify directly that

$$\int_2^3 \int_0^2 \frac{dy\,dx}{1+x-y} = \int_0^2 \int_2^3 \frac{dx\,dy}{1+x-y}$$

SOLUTION We compute the two iterated integrals:

$$I_1 = \int_2^3 \int_0^2 \frac{dy\,dx}{1+x-y} = \int_2^3 \left(\int_0^2 \frac{dy}{1+x-y}\right)dx = \int_2^3 -\ln(1+x-y)\Big|_{y=0}^{2} dx$$

$$= \int_2^3 (-\ln(1+x-2) + \ln(1+x-0))\,dx = \int_2^3 (\ln(1+x) - \ln(x-1))\,dx$$

$$= (1+x)\,(\ln(1+x)-1) - (x-1)\,(\ln(x-1)-1)\Big|_2^3$$

$$= 4(\ln 4 - 1) - 2(\ln 2 - 1) - (3(\ln 3 - 1) - (\ln 1 - 1)) = 6\ln 2 - 3\ln 3$$

$$I_2 = \int_0^2 \int_2^3 \frac{dx\,dy}{1+x-y} = \int_0^2 \left(\int_2^3 \frac{dx}{1+x-y}\right)dy = \int_0^2 \ln(1+x-y)\Big|_{x=2}^{3} dy$$

$$= \int_0^2 (\ln(1+3-y) - \ln(1+2-y))\,dy = \int_0^2 (\ln(4-y) - \ln(3-y))\,dy$$

$$= \int_{-2}^0 (\ln(4+u) - \ln(3+u))\,du = (4+u)\,(\ln(4+u)-1) - (3+u)\,(\ln(3+u)-1)\Big|_{u=-2}^{0}$$

$$= 4(\ln 4 - 1) - 3(\ln 3 - 1) - (2(\ln 2 - 1) - (\ln 1 - 1)) = 4\ln 4 - 3\ln 3 - 2\ln 2 = 6\ln 2 - 3\ln 3$$

The two integrals are equal.

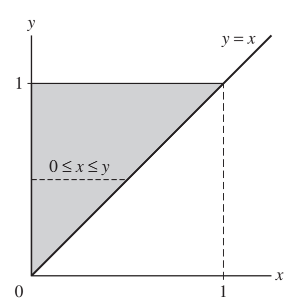
21. Prove the formula

$$\int_0^1 \int_0^y f(x)\,dx\,dy = \int_0^1 (1-x)f(x)\,dx$$

Then use it to calculate $\int_0^1 \int_0^y \frac{\sin x}{1-x}\,dx\,dy$.

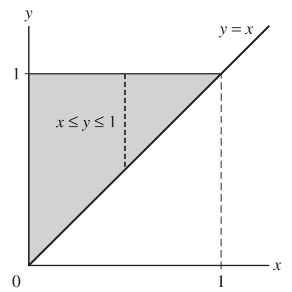
SOLUTION The region of integration of the double integral $\int_0^1 \int_0^y f(x)\,dx\,dy$ is described as horizontally simple by the inequalities

$$0 \le y \le 1, \quad 0 \le x \le y$$



The region can also be described as a vertically simple region, by the inequalities

$$0 \le x \le 1, \quad x \le y \le 1$$



Therefore,

$$\int_0^1 \int_0^y f(x)\,dx\,dy = \int_0^1 \int_x^1 f(x)\,dy\,dx = \int_0^1 f(x)y\Big|_{y=x}^{1} dx = \int_0^1 f(x)(1-x)\,dx$$

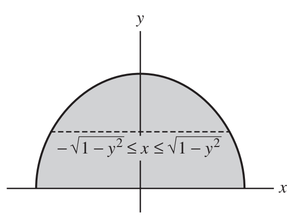
We use the formula with $f(x) = \frac{\sin x}{1-x}$. We get

$$\int_0^1 \int_0^y \frac{\sin x}{1-x}\,dx\,dy = \int_0^1 (1-x)\cdot\frac{\sin x}{1-x}\,dx = \int_0^1 \sin x\,dx = -\cos x\Big|_0^1 = 1 - \cos 1$$

22. Rewrite $\int_0^1 \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} \frac{y\,dx\,dy}{(1+x^2+y^2)^2}$ by interchanging the order of integration, and evaluate.

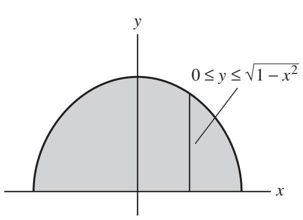
SOLUTION This integral gets simpler if we change the order of integration. We first identify the region $\mathcal{D}$ by the limits of integration. That is,

$$\mathcal{D}:\ 0 \le y \le 1,\ -\sqrt{1-y^2} \le x \le \sqrt{1-y^2}$$



The semicircle $x^2 + y^2 = 1$, $y \ge 0$ can be rewritten as $y = \sqrt{1-x^2}$. The inequalities describing $\mathcal{D}$ as a vertically simple region are thus

$$\mathcal{D}:\ -1 \le x \le 1,\ 0 \le y \le \sqrt{1-x^2}$$



We obtain the following iterated integral:

$$\iint_{\mathcal{D}} \frac{y}{(1+x^2+y^2)^2}\,dx\,dy = \int_{-1}^{1} \int_0^{\sqrt{1-x^2}} \frac{y}{(1+x^2+y^2)^2}\,dy\,dx \qquad (1)$$

We compute the inner integral with respect to y, using the substitution $u = 1 + x^2 + y^2$, $du = 2y\,dy$ (x is considered as a constant). This gives

$$\int_0^{\sqrt{1-x^2}} \frac{y\,dy}{(1+x^2+y^2)^2} = \int_{1+x^2}^{2} \frac{\frac{1}{2}\,du}{u^2} = -\frac{1}{2u}\Big|_{1+x^2}^{2} = -\frac{1}{4} + \frac{1}{2(1+x^2)}$$

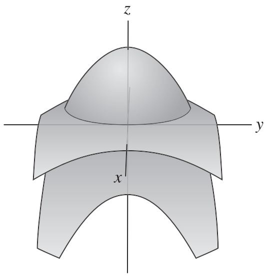
We compute the outer integral in (1):

$$\iint_{\mathcal{D}} \frac{y}{(1+x^2+y^2)}\,dx\,dy = \int_{-1}^{1}\left(-\frac{1}{4}+\frac{1}{2(1+x^2)}\right)dx = \int_0^1\left(-\frac{1}{2}+\frac{1}{1+x^2}\right)dx$$

$$= -\frac{x}{2}+\tan^{-1}x\Big|_0^1 = \left(-\frac{1}{2}+\tan^{-1}1\right)-0 = -\frac{1}{2}+\frac{\pi}{4} = \frac{\pi}{4}-\frac{1}{2}$$

23. Use cylindrical coordinates to compute the volume of the region defined by $4-x^2-y^2 \le z \le 10-4x^2-4y^2$.

SOLUTION



We first find the projection of $\mathcal{W}$ onto the xy-plane. The intersection curve of the upper and lower boundaries of $\mathcal{W}$ is obtained by solving

$$10-4x^2-4y^2 = 4-x^2-y^2$$
$$6 = 3(x^2+y^2) \quad\Rightarrow\quad x^2+y^2=2$$

Therefore, the projection of $\mathcal{W}$ onto the xy-plane is the circle $x^2+y^2 \le 2$. The upper surface is $z = 10-4(x^2+y^2)$ or $z = 10-4r^2$ and the lower surface is $z = 4-(x^2+y^2) = 4-r^2$. Therefore, the inequalities for $\mathcal{W}$ in cylindrical coordinates are

$$0 \le \theta \le 2\pi, \quad 0 \le r \le \sqrt{2}, \quad 4-r^2 \le z \le 10-4r^2$$

We use the volume as a triple integral and change of variables in cylindrical coordinates to write

$$V = \text{Volume}(\mathcal{W}) = \iiint_{\mathcal{W}} 1\,dV = \int_0^{2\pi}\int_0^{\sqrt{2}}\int_{4-r^2}^{10-4r^2} r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^{\sqrt{2}} rz\Big|_{z=4-r^2}^{10-4r^2} dr\,d\theta$$

$$= \int_0^{2\pi}\int_0^{\sqrt{2}} r\left(10-4r^2-\left(4-r^2\right)\right)dr\,d\theta = \int_0^{2\pi}\int_0^{\sqrt{2}}\left(6r-3r^3\right)dr\,d\theta$$

$$= \int_0^{2\pi} 3r^2-\frac{3}{4}r^4\Big|_{r=0}^{\sqrt{2}} d\theta = \int_0^{2\pi}(6-3)\,d\theta = 6\pi$$

24. Evaluate $\iint_{\mathcal{D}} x\,dA$, where $\mathcal{D}$ is the shaded domain in Figure 2.

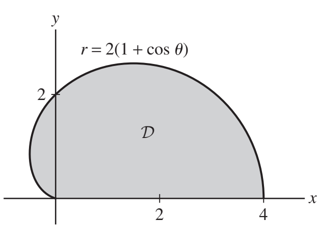


FIGURE 2

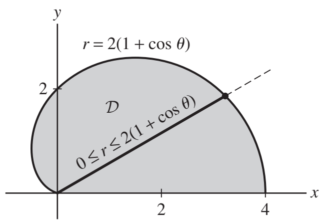
SOLUTION The domain $\mathcal{D}$ is defined by the inequalities

$$0 \le \theta \le \pi, \quad 0 \le r \le 2(1+\cos\theta).$$

Notice that the value of θ at the origin is found by solving $r = 2(1+\cos\theta) = 0$ for $0 \le \theta \le 2\pi$, that is, $\theta = \pi$.

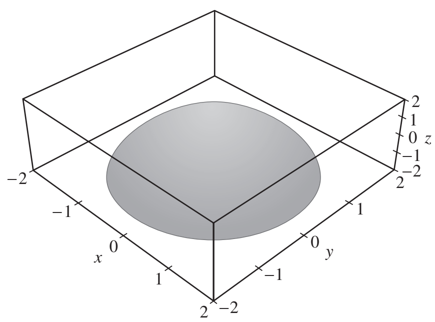


Using Double Integral in Polar Coordinates gives

$$\int_{\mathcal{D}} x\,dA = \int_0^{\pi}\int_0^{2(1+\cos\theta)} r\cos\theta\cdot r\,dr\,d\theta = \int_0^{\pi}\int_0^{2(1+\cos\theta)} r^2\cos\theta\,dr\,d\theta$$
$$= \int_0^{\pi} \frac{r^3\cos\theta}{3}\Big|_{r=0}^{2(1+\cos\theta)} d\theta = \int_0^{\pi}\frac{8(1+\cos\theta)^3\cos\theta}{3}\,d\theta$$
$$= \int_0^{\pi}\frac{8}{3}(\cos\theta + 3\cos^2\theta + 3\cos^3\theta + \cos^4\theta)\,d\theta$$
$$= \frac{8}{3}\int_0^{\pi}\cos\theta\,d\theta + 8\int_0^{\pi}\cos^2\theta\,d\theta + 8\int_0^{\pi}\cos^3\theta\,d\theta + \frac{8}{3}\int_0^{\pi}\cos^4\theta\,d\theta = 5\pi$$

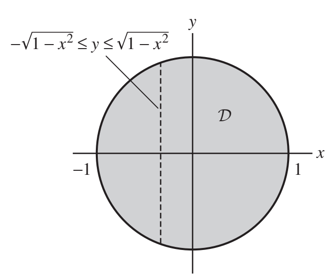
25. Find the volume of the region between the graph of the function $f(x, y) = 1 - (x^2 + y^2)$ and the xy-plane.

SOLUTION



The intersection of the surface $z = 1 - (x^2 + y^2)$ with the xy-plane is obtained by setting $z = 0$. That is, $1 - (x^2 + y^2) = 0$ or $x^2 + y^2 = 1$. Therefore, the projection of the solid onto the xy-plane is the disk $x^2 + y^2 \le 1$. We describe the disk as a vertically simple region:

$$\mathcal{D}:\ -1 \le x \le 1,\ -\sqrt{1-x^2} \le y \le \sqrt{1-x^2}$$



The volume V is the double integral of $z = 1 - (x^2 + y^2)$ over $\mathcal{D}$. That is,

$$V = \iint_{\mathcal{D}} \left(1 - (x^2 + y^2)\right) dA = \int_0^{2\pi}\int_0^1 (1 - r^2)\,r\,dr\,d\theta = 2\pi\int_0^1 (r - r^3)\,dr = \pi/2$$

26. Evaluate $\int_0^3\int_1^4\int_2^4 (x^3 + y^2 + z)\,dx\,dy\,dz$.

SOLUTION We evaluate to obtain

$$\int_0^3\int_1^4\int_2^4 (x^3 + y^2 + z)\,dx\,dy\,dz = \int_0^3\int_1^4 \left(\frac{x^4}{4} + y^2x + zx\right)\Big|_{x=2}^4 dy\,dz$$

$$= \int_0^3 \int_1^4 \left(\left(\frac{4^4}{4} + 4y^2 + 4z \right) - \left(\frac{16}{4} + 2y^2 + 2z \right) \right) dy\, dz$$

$$= \int_0^3 \int_1^4 \left(60 + 2y^2 + 2z\right) dy\, dz = \int_0^3 60y + \frac{2}{3}y^3 + 2yz \Big|_{y=1}^{4} dz$$

$$= \int_0^3 \left(240 + \frac{128}{3} + 8z\right) - \left(60 + \frac{2}{3} + 2z\right) dz$$

$$= \int_0^3 222 + 6z\, dz = 222z + 3z^2 \Big|_0^3 = 666 + 27 = 693$$

27. Calculate $\iiint_{\mathcal{B}} (xy + z)\, dV$, where

$$\mathcal{B} = \left\{0 \le x \le 2,\ 0 \le y \le 1,\ 1 \le z \le 3\right\}$$

as an iterated integral in two different ways.

SOLUTION The triple integral over the box may be evaluated in any order. For instance,

$$\iiint_{\mathcal{B}} (xy + z)\, dV = \int_0^2 \int_0^1 \int_1^3 (xy + z)\, dz\, dy\, dx = \int_0^1 \int_0^2 \int_1^3 (xy + z)\, dz\, dx\, dy$$
$$= \int_1^3 \int_0^2 \int_0^1 (xy + z)\, dy\, dx\, dz$$

We compute the integral in two of the possible orders:

$$\iiint_{\mathcal{B}} (xy + z)\, dV = \int_0^2 \int_0^1 \int_1^3 (xy + z)\, dz\, dy\, dx = \int_0^2 \int_0^1 xyz + \frac{z^2}{2} \Big|_{z=1}^{3} dy\, dx$$

$$= \int_0^2 \int_0^1 \left(\left(3xy + \frac{9}{2}\right) - \left(xy + \frac{1}{2}\right) \right) dy\, dx = \int_0^2 \int_0^1 (2xy + 4)\, dy\, dx$$

$$= \int_0^2 xy^2 + 4y \Big|_{y=0}^{1} dx = \int_0^2 (x + 4)\, dx = \frac{x^2}{2} + 4x \Big|_0^2 = \frac{4}{2} + 8 = 10$$

$$\iiint_{\mathcal{B}} (xy + z)\, dV = \int_0^1 \int_0^2 \int_1^3 (xy + z)\, dz\, dx\, dy = \int_0^1 \int_0^2 xyz + \frac{z^2}{2} \Big|_{z=1}^{3} dx\, dy$$

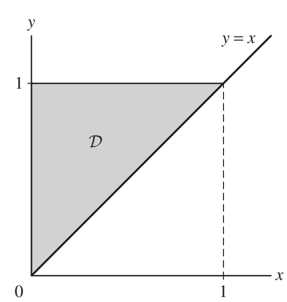
$$= \int_0^1 \int_0^2 \left(\left(3xy + \frac{9}{2}\right) - \left(xy + \frac{1}{2}\right) \right) dx\, dy = \int_0^1 \int_0^2 (2xy + 4)\, dx\, dy$$

$$= \int_0^1 x^2 y + 4x \Big|_{x=0}^{2} dy = \int_0^1 (4y + 8)\, dy = 2y^2 + 8y \Big|_0^1 = 2 + 8 = 10$$

28. Calculate $\iiint_{\mathcal{W}} xyz\, dV$, where

$$\mathcal{W} = \left\{0 \le x \le 1,\ x \le y \le 1,\ x \le z \le x + y\right\}$$

SOLUTION



$\mathcal{W}$ is the region between the two planes $z = x$ and $z = x + y$ lying over the triangle $\mathcal{D}$, defined by $0 \le x \le 1, x \le y \le 1$. Therefore, the triple integral is equal to the following iterated integral:

$$\iiint_{\mathcal{W}} xyz\,dV = \int_0^1 \int_x^1 \int_x^{x+y} xyz\,dz\,dy\,dx = \int_0^1 \int_x^1 \frac{xyz^2}{2}\bigg|_{z=x}^{x+y} dy\,dx = \int_0^1 \int_x^1 \left(\frac{xy}{2}\right)\left((x+y)^2 - x^2\right) dy\,dx$$

$$= \int_0^1 \int_x^1 \left(x^2y^2 + \frac{xy^3}{2}\right) dy\,dx = \int_0^1 \frac{x^2y^3}{3} + \frac{xy^4}{8}\bigg|_{y=x}^{1} dx$$

$$= \int_0^1 \left(\frac{x^2}{3} + \frac{x}{8} - \left(\frac{x^5}{3} + \frac{x^5}{8}\right)\right) dx = \int_0^1 \left(-\frac{11x^5}{24} + \frac{x^2}{3} + \frac{x}{8}\right) dx$$

$$= \frac{-11x^6}{144} + \frac{x^3}{9} + \frac{x^2}{16}\bigg|_0^1 = -\frac{11}{144} + \frac{1}{9} + \frac{1}{16} = \frac{7}{72}$$

29. Evaluate $I = \int_{-1}^1 \int_0^{\sqrt{1-x^2}} \int_0^1 (x + y + z)\,dz\,dy\,dx$.

SOLUTION We compute the triple integral:

$$I_1 = \int_{-1}^1 \int_0^{\sqrt{1-x^2}} \int_0^1 (x+y+z)\,dz\,dy\,dx = \int_{-1}^1 \int_0^{\sqrt{1-x^2}} (x+y)z + \frac{z^2}{2}\bigg|_{y=0}^{1} dy\,dx$$

$$= \int_{-1}^1 \int_0^{\sqrt{1-x^2}} \left(x + y + \frac{1}{2}\right) dy\,dx = \int_{-1}^1 \left(x + \frac{1}{2}\right) y + \frac{y^2}{2}\bigg|_{y=0}^{\sqrt{1-x^2}} dx$$

$$= \int_{-1}^1 \left(x + \frac{1}{2}\right)\sqrt{1-x^2} + \frac{1-x^2}{2}\,dx = \int_{-1}^1 x\sqrt{1-x^2}\,dx + \int_{-1}^1 \frac{1}{2}\sqrt{1-x^2}\,dx + \int_{-1}^1 \frac{1-x^2}{2}\,dx \qquad (1)$$

The first integral is zero since the integrand is an odd function. Therefore, using Integration Formulas we get

$$I_1 = \int_0^1 \sqrt{1-x^2}\,dx + \int_0^1 (1-x^2)\,dx = \frac{x}{2}\sqrt{1-x^2} + \frac{1}{2}\sin^{-1} x\bigg|_0^1 + \left(x - \frac{x^3}{3}\right)\bigg|_0^1$$

$$= \frac{1}{2}\sin^{-1} 1 + \frac{2}{3} = \frac{\pi}{4} + \frac{2}{3}$$

30. Describe a region whose volume is equal to:

(a) $\int_0^{2\pi} \int_0^{\pi/2} \int_4^9 \rho^2 \sin\phi\,d\rho\,d\phi\,d\theta$

(b) $\int_{-2}^1 \int_{\pi/3}^{\pi/4} \int_0^2 r\,dr\,d\theta\,dz$

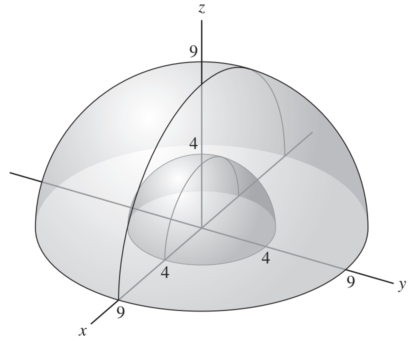
(c) $\int_0^{2\pi} \int_0^3 \int_{-\sqrt{9-r^2}}^0 r\,dz\,dr\,d\theta$

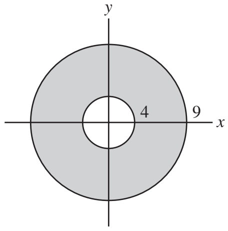
SOLUTION

(a) The limits of integration correspond to the inequalities in spherical coordinates, describing the region

$$4 \le \rho \le 9, \quad 0 \le \phi \le \frac{\pi}{2}, \quad 0 \le \theta \le 2\pi$$

This is, the region between the upper hemispheres of radii 4 and 9.

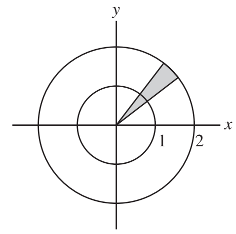




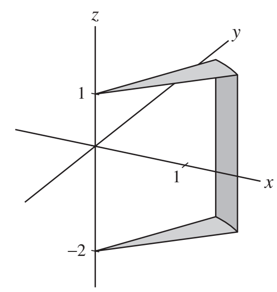
(b) The limits of integration correspond to the inequalities in cylindrical coordinates, describing the region $\mathcal{W}$:

$$0 \le r \le 2, \quad \frac{\pi}{4} \le \theta \le \frac{\pi}{3}, \quad -2 \le z \le 1.$$

The projection of $\mathcal{W}$ onto the xy-plane is the sector $\mathcal{D}$ shown in the figure.



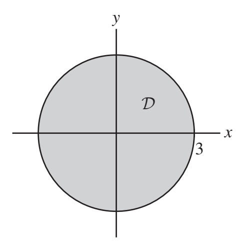
$\mathcal{W}$ is the region above and below $\mathcal{D}$, which is between the planes $z = -2$ and $z = 1$.



(c) The limits of integration correspond to the inequalities in cylindrical coordinates, describing the region $\mathcal{W}$,

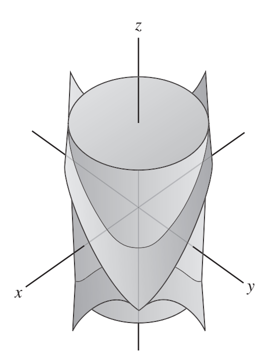
$$0 \le \theta \le 2\pi, \quad 0 \le r \le 3, \quad -\sqrt{9 - r^2} \le z \le 0.$$

The projection $\mathcal{D}$ of $\mathcal{W}$ onto the (x, y)-plane is the disk of radius 3. The lower surface is $z = -\sqrt{9 - r^2} = -\sqrt{9 - (x^2 + y^2)}$, which is the lower hemisphere $x^2 + y^2 + z^2 = 9$. Therefore, $\mathcal{W}$ is the lower half of the ball of radius 3 centered at the origin.



31. Find the volume of the solid contained in the cylinder $x^2 + y^2 = 1$ below the curve $z = (x + y)^2$ and above the curve $z = -(x - y)^2$.

SOLUTION



We rewrite the equations of the surfaces using cylindrical coordinates:

$$z = (x + y)^2 = x^2 + y^2 + 2xy = r^2 + 2(r\cos\theta)(r\sin\theta) = r^2(1 + \sin 2\theta)$$
$$z = -(x - y)^2 = -(x^2 + y^2 - 2xy) = -(r^2 - 2r^2\cos\theta\sin\theta) = -r^2(1 - \sin 2\theta)$$

The projection of the solid onto the xy-plane is the unit disk. Therefore, the solid is described by the following inequalities:

$$\mathcal{W}: \ 0 \le \theta \le 2\pi, \ 0 \le r \le 1, \ -r^2(1-\sin 2\theta) \le z \le r^2(1+\sin 2\theta)$$

Expressing the volume as a triple integral and converting the triple integral to cylindrical coordinates, we get

$$\begin{aligned}
V = \text{Volume}(\mathcal{W}) &= \iiint_{\mathcal{W}} 1\,dv = \int_0^{2\pi}\int_0^1 \int_{-r^2(1-\sin 2\theta)}^{r^2(1+\sin 2\theta)} r\,dz\,dr\,d\theta \\
&= \int_0^{2\pi}\int_0^1 rz\Big|_{z=-r^2(1-\sin 2\theta)}^{r^2(1+\sin 2\theta)} dr\,d\theta = \int_0^{2\pi}\int_0^1 r\left(r^2(1+\sin 2\theta)+r^2(1-\sin 2\theta)\right) dr\,d\theta \\
&= \int_0^{2\pi}\int_0^1 r^3\cdot 2\,dr\,d\theta = \left(\int_0^{2\pi} 2d\theta\right)\left(\int_0^1 r^3\,dr\right) = 4\pi\cdot\frac{r^4}{4}\Big|_0^1 = \pi
\end{aligned}$$

32. Use polar coordinates to evaluate $\iint_{\mathcal{D}} x\,dA$, where $\mathcal{D}$ is the shaded region between the two circles of radius 1 in Figure 3.

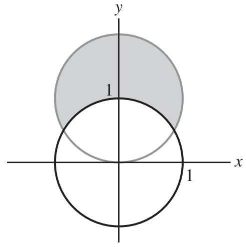


FIGURE 3

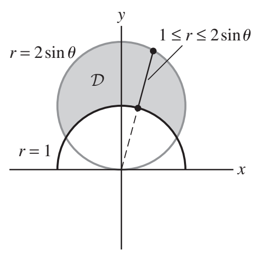
SOLUTION



To describe $\mathcal{D}$ in polar coordinates, we first find the polar equations of the circles.

- $x^2 + y^2 = 1$: $r = 1$
- $x^2 + (y-1)^2 = 1$:

$$\begin{aligned}
1 &= (r\cos\theta)^2 + (r\sin\theta - 1)^2 = r^2\cos^2\theta + r^2\sin^2\theta - 2r\sin\theta + 1 \\
&= r^2(\cos^2\theta + \sin^2\theta) - 2r\sin\theta + 1 = r^2 - 2r\sin\theta + 1
\end{aligned}$$

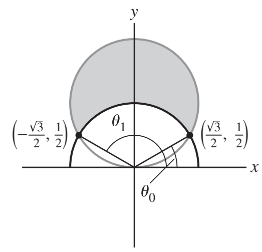
or

$$r^2 - 2r\sin\theta = 0 \quad \Rightarrow \quad r^2 = 2r\sin\theta \quad \Rightarrow \quad r = 2\sin\theta$$

To find the interval for θ, we notice that the two circles intersect at the points $\left(\frac{\sqrt{3}}{2}, \frac{1}{2}\right)$ and $\left(-\frac{\sqrt{3}}{2}, \frac{1}{2}\right)$. Hence,

$$\theta_0 = \tan^{-1}\frac{\frac{1}{2}}{\frac{\sqrt{3}}{2}} = \tan^{-1}\frac{1}{\sqrt{3}} = \frac{\pi}{6}$$

$$\theta_1 = \pi - \frac{\pi}{6} = \frac{5\pi}{6}$$



We are now able to write the polar inequalities for $\mathcal{D}$:

$$\mathcal{D}: \frac{\pi}{6} \le \theta \le \frac{5\pi}{6},\ 1 \le r \le 2\sin\theta$$

The function is $x = r\cos\theta$. Converting to polar coordinates, we get

$$\iint_{\mathcal{D}} x\,dA = \int_{\pi/6}^{5\pi/6} \int_1^{2\sin\theta} (r\cos\theta) r\,dr\,d\theta = \int_{\pi/6}^{5\pi/6} \int_1^{2\sin\theta} r^2\cos\theta\,dr\,d\theta = \int_{\pi/6}^{5\pi/6} \frac{r^3\cos\theta}{3}\bigg|_{r=1}^{2\sin\theta} d\theta$$
$$= \int_{\pi/6}^{5\pi/6} \frac{8\sin^3\theta\cos\theta - \cos\theta}{3}\,d\theta = \frac{8}{3}\int_{\pi/6}^{5\pi/6} \sin^3\theta\cos\theta\,d\theta - \frac{1}{3}\int_{\pi/6}^{5\pi/6} \cos\theta\,d\theta$$
$$= \frac{8}{3}\int_{\pi/6}^{5\pi/6} \sin^3\theta\cos\theta\,d\theta - \frac{1}{3}\sin\theta\bigg|_{\theta=\frac{\pi}{6}}^{5\pi/6} = \frac{8}{3}\int_{\pi/6}^{5\pi/6} \sin^3\theta\cos\theta\,d\theta$$

We use Integration Formulas to obtain

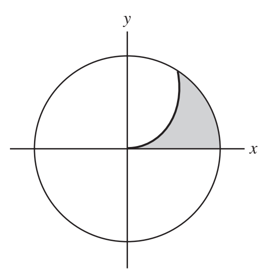
$$\iint_{\mathcal{D}} x\,dA = \frac{8}{3}\frac{\sin^4\theta}{4}\bigg|_{\pi/6}^{5\pi/6} = \frac{8}{12}\left(\left(\frac{1}{2}\right)^4 - \left(\frac{1}{2}\right)^4\right) = 0$$

Notice that since the region $\mathcal{D}$ is symmetric with respect to the y-axis, we expect the integral $\iint_{\mathcal{D}} x\,dA$ to be zero.

33. Use polar coordinates to calculate $\iint_{\mathcal{D}} \sqrt{x^2+y^2}\,dA$, where $\mathcal{D}$ is the region in the first quadrant bounded by the spiral $r = \theta$, the circle $r = 1$, and the x-axis.

SOLUTION The region of integration, shown in the figure, has the following description in polar coordinates:

$$\mathcal{D}:\ 0 \le \theta \le 1,\ \theta \le r \le 1$$



The function is $f(x, y) = \sqrt{x^2+y^2} = r$. We convert the double integral to polar coordinates and compute to obtain

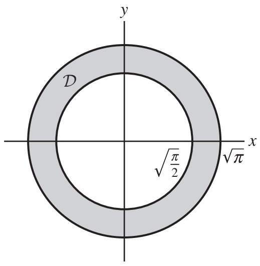
$$\iint_{\mathcal{D}} \sqrt{x^2+y^2}\,dA = \int_0^1 \int_\theta^1 r \cdot r\,dr\,d\theta = \int_0^1 \int_\theta^1 r^2\,dr\,d\theta = \int_0^1 \frac{r^3}{3}\bigg|_{r=\theta}^1 d\theta$$
$$= \int_0^1 \left(\frac{1}{3} - \frac{\theta^3}{3}\right) d\theta = \frac{\theta}{3} - \frac{\theta^4}{12}\bigg|_0^1 = \frac{1}{3} - \frac{1}{12} = \frac{1}{4}$$

34. Calculate $\iint_{\mathcal{D}} \sin(x^2+y^2)\,dA$, where

$$\mathcal{D} = \left\{\frac{\pi}{2} \le x^2+y^2 \le \pi\right\}$$

SOLUTION The annulus $\mathcal{D}$ is defined by the following inequalities in polar coordinates:

$$\mathcal{D}:\ 0 \le \theta \le 2\pi,\ \sqrt{\frac{\pi}{2}} \le r \le \sqrt{\pi}$$



The function in polar coordinates is $f(x, y) = \sin(x^2 + y^2) = \sin(r^2)$. We convert the double integral to polar coordinates and evaluate to obtain

$$\iint_{\mathcal{D}} \sin(x^2 + y^2)\,dA = \int_0^{2\pi} \int_{\sqrt{\frac{\pi}{2}}}^{\sqrt{\pi}} \sin(r^2) r\,dr\,d\theta = \left(\int_0^{2\pi} d\theta\right)\left(\int_{\sqrt{\frac{\pi}{2}}}^{\sqrt{\pi}} \sin(r^2) r\,dr\right)$$
$$= 2\pi \int_{\sqrt{\frac{\pi}{2}}}^{\sqrt{\pi}} \sin(r^2) r\,dr$$

We evaluate the integral using the substitution $u = r^2$, $du = 2r\,dr$:

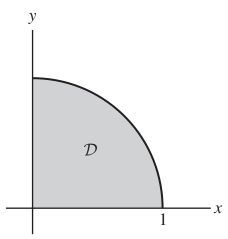
$$\iint_{\mathcal{D}} \sin(x^2 + y^2)\,dA = 2\pi \int_{\pi/2}^{\pi} \sin u \cdot \frac{du}{2} = \pi(-\cos u)\Big|_{u=\pi/2}^{\pi} = \pi(1 + 0) = \pi$$

35. Express in cylindrical coordinates and evaluate:

$$\int_0^1 \int_0^{\sqrt{1-x^2}} \int_0^{\sqrt{x^2+y^2}} z\,dz\,dy\,dx$$

SOLUTION We evaluate the integral by converting it to cylindrical coordinates. The projection of the region of integration onto the xy-plane, as defined by the limits of integration, is

$$\mathcal{D}:\ 0 \le x \le 1,\ 0 \le y \le \sqrt{1 - x^2}$$



That is, $\mathcal{D}$ is the part of the disk $x^2 + y^2 \le 1$ in the first quadrant. The inequalities defining $\mathcal{D}$ in polar coordinates are

$$\mathcal{D}:\ 0 \le \theta \le \frac{\pi}{2},\ 0 \le r \le 1$$

The upper surface is $z = \sqrt{x^2 + y^2} = r$ and the lower surface is $z = 0$. Therefore, the inequalities defining the region of integration in cylindrical coordinates are

$$\mathcal{W}:\ 0 \le \theta \le \frac{\pi}{2},\ 0 \le r \le 1,\ 0 \le z \le r$$

Converting the double integral to cylindrical coordinates gives

$$I = \int_0^{\pi/2} \int_0^1 \int_0^r zr\,dz\,dr\,d\theta = \int_0^{\pi/2} \int_0^1 \frac{z^2 r}{2}\Big|_{z=0}^{r} dr\,d\theta = \int_0^{\pi/2} \int_0^1 \frac{r^3}{2}\,dr\,d\theta$$
$$= \left(\int_0^{\pi/2} d\theta\right)\left(\int_0^1 \frac{r^3}{2}\,dr\right) = \frac{\pi}{2} \cdot \frac{r^4}{8}\Big|_0^1 = \frac{\pi}{16}$$

36. Use spherical coordinates to calculate the triple integral of $f(x, y, z) = x^2 + y^2 + z^2$ over the region

$$1 \le x^2 + y^2 + z^2 \le 4$$

SOLUTION The region of integration is the region enclosed by the spheres $x^2 + y^2 + z^2 = 1$ or $\rho = 1$, and $x^2 + y^2 + z^2 = 4$ or $\rho = 2$. In this region, θ is changing between 0 and 2π, and ϕ is changing between 0 and π. Therefore, $\mathcal{W}$ is described by the following inequalities:

$$\mathcal{W}: \ 0 \le \theta \le 2\pi, \ 0 \le \phi \le \pi, \ 1 \le \rho \le 2$$

The function is $f(x, y, z) = x^2 + y^2 + z^2 = \rho^2$. Using triple integrals in spherical coordinates we get

$$\begin{aligned}\iiint_{\mathcal{W}} (x^2 + y^2 + z^2)\, dV &= \int_0^{2\pi} \int_0^{\pi} \int_1^2 \rho^2 \cdot \rho^2 \sin\phi \, d\rho\, d\phi\, d\theta = \int_0^{2\pi} \int_0^{\pi} \int_1^2 \rho^4 \sin\phi \, d\rho\, d\phi\, d\theta \\ &= \left(\int_0^{2\pi} d\theta\right)\left(\int_0^{\pi} \sin\phi\right)\left(\int_1^2 \rho^4 d\rho\right) = 2\pi \cdot (-\cos\phi)\Big|_0^{\pi} \cdot \left(\frac{\rho^5}{5}\Big|_1^2\right) \\ &= 2\pi \cdot 2 \cdot \frac{(2^5 - 1)}{5} = \frac{124\pi}{5}\end{aligned}$$

37. Convert to spherical coordinates and evaluate:

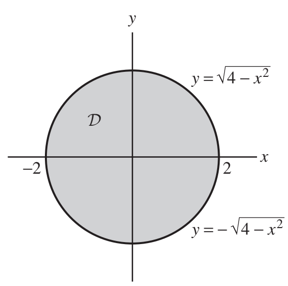
$$\int_{-2}^{2} \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} \int_0^{\sqrt{4-x^2-y^2}} e^{-(x^2+y^2+z^2)^{3/2}} \, dz\, dy\, dx$$

SOLUTION The region of integration as defined by the limits of integration is

$$\mathcal{W}: \ -2 \le x \le 2, \ -\sqrt{4 - x^2} \le y \le \sqrt{4 - x^2}, \ 0 \le z \le \sqrt{4 - x^2 - y^2}$$

That is, $\mathcal{W}$ is the region enclosed by the sphere $x^2 + y^2 + z^2 = 4$ and the xy-plane. We see that the region of integration is the upper half-ball $x^2 + y^2 + z^2 \le 4$, hence the inequalities defining $\mathcal{W}$ in spherical coordinates are

$$\mathcal{W}: \ 0 \le \theta \le 2\pi, \ 0 \le \phi \le \frac{\pi}{2}, \ 0 \le \rho \le 2$$



The function is $f(x, y, z) = e^{-(x^2+y^2+z^2)^{3/2}} = e^{-(\rho^2)^{3/2}} = e^{-\rho^3}$, therefore the integral in spherical coordinates is

$$\begin{aligned} I &= \int_0^{2\pi} \int_0^{\pi/2} \int_0^2 e^{-\rho^3} \rho^2 \sin\phi \, d\rho\, d\phi\, d\theta = \left(\int_0^{2\pi} d\theta\right)\left(\int_0^{\pi/2} \sin\phi \, d\phi\right)\left(\int_0^2 e^{-\rho^3} \rho^2 d\rho\right) \\ &= 2\pi \left(-\cos\phi \Big|_0^{\pi/2}\right) \int_0^2 e^{-\rho^3} \rho^2 d\rho = 2\pi \int_0^2 e^{-\rho^3} \rho^2 d\rho \end{aligned}$$

We compute the integral using the substitution $u = \rho^3$, $du = 3\rho^2 d\rho$. We get

$$I = 2\pi \int_0^8 e^{-u} \frac{du}{3} = \frac{2\pi}{3} (-e^{-u}) \Big|_0^8 = \frac{2\pi}{3} (-e^{-8} + 1) = \frac{2\pi \left(-1 + e^8\right)}{3e^8}$$

38. Find the average value of $f(x, y, z) = xy^2z^3$ on the box $[0, 1] \times [0, 2] \times [0, 3]$.

SOLUTION The volume of the box is $V = 1 \cdot 2 \cdot 3 = 6$, hence the average value of $f(x, y, z) = xy^2z^3$ on the box $\mathcal{B}$ is

$$\overline{f} = \frac{1}{V}\iiint_{\mathcal{B}} f(x, y, z)\, dV = \frac{1}{6}\int_0^1 \int_0^2 \int_0^3 xy^2z^3\, dz\, dy\, dx = \frac{1}{6}\left(\int_0^1 x\, dx\right)\left(\int_0^2 y^2\, dy\right)\left(\int_0^3 z^3\, dz\right)$$

$$= \frac{1}{6} \cdot \left(\frac{x^2}{2}\bigg|_0^1\right)\left(\frac{y^3}{3}\bigg|_0^2\right)\left(\frac{z^4}{4}\bigg|_0^3\right) = \frac{1}{6} \cdot \frac{1}{2} \cdot \frac{8}{3} \cdot \frac{81}{4} = 4.5$$

39. Let $\mathcal{W}$ be the ball of radius R in $\mathbf{R}^3$ centered at the origin, and let $P = (0, 0, R)$ be the North Pole. Let $d_P(x, y, z)$ be the distance from P to (x, y, z). Show that the average value of d_P over the sphere $\mathcal{W}$ is equal to $\overline{d} = 6R/5$. *Hint:* Show that

$$\overline{d} = \frac{1}{\frac{4}{3}\pi R^3}\int_{\theta=0}^{2\pi}\int_{\rho=0}^{R}\int_{\phi=0}^{\pi} \rho^2 \sin\phi\sqrt{R^2 + \rho^2 - 2\rho R\cos\phi}\, d\phi\, d\rho\, d\theta$$

and evaluate.

SOLUTION We know that the volume of the ball is $\frac{4}{3}\pi R^3$.

In spherical coordinates, the distance from P to a point on the ball is

$$\begin{aligned}
\sqrt{(x-0)^2 + (y-0)^2 + (z-R)^2} &= \sqrt{\rho^2\sin^2\phi\cos^2\theta + \rho^2\sin^2\phi\sin^2\theta + (\rho\cos\phi - R)^2} \\
&= \sqrt{\rho^2\sin^2\phi(\cos^2\theta + \sin^2\theta) + \rho^2\cos^2\phi - 2\rho R\cos\phi + R^2} \\
&= \sqrt{\rho^2\sin^2\phi + \rho^2\cos^2\phi - 2\rho R\cos\phi + R^2} \\
&= \sqrt{\rho^2(\sin^2\phi + \cos^2\phi) - 2\rho R\cos\phi + R^2} \\
&= \sqrt{R^2 + \rho^2 - 2\rho R\cos\phi}
\end{aligned}$$

Now, to write the average value of d_P we have:

$$d_P = \frac{1}{\frac{4}{3}\pi R^3}\int_{\theta=0}^{2\pi}\int_{\rho=0}^{R}\int_{\phi=0}^{\pi} \rho^2 \sin\phi\sqrt{R^2 + \rho^2 - 2\rho R\cos\phi}\, d\phi\, d\rho\, d\theta$$

Using substitution, and the fact that $0 \le \rho \le R$,

$$\begin{aligned}
\int_{\phi=0}^{\pi} \sin\phi\sqrt{R^2 + \rho^2 - 2\rho R\cos\phi}\, d\phi &= \frac{2\rho}{3R}(R^2 + \rho^2 - 2\rho R\cos\phi)^{3/2}\bigg|_0^{\pi} \\
&= \frac{2\rho}{3R}\Big((R + \rho^3) - (R - \rho)^3\Big) = \frac{2\rho}{3R}(\rho^3 + 3R^2\rho)
\end{aligned}$$

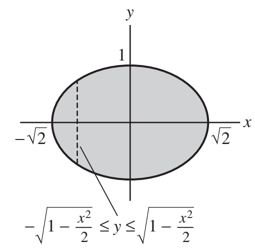
Now integrate with respect to θ and ρ:

$$\begin{aligned}
d_P &= \frac{1}{\frac{4}{3}\pi R^3}\int_0^{2\pi}\int_0^{R} \rho^2 \cdot \frac{2\rho}{3R}(\rho^3 + 3R^2\rho)\, d\rho\, d\theta \\
&= \frac{3}{4\pi R^3} \cdot \frac{2}{3R}\int_0^{2\pi}\int_0^{R} \rho^3(\rho^3 + 3R^2\rho)\, d\rho\, d\theta \\
&= \frac{1}{2\pi R^4}\int_0^{2\pi}\int_0^{R} \rho^6 + 3R^2\rho^4\, d\rho\, d\theta \\
&= \frac{1}{2\pi R^4}\int_0^{2\pi} \frac{1}{7}\rho^7 + \frac{3}{5}R^2\rho^5\bigg|_0^{R} d\theta \\
&= \frac{1}{2\pi R^4}\int_0^{2\pi} \frac{1}{7}R^7 + \frac{3}{5}R^7\, d\theta \\
&= \frac{1}{2\pi R^4}\left(\frac{26}{35}R^7\right) \cdot 2\pi = \frac{26}{35}R^3
\end{aligned}$$

to get $8\pi R^4/5$. Dividing by the volume of the sphere gives us $6R/5$

40. CAS Express the average value of $f(x, y) = e^{xy}$ over the ellipse $\frac{x^2}{2} + y^2 = 1$ as an iterated integral, and evaluate numerically using a computer algebra system.

SOLUTION



The area of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ is πab, hence the area of the given ellipse is

$$\text{Area}(\mathcal{D}) = \pi \cdot \sqrt{2} \cdot 1 = \pi\sqrt{2}$$

The average value of $f(x, y) = e^{xy}$ inside the ellipse is

$$\overline{f} = \frac{1}{\pi\sqrt{2}} \iint_{\mathcal{D}} e^{xy}\, dA \tag{1}$$

$\mathcal{D}$ is described as a vertically simple region by the inequalities

$$\mathcal{D}: \; -\sqrt{2} \le x \le \sqrt{2}, \; -\sqrt{1-\frac{x^2}{2}} \le y \le \sqrt{1-\frac{x^2}{2}}$$

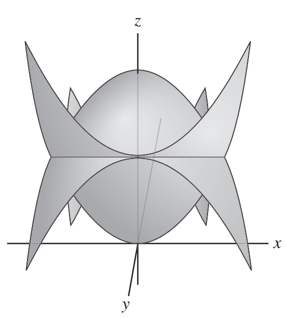
Therefore, the double integral (1) is equal to the following iterated integral, which we compute using a CAS:

$$\overline{f} = \frac{1}{\pi\sqrt{2}} \int_{-\sqrt{2}}^{\sqrt{2}} \int_{-\sqrt{1-\frac{x^2}{2}}}^{\sqrt{1-\frac{x^2}{2}}} e^{xy}\, dy\, dx \approx 1.0421$$

41. Use cylindrical coordinates to find the mass of the solid bounded by $z = 8 - x^2 - y^2$ and $z = x^2 + y^2$, assuming a mass density of $f(x, y, z) = (x^2 + y^2)^{1/2}$.

SOLUTION The mass of the solid $\mathcal{W}$ is the following integral:

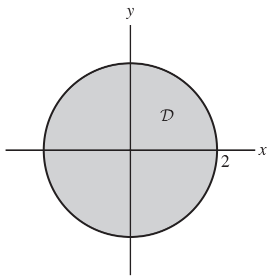
$$M = \iiint_{\mathcal{W}} \left(x^2 + y^2\right)^{1/2} dV$$



The projection of $\mathcal{W}$ on the xy-plane is obtained by equating the equations of the two surfaces:

$$\begin{aligned} 8 - x^2 - y^2 &= x^2 + y^2 \\ 2(x^2 + y^2) &= 8 \end{aligned} \quad \Rightarrow \quad x^2 + y^2 = 4$$

We conclude that the projection is the disk $\mathcal{D}: \; x^2 + y^2 \le 4$.



Therefore, $\mathcal{W}$ is described by

$$\mathcal{W}: x^2 + y^2 \le z \le 8 - (x^2 + y^2), \ (x, y) \in \mathcal{D}$$

Thus,

$$M = \iint_{\mathcal{D}} \int_{x^2+y^2}^{8-(x^2+y^2)} (x^2 + y^2)^{1/2} \, dz \, dx \, dy$$

We convert the integral to cylindrical coordinates. The inequalities for $\mathcal{W}$ are

$$0 \le r \le 2, \quad 0 \le \theta \le 2\pi, \quad r^2 \le z \le 8 - r^2.$$

Also, $(x^2 + y^2)^{1/2} = r$, hence we obtain the following integral:

$$M = \int_0^2 \int_0^{2\pi} \int_{r^2}^{8-r^2} r \cdot r \, dz \, d\theta \, dr = \int_0^2 \int_0^{2\pi} \int_{r^2}^{8-r^2} r^2 \, dz \, d\theta \, dr = \int_0^2 \int_0^{2\pi} r^2 z \Big|_{z=r^2}^{8-r^2} d\theta \, dr$$

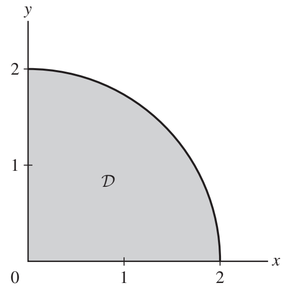
$$= \int_0^2 \int_0^{2\pi} r^2(8 - r^2 - r^2) \, d\theta \, dr = \int_0^2 \int_0^{2\pi} (8r^2 - 2r^4) \, d\theta \, dr = \left(\int_0^{2\pi} 1 \, d\theta \right) \left(\int_0^2 (8r^2 - 2r^4) \, dr \right)$$

$$= 2\pi \left(\frac{8r^3}{3} - \frac{2}{5} r^5 \Big|_0^2 \right) = \frac{256}{15}\pi \approx 53.62$$

42. Let $\mathcal{W}$ be the portion of the half-cylinder $x^2 + y^2 \le 4$, $x \ge 0$ such that $0 \le z \le 3y$. Use cylindrical coordinates to compute the mass of $\mathcal{W}$ if the mass density is $\rho(x, y, z) = z^2$.

SOLUTION Since $0 \le z \le 3y$, we have $y \ge 0$. Also $x \ge 0$, hence $\mathcal{W}$ projects onto the quarter circle $\mathcal{D}$ in the xy-plane of radius 2, where $x \ge 0$ and $y \ge 0$. In polar coordinates,

$$\mathcal{D}: 0 \le \theta \le \frac{\pi}{2}, \ 0 \le r \le 2$$



The upper boundary of $\mathcal{W}$ is the plane $z = 3y = 3r\sin\theta$ and the lower boundary is $z = 0$. Hence,

$$\mathcal{W}: 0 \le \theta \le \frac{\pi}{2}, \ 0 \le r \le 2, \ 0 \le z \le 3r\sin\theta$$

Using cylindrical coordinates, the total mass is the following integral:

$$M = \iiint_{\mathcal{W}} z^2 \, dv = \int_0^{\pi/2} \int_0^2 \int_0^{3r\sin\theta} z^2 r \, dz \, dr \, d\theta = \int_0^{\pi/2} \int_0^2 \frac{z^3 r}{3} \Big|_{z=0}^{3r\sin\theta} dr \, d\theta$$

$$= \int_0^{\pi/2} \int_0^2 \frac{r(3r\sin\theta)^3}{3} \, dr \, d\theta = \int_0^{\pi/2} \int_0^2 9r^4 \sin^3\theta \, dr \, d\theta$$

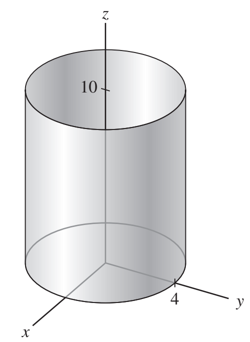
$$= \left(\int_0^{\pi/2} \sin^3\theta \, d\theta \right) \left(\int_0^2 9r^4 \, dr \right) = \left(\int_0^{\pi/2} \sin^3\theta \, d\theta \right) \frac{9r^5}{5} \Big|_{r=0}^2 = \frac{288}{5} \int_0^{\pi/2} \sin^3\theta \, d\theta$$

We compute the integral using an integration table to obtain

$$M = \frac{288}{5}\left(-\frac{\sin^2\theta\cos\theta}{3} - \frac{2}{3}\cos\theta\right)\Big|_{\theta=0}^{\pi/2} = \frac{288}{5}\left(0 - \left(-\frac{2}{3}\right)\right) = \frac{288}{5}\cdot\frac{2}{3} = 38.4$$

43. Use cylindrical coordinates to find the mass of a cylinder of radius 4 and height 10 if the mass density at a point is equal to the square of the distance from the cylinder's central axis.

SOLUTION

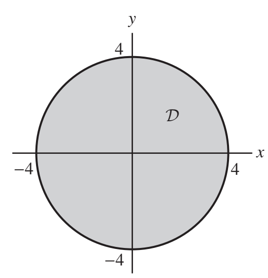


The mass density is $\rho(x, y, z) = x^2 + y^2 = r^2$, hence the mass of the cylinder is

$$M = \iiint_{\mathcal{W}} (x^2 + y^2)\, dV$$

The region $\mathcal{W}$ is described using cylindrical coordinates by the following inequalities:

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le 4,\ 0 \le z \le 10$$



Thus,

$$M = \iiint_{\mathcal{W}} (x^2 + y^2)\, dV = \int_0^{2\pi}\int_0^4\int_0^{10} r^2\cdot r\, dz\, dr\, d\theta = \int_0^{2\pi}\int_0^4\int_0^{10} r^3\, dz\, dr\, d\theta = \int_0^{2\pi}\int_0^4 r^3 z\Big|_{z=0}^{10} dr\, d\theta$$
$$= \int_0^{2\pi}\int_0^4 r^3\cdot 10\, dr\, d\theta = \int_0^{2\pi} \frac{10r^4}{4}\Big|_{r=0}^{4} d\theta = \int_0^{2\pi} 640\, d\theta = 640\cdot 2\pi = 1280\pi$$

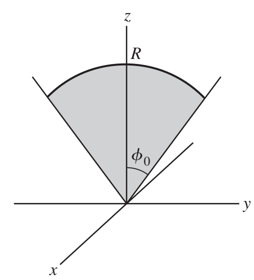
44. Find the centroid of the region $\mathcal{W}$ bounded, in spherical coordinates, by $\phi = \phi_0$ and the sphere $\rho = R$.

SOLUTION The centroid is the point $P = (\overline{x}, \overline{y}, \overline{z})$, where

$$\overline{x} = \frac{1}{V}\iiint_{\mathcal{W}} x\, dV, \quad \overline{y} = \frac{1}{V}\iiint_{\mathcal{W}} y\, dV, \quad \overline{z} = \frac{1}{V}\iiint_{\mathcal{W}} z\, dV \tag{1}$$

We first compute the volume V of $\mathcal{W}$. The region $\mathcal{W}$ has the following definition in spherical coordinates:

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le \phi \le \phi_0,\ 0 \le \rho \le R$$



Hence,

$$V = \iiint_{\mathcal{W}} 1\,dV = \int_0^{2\pi}\int_0^{\phi_0}\int_0^R \rho^2 \sin\phi\,d\rho\,d\phi\,d\theta = \left(\int_0^{2\pi} 1\,d\theta\right)\left(\int_0^{\phi_0}\sin\phi\,d\phi\right)\left(\int_0^R \rho^2 d\rho\right)$$

$$= 2\pi\cdot\left(-\cos\phi\Big|_0^{\phi_0}\right)\left(\frac{\rho^3}{3}\Big|_0^R\right) = 2\pi\cdot(1-\cos\phi_0)\cdot\frac{R^3}{3} = \frac{2\pi R^3(1-\cos\phi_0)}{3} \tag{2}$$

Since the region $\mathcal{D}$ is symmetric with respect to the z-axis, its centroid lies on the z-axis. That is, $\overline{x} = \overline{y} = 0$. To compute $\overline{z}$, we evaluate the following integral:

$$\iiint_{\mathcal{W}} z\,dV = \int_0^{2\pi}\int_0^{\phi_0}\int_0^R (\rho\cos\phi)\rho^2\sin\phi\,d\rho\,d\phi\,d\theta = \int_0^{2\pi}\int_0^{\phi_0}\int_0^R \rho^3\cdot\frac{\sin 2\phi}{2}\,d\rho\,d\phi\,d\theta$$

$$= \left(\int_0^{2\pi} 1\,d\theta\right)\left(\int_0^{\phi_0}\frac{\sin 2\phi}{2}\,d\phi\right)\left(\int_0^R \rho^3\,d\rho\right) = 2\pi\cdot\left(-\frac{\cos 2\phi}{4}\Big|_0^{\phi_0}\right)\left(\frac{\rho^4}{4}\Big|_0^R\right)$$

$$= 2\pi\cdot\frac{1-\cos 2\phi}{4}\cdot\frac{R^4}{4} = \frac{R^4(1-\cos 2\phi_0)\pi}{8}$$

Combining with (1) and (2) gives

$$\overline{z} = \frac{3}{2\pi R^3(1-\cos\phi_0)}\cdot\frac{R^4(1-\cos 2\phi_0)\pi}{8} = \frac{3R(1-\cos 2\phi_0)}{16(1-\cos\phi_0)}$$

The centroid is thus

$$P = \left(0, 0, \frac{3R(1-\cos 2\phi_0)}{16(1-\cos\phi_0)}\right).$$

45. Find the centroid of the solid bounded by the xy-plane, the cylinder $x^2+y^2=R^2$, and the plane $x/R + z/H = 1$.

SOLUTION First to find the volume of this solid. The first equation lends itself well to cylindrical coordinates:

$$x^2+y^2=R^2 \quad\Rightarrow\quad r = R, 0\le\theta\le 2\pi$$

and

$$\frac{x}{R}+\frac{z}{H} = 1 \quad\Rightarrow\quad z = H\left(1-\frac{x}{R}\right) = H\left(1-\frac{r\cos\theta}{R}\right)$$

The volume is:

$$\begin{aligned} Volume &= \int_0^{2\pi}\int_0^R\int_0^{H(1-r\cos\theta/R)} 1\,dz\,dr\,d\theta \\ &= \int_0^{2\pi}\int_0^R H\left(1-\frac{r\cos\theta}{R}\right)dr\,d\theta \\ &= H\int_0^{2\pi} r - \frac{1}{2}\cdot\frac{r^2\cos\theta}{R}\Big|_{r=0}^R d\theta \\ &= H\int_0^{2\pi} R - \frac{1}{2}R\cos\theta\,d\theta \\ &= H\left(R\theta - \frac{1}{2}R\sin\theta\Big|_0^{2\pi}\right) \\ &= 2\pi HR \end{aligned}$$

Now to compute the coordinates of the centroid:

$$\begin{aligned} \overline{x} &= \frac{1}{V}\iiint_{\mathcal{W}} x\,dV = \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R\int_0^{H(1-r\cos\theta/R)} r\cos\theta\,dz\,dr\,d\theta \\ &= \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R r\cos\theta\cdot z\Big|_0^{H(1-r\cos\theta/R)} dr\,d\theta \\ &= \frac{H}{2\pi HR}\int_0^{2\pi}\int_0^R r\cos\theta\left(1-\frac{r\cos\theta}{R}\right)dr\,d\theta \end{aligned}$$

$$= \frac{1}{2\pi R}\int_0^{2\pi}\int_0^R r\cos\theta - \frac{1}{R}r^2\cos^2\theta\,dr\,d\theta$$

$$= \frac{1}{2\pi R}\int_0^{2\pi} \frac{1}{2}r^2\cos\theta - \frac{1}{3R}r^3\cos^2\theta\Big|_0^R\,d\theta$$

$$= \frac{1}{2\pi R}\int_0^{2\pi} \frac{1}{2}R^2\cos\theta - \frac{R^2}{6}(1+\cos 2\theta)\,d\theta$$

$$= \frac{1}{2\pi R}\left(\frac{1}{2}R^2\sin\theta - \frac{R^2}{6}\left(\theta + \frac{1}{2}\sin 2\theta\right)\Big|_0^{2\pi}\right) = \frac{1}{2\pi R}\cdot -\frac{R^2}{6}(2\pi) = -\frac{R}{6}$$

$$\overline{y} = \frac{1}{V}\iiint_{\mathcal{W}} y\,dV = \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R\int_0^{H(1-r\cos\theta/R)} r\sin\theta\,dz\,dr\,d\theta$$

$$= \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R r\sin\theta\cdot z\Big|_0^{H(1-r\cos\theta/R)}\,dr\,d\theta$$

$$= \frac{H}{2\pi HR}\int_0^{2\pi}\int_0^R r\sin\theta\left(1-\frac{r\cos\theta}{R}\right)dr\,d\theta$$

$$= \frac{1}{2\pi R}\int_0^{2\pi}\int_0^R r\sin\theta - \frac{1}{R}r^2\sin\theta\cos\theta\,dr\,d\theta$$

$$= \frac{1}{2\pi R}\int_0^{2\pi} \frac{1}{2}r^2\sin\theta - \frac{1}{3R}r^3\sin\theta\cos\theta\Big|_0^R\,d\theta$$

$$= \frac{1}{2\pi R}\int_0^{2\pi} \frac{1}{2}R^2\sin\theta - \frac{R^2}{3}\sin\theta\cos\theta\,d\theta$$

$$= \frac{1}{2\pi R}\left(-\frac{1}{2}R^2\cos\theta - \frac{R^2}{6}\sin^2\theta\Big|_0^{2\pi}\right) = 0$$

$$\overline{z} = \frac{1}{V}\iiint_{\mathcal{W}} z\,dV = \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R\int_0^{H(1-r\cos\theta/R)} z\,dz\,dr\,d\theta$$

$$= \frac{1}{2\pi HR}\int_0^{2\pi}\int_0^R \frac{1}{2}z^2\Big|_0^{H(1-r\cos\theta/R)}\,dr\,d\theta$$

$$= \frac{H^2}{4\pi HR}\int_0^{2\pi}\int_0^R \left(1-\frac{r\cos\theta}{R}\right)^2 dr\,d\theta$$

$$= \frac{H}{4\pi R}\int_0^{2\pi}\int_0^R 1 - \frac{2r\cos\theta}{R} + \frac{r^2\cos^2\theta}{R^2}\,dr\,d\theta$$

$$= \frac{H}{4\pi R}\int_0^{2\pi} r - \frac{r^2\cos\theta}{R} + \frac{r^3\cos^2\theta}{3R^2}\Big|_0^R\,d\theta$$

$$= \frac{H}{4\pi R}\int_0^{2\pi} R - R\cos\theta + \frac{1}{6}R(1+\cos 2\theta)\,d\theta$$

$$= \frac{H}{4\pi R}\left(R\theta - R\sin\theta + \frac{1}{6}R\left(\theta + \frac{1}{2}\sin 2\theta\right)\Big|_0^{2\pi}\right)$$

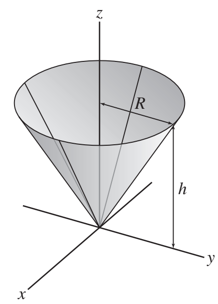
$$= \frac{H}{4\pi R}\left(2\pi R + \frac{1}{3}\pi R\right) = \frac{H}{4\pi R}\cdot\frac{7\pi R}{3} = \frac{7}{12}H$$

The coordinates of the centroid are $(-R/6, 0, 7H/12)$.

46. Using cylindrical coordinates, prove that the centroid of a right circular cone of height h and radius R is located at height $\frac{h}{4}$ on the central axis.

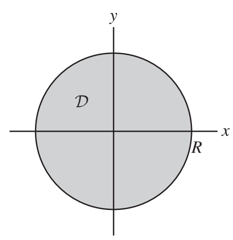
SOLUTION The volume of the cone is $V = \frac{\pi R^2 h}{3}$, therefore the coordinates of the centroid are

$$\overline{x} = \frac{3}{\pi R^2 h}\iiint_{\mathcal{W}} x\,dV, \quad \overline{y} = \frac{3}{\pi R^2 h}\iiint_{\mathcal{W}} y\,dV, \quad \overline{z} = \frac{3}{\pi R^2 h}\iiint_{\mathcal{W}} z\,dV$$



Since the cone $\mathcal{W}$ is symmetric with respect to the z-axis, its centroid lies on the z-axis. That is,

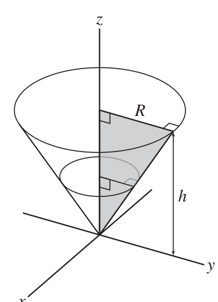
$$\overline{x} = \overline{y} = 0$$



Thus we need to find the z-coordinate. The projection of $\mathcal{W}$ on to the xy-plane is the disk $x^2 + y^2 \le R^2$, or in polar coordinates,

$$\mathcal{D} : 0 \le \theta \le 2\pi, \ 0 \le r \le R$$

The upper surface is the plane $z = h$. To find the equation of the lower surface we use proportion in similar triangles (see figure).



We get

$$\frac{r}{R} = \frac{z}{h} \quad \Rightarrow \quad z = \frac{rh}{R}$$

The inequalities defining $\mathcal{W}$ in cylindrical coordinates are thus

$$\mathcal{W} : 0 \le \theta \le 2\pi, \ 0 \le r \le R, \ \frac{rh}{R} \le z \le h$$

We now compute $\overline{z}$ using Triple Integral in Cylindrical coordinates:

$$\begin{aligned}
\overline{z} &= \frac{3}{\pi R^2 h} \int_0^{2\pi} \int_0^R \int_{\frac{rh}{R}}^h zr\,dz\,dr\,d\theta = \frac{3}{\pi R^2 h} \int_0^{2\pi} \int_0^R \frac{z^2 r}{2} \bigg|_{z=\frac{rh}{R}}^h dr\,d\theta \\
&= \frac{3}{2\pi R^2 h} \int_0^{2\pi} \int_0^R \left(h^2 r - \frac{h^2 r^3}{R^2} \right) dr\,d\theta = \frac{3}{2\pi R^2 h} \int_0^{2\pi} \frac{h^2 r^2}{2} - \frac{h^2 r^4}{4R^2} \bigg|_{r=0}^R d\theta \\
&= \frac{3}{2\pi R^2 h} \int_0^{2\pi} \left(\frac{h^2 R^2}{2} - \frac{h^2 R^4}{4R^2} \right) d\theta = \frac{3}{2\pi R^2 h} \cdot 2\pi \left(\frac{h^2 R^2}{2} - \frac{h^2 R^2}{4} \right) = \frac{3h}{4}
\end{aligned}$$

Therefore the centroid is the following point:

$$\left(0, 0, \frac{3h}{4}\right).$$

That is, the height (measured from the base) is $\frac{h}{4}$.

47. Find the centroid of solid (A) in Figure 4 defined by $x^2 + y^2 \le R^2$, $0 \le z \le H$, and $\frac{\pi}{6} \le \theta \le 2\pi$, where θ is the polar angle of (x, y).

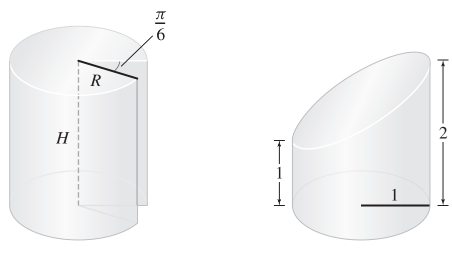


FIGURE 4

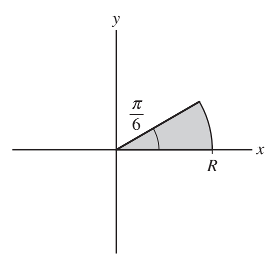
SOLUTION Since the mass distribution is uniform, we may assume that $\rho(x, y, z) = 1$, hence the center of mass is

$$x_{\text{CM}} = \frac{1}{V}\iiint_{\mathcal{W}} x\, dV, \quad y_{\text{CM}} = \frac{1}{V}\iiint_{\mathcal{W}} y\, dV, \quad z_{\text{CM}} = \frac{1}{V}\iiint_{\mathcal{W}} z\, dV$$

The inequalities describing $\mathcal{W}$ in cylindrical coordinates are

$$\mathcal{W}: 0 \le \theta \le \frac{\pi}{6},\ 0 \le r \le R,\ 0 \le z \le H$$



The entire cylinder has a total volume $\pi R^2 H$. The region $\mathcal{W}$ has the fraction $(2\pi - \frac{\pi}{6})/(2\pi)$ of this total volume, so

$$V = \frac{(2\pi - \frac{\pi}{6})}{2\pi}(\pi R^2 H) = \frac{11\pi R^2 H}{12}$$

We use cylindrical coordinates to compute the triple integrals:

$$x_{CM} = \frac{1}{V}\int_{\pi/6}^{2\pi}\int_0^R\int_0^H (r\cos\theta) r\, dz\, dr\, d\theta = \frac{12}{11\pi R^2 H}\left(\int_{\pi/6}^{2\pi}\cos\theta\, d\theta\right)\left(\int_0^R r^2\, dr\right)\left(\int_0^H dz\right)$$

$$= \frac{12}{11\pi R^2 H}\left(-\frac{1}{2}\right)\left(\frac{R^3}{3}\right)(H) = -\frac{2R}{11\pi}$$

$$y_{CM} = \frac{1}{V}\int_{\pi/6}^{2\pi}\int_0^R\int_0^H (r\sin\theta) r\, dz dr d\theta = \frac{12}{11\pi R^2 H}\left(\int_{\pi/6}^{2\pi}\sin\theta\, d\theta\right)\left(\int_0^R r^2\, dr\right)\left(\int_0^H dz\right)$$

$$= \frac{12}{11\pi R^2 H}\left(\frac{-2+\sqrt{3}}{2}\right)\left(\frac{R^3}{3}\right)(H) = \frac{2R}{11\pi}(\sqrt{3} - 2)$$

$$z_{CM} = \frac{1}{V}\int_{\pi/6}^{2\pi}\int_0^R\int_0^H zr\, dz\, dr\, d\theta = \frac{12}{11\pi R^2 H}\left(\int_{\pi/6}^{2\pi} d\theta\right)\left(\int_0^R r\, dr\right)\left(\int_0^H z\, dz\right)$$

$$= \frac{12}{11\pi R^2 H}\left(\frac{11\pi}{6}\right)\left(\frac{R^2}{2}\right)\left(\frac{H^2}{2}\right) = \frac{H}{2}$$

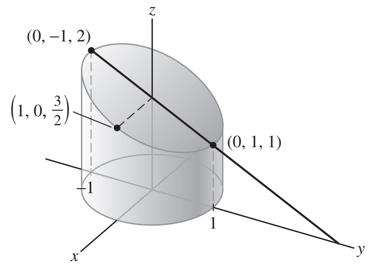
Therefore, the center of mass is the following point:

$$\left(-\frac{2R}{11\pi}, \frac{2R}{11\pi}(\sqrt{3} - 2), \frac{H}{2}\right)$$

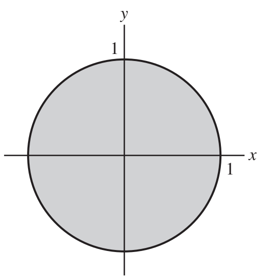
48. Calculate the coordinate y_{CM} of the centroid of solid (B) in Figure 4 defined by $x^2 + y^2 \le 1$ and $0 \le z \le \frac{1}{2}y + \frac{3}{2}$.

SOLUTION Notice that our picture here is slightly different from the one in the book; we've arranged our picture so that the top slopes down in the positive y direction. Since the mass distribution is uniform, we may assume that $\rho(x, y, z) = 1$, hence the center of mass is

$$x_{\text{CM}} = \frac{1}{V}\iiint_{\mathcal{W}} x\,dV, \quad y_{\text{CM}} = \frac{1}{V}\iiint_{\mathcal{W}} y\,dV, \quad z_{\text{CM}} = \frac{1}{V}\iiint_{\mathcal{W}} z\,dV$$



We first must find the equation of the upper plane. This plane is passing through the points $(0, -1, 2)$, $(0, 1, 1)$, and $\left(1, 0, \frac{3}{2}\right)$, hence it has the equation $y + 2z = 3$ or $z = \frac{3-y}{2} = \frac{3-r\sin\theta}{2}$.



The region $\mathcal{W}$ has the following definition in cylindrical coordinates:

$$\mathcal{W}:\ 0 \le \theta \le 2\pi,\ 0 \le r \le 1,\ 0 \le z \le \frac{3 - r\sin\theta}{2}$$

We first find the volume of $\mathcal{W}$:

$$\begin{aligned}
V &= \iiint_{\mathcal{W}} 1\,dV = \int_0^{2\pi}\int_0^1\int_0^{(3-r\sin\theta)/2} r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^1 rz\Big|_0^{(3-r\sin\theta)/2} dr\,d\theta \\
&= \int_0^{2\pi}\int_0^1 r\frac{3-r\sin\theta}{2}\,dr\,d\theta = \int_0^{2\pi}\int_0^1 \left(\frac{3r}{2} - \frac{r^2}{2}\sin\theta\right) dr\,d\theta = \int_0^{2\pi} \frac{3r^2}{4} - \frac{r^3\sin\theta}{6}\Big|_{r=0}^1 d\theta \\
&= \int_0^{2\pi}\left(\frac{3}{4} - \frac{\sin\theta}{6}\right) d\theta = \frac{3}{4}\theta + \frac{\cos\theta}{6}\Big|_0^{2\pi} = \frac{3\pi}{2} + \frac{1}{6} - \frac{1}{6} = \frac{3\pi}{2}
\end{aligned}$$

$V = \frac{3\pi}{2}$: Since the region is symmetric with respect to the yz-plane, we have

$$x_{\text{CM}} = \frac{1}{V}\iiint_{\mathcal{W}} x\,dV = 0$$

We compute y_{CM}:

$$\begin{aligned}
y_{\text{CM}} &= \frac{2}{3\pi}\int_0^{2\pi}\int_0^1\int_0^{(3-r\sin\theta)/2} (r\sin\theta)r\,dz\,dr\,d\theta = \frac{2}{3\pi}\int_0^{2\pi}\int_0^1\int_0^{(3-r\sin\theta)/2} r^2\sin\theta\,dz\,dr\,d\theta \\
&= \frac{2}{3\pi}\int_0^{2\pi}\int_0^1 r^2\sin\theta\left(\frac{3-r\sin\theta}{2}\right) dr\,d\theta = \frac{2}{3\pi}\int_0^{2\pi}\int_0^1\left(\frac{3r^2\sin\theta}{2} - \frac{r^3\sin^2\theta}{2}\right) dr\,d\theta \\
&= \frac{2}{3\pi}\int_0^{2\pi}\left(\frac{3\sin\theta}{2}\frac{r^3}{3} - \frac{r^4\sin^2\theta}{8}\Big|_{r=0}^1\right) d\theta = \frac{2}{3\pi}\int_0^{2\pi}\left(\frac{\sin\theta}{2} - \frac{\sin^2\theta}{8}\right) d\theta \\
&= \frac{1}{3\pi}\int_0^{2\pi}\sin\theta\,d\theta - \frac{1}{12\pi}\int_0^{2\pi}\sin^2\theta\,d\theta = -\frac{1}{12\pi}\left(\frac{\theta}{2} - \frac{\sin 2\theta}{4}\Big|_{\theta=0}^{2\pi}\right) = -\frac{1}{12\pi}\cdot\pi = -\frac{1}{12}
\end{aligned}$$

Finally we find z_{CM}:

$$\begin{aligned} z_{CM} &= \frac{2}{3\pi}\int_0^{2\pi}\int_0^1\int_0^{(3-r\sin\theta)/2} zr\,dz\,dr\,d\theta = \frac{2}{3\pi}\int_0^{2\pi}\int_0^1 \frac{z^2r}{2}\bigg|_{z=0}^{(3-r\sin\theta)/2} dr\,d\theta \\ &= \frac{2}{3\pi}\int_0^{2\pi}\int_0^1 \frac{r}{2}\left(\frac{3-r\sin\theta}{2}\right)^2 dr\,d\theta = \frac{2}{8\cdot 3\pi}\int_0^{2\pi}\int_0^1 \left(r^3\sin^2\theta - 6r^2\sin\theta + 9r\right) dr\,d\theta \\ &= \frac{1}{12\pi}\int_0^{2\pi} \frac{r^4\sin^2\theta}{4} - 2r^3\sin\theta + \frac{9}{2}r^2\bigg|_0^1 d\theta = \frac{1}{12\pi}\int_0^{2\pi}\left(\frac{\sin^2\theta}{4} - 2\sin\theta + \frac{9}{2}\right) d\theta \\ &= \frac{1}{48\pi}\int_0^{2\pi}\sin^2\theta\,d\theta - \frac{1}{6\pi}\int_0^{2\pi}\sin\theta\,d\theta + \frac{9}{24\pi}\int_0^{2\pi} d\theta = \frac{1}{48\pi}\left(\frac{\theta}{2} - \frac{\sin 2\theta}{4}\bigg|_0^{2\pi}\right) - 0 + \frac{9}{24\pi}\cdot 2\pi \\ &= \frac{1}{48} + \frac{3}{4} = \frac{37}{48} \end{aligned}$$

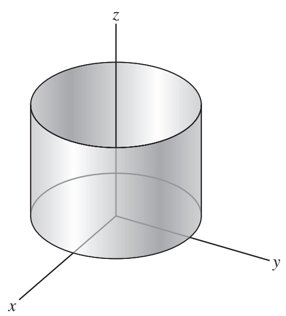
The center of mass is the following point:

$$\left(0, -\frac{1}{12}, \frac{37}{48}\right)$$

If you had arranged the axes differently, you could have computed the answer as $\left(0, \frac{1}{12}, \frac{37}{48}\right)$ (depending on orientation).

49. Find the center of mass of the cylinder $x^2 + y^2 = 1$ for $0 \le z \le 1$, assuming a mass density of $\rho(x, y, z) = z$.

SOLUTION By symmetry, we can note that the center of mass lies on the z-axis.

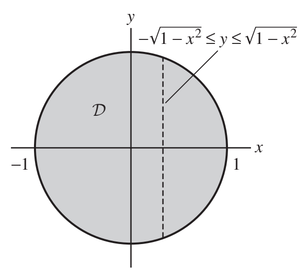


The coordinates of the center of mass are defined as,

$$\begin{aligned} x_{CM} &= \frac{\iiint_{\mathcal{W}} x\left(x^2+y^2\right) dV}{M} \\ y_{CM} &= \frac{\iiint_{\mathcal{W}} y\left(x^2+y^2\right) dV}{M} \\ z_{CM} &= \frac{\iiint_{\mathcal{W}} z\left(x^2+y^2\right) dV}{M} \end{aligned} \qquad (1)$$

where M is the total mass of $\mathcal{W}$. The cylinder $\mathcal{W}$ is defined by the inequalities

$$-1 \le x \le 1, \quad -\sqrt{1-x^2} \le y \le \sqrt{1-x^2}, \quad 0 \le z \le 1$$



We compute the total mass of $\mathcal{W}$:

$$\begin{aligned} M &= \iiint_{\mathcal{W}} z\,dV = \int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}}\int_0^1 z\,dz\,dy\,dx = \int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \frac{1}{2}z^2\Big|_{z=0}^{1} dy\,dx \\ &= \frac{1}{2}\int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} 1\,dy\,dx = \int_{-1}^{1}\int_0^{\sqrt{1-x^2}} 1\,dy\,dx = \int_{-1}^{1} y\Big|_{y=0}^{\sqrt{1-x^2}} dx \\ &= \int_{-1}^{1}\sqrt{1-x^2}\,dx \end{aligned}$$

This integral is the area of a half of the unit circle, hence the total mass is

$$\int_{-1}^{1}\sqrt{1-x^2}\,dx = \frac{\pi}{2} = M$$

We now compute the numerators in (1). Using (2), we get

$$\begin{aligned} \iiint_{\mathcal{W}} xz\,dV &= \int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}}\int_0^1 xz\,dz\,dy\,dx = \int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \frac{1}{2}xz^2\Big|_{z=0}^{1} dy\,dx \\ &= 2\int_{-1}^{1}\int_0^{\sqrt{1-x^2}} \frac{1}{2}x\,dy\,dx = \int_{-1}^{1} xy\Big|_{y=0}^{\sqrt{1-x^2}} dx \\ &= \int_{-1}^{1} x\sqrt{1-x^2}\,dx = -\frac{2}{3}(1-x^2)^{3/2}\Big|_{-1}^{1} = 0 \end{aligned} \tag{2}$$

Now to compute the next numerator:

$$\begin{aligned} \iiint_{\mathcal{W}} yz\,dV &= \int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}}\int_0^1 yz\,dz\,dy\,dx = \int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \frac{1}{2}yz^2\Big|_{z=0}^{1} dy\,dx \\ &= 2\int_{-1}^{1}\int_0^{\sqrt{1-x^2}} \frac{1}{2}y\,dy\,dx = \int_{-1}^{1} \frac{1}{2}y^2\Big|_{y=0}^{\sqrt{1-x^2}} dx \\ &= \int_{-1}^{1}(1-x^2)\,dx = \left(x-x^3\right)\Big|_{-1}^{1} = 0 \end{aligned} \tag{3}$$

Thus far we have:

$$\iiint_{\mathcal{W}} yz\,dV = \iiint_{\mathcal{W}} xz\,dV = 0 \tag{4}$$

We compute the numerator of z_{CM} in (1):

$$\begin{aligned} \iiint_{\mathcal{W}} z\cdot z\,dV &= \int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}}\int_0^1 z^2\,dz\,dy\,dx = \int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \frac{1}{3}z^3\Big|_{z=0}^{1} dy\,dx \\ &= \int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \frac{1}{3}\,dy\,dx = \int_{-1}^{1}\int_0^{\sqrt{1-x^2}} \frac{2}{3}\,dy\,dx \\ &= \int_{-1}^{1} \frac{2}{3}y\Big|_0^{\sqrt{1-x^2}} dx \\ &= \frac{2}{3}\int_{-1}^{1}\sqrt{1-x^2}\,dx \end{aligned}$$

This is $2/3$ times half of the area of the circle, centered at the origin, having radius 1, so the integral is $1/3\pi$.

Finally, we substitute $M = \frac{\pi}{2}$ and the computed integrals for (1) to obtain the following solution:

$$(x_{\text{CM}}, y_{\text{CM}}, z_{\text{CM}}) = \left(0, 0, \frac{\frac{\pi}{3}}{\frac{\pi}{2}}\right) = \left(0, 0, \frac{2}{3}\right).$$

50. Find the center of mass of the sector of central angle $2\theta_0$ (symmetric with respect to the y-axis) in Figure 5, assuming that the mass density is $\rho(x, y) = x^2$.

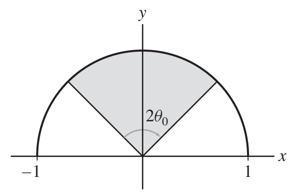


FIGURE 5

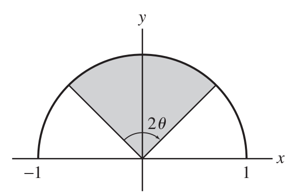
SOLUTION Since the region is symmetric with respect to the y-axis, the x-coordinate of the center of mass is zero, hence the center of mass is located on the y-axis. We first compute the mass:

$$M = \iint \rho\, dA = \int_0^1 \int_{\pi/2-\theta_0}^{\pi/2+\theta_0} r^2 \cos^2\alpha \cdot r\, dr\, d\alpha = \frac{1}{4}r^4\Big|_0^1 \cdot \left[\frac{\alpha}{2} + \frac{\sin 2\alpha}{4}\right]\Big|_{\pi/2-\theta_0}^{\pi/2+\theta_0}$$

$$= \frac{1}{4}\left[\theta_0 + \frac{1}{4}\left(\sin(\pi + 2\theta_0) - \sin(\pi - 2\theta_0)\right)\right] = \frac{1}{4}\left[\theta_0 + \frac{1}{4}\left(-\sin(2\theta_0) - \sin(2\theta_0)\right)\right]$$

$$= \frac{1}{4}\left[\theta_0 - \frac{1}{2}\sin(2\theta_0)\right]$$

We now compute y_{CM}.



We obtain the integral

$$y_{CM} = \frac{1}{M}\int_0^1 \int_{\frac{\pi}{2}-\theta_0}^{\pi/2+\theta_0} r\sin\alpha \cdot r^2\cos^2\alpha \cdot r\, d\alpha\, dr = \frac{1}{M}\frac{1}{5}r^5\Big|_0^1 \cdot \left[\frac{-1}{3}\cos^3\alpha\right]\Big|_{\pi/2-\theta_0}^{\pi/2+\theta_0}$$

$$= \frac{1}{15M}\left[\cos^3(\pi/2 - \theta_0) - \cos^3(\pi/2 + \theta_0)\right] = \frac{1}{15M}\left[\sin^3(\theta_0) + \sin^3(\theta_0)\right] = \frac{2\sin^3(\theta_0)}{15M}$$

Substituting in the previous value for the mass M, we obtain

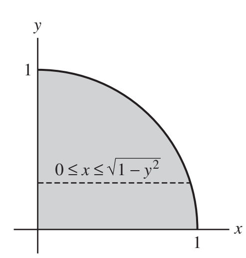
$$y_{CM} = \frac{8\sin^3\theta_0}{15(\theta_0 - \frac{1}{2}\sin 2\theta_0)}$$

51. Find the center of mass of the first octant of the ball $x^2 + y^2 + z^2 = 1$, assuming a mass density of $\rho(x, y, z) = x$.

SOLUTION

(a) The solid is the part of the unit sphere in the first octant. The inequalities defining the projection of the solid onto the xy-plane are

$$\mathcal{D} : 0 \le y \le 1,\ 0 \le x \le \sqrt{1 - y^2}$$



$\mathcal{W}$ is the region bounded by $\mathcal{D}$ and the sphere $z = \sqrt{1 - x^2 - y^2}$, hence $\mathcal{W}$ is defined by the inequalities

$$\mathcal{W} : 0 \le y \le 1,\ 0 \le x \le \sqrt{1 - y^2},\ 0 \le z \le \sqrt{1 - x^2 - y^2} \qquad (1)$$

We first must compute the mass of the solid. Using the mass as a triple integral, we have

$$M = \int_0^1 \int_0^{\sqrt{1-y^2}} \int_0^{\sqrt{1-x^2-y^2}} x\,dz\,dx\,dy = \int_0^1 \int_0^{\sqrt{1-y^2}} xz\Big|_{z=0}^{\sqrt{1-x^2-y^2}} dx\,dy$$
$$= \int_0^1 \int_0^{\sqrt{1-y^2}} x\sqrt{1-x^2-y^2}\,dx\,dy$$

We compute the inner integral using the substitution $u = \sqrt{1-x^2-y^2}$, $du = -\frac{x}{u}\,dx$, or $x\,dx = -u\,du$. We get

$$\int_0^{\sqrt{1-y^2}} x\sqrt{1-x^2-y^2}\,dx = \int_{\sqrt{1-y^2}}^0 u(-u\,du) = \int_0^{\sqrt{1-y^2}} u^2\,du = \frac{u^3}{3}\Big|_0^{\sqrt{1-y^2}} = \frac{(1-y^2)^{3/2}}{3} \tag{2}$$

We substitute in (2) and compute the resulting integral substituting $y = \sin t$, $dy = \cos t\,dt$:

$$M = \int_0^1 \frac{(1-y^2)^{3/2}}{3}\,dy = \frac{1}{3}\int_0^{\pi/2} (1-\sin^2 t)^{3/2}\cos t\,dt = \frac{1}{3}\int_0^{\pi/2} \cos^4 t\,dt$$
$$= \frac{1}{3}\left(\frac{\cos^3 t\sin t}{4} + \frac{3}{4}\left(\frac{t}{2} + \frac{\sin 2t}{4}\right)\Big|_0^{\pi/2}\right) = \frac{1}{4}\cdot\frac{\pi}{4} = \frac{\pi}{16}$$

That is, $M = \frac{\pi}{16}$. We now find the coordinates of the center of mass. To compute $x_{\rm CM}$ we use the definition of $\mathcal{D}$ as a vertically simple region to obtain a simpler integral. That is, we write the inequalities for $\mathcal{W}$ as

$$\mathcal{W}: 0 \le x \le 1,\ 0 \le y \le \sqrt{1-x^2},\ 0 \le z \le \sqrt{1-x^2-y^2} \tag{3}$$

Thus,

$$x_{\rm CM} = \frac{1}{M}\iiint_{\mathcal{W}} x\rho\,dV = \frac{16}{\pi}\int_0^1 \int_0^{\sqrt{1-x^2}} \int_0^{\sqrt{1-x^2-y^2}} x^2\,dz\,dy\,dx = \frac{16}{\pi}\int_0^1 \int_0^{\sqrt{1-x^2}} x^2 z\Big|_{z=0}^{\sqrt{1-x^2-y^2}} dy\,dx$$
$$= \frac{16}{\pi}\int_0^1 \int_0^{\sqrt{1-x^2}} x^2\sqrt{1-x^2-y^2}\,dy\,dx = \frac{16}{\pi}\int_0^1 x^2\left(\int_0^{\sqrt{1-x^2}} \sqrt{1-x^2-y^2}\,dy\right)dx \tag{4}$$

We compute the inner integral using Integration Formulas:

$$\int_0^{\sqrt{1-x^2}} \sqrt{1-x^2-y^2}\,dy = \frac{y}{2}\sqrt{1-x^2-y^2} + \frac{1-x^2}{2}\sin^{-1}\frac{y}{\sqrt{1-x^2}}\Big|_{y=0}^{\sqrt{1-x^2}}$$
$$= \frac{1-x^2}{2}\sin^{-1} 1 = \frac{1-x^2}{2}\cdot\frac{\pi}{2} = \frac{\pi}{4}(1-x^2)$$

Substituting in (4) gives

$$x_{\rm CM} = \frac{16}{\pi}\int_0^1 x^2\cdot\frac{\pi}{4}(1-x^2)\,dx = 4\int_0^1 (x^2-x^4)\,dx = 4\left(\frac{x^3}{3} - \frac{x^5}{5}\right)\Big|_0^1 = 4\left(\frac{1}{3} - \frac{1}{5}\right) = \frac{8}{15}$$

(b) We compute the y-coordinate of the center of mass, using (1):

$$y_{\rm CM} = \frac{1}{M}\iiint_{\mathcal{W}} y\rho\,dV = \frac{16}{\pi}\int_0^1 \int_0^{\sqrt{1-y^2}} \int_0^{\sqrt{1-x^2-y^2}} yx\,dz\,dx\,dy = \frac{16}{\pi}\int_0^1 \int_0^{\sqrt{1-y^2}} yxz\Big|_{z=0}^{\sqrt{1-x^2-y^2}} dx\,dy$$
$$= \frac{16}{\pi}\int_0^1 \int_0^{\sqrt{1-y^2}} yx\sqrt{1-x^2-y^2}\,dx\,dy = \frac{16}{\pi}\int_0^1 y\left(\int_0^{\sqrt{1-y^2}} x\sqrt{1-x^2-y^2}\,dx\right)dy$$

The inner integral was computed in (2), therefore,

$$y_{\rm CM} = \frac{16}{\pi}\int_0^1 y\cdot\frac{(1-y^2)^{3/2}}{3}\,dy = \frac{16}{3\pi}\int_0^1 y(1-y^2)^{3/2}\,dy$$

We compute the integral using the substitution $u = 1-y^2$, $du = -2y\,dy$. We get

$$y_{\rm CM} = \frac{16}{3\pi}\int_1^0 u^{3/2}\cdot\left(-\frac{du}{2}\right) = \frac{8}{3\pi}\int_0^1 u^{3/2}\,du = \frac{8}{3\pi}\cdot\frac{2}{5}\cdot u^{5/2}\Big|_0^1 = \frac{16}{15\pi}$$

Finally we find the z-coordinate of the center of mass, using (1):

$$z_{\mathrm{CM}} = \frac{1}{M}\iiint_{\mathcal{W}} z\rho\,dV = \frac{16}{\pi}\int_0^1\int_0^{\sqrt{1-y^2}}\int_0^{\sqrt{1-x^2-y^2}} zx\,dz\,dx\,dy = \frac{16}{\pi}\int_0^1\int_0^{\sqrt{1-y^2}} \frac{z^2x}{2}\Big|_{z=0}^{\sqrt{1-x^2-y^2}} dx\,dy$$

$$= \frac{16}{\pi}\int_0^1\int_0^{\sqrt{1-y^2}} \frac{x}{2}(1-x^2-y^2)\,dx\,dy = \frac{8}{\pi}\int_0^1\int_0^{\sqrt{1-y^2}}(x-x^3-xy^2)\,dx\,dy$$

$$= \frac{8}{\pi}\int_0^1 \frac{x^2}{2}-\frac{x^4}{4}-\frac{x^2y^2}{2}\Big|_{x=0}^{\sqrt{1-y^2}} dy = \frac{8}{\pi}\int_0^1\left(\frac{1-y^2}{2}-\frac{(1-y^2)^2}{4}-\frac{(1-y^2)y^2}{2}\right)dy$$

$$= \frac{2}{\pi}\int_0^1 (y^4-2y^2+1)\,dy = \frac{2}{\pi}\left(\frac{y^5}{5}-\frac{2y^3}{3}+y\right)\Big|_{y=0}^1 = \frac{2}{\pi}\left(\frac{1}{5}-\frac{2}{3}+1\right) = \frac{16}{15\pi}$$

The center mass is the following point:

$$P = \left(\frac{8}{15}, \frac{16}{15\pi}, \frac{16}{15\pi}\right).$$

52. Find a constant C such that

$$p(x,y) = \begin{cases} C(4x-y+3) & \text{if } 0\le x\le 2 \text{ and } 0\le y\le 3 \\ 0 & \text{otherwise}\end{cases}$$

is a probability distribution and calculate $P(X\le 1; Y\le 2)$.

SOLUTION For $p(x,y)$ to be a probability distribution, we need:

$$\int_{x=0}^2\int_{y=0}^3 p(x,y)\,dy\,dx = 1$$

Solving we see:

$$\int_{x=0}^2\int_{y=0}^3 p(x,y)\,dy\,dx = \int_0^2\int_0^3 C(4x-y+3)\,dy\,dx$$

$$= C\int_0^2\int_0^3 4x-y+3\,dy\,dx = C\int_0^2 4xy-\frac{1}{2}y^2+3y\Big|_0^3 dx$$

$$= C\int_0^2 12x-\frac{9}{2}+9\,dx = C\int_0^2 12+\frac{9}{2}\,dx$$

$$= C\left(6x^2+\frac{9}{2}x\right)\Big|_0^2 = C\,(24+9) = 33C$$

Therefore we have $C = 1/33$.

Now to compute $P(X\le 1; Y\le 2)$ we have to write

$$\int_0^1\int_0^2 \frac{1}{33}(4x-y+3)\,dy\,dx = \frac{1}{33}\int_0^1 4xy-\frac{1}{2}y^2+3y\Big|_0^2 dx$$

$$= \frac{1}{33}\int_0^1 8x-2+6\,dx = \frac{1}{33}\left(4x^2+4x\right)\Big|_0^1 = \frac{8}{33}$$

53. Calculate $P(3X+2Y\ge 6)$ for the probability density in Exercise 52.

SOLUTION Previously we found $p(x,y)=\frac{1}{33}(4x-y+3)$. Then using $P(3X+2Y\ge 6)$ we want to find $1-P(3X+2Y\le 6)$. Hence we need to integrate the following:

$$P(3X+2Y\le 6) = \int_{x=0}^2\int_{y=0}^{3-3/2x}\frac{1}{33}(4x-y+3)\,dy\,dx$$

$$= \frac{1}{33}\int_0^2 4xy-\frac{1}{2}y^2+3y\Big|_0^{3-3/2x} dx$$

$$= \frac{1}{33}\int_0^2 4x\left(3-\frac{3}{2}x\right)-\frac{1}{2}\left(3-\frac{3}{2}x\right)^2+3\left(3-\frac{3}{2}x\right)\,dx$$

$$= \frac{1}{33}\int_0^2 -\frac{57}{8}x^2 + 12x + \frac{9}{2}\,dx$$
$$= \frac{1}{33}\left(-\frac{57}{24}x^3 + 6x^2 + \frac{9}{2}x\right)\Big|_0^2$$
$$= \frac{1}{33}(-19 + 24 + 9) = \frac{14}{33}$$

Thus we have:

$$P(3X + 2Y \geq 6) = 1 - P(3X + 2Y \leq 6) = 1 - \frac{14}{33} = \frac{19}{33}$$

54. The lifetimes X and Y (in years) of two machine components have joint probability density

$$p(x, y) = \begin{cases} \frac{6}{125}(5 - x - y) & \text{if } 0 \leq x \leq 5 - y \text{ and } 0 \leq y \leq 5 \\ 0 & \text{otherwise} \end{cases}$$

What is the probability that both components are still functioning after 2 years?

SOLUTION This problem asks for $P(X \geq 2; Y \geq 2)$. We will find $P(X \geq 2; Y \geq 2)$ using the following inequalities on x and y:

$$2 \leq x \leq 5 - y, \quad 2 \leq y \leq 5$$

$$P(X \geq 2; Y \geq 2) = \int_{y=2}^{5}\int_{x=2}^{5-y} p(x, y)\,dx\,dy = \frac{6}{125}\int_{y=2}^{5}\int_{x=2}^{5-y} 5 - x - y\,dx\,dy$$
$$= \frac{6}{125}\int_2^5 5x - \frac{1}{2}x^2 - xy\Big|_2^{5-y}\,dy$$
$$= \frac{6}{125}\int_2^5 5(5 - y) - \frac{1}{2}(5 - y)^2 - (5 - y)y - [10 - 2 - 2y]\,dy$$
$$= \frac{6}{125}\int_2^5 \frac{9}{2} - 3y + \frac{1}{2}y^2\,dy$$
$$= \frac{6}{125}\left(\frac{9}{2}y - \frac{3}{2}y^2 + \frac{1}{6}y^3\right)\Big|_2^5$$
$$= \frac{6}{125}\left(\frac{45}{2} - \frac{75}{2} + \frac{125}{6}\right) - \frac{6}{125}\left(9 - 6 + \frac{4}{3}\right) = \frac{9}{125}$$

Hence,

$$P(X \geq 2; Y \geq 2) = \frac{9}{125}$$

55. An insurance company issues two kinds of policies A and B. Let X be the time until the next claim of type A is filed, and let Y be the time (in days) until the next claim of type B is filed. The random variables have joint probability density

$$p(x, y) = 12e^{-4x-3y}$$

Find the probability that $X \leq Y$.

SOLUTION We must compute

$$P(X \leq Y) = \int_{x=0}^{\infty}\int_{y=x}^{\infty} p(x, y)\,dy\,dx$$

Now evaluating we get:

$$P(X \leq Y) = \int_{x=0}^{\infty}\int_{y=x}^{\infty} 12e^{-4x-3y}\,dy\,dx = 12\int_0^{\infty}\int_x^{\infty} e^{-4x}e^{-3y}\,dy\,dx$$
$$= 12\int_0^{\infty} e^{-4x}\left(-\frac{1}{3}e^{-3y}\right)\Big|_x^{\infty}\,dx = -4\int_0^{\infty} e^{-4x}\left(\lim_{t\to\infty} e^{-3t} - e^{-3x}\right)dx$$
$$= 4\int_0^{\infty} e^{-4x}\cdot e^{-3x}\,dx = 4\int_0^{\infty} e^{-7x}\,dx$$
$$= -\frac{4}{7}\left(e^{-7x}\right)\Big|_0^{\infty} = -\frac{4}{7}\lim_{t\to\infty}\left(e^{-7t} - 1\right) = \frac{4}{7}$$

56. Compute the Jacobian of the map

$$\Phi(r,s) = \left(e^r\cosh(s), e^r\sinh(s)\right)$$

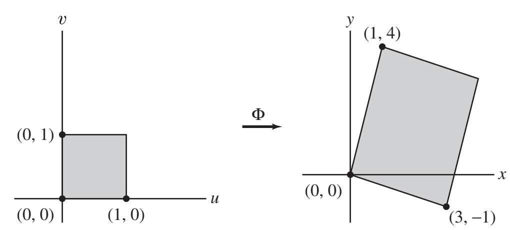
SOLUTION We have $x = e^r\cosh(s)$ and $y = e^r\sinh(s)$. Therefore,

$$\mathrm{Jac}(G) = \frac{\partial(x,y)}{\partial(r,s)} = \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial s} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial s} \end{vmatrix} = \begin{vmatrix} e^r\cosh(s) & e^r\sinh(s) \\ e^r\sinh(s) & e^r\cosh(s) \end{vmatrix}$$
$$= e^{2r}\cosh^2(s) - e^{2r}\sinh^2(s) = e^{2r}(\cosh^2(s) - \sinh^2(s)) = e^{2r}$$

57. Find a linear mapping $\Phi(u,v)$ that maps the unit square to the parallelogram in the xy-plane spanned by the vectors $\langle 3,-1\rangle$ and $\langle 1,4\rangle$. Then, use the Jacobian to find the area of the image of the rectangle $\mathcal{R} = [0,4]\times[0,3]$ under Φ.

SOLUTION We denote the linear map by

$$G(u,v) = (Au + Cv, Bu + Dv) \tag{1}$$



The image of the unit square is the quadrangle whose vertices are the images of the vertices of the square. Therefore we ask that

$$\begin{aligned} G(0,0) &= (A\cdot 0 + C\cdot 0, B\cdot 0 + D\cdot 0) = (0,0) & & (0,0) = (0,0) \\ G(1,0) &= (A\cdot 1 + C\cdot 0, B\cdot 1 + D\cdot 0) = (3,-1) & \Rightarrow\quad & (A,B) = (3,-1) \\ G(0,1) &= (A\cdot 0 + C\cdot 1, B\cdot 0 + D\cdot 1) = (1,4) & & (C,D) = (1,4) \end{aligned}$$

These equations imply that $A = 3$, $B = -1$, $C = 1$, and $D = 4$. Substituting in (1) we obtain the following map:

$$G(u,v) = (3u + v, -u + 4v)$$

The area of the rectangle $R = [0,4]\times[0,3]$ is $4\cdot 3 = 12$, therefore the transformed area is

$$\text{Area} = |\mathrm{Jac}(G)|\cdot 12$$

The Jacobian of the linear map G is

$$\mathrm{Jac}\,(G) = \begin{vmatrix} A & C \\ B & D \end{vmatrix} = \begin{vmatrix} 3 & 1 \\ -1 & 4 \end{vmatrix} = 12 - (-1) = 13$$

Therefore,

$$\text{Area} = 13\cdot 12 = 156.$$

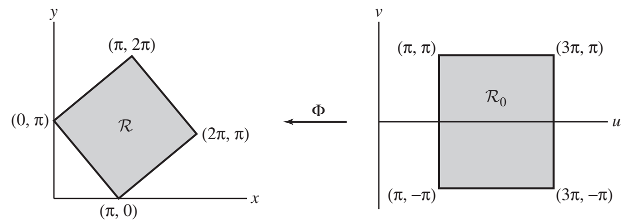
58. Use the map

$$\Phi(u,v) = \left(\frac{u+v}{2}, \frac{u-v}{2}\right)$$

to compute $\iint_{\mathcal{R}} \left((x-y)\sin(x+y)\right)^2\,dx\,dy$, where $\mathcal{R}$ is the square with vertices $(\pi,0)$, $(2\pi,\pi)$, $(\pi,2\pi)$, and $(0,\pi)$.

SOLUTION We express $f(x,y) = ((x-y)\sin(x+y))^2$ in terms of u and v. Since $x = \frac{u+v}{2}$ and $y = \frac{u-v}{2}$, we have $x - y = v$ and $x + y = u$. Hence, $f(x,y) = v^2\sin^2 u$. We find the Jacobian of the linear transformation:

$$\mathrm{Jac}(G) = \begin{vmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} \end{vmatrix} = -\frac{1}{4} - \frac{1}{4} = -\frac{1}{2}$$



To compute the vertices of the quadrangle $\mathcal{R}$ mapped by Φ onto $\mathcal{R}$, we first find the inverse of Φ by solving the following equations for u, v in terms of x and y:

$$\begin{array}{l} x = \dfrac{u+v}{2} \\ y = \dfrac{u-v}{2} \end{array} \quad \Rightarrow \quad \begin{array}{l} u+v = 2x \\ u-v = 2y \end{array} \quad \Rightarrow \quad u = x+y, \quad v = x-y$$

Hence,

$$\Phi^{-1}(x, y) = (x+y, x-y)$$

We now compute the vertices of P as the following images:

$$\begin{aligned} G^{-1}(\pi, 0) &= (\pi, \pi) \\ G^{-1}(2\pi, \pi) &= (3\pi, \pi) \\ G^{-1}(\pi, 2\pi) &= (3\pi, -\pi) \\ G^{-1}(0, \pi) &= (\pi, -\pi) \end{aligned}$$

Finally, we apply the change of variable formula to compute the integral:

$$\begin{aligned} \iint_{\mathcal{R}} (x-y)^2 \sin^2(x+y)\, dx\, dy &= \iint_{R_0} v^2 \sin^2 u |\text{Jac}(G)|\, du\, dv = \frac{1}{2} \int_{\pi}^{3\pi} \int_{-\pi}^{\pi} v^2 \sin^2 u\, dv\, du \\ &= \frac{1}{2} \left(\int_{\pi}^{3\pi} (\sin^2 u)\, du \right) \left(\int_{-\pi}^{\pi} v^2\, dv \right) = \left(\frac{u}{4} - \frac{\sin 2u}{8} \Big|_{\pi}^{3\pi} \right) \left(\frac{v^3}{3} \Big|_{-\pi}^{\pi} \right) \\ &= \left(\frac{3\pi}{4} - \frac{\pi}{4} \right) \cdot \frac{2\pi^3}{3} = \frac{\pi^4}{3} \end{aligned}$$

59. Let $\mathcal{D}$ be the shaded region in Figure 6, and let F be the map

$$u = y + x^2, \qquad v = y - x^3$$

(a) Show that F maps $\mathcal{D}$ to a rectangle $\mathcal{R}$ in the uv-plane.

(b) Apply Eq. (7) in Section 15.6 with $P = (1, 7)$ to estimate Area($\mathcal{D}$).

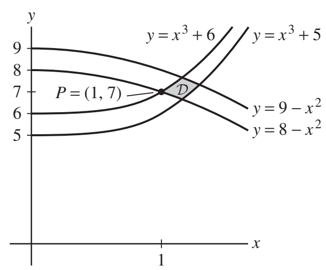


FIGURE 6

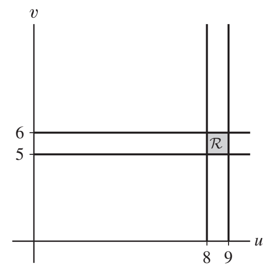
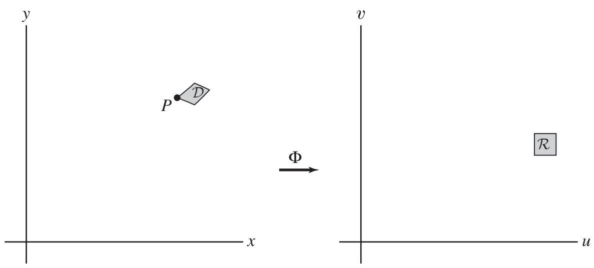
SOLUTION

(a) Note that the appropriate map should be $u = y + x^2$ rather than $u = -y + x^2$. We examine the images of the boundary curves of $\mathcal{D}$ under the map $(u, v) = \Phi(x, y) = (x^2 + y, y - x^3)$. The curves $y = x^3 + 6$ and $y = x^3 + 5$ can be rewritten as $y - x^3 = 6$ and $y - x^3 = 5$. Since $v = y - x^3$, these curves are mapped to the horizontal lines $v = 6$ and $v = 5$, respectively. The curves $y = 8 - x^2$ and $y = 9 - x^2$ can be rewritten as $y + x^2 = 8$ and $y + x^2 = 9$. Since $u = y + x^2$, these curves are mapped to the vertical lines $u = 8$ and $u = 9$, respectively. We conclude that $\mathcal{D}$ is mapped to the rectangle $\mathcal{R} = [8, 9] \times [5, 6]$ in the (u, v)-plane.



(b) We use Eq. (5) in section 16.5, where this time Φ is a mapping from the (x, y)-plane to the (u, v)-plane, and $P = (1, 7)$ is a point in $\mathcal{D}$:

$$\text{Area}\Phi(\mathcal{D}) \approx |\text{Jac}(\Phi)(P)|\text{Area}(\mathcal{D})$$



Here, $\text{Area}\Phi(\mathcal{D}) = \text{Area}(\mathcal{R}) = 1^2 = 1$, therefore we get

$$1 \approx |\text{Jac}(\Phi)(P)|\text{Area}(\mathcal{D})$$

or

$$\text{Area}(\mathcal{D}) \approx |\text{Jac}(\Phi)(P)|^{-1} \tag{1}$$

We compute the Jacobian of $\Phi(x, y) = (u, v) = (y + x^2, y - x^3)$ at $P = (1, 7)$:

$$\text{Jac}(\Phi) = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix} = \begin{vmatrix} 2x & 1 \\ -3x^2 & 1 \end{vmatrix} = 2x + 3x^2 \quad \Rightarrow \quad \text{Jac}(\Phi)(P) = 2 \cdot 1 + 3 \cdot 7^2 = 149$$

Combining with (1) gives

$$\text{Area}(\mathcal{D}) \approx (149)^{-1} = \frac{1}{149}.$$

60. Calculate the integral of $f(x, y) = e^{3x-2y}$ over the parallelogram in Figure 7.

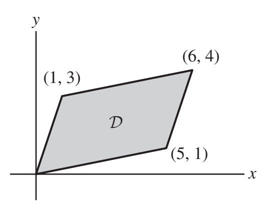


FIGURE 7

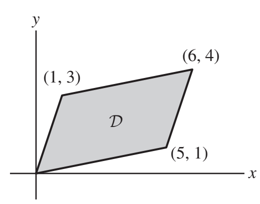
SOLUTION The equation of the boundary lines are $y = \frac{1}{5}x$, $y = \frac{1}{5}x + \frac{14}{5}$, $y = 3x$, and $y = 3x - 14$. These equations may be written as

$$x - 5y = 0, \quad x - 5y = -14, \quad 3x - y = 0, \quad 3x - y = 14$$

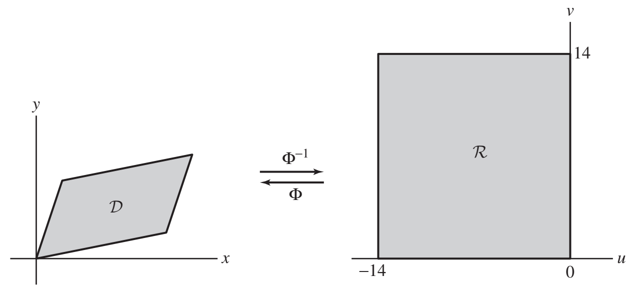


We define the following map:

$$\Phi^{-1}(x, y) = (u, v) = (x - 5y, 3x - y)$$

Φ^{-1} maps the boundary lines to the lines $u = 0$, $u = -14$, $v = 0$, and $v = 14$ in the (u, v)-plane. Therefore the image of $\mathcal{D}$ under Φ^{-1} is the rectangle $\mathcal{R} = [-14, 0] \times [0, 14]$ in the (u, v)-plane. Using the Change of variables Formula, we have

$$\iint_{\mathcal{D}} f(x, y)\, dx\, dy = \iint_{\mathcal{R}} f\left(x(u, v), y(u, v)\right) |\text{Jac}(\Phi)|\, du\, dv \qquad (1)$$



We compute the inverse Φ of Φ^{-1} by solving the equations $u = x - 5y$, $v = 3x - y$ for x, y in terms of u, v. We get

$$\begin{aligned} u &= x - 5y \\ v &= 3x - y \end{aligned} \quad \Rightarrow \quad x = \frac{-u + 5v}{14}, \quad y = \frac{-3u + v}{14}$$

Therefore the function $f(x, y) = e^{3x-2y}$ in terms of u and v is

$$f\left(x(u, v), y(u, v)\right) = e^{3\left(\frac{-u+5v}{14}\right) - 2\left(\frac{-3u+v}{14}\right)} = e^{\frac{3u+13v}{14}} \qquad (2)$$

The Jacobian of $\Phi(u, v) = (x, y) = \left(\frac{-u+5v}{14}, \frac{-3u+v}{14}\right)$ is

$$\text{Jac}(\Phi) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} -\frac{1}{14} & \frac{5}{14} \\ -\frac{3}{14} & \frac{1}{14} \end{vmatrix} = \frac{1}{14} \qquad (3)$$

Substituting (2) and (3) in (1) gives

$$\begin{aligned} \iint_{\mathcal{D}} e^{3x-2y}\, dx\, dy &= \int_0^{14} \int_{-14}^{0} e^{\frac{3u+13v}{14}} \cdot \frac{1}{14}\, du\, dv = \frac{1}{14} \int_0^{14} \int_{-14}^{0} e^{\frac{3u}{14}} \cdot e^{\frac{13v}{14}}\, du\, dv \\ &= \frac{1}{14} \left(\int_{-14}^{0} e^{\frac{3u}{14}}\, du \right) \left(\int_0^{14} e^{\frac{13v}{14}}\, dv \right) = \frac{1}{14} \left(\frac{14}{3} e^{\frac{3u}{14}} \Big|_{u=-14}^{0} \right) \left(\frac{14}{13} e^{\frac{13v}{14}} \Big|_{v=0}^{14} \right) \\ &= \frac{1}{3}(1 - e^{-3}) \cdot \frac{14}{13}(e^{13} - 1) = \frac{14}{39}(1 - e^{-3})(e^{13} - 1) \end{aligned}$$

61. Sketch the region $\mathcal{D}$ bounded by the curves $y = 2/x$, $y = 1/(2x)$, $y = 2x$, $y = x/2$ in the first quadrant. Let F be the map $u = xy$, $v = y/x$ from the xy-plane to the uv-plane.

(a) Find the image of $\mathcal{D}$ under F.

(b) Let $\Phi = F^{-1}$. Show that $|\text{Jac}(\Phi)| = \dfrac{1}{2|v|}$.

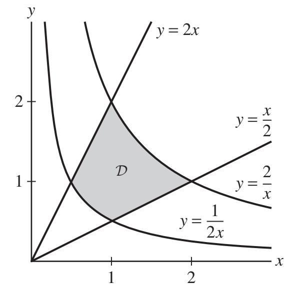
(c) Apply the Change of Variables Formula to prove the formula

$$\iint_{\mathcal{D}} f\left(\frac{y}{x}\right) dx\, dy = \frac{3}{4} \int_{1/2}^{2} \frac{f(v)\, dv}{v}$$

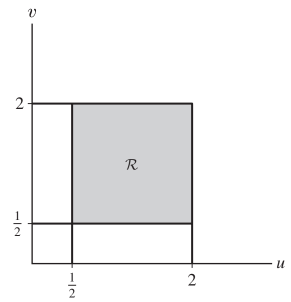
(d) Apply (c) to evaluate $\displaystyle\iint_{\mathcal{D}} \frac{ye^{y/x}}{x}\, dx\, dy$.

SOLUTION

(a) The region $\mathcal{D}$ is shown in the figure:



We rewrite the equations of the boundary curves as $xy = 2$, $xy = \frac{1}{2}$, $\frac{y}{x} = 2$, and $\frac{y}{x} = \frac{1}{2}$. These curves are mapped by Φ to the lines $u = 2$, $u = \frac{1}{2}$, $v = 2$, and $v = \frac{1}{2}$. Therefore, the image of $\mathcal{D}$ is the rectangle $\mathcal{R} = \left[\frac{1}{2}, 2\right] \times \left[\frac{1}{2}, 2\right]$ in the (u, v)-plane.



(b) We use the Jacobian of the inverse map:

$$\text{Jac}(F^{-1}) = (\text{Jac}(F))^{-1}$$

We compute the Jacobian of $F(x, y) = (u, v) = \left(xy, \frac{y}{x}\right)$:

$$\text{Jac}(F) = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix} = \begin{vmatrix} y & x \\ -\frac{y}{x^2} & \frac{1}{x} \end{vmatrix} = \frac{y}{x} + \frac{yx}{x^2} = \frac{2y}{x} = 2v$$

(Note that everything is positive, so we don't need absolute values!) Thus,

$$\text{Jac}(F^{-1}) = (\text{Jac}(F))^{-1} = \frac{1}{2v} = \frac{1}{|2v|}.$$

(c) The general change of variables formula is

$$\iint_{\mathcal{D}} f(x, y)\, dA = \iint_{\mathcal{R}} f\left(x(u, v), y(u, v)\right) |\text{Jac}(F^{-1})(u, v)|\, du\, dv$$

Here, $f\left(\frac{y}{x}\right) = f(v)$, $\mathcal{R} = \left[\frac{1}{2}, 2\right] \times \left[\frac{1}{2}, 2\right]$ in the (u, v)-plane and $|\text{Jac}(F^{-1})(u, v)| = |\frac{1}{2v}| = \frac{1}{2v}$ ($v > 0$ in $\mathcal{R}$). Therefore, we have

$$\iint_{\mathcal{D}} f\left(\frac{y}{x}\right) dA = \int_{1/2}^{2} \int_{1/2}^{2} f(v) \cdot \frac{1}{2v}\, du\, dv = \left(\int_{1/2}^{2} 1\, du\right) \left(\int_{1/2}^{2} \frac{f(v)}{2v}\, dv\right) = \frac{3}{4} \int_{1/2}^{2} \frac{f(v)}{v}\, dv$$

(d) We use part (c) with $f\left(\frac{y}{x}\right) = \frac{y}{x} \cdot e^{y/x}$. We have $f(v) = v \cdot e^v$, hence

$$\iint_{\mathcal{D}} \frac{ye^{y/x}}{x}\, dx\, dy = \frac{3}{4} \int_{1/2}^{2} \frac{ve^v}{v}\, dv = \frac{3}{4} \int_{1/2}^{2} e^v\, dv = \frac{3}{4} e^v \Big|_{1/2}^{2} = \frac{3}{4}(e^2 - e^{1/2}) = \frac{3}{4}\left(e^2 - \sqrt{e}\right)$$

16 LINE AND SURFACE INTEGRALS

16.1 Vector Fields (LT Section 17.1)

Preliminary Questions

1. Which of the following is a unit vector field in the plane?

(a) $\mathbf{F} = \langle y, x\rangle$

(b) $\mathbf{F} = \left\langle \dfrac{y}{\sqrt{x^2+y^2}}, \dfrac{x}{\sqrt{x^2+y^2}} \right\rangle$

(c) $\mathbf{F} = \left\langle \dfrac{y}{x^2+y^2}, \dfrac{x}{x^2+y^2} \right\rangle$

SOLUTION

(a) The length of the vector $\langle y, x\rangle$ is

$$\|\langle y, x\rangle\| = \sqrt{y^2+x^2}$$

This value is not 1 for all points, hence it is not a unit vector field.

(b) We have

$$\left\|\left\langle \frac{y}{\sqrt{x^2+y^2}}, \frac{x}{\sqrt{x^2+y^2}} \right\rangle\right\| = \sqrt{\left(\frac{y}{\sqrt{x^2+y^2}}\right)^2 + \left(\frac{x}{\sqrt{x^2+y^2}}\right)^2}$$

$$= \sqrt{\frac{y^2}{x^2+y^2} + \frac{x^2}{x^2+y^2}} = \sqrt{\frac{y^2+x^2}{x^2+y^2}} = 1$$

Hence the field is a unit vector field, for $(x, y) \neq (0, 0)$.

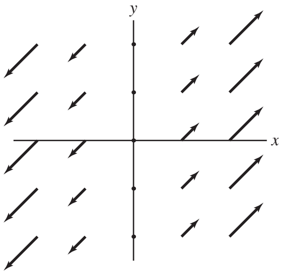
(c) We compute the length of the vector:

$$\left\|\left\langle \frac{y}{x^2+y^2}, \frac{x}{x^2+y^2} \right\rangle\right\| = \sqrt{\left(\frac{y}{x^2+y^2}\right)^2 + \left(\frac{x}{x^2+y^2}\right)^2} = \sqrt{\frac{y^2+x^2}{\left(x^2+y^2\right)^2}} = \sqrt{\frac{1}{x^2+y^2}}$$

Since the length is not identically 1, the field is not a unit vector field.

2. Sketch an example of a nonconstant vector field in the plane in which each vector is parallel to $\langle 1, 1\rangle$.

SOLUTION The non-constant vector $\langle x, x\rangle$ is parallel to the vector $\langle 1, 1\rangle$.



3. Show that the vector field $\mathbf{F} = \langle -z, 0, x\rangle$ is orthogonal to the position vector $\overrightarrow{OP}$ at each point P. Give an example of another vector field with this property.

SOLUTION The position vector at $P = (x, y, z)$ is $\langle x, y, z\rangle$. We must show that the following dot product is zero:

$$\langle x, y, z\rangle \cdot \langle -z, 0, x\rangle = x \cdot (-z) + y \cdot 0 + z \cdot x = 0$$

Therefore, the vector field $\mathbf{F} = \langle -z, 0, x\rangle$ is orthogonal to the position vector. Another vector field with this property is $\mathbf{F} = \langle 0, -z, y\rangle$, since

$$\langle 0, -z, y\rangle \cdot \langle x, y, z\rangle = 0 \cdot x + (-z) \cdot y + y \cdot z = 0$$

4. Give an example of a potential function for $\langle yz, xz, xy\rangle$ other than $f(x, y, z) = xyz$.

SOLUTION Since any two potential functions of a gradient vector field differ by a constant, a potential function for the given field other than $V(x, y, z) = xyz$ is, for instance, $V_1(x, y, z) = xyz + 1$.

Exercises

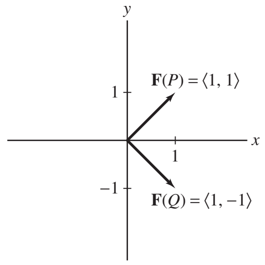
1. Compute and sketch the vector assigned to the points $P = (1, 2)$ and $Q = (-1, -1)$ by the vector field $\mathbf{F} = \langle x^2, x\rangle$.

SOLUTION The vector assigned to $P = (1, 2)$ is obtained by substituting $x = 1$ in $\mathbf{F}$, that is,

$$\mathbf{F}(1, 2) = \langle 1^2, 1\rangle = \langle 1, 1\rangle$$

Similarly,

$$\mathbf{F}(-1, -1) = \langle (-1)^2, -1\rangle = \langle 1, -1\rangle$$



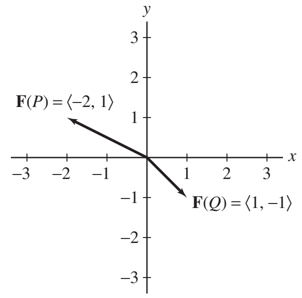
2. Compute and sketch the vector assigned to the points $P = (1, 2)$ and $Q = (-1, -1)$ by the vector field $\mathbf{F} = \langle -y, x\rangle$.

SOLUTION To find the vector assigned to the point $P = (1, 2)$, we substitute $x = 1$, $y = 2$ in $\mathbf{F} = \langle -y, x\rangle$, obtaining

$$\mathbf{F}(P) = \langle -2, 1\rangle$$

Similarly, the vector assigned to $Q = (-1, -1)$ is

$$\mathbf{F}(Q) = \langle -(-1), -1\rangle = \langle 1, -1\rangle$$



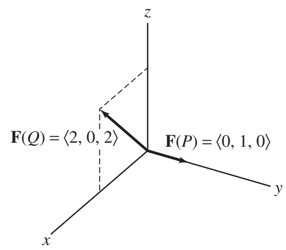
3. Compute and sketch the vector assigned to the points $P = (0, 1, 1)$ and $Q = (2, 1, 0)$ by the vector field $\mathbf{F} = \langle xy, z^2, x\rangle$.

SOLUTION To find the vector assigned to the point $P = (0, 1, 1)$, we substitute $x = 0$, $y = 1$, $z = 1$ in $\mathbf{F} = \langle xy, z^2, x\rangle$. We get

$$\mathbf{F}(P) = \langle 0 \cdot 1, 1^2, 0\rangle = \langle 0, 1, 0\rangle$$

Similarly, $\mathbf{F}(Q)$ is obtained by substituting $x = 2$, $y = 1$, $z = 0$ in $\mathbf{F}$. That is,

$$\mathbf{F}(Q) = \langle 2 \cdot 1, 0^2, 2\rangle = \langle 2, 0, 2\rangle$$



4. Compute the vector assigned to the points $P = (1, 1, 0)$ and $Q = (2, 1, 2)$ by the vector fields $\mathbf{e}_r$, $\frac{\mathbf{e}_r}{r}$, and $\frac{\mathbf{e}_r}{r^2}$.

SOLUTION The unit radial vector is

$$\mathbf{e}_r = \left\langle \frac{x}{r}, \frac{y}{r}, \frac{z}{r} \right\rangle$$

Hence,

$$\frac{\mathbf{e}_r}{r} = \left\langle \frac{x}{r^2}, \frac{y}{r^2}, \frac{z}{r^2} \right\rangle \quad \text{and} \quad \frac{\mathbf{e}_r}{r^2} = \left\langle \frac{x}{r^3}, \frac{y}{r^3}, \frac{z}{r^3} \right\rangle.$$

For $P = (1, 1, 0)$ we have $r = \sqrt{1^2 + 1^2 + 0^2} = \sqrt{2}$, and for $Q = (2, 1, 2)$ we have $r = \sqrt{2^2 + 1^2 + 2^2} = 3$. Therefore,

$$\mathbf{e}_r(P) = \left\langle \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, \frac{0}{\sqrt{2}} \right\rangle = \left\langle \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 0 \right\rangle$$

$$\mathbf{e}_r(Q) = \left\langle \frac{2}{3}, \frac{1}{3}, \frac{2}{3} \right\rangle$$

$$\frac{\mathbf{e}_r}{r}(P) = \left\langle \frac{1}{2}, \frac{1}{2}, \frac{0}{2} \right\rangle = \left\langle \frac{1}{2}, \frac{1}{2}, 0 \right\rangle$$

$$\frac{\mathbf{e}_r}{r}(Q) = \left\langle \frac{2}{9}, \frac{1}{9}, \frac{2}{9} \right\rangle$$

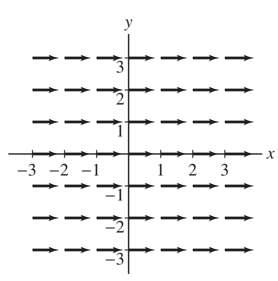
$$\frac{\mathbf{e}_r}{r^2}(P) = \left\langle \frac{1}{2\sqrt{2}}, \frac{1}{2\sqrt{2}}, \frac{0}{2\sqrt{2}} \right\rangle = \left\langle \frac{1}{2\sqrt{2}}, \frac{1}{2\sqrt{2}}, 0 \right\rangle$$

$$\frac{\mathbf{e}_r}{r^2}(Q) = \left\langle \frac{2}{27}, \frac{1}{27}, \frac{2}{27} \right\rangle$$

In Exercises 5–12, sketch the following planar vector fields by drawing the vectors attached to points with integer coordinates in the rectangle $-3 \le x \le 3$, $-3 \le y \le 3$. Instead of drawing the vectors with their true lengths, scale them if necessary to avoid overlap.

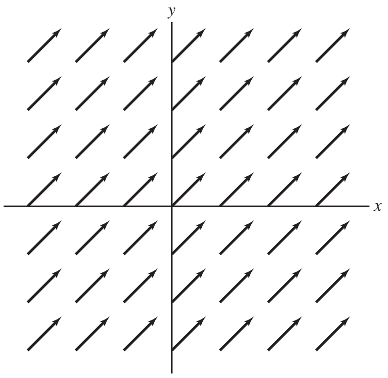
5. $\mathbf{F} = \langle 1, 0\rangle$

SOLUTION The constant vector field $\langle 1, 0\rangle$ is shown in the figure:



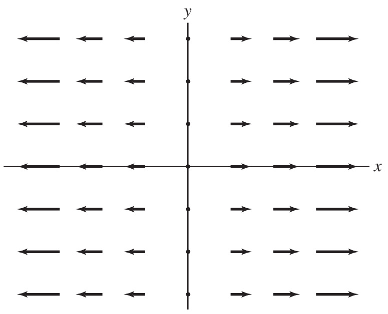
6. $\mathbf{F} = \langle 1, 1\rangle$

SOLUTION We sketch the graph of the constant vector field $\mathbf{F}(x, y) = \langle 1, 1\rangle$:



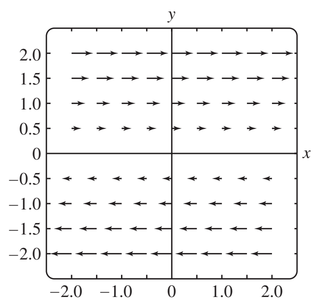
7. $\mathbf{F} = x\mathbf{i}$

SOLUTION The vector field $\mathbf{F}(x, y) = x\mathbf{i} = (x, 0)$ is sketched in the following figure:



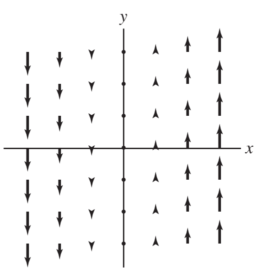
8. $\mathbf{F} = y\mathbf{i}$

SOLUTION



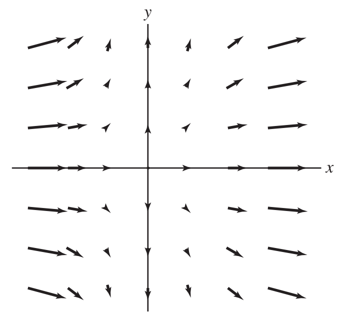
9. $\mathbf{F} = \langle 0, x\rangle$

SOLUTION We sketch the vector field $\mathbf{F}(x, y) = \langle 0, x\rangle$:



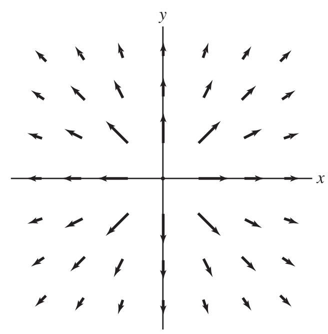
10. $\mathbf{F} = x^2\mathbf{i} + y\mathbf{j}$

SOLUTION The graph of the vector field $\mathbf{F}(x, y) = x^2\mathbf{i} + y\mathbf{j}$ is shown in the following figure:



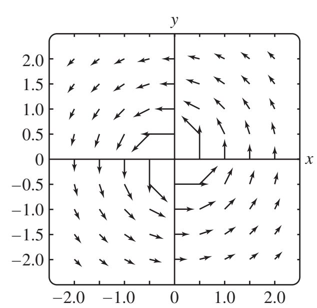
11. $\mathbf{F} = \left\langle \dfrac{x}{x^2 + y^2}, \dfrac{y}{x^2 + y^2} \right\rangle$

SOLUTION



12. $\mathbf{F} = \left\langle \dfrac{-y}{\sqrt{x^2 + y^2}}, \dfrac{x}{\sqrt{x^2 + y^2}} \right\rangle$

SOLUTION



In Exercises 13–16, match each of the following planar vector fields with the corresponding plot in Figure 10.

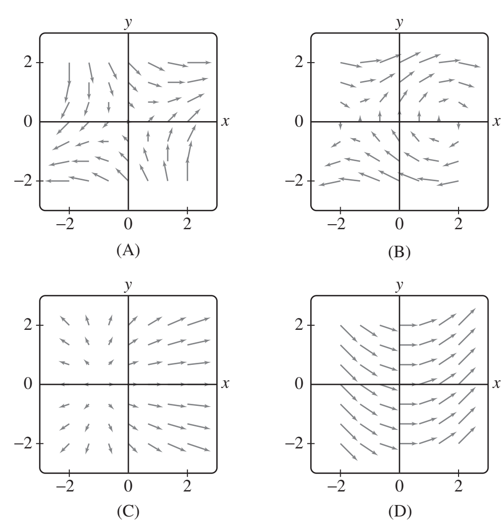


FIGURE 10

13. $\mathbf{F} = \langle 2, x \rangle$

SOLUTION The x coordinate of the vector field $\langle 2, x \rangle$ is always 2. This matches only with Plot (D).

14. $\mathbf{F} = \langle 2x + 2, y \rangle$

SOLUTION We compute the images of the point $(0, 2)$, for instance, and identify the corresponding graph accordingly:

$$\mathbf{F}(x, y) = \langle 2x + 2, y \rangle \quad \Rightarrow \quad \mathbf{F}(0, 2) = \langle 2, 2 \rangle \quad \Rightarrow \quad \text{Plot(C)}$$

15. $\mathbf{F} = \langle y, \cos x \rangle$

SOLUTION We compute the images of the point $(0, 2)$, for instance, and identify the corresponding graph accordingly:

$$\mathbf{F}(x, y) = \langle y, \cos x \rangle \quad \Rightarrow \quad \mathbf{F}(0, 2) = \langle 2, 1 \rangle \quad \Rightarrow \quad \text{Plot(B)}$$

16. $\mathbf{F} = \langle x + y, x - y \rangle$

SOLUTION We compute the images of the point $(0, 2)$, for instance, and identify the corresponding graph accordingly:

$$\mathbf{F}(x, y) = \langle x + y, x - y \rangle \quad \Rightarrow \quad \mathbf{F}(0, 2) = \langle 2, -2 \rangle \quad \Rightarrow \quad \text{Plot(A)}$$

In Exercises 17–20, match each three-dimensional vector field with the corresponding plot in Figure 11.

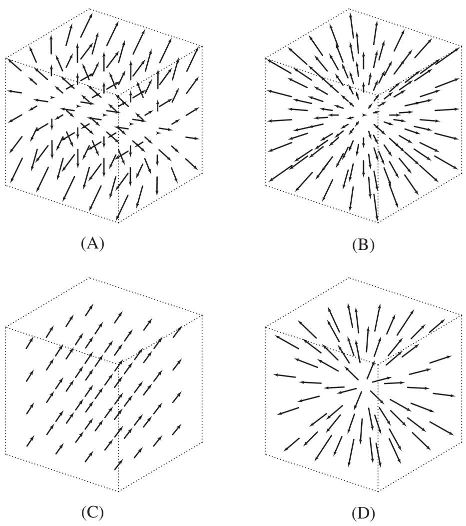

FIGURE 11

17. $\mathbf{F} = \langle 1, 1, 1 \rangle$

SOLUTION The constant vector field $\langle 1, 1, 1 \rangle$ is shown in plot (C).

18. $\mathbf{F} = \langle x, 0, z \rangle$

SOLUTION This vector field is shown in (A) (by process of elimination).

19. $\mathbf{F} = \langle x, y, z \rangle$

SOLUTION $\langle x, y, z \rangle$ is shown in plot (B). Note that the vectors are pointing away from the origin and are of increasing magnitude.

20. $\mathbf{F} = \mathbf{e}_r$

SOLUTION The unit radial vector field is shown in plot (D), as these vectors are radial and of uniform length.

21. Find (by inspection) a potential function for $\mathbf{F} = \langle x, 0 \rangle$ and prove that $\mathbf{G} = \langle y, 0 \rangle$ is not conservative.

SOLUTION For $f(x, y) = \frac{1}{2}x^2$ we have $\nabla f = \langle x, 0 \rangle$.

$$\frac{\partial G_1}{\partial y} = 1 \neq \frac{\partial G_2}{\partial x} = 0$$

Thus $\mathbf{G}$ is not conservative.

22. Prove that $\mathbf{F} = \langle yz, xz, y \rangle$ is not conservative.

SOLUTION

$$\frac{\partial F_2}{\partial z} = x \neq \frac{\partial F_3}{\partial y} = 1$$

Thus $\mathbf{F}$ is not conservative.

In Exercises 23–26, find a potential function for the vector field $\mathbf{F}$ *by inspection.*

23. $\mathbf{F} = \langle x, y \rangle$

SOLUTION We must find a function $\varphi(x, y)$ such that $\frac{\partial \varphi}{\partial x} = x$ and $\frac{\partial \varphi}{\partial y} = y$. We choose the following function:

$$\varphi(x, y) = \frac{1}{2}x^2 + \frac{1}{2}y^2.$$

24. $\mathbf{F} = \left\langle ye^{xy}, xe^{xy} \right\rangle$

SOLUTION The function $\varphi(x, y) = e^{xy}$ satisfies $\frac{\partial \varphi}{\partial x} = ye^{xy}$ and $\frac{\partial \varphi}{\partial y} = xe^{xy}$, hence φ is a potential function for the given vector field.

25. $\mathbf{F} = \left\langle yz^2, xz^2, 2xyz \right\rangle$

SOLUTION We choose a function $\varphi(x, y, z)$ such that

$$\frac{\partial \varphi}{\partial x} = yz^2, \quad \frac{\partial \varphi}{\partial y} = xz^2, \quad \frac{\partial \varphi}{\partial z} = xyz$$

The function $\varphi(x, y, z) = xyz^2$ is a potential function for the given field.

26. $\mathbf{F} = \left\langle 2xze^{x^2}, 0, e^{x^2} \right\rangle$

SOLUTION The function $\varphi(x, y, z) = ze^{x^2}$ satisfies $\frac{\partial \varphi}{\partial y} = 0$, $\frac{\partial \varphi}{\partial x} = 2xze^{x^2}$ and $\frac{\partial \varphi}{\partial z} = e^{x^2}$, hence φ is a potential function for the given vector field.

27. Find potential functions for $\mathbf{F} = \frac{\mathbf{e}_r}{r^3}$ and $\mathbf{G} = \frac{\mathbf{e}_r}{r^4}$ in $\mathbf{R}^3$. *Hint:* See Example 6.

SOLUTION We use the gradient of r, $\nabla r = \mathbf{e}_r$, and the Chain Rule for Gradients to write

$$\nabla\left(-\frac{1}{2}r^{-2}\right) = r^{-3}\nabla r = r^{-3}\mathbf{e}_r = \frac{\mathbf{e}_r}{r^3} = \mathbf{F}$$

$$\nabla\left(-\frac{1}{3}r^{-3}\right) = r^{-4}\nabla r = r^{-4}\mathbf{e}_r = \frac{\mathbf{e}_r}{r^4} = \mathbf{G}$$

Therefore $\varphi_1(r) = -\frac{1}{2r^2}$ and $\varphi_2(r) = -\frac{1}{3r^3}$ are potential functions for $\mathbf{F}$ and $\mathbf{G}$, respectively.

28. Show that $\mathbf{F} = \langle 3, 1, 2 \rangle$ is conservative. Then prove more generally that any constant vector field $\mathbf{F} = \langle a, b, c \rangle$ is conservative.

SOLUTION $\mathbf{F} = \nabla\varphi$ for $\varphi(x, y, z) = 3x + y + 2z$. Further for $\mathbf{F} = \langle a, b, c \rangle$, $\mathbf{F} = \nabla\varphi$ for $\varphi(x, y, z) = ax + by + cz$.

29. Let $\varphi = \ln r$, where $r = \sqrt{x^2 + y^2}$. Express $\nabla\varphi$ in terms of the unit radial vector $\mathbf{e}_r$ in $\mathbf{R}^2$.

SOLUTION Since $r = (x^2 + y^2 + z^2)^{1/2}$, we have $\varphi = \ln (x^2 + y^2 + z^2)^{1/2} = \frac{1}{2}\ln(x^2 + y^2 + z^2)$. We compute the partial derivatives:

$$\frac{\partial \varphi}{\partial x} = \frac{1}{2}\frac{2x}{x^2 + y^2 + z^2} = \frac{x}{r^2}$$

$$\frac{\partial \varphi}{\partial y} = \frac{1}{2}\frac{2y}{x^2 + y^2 + z^2} = \frac{y}{r^2}$$

$$\frac{\partial \varphi}{\partial z} = \frac{1}{2}\frac{2z}{x^2 + y^2 + z^2} = \frac{z}{r^2}$$

Therefore, the gradient of φ is the following vector:

$$\nabla\varphi = \left\langle \frac{\partial \varphi}{\partial x}, \frac{\partial \varphi}{\partial y}, \frac{\partial \varphi}{\partial z} \right\rangle = \left\langle \frac{x}{r^2}, \frac{y}{r^2}, \frac{z}{r^2} \right\rangle = \frac{1}{r}\left\langle \frac{x}{r}, \frac{y}{r}, \frac{z}{r} \right\rangle = \frac{\mathbf{e}_r}{r}$$

30. For $P = (a, b)$, we define the unit radial vector field based at P:

$$\mathbf{e}_P = \frac{\langle x-a, y-b\rangle}{\sqrt{(x-a)^2+(y-b)^2}}$$

(a) Verify that $\mathbf{e}_P$ is a unit vector field.
(b) Calculate $\mathbf{e}_P(1, 1)$ for $P = (3, 2)$.
(c) Find a potential function for $\mathbf{e}_P$.

SOLUTION
(a)

$$\mathbf{e}_P \cdot \mathbf{e}_P = \frac{(x-a)^2+(y-b)^2}{\left(\sqrt{(x-a)^2+(y-b)^2}\right)^2} = 1$$

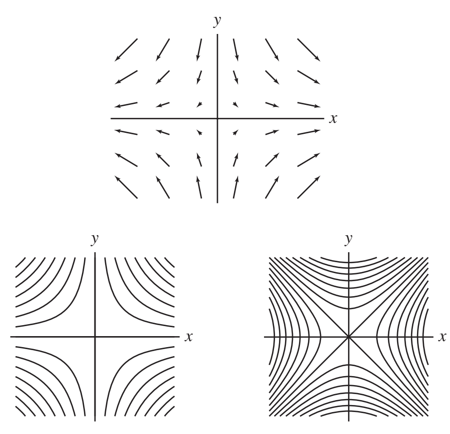
(b)

$$\mathbf{e}_{(3,2)}(1, 1) = \frac{\langle 1-3, 1-2\rangle}{\sqrt{(1-3)^2+(1-2)^2}} = \frac{\langle -2, -1\rangle}{\sqrt{5}}$$

(c) Let $\varphi(x, y) = \sqrt{(x-a)^2+(y-b)^2}$. Then,

$$\nabla\varphi = \frac{1}{2}((x-a)^2+(y-b)^2)^{-1/2}\langle 2(x-a), 2(y-b)\rangle = \mathbf{e}_P$$

31. Which of (A) or (B) in Figure 12 is the contour plot of a potential function for the vector field $\mathbf{F}$? Recall that the gradient vectors are perpendicular to the level curves.

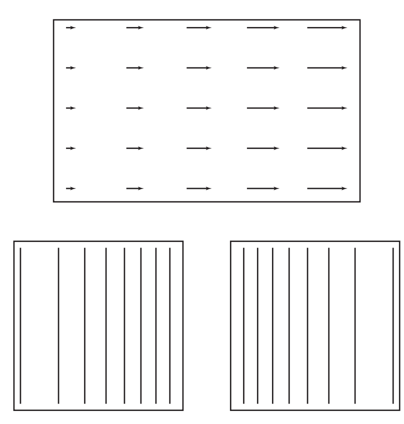


(A) (B)

FIGURE 12

SOLUTION By the equality $\nabla\varphi = \mathbf{F}$ and since the gradient vectors are perpendicular to the level curves, it follows that the vectors $\mathbf{F}$ are perpendicular to the corresponding level curves of φ. This property is satisfied in (B) and not satisfied in (A). Therefore (B) is the contour plot of φ.

32. Which of (A) or (B) in Figure 13 is the contour plot of a potential function for the vector field $\mathbf{F}$?



(A) (B)

FIGURE 13

SOLUTION Since $\nabla\varphi = \mathbf{F}$, $\mathbf{F}$ is perpendicular to the level curves of φ, as seen in both the contour plots (A) and (B). The plot of $\mathbf{F}$ shows that $\mathbf{F}$ has the form $\mathbf{F} = \langle f(x), 0\rangle$ for an increasing function $f(x)$. Therefore, $\frac{\partial\varphi}{\partial x} = f(x)$ is increasing, implying that the rate of change of φ with respect to x is increasing. Hence, the density of the vertical lines is greater in the direction of growing x. We conclude that (A) is the contour plot of φ.

33. Match each of these descriptions with a vector field in Figure 14:

(a) The gravitational field created by two planets of equal mass located at P and Q.

(b) The electrostatic field created by two equal and opposite charges located at P and Q (representing the force on a negative test charge; opposite charges attract and like charges repel).

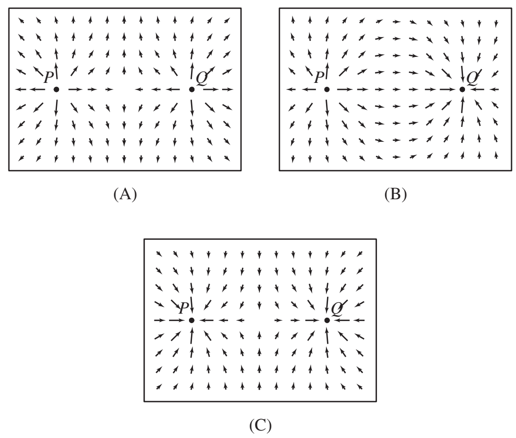


FIGURE 14

SOLUTION

(a) There will be an equilibrium point half way between the two planets. The vector field should pull objects near one planet toward that planet. (C)

(b) A test charge at the midpoint between the two charges will be drawn by one, and repelled by the other. Therefore no equilibrium. (B)

34. In this exercise, we show that the vector field $\mathbf{F}$ in Figure 15 is not conservative. Explain the following statements:

(a) If a potential function V for $\mathbf{F}$ exists, then the level curves of V must be vertical lines.

(b) If a potential function V for $\mathbf{F}$ exists, then the level curves of V must grow farther apart as y increases.

(c) Explain why (a) and (b) are incompatible, and hence V cannot exist.

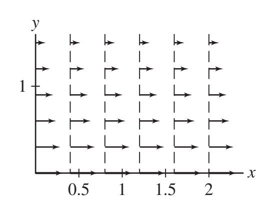

FIGURE 15

SOLUTION

(a) If V is a potential function for $\mathbf{F}$, then $\nabla V = \mathbf{F}$. Therefore, $\mathbf{F}$ is orthogonal to the level curves of V. The plot shows that the vectors $\mathbf{F}(x, y)$ are horizontal, hence the level curves of V are vertical lines.

(b) As indicated by the graph of the vector field $\mathbf{F} = \langle F_1, F_2\rangle$, $F_2 = 0$ and F_1 is decreasing as y increases. Since $\mathbf{F} = \frac{\partial V}{\partial x}$, it follows that $\frac{\partial V}{\partial x}$ is decreasing as y increases, or the rate of change of V with respect to x is decreasing as y increases. Therefore, as y increases, the level curves of V are getting farther apart.

(c) By (a), the level curves of V are vertical lines, hence the distance between any two level curves is constant rather than increasing with y as concluded in (b).

Further Insights and Challenges

35. Show that any vector field of the form

$$\mathbf{F} = \langle f(x), g(y), h(z) \rangle$$

has a potential function. Assume that f, g, and h are continuous.

SOLUTION Let $F(x)$, $G(y)$, and $H(z)$ be antiderivatives of $f(x)$, $g(y)$, and $h(z)$, respectively. That is, $F'(x) = f(x)$, $G'(y) = g(y)$, and $H'(y) = h(z)$. We define the function

$$\varphi(x, y, z) = F(x) + G(y) + H(z)$$

Then,

$$\frac{\partial \varphi}{\partial x} = F'(x) = f(x), \quad \frac{\partial \varphi}{\partial x} = G'(y) = g(y), \quad \frac{\partial \varphi}{\partial z} = H'(z) = h(z)$$

Therefore, $\nabla \varphi = \mathbf{F}$, or φ is a potential function for $\mathbf{F}$.

36. Let $\mathcal{D}$ be a disk in $\mathbf{R}^2$. This exercise shows that if

$$\nabla V(x, y) = \mathbf{0}$$

for all (x, y) in $\mathcal{D}$, then V is constant. Consider points $P = (a, b)$, $Q = (c, d)$ and $R = (c, b)$ as in Figure 16.

(a) Use single-variable calculus to show that V is constant along the segments $\overline{PR}$ and $\overline{RQ}$.

(b) Conclude that $V(P) = V(Q)$ for any two points $P, Q \in \mathcal{D}$.

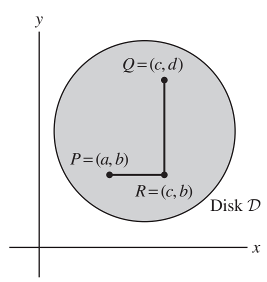

FIGURE 16

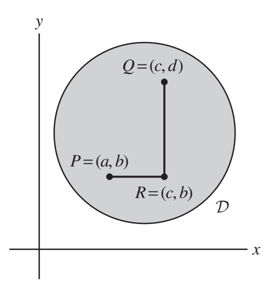
SOLUTION Given any two points $P = (a, b)$ and $Q = (c, d)$ in $\mathcal{D}$, we must show that

$$V(P) = V(Q)$$

We consider the point $R = (c, b)$ and the segments $\overline{PR}$ and $\overrightarrow{RQ}$. (We assume that (c, b) is in $\mathcal{D}$; if not, just use $R' = (a, d)$.)



Since $\frac{\partial V}{\partial x}(x, y) = 0$ in $\mathcal{D}$, in particular $\frac{\partial V}{\partial x}(x, b) = 0$ for $a \le x \le c$. Therefore, for $a \le x \le c$ we have

$$V(x, b) = \int_a^x \frac{\partial V}{\partial u}(u, b)\, du + V(a, b) = \int_a^x 0\, du + V(a, b) = k + V(a, b)$$

Substituting $x = a$ determines $k = 0$. Hence,

$$V(x, b) = V(a, b) \quad \text{for} \quad a \le x \le c$$

In particular,

$$V(c, b) = V(a, b) \quad \Rightarrow \quad V(R) = V(P) \tag{1}$$

Similarly, since $\frac{\partial V}{\partial y}(x, y) = 0$ in $\mathcal{D}$, we have $\frac{\partial V}{\partial y}(c, y) = 0$ for $b \le y \le d$. Therefore for $b \le y \le d$ we have

$$V(c, y) = \int_b^y \frac{\partial V}{\partial v}(c, v)\, dv + V(c, b) = \int_b^y 0\, dv + V(c, b) = k + V(c, b)$$

Substituting $y = b$ gives $V(c, b) = k + V(c, b)$ or $k = 0$. Therefore,

$$V(c, y) = V(c, b) \quad \text{for} \quad b \le y \le d$$

In particular,

$$V(c, d) = V(c, b) \quad \Rightarrow \quad V(Q) = V(R) \tag{2}$$

Combining (1) and (2) we obtain the desired equality $V(P) = V(Q)$. Since P and Q are any two points in $\mathcal{D}$, we conclude that V is constant on $\mathcal{D}$.

16.2 Line Integrals (LT Section 17.2)

Preliminary Questions

1. What is the line integral of the constant function $f(x, y, z) = 10$ over a curve $\mathcal{C}$ of length 5?

SOLUTION Since the length of $\mathcal{C}$ is the line integral $\int_{\mathcal{C}} 1\, ds = 5$, we have

$$\int_{\mathcal{C}} 10\, ds = 10 \int_{\mathcal{C}} 1\, ds = 10 \cdot 5 = 50$$

2. Which of the following have a zero line integral over the vertical segment from (0, 0) to (0, 1)?

(a) $f(x, y) = x$
(b) $f(x, y) = y$
(c) $\mathbf{F} = \langle x, 0 \rangle$
(d) $\mathbf{F} = \langle y, 0 \rangle$
(e) $\mathbf{F} = \langle 0, x \rangle$
(f) $\mathbf{F} = \langle 0, y \rangle$

SOLUTION The vertical segment from (0, 0) to (0, 1) has the parametrization

$$\mathbf{c}(t) = (0, t), \quad 0 \le t \le 1$$

Therefore, $\mathbf{c}'(t) = \langle 0, 1 \rangle$ and $\|\mathbf{c}'(t)\| = 1$. The line integrals are thus computed by

$$\int_{\mathcal{C}} f(x, y)\, ds = \int_0^1 f(\mathbf{c}(t))\, \|\mathbf{c}'(t)\|\, dt \tag{1}$$

$$\int_{\mathcal{C}} \mathbf{F} \cdot ds = \int_0^1 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt \tag{2}$$

(a) We have $f(\mathbf{c}(t)) = x = 0$. Therefore by (1) the line integral is zero.

(b) By (1), the line integral is

$$\int_{\mathcal{C}} f(x, y)\, ds = \int_0^1 t \cdot 1\, dt = \frac{1}{2}t^2 \Big|_0^1 = \frac{1}{2} \ne 0$$

(c) This vector line integral is computed using (2). Since $\mathbf{F}(\mathbf{c}(t)) = \langle x, 0 \rangle = \langle 0, 0 \rangle$, the vector line integral is zero.

(d) By (2) we have

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \langle t, 0 \rangle \cdot \langle 0, 1 \rangle\, dt = \int_0^1 0\, dt = 0$$

(e) The vector integral is computed using (2). Since $\mathbf{F}(\mathbf{c}(t)) = \langle 0, x \rangle = \langle 0, 0 \rangle$, the line integral is zero.

(f) For this vector field we have

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^1 \langle 0, t \rangle \cdot \langle 0, 1 \rangle\, dt = \int_0^1 t\, dt = \frac{t^2}{2}\Big|_0^1 = \frac{1}{2} \ne 0$$

So, we conclude that (a), (c), (d), and (e) have an integral of zero.

3. State whether each statement is true or false. If the statement is false, give the correct statement.

(a) The scalar line integral does not depend on how you parametrize the curve.

(b) If you reverse the orientation of the curve, neither the vector line integral nor the scalar line integral changes sign.

SOLUTION

(a) True: It can be shown that any two parametrizations of the curve yield the same value for the scalar line integral, hence the statement is true.

(b) False: For the definition of the scalar line integral, there is no need to specify a direction along the path, hence reversing the orientation of the curve does not change the sign of the integral. However, reversing the orientation of the curve changes the sign of the vector line integral.

4. Suppose that $\mathcal{C}$ has length 5. What is the value of $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$ if:

(a) $\mathbf{F}(P)$ is normal to $\mathcal{C}$ at all points P on $\mathcal{C}$?

(b) $\mathbf{F}(P)$ is a unit vector pointing in the negative direction along the curve?

SOLUTION

(a) The vector line integral is the integral of the tangential component of the vector field along the curve. Since $\mathbf{F}(P)$ is normal to $\mathcal{C}$ at all points P on $\mathcal{C}$, the tangential component is zero, hence the line integral $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$ is zero.

(b) In this case we have

$$\mathbf{F}(P) \cdot \mathbf{T}(P) = \mathbf{T}(P) \cdot \mathbf{T}(P) = \|\mathbf{T}(P)\|^2 = 1$$

Therefore,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}} (\mathbf{F} \cdot \mathbf{T})\, ds = \int_{\mathcal{C}} 1\, ds = \text{Length of } \mathcal{C} = 5.$$

Exercises

1. Let $f(x, y, z) = x + yz$, and let $\mathcal{C}$ be the line segment from $P = (0, 0, 0)$ to $(6, 2, 2)$.

(a) Calculate $f(\mathbf{c}(t))$ and $ds = \|\mathbf{c}'(t)\|\, dt$ for the parametrization $\mathbf{c}(t) = (6t, 2t, 2t)$ for $0 \le t \le 1$.

(b) Evaluate $\int_{\mathcal{C}} f(x, y, z)\, ds$.

SOLUTION

(a) We substitute $x = 6t$, $y = 2t$, $z = 2t$ in the function $f(x, y, z) = x + yz$ to find $f(\mathbf{c}(t))$:

$$f(\mathbf{c}(t)) = 6t + (2t)(2t) = 6t + 4t^2$$

We differentiate the vector $c(t)$ and compute the length of the derivative vector:

$$\mathbf{c}'(t) = \frac{d}{dt}\langle 6t, 2t, 2t\rangle = \langle 6, 2, 2\rangle \quad \Rightarrow \quad \mathbf{c}'(t) = \sqrt{6^2 + 2^2 + 2^2} = \sqrt{44} = 2\sqrt{11}$$

Hence,

$$ds = \|\mathbf{c}'(t)\|\, dt = 2\sqrt{11}\, dt$$

(b) Computing the scalar line integral, we obtain

$$\int_{\mathcal{C}} f(x, y, z)\, ds = \int_0^1 f(\mathbf{c}(t))\, \|\mathbf{c}'(t)\|\, dt = \int_0^1 (6t + 4t^2) \cdot 2\sqrt{11}\, dt$$

$$= 2\sqrt{11}\left(3t^2 + \frac{4}{3}t^3\right)\Big|_0^1 = 2\sqrt{11}\left(3 + \frac{4}{3}\right) = \frac{26\sqrt{11}}{3}$$

2. Repeat Exercise 1 with the parametrization $\mathbf{c}(t) = (3t^2, t^2, t^2)$ for $0 \le t \le \sqrt{2}$.

SOLUTION

(a) We substitute $x = 3t^2$, $y = t^2$, $z = t^2$ in the function $f(x, y, z) = x + yz$ to find $f(\mathbf{c}(t))$:

$$f(\mathbf{c}(t)) = 3t^2 + (t^2)(t^2) = 3t^2 + t^4$$

We differentiate the vector $c(t)$ and compute the length of the derivative vector:

$$\mathbf{c}'(t) = \frac{d}{dt}\left\langle 3t^2, t^2, t^2\right\rangle = \langle 6t, 2t, 2t\rangle \quad \Rightarrow \quad \mathbf{c}'(t) = \sqrt{(6t)^2 + (2t)^2 + (2t)^2} = \sqrt{44t^2} = 2\sqrt{11}t$$

Hence,

$$ds = \|\mathbf{c}'(t)\|\, dt = 2\sqrt{11}t\, dt$$

(b) Computing the scalar line integral, we obtain

$$\int_{\mathcal{C}} f(x, y, z)\, ds = \int_0^{\sqrt{2}} (3t^2 + t^4) \cdot 2\sqrt{11}t\, dt = 2\sqrt{11} \int_0^{\sqrt{2}} (3t^3 + t^5)\, dt$$
$$= 2\sqrt{11} \left(\frac{3t^4}{4} + \frac{t^6}{6} \right) \Big|_0^{\sqrt{2}} = 2\sqrt{11} \left(3 + \frac{8}{6} \right) = \frac{26\sqrt{11}}{3}$$

3. Let $\mathbf{F} = \langle y^2, x^2 \rangle$, and let $\mathcal{C}$ be the curve $y = x^{-1}$ for $1 \le x \le 2$, oriented from left to right.

(a) Calculate $\mathbf{F}(\mathbf{c}(t))$ and $d\mathbf{s} = \mathbf{c}'(t)\, dt$ for the parametrization of $\mathcal{C}$ given by $\mathbf{c}(t) = (t, t^{-1})$.

(b) Calculate the dot product $\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt$ and evaluate $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$.

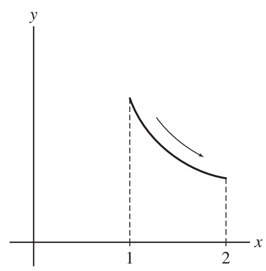
SOLUTION

(a) We calculate $\mathbf{F}(\mathbf{c}(t))$ by substituting $x = t$, $y = t^{-1}$ in $\mathbf{F} = \langle y^2, x^2 \rangle$. We get

$$\mathbf{F}(\mathbf{c}(t)) = \langle (t^{-1})^2, t^2 \rangle = \langle t^{-2}, t^2 \rangle$$

We compute $\mathbf{c}'(t)$:

$$\mathbf{c}'(t) = \frac{d}{dt} \langle t, t^{-1} \rangle = \langle 1, -t^{-2} \rangle \quad \Rightarrow \quad d\mathbf{s} = \langle 1, -t^{-2} \rangle\, dt$$



(b) We compute the dot product:

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \langle t^{-2}, t^2 \rangle \cdot \langle 1, -t^{-2} \rangle = t^{-2} \cdot 1 + t^2 \cdot (-t^{-2}) = t^{-2} - 1$$

Computing the vector line integral, we obtain

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_1^2 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_1^2 (t^{-2} - 1)\, dt = -t^{-1} - t \Big|_1^2 = \left(-\frac{1}{2} - 2 \right) - (-1 - 1) = -\frac{1}{2}$$

4. Let $\mathbf{F} = \langle z^2, x, y \rangle$ and let $\mathcal{C}$ be the path $\mathbf{c}(t) = \langle 3 + 5t^2, 3 - t^2, t \rangle$ for $0 \le t \le 2$.

(a) Calculate $\mathbf{F}(\mathbf{c}(t))$ and $d\mathbf{s} = \mathbf{c}'(t)\, dt$.

(b) Calculate the dot product $\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt$ and evaluate $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$.

SOLUTION

(a) We compute $\mathbf{F}(\mathbf{c}(t))$ by substituting $x = 3 + 5t^2$, $y = 3 - t^2$, $z = t$ in $\mathbf{F} = \langle z^2, x, y \rangle$. We get

$$\mathbf{F}(\mathbf{c}(t)) = \langle t^2, 3 + 5t^2, 3 - t^2 \rangle$$

We differentiate $\mathbf{c}(t)$:

$$\mathbf{c}'(t) = \frac{d}{dt} \langle 3 + 5t^2, 3 - t^2, t \rangle = \langle 10t, -2t, 1 \rangle \quad \Rightarrow \quad d\mathbf{s} = \langle 10t, -2t, 1 \rangle\, dt$$

(b) We compute the dot product:

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \langle t^2, 3 + 5t^2, 3 - t^2 \rangle \cdot \langle 10t, -2t, 1 \rangle\, dt$$
$$= \left(t^2 \cdot 10t + (3 + 5t^2)(-2t) + (3 - t^2) \cdot 1 \right) dt$$
$$= (10t^3 - 6t - 10t^3 + 3 - t^2)\, dt = (-t^2 - 6t + 3)\, dt$$

Computing the vector line integral gives

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^2 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^2 (-t^2 - 6t + 3)\, dt = -\frac{t^3}{3} - 3t^2 + 3t \Big|_0^2 = -\frac{26}{3} = -8\frac{2}{3}$$

In Exercises 5–8, compute the integral of the scalar function or vector field over $\mathbf{c}(t) = (\cos t, \sin t, t)$ *for* $0 \le t \le \pi$.

5. $f(x, y, z) = x^2 + y^2 + z^2$

SOLUTION

Step 1. Compute $\|\mathbf{c}'(t)\|$. We differentiate $\mathbf{c}(t)$:

$$\mathbf{c}'(t) = \frac{d}{dt}\langle \cos t, \sin t, t\rangle = \langle -\sin t, \cos t, 1\rangle$$

Hence,

$$\|\mathbf{c}'(t)\| = \sqrt{(-\sin t)^2 + \cos^2 t + 1^2} = \sqrt{\sin^2 t + \cos^2 t + 1} = \sqrt{2}$$
$$ds = \|\mathbf{c}'(t)\|\, dt = \sqrt{2}\, dt$$

Step 2. Write out $f(\mathbf{c}(t))$. We substitute $x = \cos t$, $y = \sin t$, $z = t$ in $f(x, y, z) = x^2 + y^2 + z^2$ to obtain

$$f(\mathbf{c}(t)) = \cos^2 t + \sin^2 t + t^2 = 1 + t^2$$

Step 3. Compute the line integral. Using the Theorem on Scalar Line Integrals we obtain

$$\int_{\mathcal{C}} (x^2 + y^2 + z^2)\, ds = \int_0^{\pi} f(\mathbf{c}(t))\, \|\mathbf{c}'(t)\|\, dt = \int_0^{\pi} (1 + t^2)\sqrt{2}\, dt = \sqrt{2}\left(t + \frac{t^3}{3}\right)\Big|_0^{\pi} = \sqrt{2}\left(\pi + \frac{\pi^3}{3}\right)$$

6. $f(x, y, z) = xy + z$

SOLUTION

Step 1. Compute $\|\mathbf{c}'(t)\|$. We differentiate $\mathbf{c}(t)$:

$$\mathbf{c}'(t) = \frac{d}{dt}\langle \cos t, \sin t, t\rangle = \langle -\sin t, \cos t, 1\rangle$$

Hence,

$$\|\mathbf{c}'(t)\| = \sqrt{(-\sin t)^2 + \cos^2 t + 1^2} = \sqrt{\sin^2 t + \cos^2 t + 1} = \sqrt{2}$$
$$ds = \|\mathbf{c}'(t)\|\, dt = \sqrt{2}\, dt$$

Step 2. Write out $f(\mathbf{c}(t))$. We substitute $x = \cos t$, $y = \sin t$, $z = t$ in $f(x, y, z) = xy + z$ to obtain

$$f(\mathbf{c}(t)) = \cos t \sin t + t$$

Step 3. Compute the line integral. Using the Theorem on Scalar Line Integrals we obtain

$$\int_{\mathcal{C}} (xy + z)\, ds = \int_0^{\pi} (\cos t \sin t + t)\sqrt{2}\, dt = \sqrt{2}\left(\frac{\sin^2 t}{2} + \frac{t^2}{2}\right)\Big|_0^{\pi} = \sqrt{2}\frac{\pi^2}{2} = \frac{\pi^2}{\sqrt{2}}$$

7. $\mathbf{F} = \langle x, y, z\rangle$

SOLUTION

Step 1. Calculate the integrand. We write out the vectors:

$$\mathbf{c}(t) = (\cos t, \sin t, t)$$
$$\mathbf{F}(\mathbf{c}(t)) = \langle x, y, z\rangle = \langle \cos t, \sin t, t\rangle$$
$$\mathbf{c}'(t) = \langle -\sin t, \cos t, 1\rangle$$

The integrand is the dot product:

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \langle \cos t, \sin t, t\rangle \cdot \langle -\sin t, \cos t, 1\rangle = -\cos t \sin t + \sin t \cos t + t = t$$

Step 2. Evaluate the integral. We use the Theorem on Vector Line Integrals to evaluate the integral:

$$\int_{\mathcal{C}} \mathbf{F}\, d\mathbf{s} = \int_0^{\pi} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^{\pi} t\, dt = \frac{1}{2}t^2\Big|_0^{\pi} = \frac{\pi^2}{2}$$

8. $\mathbf{F} = \langle xy, 2, z^3 \rangle$

SOLUTION

Step 1. Calculate the integrand. We write out the vectors:

$$\mathbf{c}(t) = (\cos t, \sin t, t)$$
$$\mathbf{c}'(t) = (-\sin t, \cos t, 1)$$
$$F(\mathbf{c}(t)) = \left\langle \cos t \sin t, 2, t^3 \right\rangle$$

The integrand is the dot product:

$$F(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle \cos t \sin t, 2, t^3 \right\rangle \cdot \langle -\sin t, \cos t, 1 \rangle = -\cos t \sin^2 t + 2\cos t + t^3$$

Step 2. Evaluate the integral. We have

$$\int_{\mathcal{C}} \mathbf{F} d\mathbf{s} = \int_0^{\pi} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^{\pi} \left(-\cos t \ \sin^2 t + 2\cos t + t^3 \right) dt$$
$$= -\int_0^{\pi} \cos t \ \sin^2 t\, dt + 2\int_0^{\pi} \cos t\, dt + \int_0^{\pi} t^3\, dt$$

Since $\int_0^{\pi} \cos t\, dt = 0$ and $\int_0^{\pi} \cos t \sin^2 t = 0$,

$$\int_{\mathcal{C}} \mathbf{F}\, d\mathbf{s} = \int_0^{\pi} t^3\, dt = \frac{t^4}{4}\bigg|_0^{\pi} = \frac{\pi^4}{4}$$

In Exercises 9–16, compute $\int_{\mathcal{C}} f\, ds$ *for the curve specified.*

9. $f(x, y) = \sqrt{1 + 9xy}, \quad y = x^3$ for $0 \le x \le 1$

SOLUTION The curve is parametrized by $\mathbf{c}(t) = \left(t, t^3\right)$ for $0 \le t \le 1$

Step 1. Compute $\|\mathbf{c}'(t)\|$. We have

$$\mathbf{c}'(t) = \frac{d}{dt}\left\langle t, t^3 \right\rangle = \left\langle 1, 3t^2 \right\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{1 + 9t^4}$$

Step 2. Write out $f(\mathbf{c}(t))$. We substitute $x = t$, $y = t^3$ in $f(x, y) = \sqrt{1 + 9xy}$ to obtain

$$f(\mathbf{c}(t)) = \sqrt{1 + 9t \cdot t^3} = \sqrt{1 + 9t^4}$$

Step 3. Compute the line integral. We use the Theorem on Scalar Line Integrals to write

$$\int_{\mathcal{C}} f(x, y)\, ds = \int_0^1 f(\mathbf{c}(t))\, \|\mathbf{c}'(t)\|\, dt = \int_0^1 \sqrt{1 + 9t^4}\sqrt{1 + 9t^4}\, dt = \int_0^1 \left(1 + 9t^4\right) dt$$
$$= t + \frac{9t^5}{5}\bigg|_0^1 = \frac{14}{5} = 2.8$$

10. $f(x, y) = \dfrac{y^3}{x^7}, \quad y = \frac{1}{4}x^4$ for $1 \le x \le 2$

SOLUTION We parametrize the curve by $\mathbf{c}(t) = \left\langle t, \frac{t^4}{4} \right\rangle$ for $1 \le t \le 2$.

Step 1. Compute $\|\mathbf{c}'(t)\|$. We have

$$\mathbf{c}'(t) = \frac{d}{dt}\left\langle t, \frac{t^4}{4} \right\rangle = \left\langle 1, t^3 \right\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{1 + t^6}$$

Step 2. Write out $f(\mathbf{c}(t))$. We substitute $x = t$, $y = \frac{t^4}{4}$ in $f(x, y) = \frac{y^3}{x^7}$ to obtain:

$$f(\mathbf{c}(t)) = \frac{\left(\frac{t^4}{4}\right)^3}{t^7} = \frac{t^5}{64}$$

Step 3. Compute the line integral. We have

$$\int_{\mathcal{C}} f(x, y)\, ds = \int_1^2 f(\mathbf{c}(t))\, \|\mathbf{c}'(t)\|\, dt = \int_1^2 \frac{t^5}{64}\sqrt{1+t^6}\, dt$$

We substitute $u = 1 + t^6$, $du = 6t^5\, dt$:

$$\int_{\mathcal{C}} f(x, y)\, ds = \frac{1}{384}\int_2^{65} \sqrt{u}\, du = \frac{1}{384}\frac{2}{3}u^{3/2}\Big|_2^{65} = \frac{1}{576}(65^{3/2} - 2^{3/2}) \approx 0.9049$$

11. $f(x, y, z) = z^2, \quad \mathbf{c}(t) = (2t, 3t, 4t)$ for $0 \le t \le 2$

SOLUTION

Step 1. Compute $\|\mathbf{c}'(t)\|$ We have

$$\mathbf{c}'(t) = \frac{d}{dt}\langle 2t, 3t, 4t\rangle = \langle 2, 3, 4\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{2^2 + 3^2 + 4^2} = \sqrt{29}$$

Step 2. Write out $f(\mathbf{c}(t))$ We substitute $z = 4t$ in $f(x, y, z) = z^2$ to obtain:

$$f(\mathbf{c}(t)) = 16t^2$$

Step 3. Compute the line integral. By the Theorem on Scalar Line Integrals we have

$$\int_{\mathcal{C}} f(x, y, z)\, ds = \int_0^2 f(\mathbf{c}(t))\, \|\mathbf{c}'(t)\|\, dt = \int_0^2 16t^2 \cdot \sqrt{29}\, dt = \sqrt{29} \cdot \frac{16}{3}t^3\Big|_0^2 = \frac{128\sqrt{29}}{3} \approx 229.8$$

12. $f(x, y, z) = 3x - 2y + z, \quad \mathbf{c}(t) = (2 + t, 2 - t, 2t)$
for $-2 \le t \le 1$

SOLUTION

Step 1. Compute $\|\mathbf{c}'(t)\|$. We differentiate $\mathbf{c}(t) = (2 + t, 2 - t, 2t)$ and compute the length of the derivative vector:

$$\mathbf{c}'(t) = (1, -1, 2) \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{1^2 + (-1)^2 + 2^2} = \sqrt{6}$$

Step 2. Write out $f(\mathbf{c}(t))$. We substitute $x = 2 + t$, $y = 2 - t$, $z = 2t$ in $f(x, y, z) = 3x - 2y + z$ to obtain:

$$f(\mathbf{c}(t)) = 3(2 + t) - 2(2 - t) + 2t = 7t + 2$$

Step 3. Compute the line integral. We have

$$\int_{\mathcal{C}} f(x, y, z)\, ds = \int_{-2}^1 f(\mathbf{c}(t))\, \|\mathbf{c}'(t)\|\, dt = \int_{-2}^1 (7t + 2)\sqrt{6}\, dt = \sqrt{6}\left(\frac{7t^2}{2} + 2t\right)\Big|_{-2}^1$$

$$= \sqrt{6}\left(\left(\frac{7}{2} + 2\right) - \left(\frac{28}{2} - 4\right)\right) = -\frac{9\sqrt{6}}{2}$$

13. $f(x, y, z) = xe^{z^2}$, piecewise linear path from $(0, 0, 1)$ to $(0, 2, 0)$ to $(1, 1, 1)$

SOLUTION Let $\mathcal{C}_1$ be the segment joining the points $(0, 0, 1)$ and $(0, 2, 0)$ and $\mathcal{C}_2$ be the segment joining the points $(0, 2, 0)$ and $(1, 1, 1)$. We parametrize $\mathcal{C}_1$ and $\mathcal{C}_2$ by the following parametrization:

$$\mathcal{C}_1 : \mathbf{c}_1(t) = (0, 2t, 1 - t),\ 0 \le t \le 1$$
$$\mathcal{C}_2 : \mathbf{c}_2(t) = (t, 2 - t, t),\ 0 \le t \le 1$$

For $\mathcal{C} = \mathcal{C}_1 + \mathcal{C}_1$ we have

$$\int_{\mathcal{C}} f(x, y, z)\, ds = \int_{\mathcal{C}_1} f(x, y, z)\, ds + \int_{\mathcal{C}_2} f(x, y, z)\, ds \tag{1}$$

We compute the integrals on the right hand side.

- The integral over $\mathcal{C}_1$: We have

$$\mathbf{c}_1'(t) = \frac{d}{dt}\langle 0, 2t, 1 - t\rangle = \langle 0, 2, -1\rangle \quad \Rightarrow \quad \|\mathbf{c}_1'(t)\| = \sqrt{0 + 4 + 1} = \sqrt{5}$$
$$f(\mathbf{c}(t)) = xe^{z^2} = 0 \cdot e^{(1-t)^2} = 0$$

Hence,

$$\int_{\mathcal{C}_1} f(x,y,z)\,ds = \int_0^1 f(\mathbf{c}_1(t))\,\|\mathbf{c}_1'(t)\|\,dt = \int_0^1 0\,dt = 0 \qquad (2)$$

- The integral over $\mathcal{C}_2$: We have

$$\mathbf{c}_2'(t) = \frac{d}{dt}\langle t, 2-t, t\rangle = \langle 1, -1, 1\rangle \quad \Rightarrow \quad \|\mathbf{c}_2'(t)\| = \sqrt{1+1+1} = \sqrt{3}$$

$$f(\mathbf{c}_2(t)) = xe^{z^2} = te^{t^2}$$

Hence,

$$\int_{\mathcal{C}_2} f(x,y,z)\,ds = \int_0^1 te^{t^2}\sqrt{3}\,dt \qquad (3)$$

Using the substitution $u = t^2$ we find that

$$\int_{\mathcal{C}_2} f(x,y,z)\,ds = \int_0^1 \frac{\sqrt{3}}{2}e^u\,du = \frac{\sqrt{3}}{2}(e-1) \approx 1.488$$

Hence,

$$\int_{\mathcal{C}} f(x,y,z)\,ds \approx 1.488$$

14. $f(x,y,z) = x^2z, \quad \mathbf{c}(t) = (e^t, \sqrt{2}t, e^{-t})$ for $0 \le t \le 1$

SOLUTION

Step 1. Compute $\|\mathbf{c}'(t)\|$. We have

$$\mathbf{c}'(t) = \frac{d}{dt}\left\langle e^t, \sqrt{2}t, e^{-t}\right\rangle = \left\langle e^t, \sqrt{2}, -e^{-t}\right\rangle$$

Hence,

$$\|\mathbf{c}'(t)\| = \sqrt{\left(e^t\right)^2 + \left(\sqrt{2}\right)^2 + \left(-e^{-t}\right)^2} = \sqrt{e^{2t} + 2 + e^{-2t}} = \sqrt{\left(e^t + e^{-t}\right)^2} = e^t + e^{-t}$$

Step 2. Write out $f(\mathbf{c}(t))$. We substitute $x = e^t$, $y = \sqrt{2}t$, $z = e^{-t}$ in $f(x,y,z) = x^2z$ to obtain

$$f(\mathbf{c}(t)) = e^{2t}\cdot e^{-t} = e^t$$

Step 3. Compute the integral. We use the Theorem on Scalar Line Integral to obtain the following integral:

$$\int_{\mathcal{C}} f(x,y,z)\,ds = \int_0^1 f(\mathbf{c}(t))\,\|\mathbf{c}'(t)\|\,dt = \int_0^1 e^t\left(e^t + e^{-t}\right)dt = \int_0^1 \left(e^{2t} + 1\right)dt$$

$$= \frac{1}{2}e^{2t} + t\Big|_0^1 = \left(\frac{1}{2}e^2 + 1\right) - \left(\frac{1}{2}\right) = \frac{1}{2}\left(e^2 + 1\right)$$

15. $f(x,y,z) = 2x^2 + 8z, \quad \mathbf{c}(t) = (e^t, t^2, t), \quad 0 \le t \le 1$

SOLUTION

Step 1. Compute $\|\mathbf{c}'(t)\|$.

$$\mathbf{c}'(t) = \frac{d}{dt}\left\langle e^t, t^2, t\right\rangle = \left\langle e^t, 2t, 1\right\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{e^{2t} + 4t^2 + 1}$$

Step 2. Write out $f(\mathbf{c}(t))$. We substitute $x = e^t$, $y = t^2$, $z = t$ in $f(x,y,z) = 2x^2 + 8z$ to obtain:

$$f(\mathbf{c}(t)) = 2e^{2t} + 8t$$

Step 3. Compute the line integral. We have

$$\int_{\mathcal{C}} f(x,y,z)\,ds = \int_0^1 f(\mathbf{c}(t))\,\|\mathbf{c}'(t)\|\,dt = \int_0^1 (2e^{2t} + 8t)\sqrt{e^{2t} + 4t^2 + 1}\,dt$$

We compute the integral using the substitution $u = e^{2t} + 4t^2 + 1$, $du = 2e^{2t} + 8t\,dt$. We get:

$$\int_{\mathcal{C}} f(x,y,z)\,ds = \int_2^{e^2+5} u^{1/2}\,du = \frac{2}{3}u^{3/2}\Big|_2^{e^2+5} = \frac{2}{3}\left((e^2+5)^{3/2} - 2^{3/2}\right)$$

16. $f(x, y, z) = 6xz - 2y^2$, $\mathbf{c}(t) = \left(t, \frac{t^2}{\sqrt{2}}, \frac{t^3}{3}\right)$, $0 \le t \le 2$

SOLUTION

Step 1. Compute $\|\mathbf{c}'(t)\|$.

$$\mathbf{c}'(t) = \frac{d}{dt}\left\langle t, \frac{t^2}{\sqrt{2}}, \frac{t^3}{3}\right\rangle = \left\langle 1, \sqrt{2}t, t^2\right\rangle$$

$$\Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{1^2 + (\sqrt{2}t)^2 + (t^2)^2} = \sqrt{1 + 2t^2 + t^4} = \sqrt{(1 + t^2)^2} = 1 + t^2$$

Step 2. Write out $f(\mathbf{c}(t))$. We substitute $x = t$, $y = \frac{t^2}{\sqrt{2}}$, $z = \frac{t^3}{3}$ in $f(x, y, z) = 6xz - 2y^2$ to obtain:

$$f(\mathbf{c}(t)) = 6t\left(\frac{t^3}{3}\right) - 2\left(\frac{t^2}{\sqrt{2}}\right)^2 = 2t^4 - t^4 = t^4$$

Step 3. Compute the line integral. We have

$$\int_{\mathcal{C}} f(x, y, z)\, ds = \int_0^2 f(\mathbf{c}(t))\, \|\mathbf{c}'(t)\|\, dt = \int_0^2 t^4(1 + t^2)\, dt = \int_0^2 t^4 + t^6\, dt$$

$$= \left.\frac{t^5}{5} + \frac{t^7}{7}\right|_0^2 = \frac{32}{5} + \frac{128}{7} = \frac{864}{35}$$

17. Calculate $\int_{\mathcal{C}} 1\, ds$, where the curve $\mathcal{C}$ is parametrized by $\mathbf{c}(t) = (4t, -3t, 12t)$ for $2 \le t \le 5$. What does this integral represent?

SOLUTION Compute $\|\mathbf{c}'(t)\|$.

$$\mathbf{c}'(t) = \frac{d}{dt} < 4t, -3t, 12t > = < 4, -3, 12 > \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{4^2 + (-3)^2 + (12)^2} = 13$$

Compute the line integral. We have

$$\int_{\mathcal{C}} 1\, ds = \int_2^5 \|\mathbf{c}'(t)\|\, dt = \int_2^5 13\, dt = 13(5 - 2) = 39$$

This represents the distance from the point $(8, -6, 24)$ to the point $(20, -15, 60)$.

18. Calculate $\int_{\mathcal{C}} 1\, ds$, where the curve $\mathcal{C}$ is parametrized by $\mathbf{c}(t) = (e^t, \sqrt{2}t, e^{-t})$ for $0 \le t \le 2$.

SOLUTION Compute $\|\mathbf{c}'(t)\|$.

$$\mathbf{c}'(t) = \frac{d}{dt} < e^t, \sqrt{2}t, e^{-t} > = < e^t, \sqrt{2}, -e^{-t} >$$

$$\Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{(e^t)^2 + (\sqrt{2})^2 + (-e^{-t})^2} = \sqrt{e^{2t} + 2 + e^{-2t}} = \sqrt{(e^t + e^{-t})^2} = e^t + e^{-t}$$

Compute the line integral. We have

$$\int_{\mathcal{C}} 1\, ds = \int_0^2 \|\mathbf{c}'(t)\|\, dt = \int_0^2 e^t + e^{-t}\, dt = \left. e^t - e^{-t}\right|_0^2 = e^2 - e^{-2}$$

In Exercises 19–26, compute $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$ *for the oriented curve specified.*

19. $\mathbf{F} = \langle x^2, xy\rangle$, line segment from $(0, 0)$ to $(2, 2)$

SOLUTION The oriented line segment is parametrized by

$$\mathbf{c}(t) = (t, t), \quad t \text{ varies from 0 to 2.}$$

Therefore,

$$\mathbf{F}(\mathbf{c}(t)) = \left\langle x^2, xy\right\rangle = \left\langle t^2, t \cdot t\right\rangle = \left\langle t^2, t^2\right\rangle$$

$$\mathbf{c}'(t) = \frac{d}{dt}\langle t, t\rangle = \langle 1, 1\rangle$$

The integrand is the dot product:

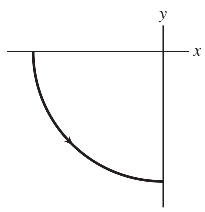
$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle t^2, t^2 \right\rangle \cdot \langle 1, 1\rangle = t^2 + t^2 = 2t^2$$

We now use the Theorem on vector line integral to compute $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^2 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^2 2t^2\, dt = \frac{2t^3}{3}\bigg|_0^2 = \frac{16}{3}$$

20. $\mathbf{F} = \langle 4, y\rangle$, quarter circle $x^2 + y^2 = 1$ with $x \le 0$, $y \le 0$, oriented counterclockwise

SOLUTION



The oriented path is parametrized by:

$$\mathbf{c}(t) = (\cos t, \sin t), \quad \pi \le t \le \frac{3\pi}{2}$$

We compute the integrand:

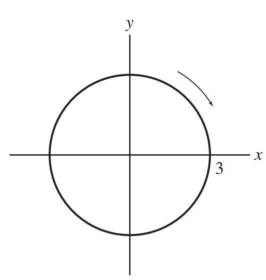
$$\begin{aligned} \mathbf{F}(\mathbf{c}(t)) &= \langle 4, \sin t\rangle \\ \mathbf{c}'(t) &= \langle -\sin t, \cos t\rangle \\ \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) &= \langle 4, \sin t\rangle \cdot \langle -\sin t, \cos t\rangle = -4\sin t + \sin t\cos t = -4\sin t + \frac{1}{2}\sin 2t \end{aligned}$$

The vector line integral is the following integral:

$$\begin{aligned} \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} &= \int_{\pi}^{3\pi/2} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_{\pi}^{3\pi/2} \left(-4\sin t + \frac{1}{2}\sin 2t\right) dt = 4\cos t - \frac{1}{4}\cos 2t\bigg|_{\pi}^{3\pi/2} \\ &= \left(4\cos\frac{3\pi}{2} - \frac{1}{4}\cos 3\pi\right) - \left(4\cos\pi - \frac{1}{4}\cos 2\pi\right) = \frac{1}{4} + 4 + \frac{1}{4} = 4.5 \end{aligned}$$

21. $\mathbf{F} = \left\langle x^2, xy \right\rangle$, part of circle $x^2 + y^2 = 9$ with $x \le 0$, $y \ge 0$, oriented clockwise

SOLUTION



The oriented path is parametrized by

$$\mathbf{c}(t) = (-3\cos t, 3\sin t); \quad t \text{ is changing from } 0 \text{ to } \frac{\pi}{2}.$$

Note: $\mathbf{c}(0) = (-3, 0)$ and $\mathbf{c}\left(\frac{\pi}{2}\right) = (0, 3)$. $\cos t$ and $\sin t$ are both positive in this range, so $x = -3\cos t \le 0$ and $y = 3\sin t \ge 0$. We compute the integrand:

$$\mathbf{F}(\mathbf{c}(t)) = \left\langle x^2, xy \right\rangle = \left\langle 9\cos^2 t, -9\cos t \sin t \right\rangle$$

$$\mathbf{c}'(t) = \langle 3\sin t, 3\cos t\rangle$$
$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle 9\cos^2 t, -9\cos t \sin t\right\rangle \cdot \langle 3\sin t, 3\cos t\rangle = 27\cos^2 t\sin t - 27\cos^2 t\sin t = 0$$

Hence,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{\frac{\pi}{2}} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^{\frac{\pi}{2}} 0\, dt = 0$$

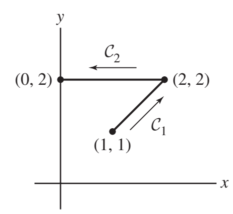
22. $\mathbf{F} = \left\langle e^{y-x}, e^{2x}\right\rangle$, piecewise linear path from (1, 1) to (2, 2) to (0, 2)

SOLUTION Let $\mathcal{C}_1$ be the linear path from (1, 1) to (2, 2), $\mathcal{C}_2$ the linear path from (2, 2) to (0, 2) and

$$\mathcal{C} = \mathcal{C}_1 + \mathcal{C}_2$$

We use the following parametrizations:

- $\mathcal{C}_1 : \mathbf{c}_1(t) = (t, t)$ t is changing from $t = 1$ to $t = 2$
- $\mathcal{C}_2 : \mathbf{c}_2(t) = (t, 2)$ t is changing from $t = 2$ to $t = 0$



By properties of line integrals,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} + \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} \tag{1}$$

We compute each integral on the right-hand side:

- The integral over $\mathcal{C}_1$:

$$\mathbf{F}(\mathbf{c}_1(t)) = \left\langle e^{y-x}, e^{2x}\right\rangle = \left\langle e^{t-t}, e^{2t}\right\rangle = \left\langle 1, e^{2t}\right\rangle$$
$$\mathbf{c}_1'(t) = \langle 1, 1\rangle$$
$$\mathbf{F}(\mathbf{c}_1(t)) \cdot \mathbf{c}_1'(t) = \left\langle 1, e^{2t}\right\rangle \cdot \langle 1, 1\rangle = 1 + e^{2t}$$

Hence,

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = \int_1^2 \left(1 + e^{2t}\right) dt = t + \frac{1}{2}e^{2t}\Big|_1^2 = \left(2 + \frac{1}{2}e^4\right) - \left(1 + \frac{1}{2}e^2\right) = 1 + \frac{1}{2}e^4 - \frac{1}{2}e^2 \tag{2}$$

- The integral over $\mathcal{C}_2$:

$$\mathbf{F}(\mathbf{c}_2(t)) = \left\langle e^{y-x}, e^{2x}\right\rangle = \left\langle e^{2-t}, e^{2t}\right\rangle$$
$$\mathbf{c}_2'(t) = \langle 1, 0\rangle$$
$$\mathbf{F}(\mathbf{c}_2(t)) \cdot \mathbf{c}_2'(t) = \left\langle e^{2-t}, e^{2t}\right\rangle \cdot \langle 1, 0\rangle = e^{2-t} \cdot 1 + e^{2t} \cdot 0 = e^{2-t}$$

Hence,

$$\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = \int_2^0 \mathbf{F}(\mathbf{c}_2(t)) \cdot \mathbf{c}_2'(t)\, dt = \int_2^0 e^{2-t}\, dt = -e^{2-t}\Big|_2^0 = -e^{2-0} + e^{2-2} = -e^2 + 1 \tag{3}$$

We combine (1), (2), and (3) to obtain the following solution:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \left(1 + \frac{1}{2}e^4 - \frac{1}{2}e^2\right) + \left(-e^2 + 1\right) = \frac{1}{2}e^4 - \frac{3}{2}e^2 + 2$$

23. $\mathbf{F} = \langle 3zy^{-1}, 4x, -y \rangle$, $\mathbf{c}(t) = (e^t, e^t, t)$ for $-1 \le t \le 1$

SOLUTION

Step 1. Calculate the integrand. We write out the vectors and compute the integrand:

$$\mathbf{c}(t) = \left(e^t, e^t, t\right)$$
$$\mathbf{F}(\mathbf{c}(t)) = \left\langle 3zy^{-1}, 4x, -y \right\rangle = \left\langle 3te^{-t}, 4e^t, -e^t \right\rangle$$
$$\mathbf{c}'(t) = \left\langle e^t, e^t, 1 \right\rangle$$

The integrand is the dot product:

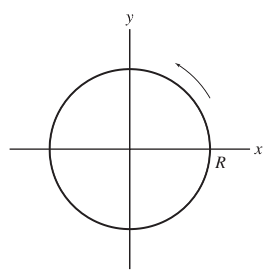
$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle 3te^{-t}, 4e^t, -e^t \right\rangle \cdot \left\langle e^t, e^t, 1 \right\rangle = 3te^{-t} \cdot e^t + 4e^t \cdot e^t - e^t \cdot 1 = 3t + 4e^{2t} - e^t$$

Step 2. Evaluate the integral. The vector line integral is:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{-1}^{1} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_{-1}^{1} \left(3t + 4e^{2t} - e^t\right) dt = 0 + \int_{-1}^{1} \left(4e^{2t} - e^t\right) dt = 2e^{2t} - e^t \Big|_{-1}^{1}$$
$$= \left(2e^2 - e\right) - \left(2e^{-2} - e^{-1}\right) = 2\left(e^2 - e^{-2}\right) - \left(e - e^{-1}\right) \approx 12.157$$

24. $\mathbf{F} = \left\langle \dfrac{-y}{(x^2+y^2)^2}, \dfrac{x}{(x^2+y^2)^2} \right\rangle$, circle of radius R with center at the origin oriented counterclockwise

SOLUTION



The path has the following parametrization:

$$\mathbf{c}(t) = \langle R\cos t, R\sin t \rangle, \quad 0 \le t \le 2\pi$$

Step 1. Calculate the integrand. Since $x^2 + y^2 = R^2$ on the circle, we have

$$\mathbf{F}(\mathbf{c}(t)) = \left\langle \frac{-y}{(x^2+y^2)^2}, \frac{x}{(x^2+y^2)^2} \right\rangle = \left\langle \frac{-R\sin t}{R^4}, \frac{R\cos t}{R^4} \right\rangle = \frac{1}{R^3}\langle -\sin t, \cos t \rangle$$
$$\mathbf{c}'(t) = \frac{d}{dt}\langle R\cos t, R\sin t \rangle = R\langle -\sin t, \cos t \rangle$$

The integrand is the dot product:

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \frac{1}{R^3}\langle -\sin t, \cos t \rangle \cdot R\langle -\sin t, \cos t \rangle = \frac{1}{R^2}(\cos^2 t + \sin^2 t) = \frac{1}{R^2}$$

Step 2. Evaluate the integral. We obtain the following integral:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{2\pi} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^{2\pi} \frac{dt}{R^2} = \frac{2\pi}{R^2}$$

25. $\mathbf{F} = \left\langle \dfrac{1}{y^3+1}, \dfrac{1}{z+1}, 1 \right\rangle$, $\mathbf{c}(t) = (t^3, 2, t^2)$ for $0 \le t \le 1$

SOLUTION

Step 1. Calculate the integrand. We have

$$\mathbf{c}(t) = \left(t^3, 2, t^2\right)$$
$$\mathbf{F}(\mathbf{c}(t)) = \left\langle \frac{1}{y^3+1}, \frac{1}{z+1}, 1 \right\rangle = \left\langle \frac{1}{2^3+1}, \frac{1}{t^2+1}, 1 \right\rangle = \left\langle \frac{1}{9}, \frac{1}{t^2+1}, 1 \right\rangle$$

$$\mathbf{c}'(t) = \left\langle 3t^2, 0, 2t \right\rangle$$

Hence,

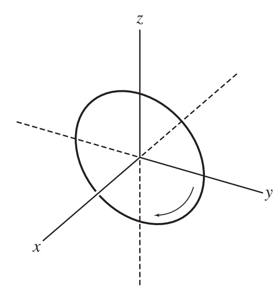
$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle \frac{1}{9}, \frac{1}{t^2+1}, 1 \right\rangle \cdot \left\langle 3t^2, 0, 2t \right\rangle = \frac{3t^2}{9} + 0 + 2t$$

Step 2. Evaluate the integral. Using the Theorem on vector line integrals we obtain:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^1 \frac{t^2}{3}\, dt + \int_0^1 2t\, dt$$
$$= \left.\frac{t^3}{9}\right|_0^1 + \left.t^2\right|_0^1 = \frac{10}{9}$$

26. $\mathbf{F} = \left\langle z^3, yz, x \right\rangle$, quarter of the circle of radius 2 in the yz-plane with center at the origin where $y \geq 0$ and $z \geq 0$, oriented clockwise when viewed from the positive x-axis

SOLUTION



The oriented path has the following parametrization:

$$\mathbf{c}(t) = (0, 2\cos t, 2\sin t)$$

t is changing from $\frac{\pi}{2}$ to 0.

Step 1. Calculate the integrand. We write out the vectors and compute the integrand:

$$\mathbf{c}(t) = (0, 2\cos t, 2\sin t)$$
$$\mathbf{F}(\mathbf{c}(t)) = \left\langle z^3, yz, x \right\rangle = \left\langle 8\,\sin^3 t, 4\cos t \sin t, 0 \right\rangle$$
$$\mathbf{c}'(t) = \langle 0, -2\sin t, 2\cos t \rangle$$

The integrand is the dot product:

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle 8\sin^3 t, 4\cos t \sin t, 0 \right\rangle \cdot \langle 0, -2\sin t, 2\cos t \rangle = -8\cos t \sin^2 t$$

Step 2. Evaluate the integral. We obtain the following vector line integral:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{\frac{\pi}{2}}^0 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_{\frac{\pi}{2}}^0 -8\cos t \sin^2 t\, dt = \int_0^{\frac{\pi}{2}} 8\sin^2 t \cos t\, dt = 8\left(\left.\frac{\sin^3 t}{3}\right|_0^{\frac{\pi}{2}} \right) = \frac{8}{3}$$

In Exercises 27–32, evaluate the line integral.

27. $\int_{\mathcal{C}} y\, dx - x\, dy$, parabola $y = x^2$ for $0 \leq x \leq 2$

SOLUTION

Step 1. Calculate the integrand.

$$\mathbf{c}(t) = (t, t^2)$$
$$\mathbf{F}(\mathbf{c}(t)) = \langle y, -x \rangle = \left\langle t^2, -t \right\rangle$$
$$\mathbf{c}'(t) = \langle 1, 2t \rangle$$

The integrand is the dot product

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle t^2, -t \right\rangle \cdot \langle 1, 2t \rangle = t^2 - 2t^2 = -t^2$$

Step 2.

$$\int_{\mathcal{C}} y\,dx - x\,dy = \int_0^2 -t^2\,dt = -\frac{t^3}{3}\bigg|_0^2 = -\frac{8}{3}$$

28. $\int_{\mathcal{C}} y\,dx + z\,dy + x\,dz$, $\quad \mathbf{c}(t) = (2 + t^{-1}, t^3, t^2)$ for $0 \le t \le 1$

SOLUTION

Step 1. Calculate the integrand.

$$\mathbf{c}(t) = (2 + t^{-1}, t^3, t^2)$$
$$\mathbf{F}(\mathbf{c}(t)) = \langle y, z, x \rangle = \left\langle t^3, t^2, 2 + t^{-1} \right\rangle$$
$$\mathbf{c}'(t) = \left\langle -t^{-2}, 3t^2, 2t \right\rangle$$

The integrand is the dot product

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle t^3, t^2, 2 + t^{-1} \right\rangle \cdot \left\langle -t^{-2}, 3t^2, 2t \right\rangle = (t^3)(-t^{-2}) + t^2(3t^2) + (2 + t^{-1})2t = 3t^4 + 3t + 2$$

Step 2.

$$\int_{\mathcal{C}} y\,dx + z\,dy + x\,dz = \int_0^1 3t^4 + 3t + 2\,dt = \frac{3t^5}{5} + \frac{3t^2}{2} + 2t\bigg|_0^1 = \frac{41}{10}$$

29. $\int_{\mathcal{C}} (x - y)\,dx + (y - z)\,dy + z\,dz$, $\quad$ line segment from $(0, 0, 0)$ to $(1, 4, 4)$

SOLUTION The oriented line segment from $(0, 0, 0)$ to $(1, 4, 4)$ has the parametrization:

$$\mathbf{c}(t) = (t, 4t, 4t),\ 0 \le t \le 1$$

Step 1. Calculate the integrand. We have

$$\mathbf{F}(\mathbf{c}(t)) = \langle x - y, y - z, z \rangle = \langle t - 4t, 4t - 4t, 4t \rangle = \langle -3t, 0, 4t \rangle$$
$$\mathbf{c}'(t) = \frac{d}{dt}\langle t, 4t, 4t \rangle = \langle 1, 4, 4 \rangle$$

The integrand is the dot product:

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \langle -3t, 0, 4t \rangle \cdot \langle 1, 4, 4 \rangle = -3t \cdot 1 + 0 \cdot 4 + 4t \cdot 4 = 13t$$

Step 2. Evaluate the integral. The vector line integral is:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\,dt = \int_0^1 13t\,dt = \frac{13}{2}t^2\bigg|_0^1 = 6.5$$

30. $\int_{\mathcal{C}} z\,dx + x^2\,dy + y\,dz$, $\quad \mathbf{c}(t) = (\cos t, \tan t, t)$ for $0 \le t \le \frac{\pi}{4}$

SOLUTION

Step 1. Calculate the integrand.

$$\mathbf{c}(t) = (\cos t, \tan t, t)$$
$$\mathbf{F}(\mathbf{c}(t)) = \left\langle z, x^2, y \right\rangle = \left\langle t, \cos^2 t, \tan t \right\rangle$$
$$\mathbf{c}'(t) = \left\langle -\sin t, \sec^2 t, 1 \right\rangle$$

The integrand is the dot product

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle t, \cos^2 t, \tan t \right\rangle \cdot \left\langle -\sin t, \sec^2 t, 1 \right\rangle = t(-\sin t) + \cos^2 t \sec^2 t + \tan t = -t\sin t + 1 + \tan t$$

Step 2.

$$\int_{\mathcal{C}} y\,dx + z\,dy + x\,dz = \int_0^{\frac{\pi}{4}} -t\sin t + 1 + \tan t\,dt$$
$$= t\cos t - \sin t + t - \ln(\cos t)\bigg|_0^{\frac{\pi}{4}} = \frac{\pi\sqrt{2}}{8} - \frac{\sqrt{2}}{2} + \frac{\pi}{4} + \frac{1}{2}\ln(2)$$

31. $\displaystyle\int_{\mathcal{C}} \frac{-y\,dx + x\,dy}{x^2+y^2}$, segment from (1, 0) to (0, 1).

SOLUTION

Step 1. Calculate the integrand.

$$\mathbf{c}(t) = (1-t, t) \quad (0 \le t \le 1)$$
$$\mathbf{F}(\mathbf{c}(t)) = \frac{1}{x^2+y^2}\langle -y, x\rangle = \frac{1}{(1-t)^2+t^2}\langle -t, 1-t\rangle$$
$$\mathbf{c}'(t) = \langle -1, 1\rangle$$

The integrand is the dot product

$$\mathbf{F}(\mathbf{c}(t))\cdot \mathbf{c}'(t) = \frac{1}{(1-t)^2+t^2}\langle -t, 1-t\rangle \cdot \langle -1, 1\rangle = \frac{t+1-t}{(1-t)^2+t^2} = \frac{1}{2t^2-2t+1}$$

Step 2.

$$\int_{\mathcal{C}} \frac{-y\,dx + x\,dy}{x^2+y^2} = \int_0^1 \frac{dt}{2t^2-2t+1} = \frac{1}{2}\int_0^1 \frac{dt}{\left(t-\frac{1}{2}\right)^2+\frac{1}{4}}$$

We use the trigonometric substitution $t = \frac{1}{2} + \frac{1}{2}\tan\theta \Rightarrow dt = \frac{1}{2}\sec^2\theta\,d\theta$.

$$= \frac{1}{2}\int_{-\frac{\pi}{4}}^{\frac{\pi}{4}} \frac{\frac{1}{2}\sec^2\theta\,d\theta}{\frac{1}{4}(\tan^2\theta+1)} = \int_{-\frac{\pi}{4}}^{\frac{\pi}{4}} d\theta = \frac{\pi}{2}$$

32. $\displaystyle\int_{\mathcal{C}} y^2\,dx + z^2\,dy + (1-x^2)\,dz$, quarter of the circle of radius 1 in the xz-plane with center at the origin in the quadrant $x \ge 0$, $z \le 0$, oriented counterclockwise when viewed from the positive y-axis.

SOLUTION

Step 1. Calculate the integrand.

$$\mathbf{c}(t) = (\cos t, 0, \sin t) \quad \left(\frac{3\pi}{2} \le t \le 2\pi\right)$$
$$\mathbf{F}(\mathbf{c}(t)) = \left\langle y^2, z^2, 1-x^2\right\rangle = \left\langle 0^2, \sin^2 t, 1-\cos^2 t\right\rangle = \left\langle 0, \sin^2 t, \sin^2 t\right\rangle$$
$$\mathbf{c}'(t) = \langle -\sin t, 0, \cos t\rangle$$

The integrand is the dot product

$$\mathbf{F}(\mathbf{c}(t))\cdot\mathbf{c}'(t) = \left\langle 0, \sin^2 t, \sin^2 t\right\rangle \cdot \langle -\sin t, 0, \cos t\rangle$$
$$= \sin^2 t\ \cos t$$

Step 2.

$$\int_{\mathcal{C}} y^2\,dx + z^2\,dy + (1-x^2)\,dz = \int_{\frac{3\pi}{2}}^{2\pi} \sin^2 t\ \cos t\,dt$$
$$= \left.\frac{\sin^3 t}{3}\right|_{\frac{3\pi}{2}}^{2\pi}$$
$$= \frac{1}{3}(0-(-1)^3) = \frac{1}{3}$$

33. CAS Let $f(x,y,z) = x^{-1}yz$, and let $\mathcal{C}$ be the curve parametrized by $\mathbf{c}(t) = (\ln t, t, t^2)$ for $2 \le t \le 4$. Use a computer algebra system to calculate $\int_{\mathcal{C}} f(x,y,z)\,ds$ to four decimal places.

SOLUTION Note that $\mathbf{c}'(t) = \langle 1/t, 1, 2t\rangle$, so $\|\mathbf{c}'(t)\| = \sqrt{1/t^2+1+4t^2}$. Our line integral is

$$\int_2^4 f(\ln t, t, t^2)\sqrt{1/t^2+1+4t^2}\,dt,$$

which we calculate to be 339.5587.

34. CAS Use a CAS to calculate $\int_{\mathcal{C}} \langle e^{x-y}, e^{x+y}\rangle \cdot d\mathbf{s}$ to four decimal places, where $\mathcal{C}$ is the curve $y = \sin x$ for $0 \le x \le \pi$, oriented from left to right.

SOLUTION Using the parameterization $\mathbf{c}(t) = \langle t, \sin t\rangle$, our integral becomes $\int_0^{\pi} \left\langle e^{t-\sin t}, e^{t+\sin t}\right\rangle \cdot \langle 1, \cos t\rangle\, dt$, which is calculated to be -4.5088.

In Exercises 35 and 36, calculate the line integral of $\mathbf{F} = \left\langle e^z, e^{x-y}, e^y\right\rangle$ *over the given path.*

35. The blue path from P to Q in Figure 14

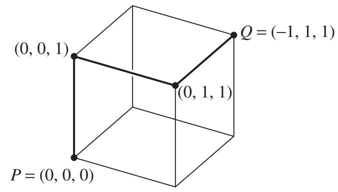


FIGURE 14

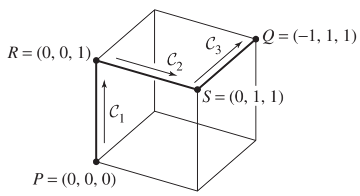
SOLUTION



Let $\mathcal{C}_1, \mathcal{C}_2, \mathcal{C}_3$ denote the oriented segments from P to R, from R to S and S to Q respectively. These paths have the following parametrizations (see figure):

$$\begin{array}{llll} \mathcal{C}_1: & \mathbf{c}_1(t) = (0,0,t) & 0 \le t \le 1 & & \mathbf{c}_1'(t) = \langle 0,0,1\rangle \\ \mathcal{C}_2: & \mathbf{c}_2(t) = (0,t,1) & 0 \le t \le 1 & \Rightarrow & \mathbf{c}_2'(t) = \langle 0,1,0\rangle \\ \mathcal{C}_3: & \mathbf{c}_3(t) = (-t,1,1) & 0 \le t \le 1 & & \mathbf{c}_3'(t) = \langle -1,0,0\rangle \end{array}$$

Since $\mathcal{C} = \mathcal{C}_1 + \mathcal{C}_2 + \mathcal{C}_3$ we have

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} + \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} + \int_{\mathcal{C}_3} \mathbf{F} \cdot d\mathbf{s} \tag{1}$$

We compute each integral on the right hand side separately.

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}_1(t)) \cdot \mathbf{c}_1'(t)\, dt = \int_0^1 \left\langle e^t, e^{0-0}, e^0\right\rangle \cdot \langle 0,0,1\rangle\, dt = \int_0^1 1\, dt = 1$$

$$\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}_2(t)) \cdot \mathbf{c}_2'(t)\, dt = \int_0^1 \left\langle e^1, e^{0-t}, e^t\right\rangle \cdot \langle 0,1,0\rangle\, dt = \int_0^1 e^{-t}\, dt = -e^{-t}\Big|_0^1 = 1 - e^{-1}$$

$$\int_{\mathcal{C}_3} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}_3(t)) \cdot \mathbf{c}_3'(t)\, dt = \int_0^1 \left\langle e^1, e^{t-1}, e^1\right\rangle \cdot \langle -1,0,0\rangle\, dt = \int_0^1 -e\, dt = -e$$

Substituting these integrals in (1) gives

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = 1 + (1 - e^{-1}) - e = 2 - e^{-1} - e$$

36. The closed path *ABCA* in Figure 15

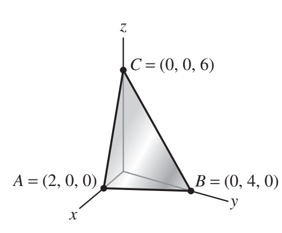


FIGURE 15

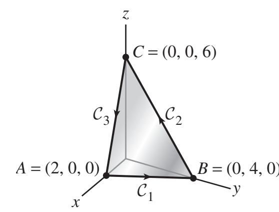
SOLUTION



We denote by $\mathcal{C}_1, \mathcal{C}_2, \mathcal{C}_3$ the oriented segments from A to B, from B to C and from C to A. We parametrize these paths by,

$$\begin{aligned}
&\mathcal{C}_1 : \mathbf{c}_1(t) = (1-t)(2,0,0) + t(0,4,0) = (2-2t, 4t, 0),\ 0 \le t \le 1 && \mathbf{c}_1'(t) = \langle -2, 4, 0\rangle \\
&\mathcal{C}_2 : \mathbf{c}_2(t) = (1-t)(0,4,0) + t(0,0,6) = (0, 4-4t, 6t),\ 0 \le t \le 1 \quad \Rightarrow && \mathbf{c}_2'(t) = \langle 0, -4, 6\rangle \\
&\mathcal{C}_3 : \mathbf{c}_3(t) = (1-t)(0,0,6) + t(2,0,0) = (2t, 0, 6-6t),\ 0 \le t \le 1 && \mathbf{c}_3'(t) = \langle 2, 0, -6\rangle
\end{aligned}$$

Since $\mathcal{C} = \mathcal{C}_1 + \mathcal{C}_2 + \mathcal{C}_3$ we have,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \sum_{i=1}^{3} \int_{\mathcal{C}_i} \mathbf{F} \cdot d\mathbf{s} \tag{1}$$

We compute the integrals on the right-hand side:

$$\begin{aligned}
\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} &= \int \left\langle e^0, e^{2-6t}, e^{4t} \right\rangle \cdot \langle -2, 4, 0\rangle\, dt = \int_0^1 \left\langle 1, e^{2-6t}, e^{4t} \right\rangle \cdot \langle -2, 4, 0\rangle\, dt \\
&= \int_0^1 \left(-2 + 4e^{2-6t}\right) dt = -2t - \frac{2}{3}e^{2-6t}\Big|_0^1 = \frac{2}{3}e^2 - \frac{2}{3}e^{-4} - 2 \\
\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} &= \int_0^1 \left\langle e^{6t}, e^{-4+4t}, e^{4-4t} \right\rangle \cdot \langle 0, -4, 6\rangle\, dt = \int_0^1 \left(-4e^{-4+4t} + 6e^{4-4t}\right) dt \\
&= -e^{-4+4t} - \frac{3}{2}e^{4-4t}\Big|_0^1 = \frac{3}{2}e^4 + e^{-4} - \frac{5}{2} \\
\int_{\mathcal{C}_3} \mathbf{F} \cdot d\mathbf{s} &= \int_0^1 \left\langle e^{6-6t}, e^{2t}, e^0 \right\rangle \cdot \langle 2, 0, -6\rangle\, dt = \int_0^1 \left(2e^{6-6t} - 6\right) dt \\
&= -\frac{1}{3}e^{6-6t} - 6t\Big|_0^1 = \frac{1}{3}e^6 - \frac{19}{3}
\end{aligned}$$

We substitute these values in (1) to obtain the solution:

$$\begin{aligned}
\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} &= \left(\frac{2}{3}e^2 - \frac{2}{3}e^{-4} - 2\right) + \left(\frac{3}{2}e^4 + e^{-4} - \frac{5}{2}\right) + \left(\frac{1}{3}e^6 - \frac{19}{3}\right) \\
&= \frac{1}{3}e^6 + \frac{3}{2}e^4 + \frac{2}{3}e^2 - \frac{65}{6} + \frac{1}{3}e^{-4}
\end{aligned}$$

In Exercises 37 and 38, $\mathcal{C}$ is the path from P to Q in Figure 16 that traces $\mathcal{C}_1$, $\mathcal{C}_2$, and $\mathcal{C}_3$ in the orientation indicated, and **F** *is a vector field such that*

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = 5, \qquad \int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = 8, \qquad \int_{\mathcal{C}_3} \mathbf{F} \cdot d\mathbf{s} = 8$$

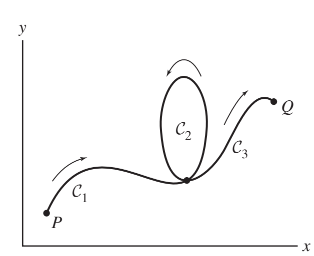


FIGURE 16

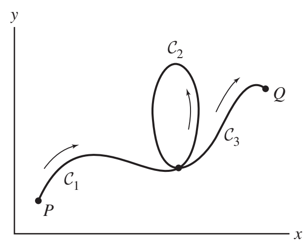
37. Determine:

(a) $\displaystyle\int_{-\mathcal{C}_3} \mathbf{F}\cdot d\mathbf{s}$ **(b)** $\displaystyle\int_{\mathcal{C}_2} \mathbf{F}\cdot d\mathbf{s}$ **(c)** $\displaystyle\int_{-\mathcal{C}_1-\mathcal{C}_3} \mathbf{F}\cdot d\mathbf{s}$

SOLUTION



(a) If the orientation of the path is reversed, the line integral changes sign, thus:

$$\int_{-\mathcal{C}_3} \mathbf{F}\cdot d\mathbf{s} = -\int_{\mathcal{C}_3} \mathbf{F}\cdot d\mathbf{s} = -8$$

(b) By additivity of line integrals, we have

$$\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} = \int_{\mathcal{C}_1} \mathbf{F}\cdot d\mathbf{s} + \int_{\mathcal{C}_2} \mathbf{F}\cdot d\mathbf{s} + \int_{\mathcal{C}_3} \mathbf{F}\cdot d\mathbf{s}$$

Substituting the given values we obtain

$$5 = 8 + \int_{\mathcal{C}_2} \mathbf{F}\cdot d\mathbf{s} + 8$$

or

$$\int_{\mathcal{C}_2} \mathbf{F}\cdot d\mathbf{s} = 5 - 16 = -11$$

(c) Using properties of line integrals gives

$$\int_{-\mathcal{C}_1-\mathcal{C}_3} \mathbf{F}\cdot d\mathbf{s} = \int_{-\mathcal{C}_1} \mathbf{F}\cdot d\mathbf{s} + \int_{-\mathcal{C}_3} \mathbf{F}\cdot d\mathbf{s} = -\int_{\mathcal{C}_1} \mathbf{F}\cdot d\mathbf{s} - \int_{\mathcal{C}_3} \mathbf{F}\cdot d\mathbf{s} = -8 - 8 = -16$$

38. Find the value of $\displaystyle\int_{\mathcal{C}'} \mathbf{F}\cdot d\mathbf{s}$, where $\mathcal{C}'$ is the path that traverses the loop $\mathcal{C}_2$ four times in the clockwise direction.

SOLUTION Using additivity and the integral over the curve with the reversed orientation, the line integral of **F** over the path that traverses the loop $\mathcal{C}_2$ four times in the clockwise direction is:

$$4\int_{-\mathcal{C}_2} \mathbf{F}\cdot d\mathbf{s} = 4\cdot\left(-\int_{\mathcal{C}_2} \mathbf{F}\cdot d\mathbf{s}\right) = -4\int_{\mathcal{C}_2} \mathbf{F}\cdot d\mathbf{s} = -4\cdot(-11) = 44$$

39. The values of a function $f(x, y, z)$ and vector field $\mathbf{F}(x, y, z)$ are given at six sample points along the path ABC in Figure 17. Estimate the line integrals of f and **F** along ABC.

Point	$f(x, y, z)$	$\mathbf{F}(x, y, z)$
$\left(1, \frac{1}{6}, 0\right)$	3	$\langle 1, 0, 2\rangle$
$\left(1, \frac{1}{2}, 0\right)$	3.3	$\langle 1, 1, 3\rangle$
$\left(1, \frac{5}{6}, 0\right)$	3.6	$\langle 2, 1, 5\rangle$
$\left(1, 1, \frac{1}{6}\right)$	4.2	$\langle 3, 2, 4\rangle$
$\left(1, 1, \frac{1}{2}\right)$	4.5	$\langle 3, 3, 3\rangle$
$\left(1, 1, \frac{5}{6}\right)$	4.2	$\langle 5, 3, 3\rangle$

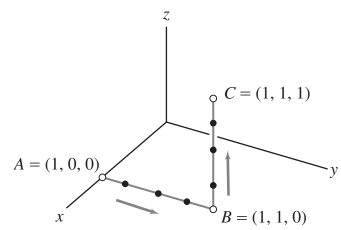


FIGURE 17

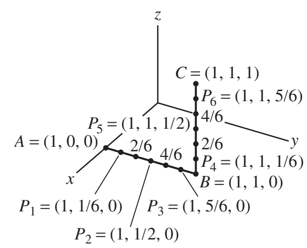
SOLUTION



We write the integrals as sum of integrals and estimate each integral by a Riemann Sum. That is,

$$\int_{ABC} f(x, y, z)\,ds = \int_{AB} f(x, y, z)\,ds + \int_{BC} f(x, y, z)\,d\mathbf{s} \approx \sum_{i=1}^{3} f(P_i)\,\Delta s_i + \sum_{i=4}^{6} f(P_i)\Delta s_i \qquad (1)$$

$$\int_{ABC} \mathbf{F}\cdot d\mathbf{s} = \int_{AB} \mathbf{F}\cdot d\mathbf{s} + \int_{BC} \mathbf{F}\cdot d\mathbf{s} = \int_{AB} (\mathbf{F}\cdot\mathbf{T})ds + \int_{BC} (\mathbf{F}\cdot\mathbf{T})ds$$

On AB, the unit tangent vector is $\mathbf{T} = \langle 0, 1, 0\rangle$, hence $\mathbf{F}\cdot\mathbf{T} = F_2$. On BC, the unit tangent vector is $\mathbf{T} = \langle 0, 0, 1\rangle$, hence $\mathbf{F}\cdot\mathbf{T} = F_3$. Therefore,

$$\int_{ABC} \mathbf{F}\,ds = \int_{AB} F_1\,ds + \int_{BC} F_3\,ds \approx \sum_{i=1}^{3} F_1(P_i)\,\Delta s_i + \sum_{i=4}^{6} F_3(P_i)\,\Delta s_i \qquad (2)$$

We consider the partitions of AB and BC to three subarcs with equal length $\Delta s_i = \frac{1}{3}$, therefore (1) and (2) give

$$\int_{ABC} f(x, y, z)\,ds \approx \frac{1}{3}\left(f(P_1) + f(P_2) + f(P_3) + f(P_4) + f(P_5) + f(P_6)\right)$$

$$\int_{ABC} \mathbf{F}\,d\mathbf{s} \approx \frac{1}{3}\left(F_2(P_1) + F_2(P_2) + F_2(P_3) + F_3(P_4) + F_3(P_5) + F_3(P_6)\right)$$

We now substitute the values of the functions at the sample points to obtain the following approximations:

$$\int_{ABC} f(x, y, z)\,ds \approx \frac{1}{3}(3 + 3.3 + 3.6 + 4.2 + 4.5 + 4.2) = 7.6$$

$$\int_{ABC} \mathbf{F}\cdot d\mathbf{s} \approx \frac{1}{3}(0 + 1 + 1 + 4 + 3 + 3) = 4$$

40. Estimate the line integrals of $f(x, y)$ and $\mathbf{F}(x, y)$ along the quarter circle (oriented counterclockwise) in Figure 18 using the values at the three sample points along each path.

Point	$f(x, y)$	$\mathbf{F}(x, y)$
A	1	$\langle 1, 2\rangle$
B	-2	$\langle 1, 3\rangle$
C	4	$\langle -2, 4\rangle$

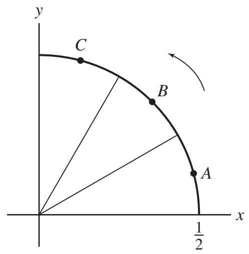


FIGURE 18

SOLUTION We estimate the line integral of $f(x, y)$ along the quarter circle $\mathcal{C}$ by the Riemann sum:

$$\int_{\mathcal{C}} f(x, y)\, d\mathbf{s} \approx f(A)\Delta s_1 + f(B)\Delta s_2 + f(C)\Delta s_3$$

We consider the partition of $\mathcal{C}$ to three arcs with equal length $\Delta s_i = \frac{\pi}{12}$. Using the values of f at the sample points, we get

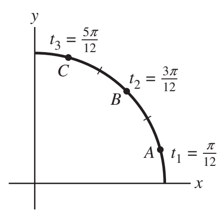
$$\int_{\mathcal{C}} f(x, y) d\mathbf{s} \approx \frac{\pi}{12}(1 - 2 + 4) = \frac{\pi}{4}$$

To estimate the vector line integral $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$ we use the parametrization

$$\mathcal{C} : \ \mathbf{c}(t) = \frac{1}{2}(\cos t, \sin t), \ 0 \le t \le \frac{\pi}{2}$$

Then,

$$\mathbf{c}'(t) = \frac{1}{2}(-\sin t, \cos t)$$



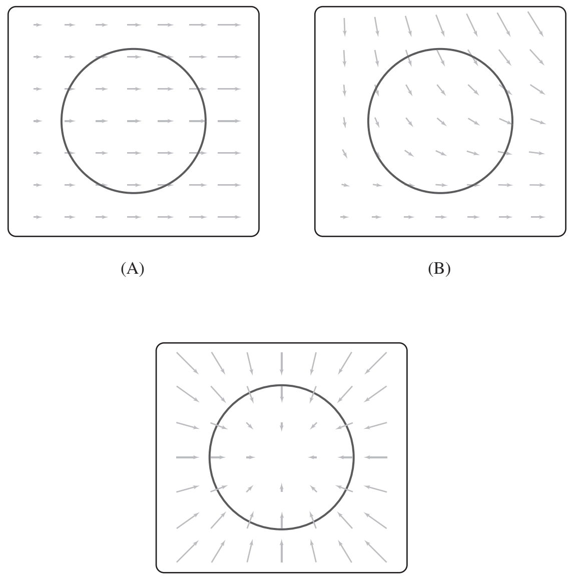
The partition points correspond to $t_1 = \frac{\pi}{12}, t_2 = \frac{3\pi}{12}, t_3 = \frac{5\pi}{12}$. By the theorem on vector line integrals, we have

$$\int_{\mathcal{C}} \mathbf{F} \cdot \mathbf{T}\, ds = \int_0^{\pi/2} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt$$

We estimate the integral using the Riemann sum, corresponding to the partition of the interval $0 \le t \le \frac{\pi}{2}$ to three intervals with equal length $\Delta t = \frac{\pi}{6}$. We get

$$\begin{aligned}
\int_{\mathcal{C}} \mathbf{F} \cdot \mathbf{T}\, ds &= \frac{\pi}{6}\left(\mathbf{F}(\mathbf{c}(t_1)) \cdot \mathbf{c}'(t_1) + \mathbf{F}(\mathbf{c}(t_2)) \cdot \mathbf{c}'(t_2) + \mathbf{F}(\mathbf{c}(t_3)) \cdot \mathbf{c}'(t_3)\right) \\
&= \frac{\pi}{6}\left(\mathbf{F}(A) \cdot \mathbf{c}'\left(\frac{\pi}{12}\right) + \mathbf{F}(B) \cdot \mathbf{c}'\left(\frac{3\pi}{12}\right) + \mathbf{F}(C) \cdot \mathbf{c}'\left(\frac{5\pi}{12}\right)\right) \\
&= \frac{\pi}{6}\left(\langle 1, 2\rangle \cdot \frac{1}{2}\left\langle -\sin\frac{\pi}{12}, \cos\frac{\pi}{12}\right\rangle + \langle 1, 3\rangle \cdot \frac{1}{2}\left\langle -\sin\frac{\pi}{4}, \cos\frac{\pi}{4}\right\rangle + \langle -2, 4\rangle \cdot \frac{1}{2}\left\langle -\sin\frac{5\pi}{12}, \cos\frac{5\pi}{12}\right\rangle\right) \\
&= \frac{\pi}{12}\left(-\sin\frac{\pi}{12} + 2\cos\frac{\pi}{12} - \sin\frac{\pi}{4} + 3\cos\frac{\pi}{4} + 2\sin\frac{5\pi}{12} + 4\cos\frac{5\pi}{12}\right) = 0.505\pi
\end{aligned}$$

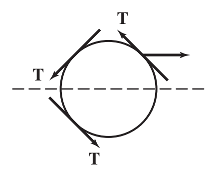
41. Determine whether the line integrals of the vector fields around the circle (oriented counterclockwise) in Figure 19 are positive, negative, or zero.



(A) (B) (C)

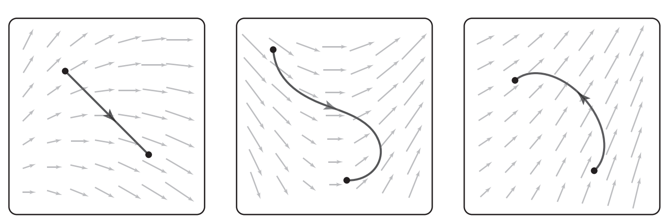
FIGURE 19

SOLUTION The vector line integral of F is the integral of the tangential component of F along the curve. The positive direction of a curve is counterclockwise.



For the vector field in (A), the line integral around the circle is zero because the contribution of the negative tangential components from the upper part of the circle is the same as the contribution of the positive tangential components from the lower part. For the vector in (B) the contribution of the negative tangential component appear to dominate over the positive contribution, hence the line integral is negative. In (C), the vector field is orthogonal to the unit tangent vector at each point, hence the line integral is zero.

42. Determine whether the line integrals of the vector fields along the oriented curves in Figure 20 are positive or negative.



(A) (B) (C)

FIGURE 20

SOLUTION

(A) Positive: The direction of the path is initially perpendicular to the vector field, becoming more and more oriented along the vector field.

(B) Positive: The path is oriented along the vector field when the vectors have a large magnitude. A short section of the path near the end is oriented against the vector field, but the magnitude of these vectors is small. The negative contribution of this section should not cancel out the earlier, strongly positive section.

(C) Positive: As before, the vector field has larger magnitude vectors in the section where the path is oriented along the vector field than the section where it is oriented against the vector field.

43. Calculate the total mass of a circular piece of wire of radius 4 cm centered at the origin whose mass density is $\rho(x, y) = x^2$ g/cm.

SOLUTION The total mass is the following integral:

$$M = \int_{\mathcal{C}} x^2 \, ds$$

We use the following parametrization of the wire:

$$\mathbf{c}(t) = (4\cos t, 4\sin t), \quad 0 \le t \le 2\pi$$

Hence,

$$\mathbf{c}'(t) = \langle -4\sin t,\ 4\cos t\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{(-4\sin t)^2 + (4\cos t)^2} = 4$$

We compute the line integral using the Theorem on Scalar Line Integrals. We get

$$\begin{aligned} M &= \int_0^{2\pi} \rho\left(\mathbf{c}(t)\right) \|\mathbf{c}'(t)\| \, dt = \int_0^{2\pi} (4\cos t)^2 \cdot 4 \, dt \\ &= 64 \int_0^{2\pi} \cos^2 t \, dt = 64 \left(\frac{t}{2} + \frac{\sin 2t}{4} \right) \Big|_0^{2\pi} = 64 \cdot \frac{2\pi}{2} = 64\pi \text{ g} \end{aligned}$$

44. Calculate the total mass of a metal tube in the helical shape $\mathbf{c}(t) = (\cos t, \sin t, t^2)$ (distance in centimeters) for $0 \le t \le 2\pi$ if the mass density is $\rho(x, y, z) = \sqrt{z}$ g/cm.

SOLUTION The total mass is the following integral:

$$M = \int_{\mathcal{C}} \sqrt{z} \, ds$$

We have

$$\mathbf{c}'(t) = \frac{d}{dt} \left\langle \cos t, \sin t, t^2 \right\rangle = \langle -\sin t, \cos t, 2t\rangle$$

Hence,

$$\|\mathbf{c}'(t)\| = \sqrt{(-\sin t)^2 + (\cos t)^2 + (2t)^2} = \sqrt{1 + 4t^2}$$

Using the Theorem on Scalar Line Integrals, we get

$$M = \int_{\mathcal{C}} \sqrt{z} \, ds = \int_0^{2\pi} \rho\left(\mathbf{c}(t)\right) \|\mathbf{c}'(t)\| \, dt = \int_0^{2\pi} \sqrt{t^2}\sqrt{1 + 4t^2} \, dt = \int_0^{2\pi} t\sqrt{1 + 4t^2} \, dt$$

We compute the integral using the substitution $u = 1 + 4t^2$, $du = 8t \, dt$. This gives

$$M = \int_1^{1+16\pi^2} \frac{u^{1/2}}{8} \, du = \frac{u^{3/2}}{12} \Big|_1^{1+16\pi^2} = \frac{1}{12} \left(\left(1 + 16\pi^2\right)^{3/2} - 1 \right) \approx 166.86 \text{ g}$$

45. Find the total charge on the curve $y = x^{4/3}$ for $1 \le x \le 8$ (in cm) assuming a charge density of $\rho(x, y) = x/y$ (in units of 10^{-6} C/cm).

SOLUTION We parametrize the curve by $\mathbf{c}(t) = (t, t^{\frac{4}{3}}) \quad (1 \le t \le 8)$. Then

$$\mathbf{c}'(t) = \left\langle 1, \frac{4}{3} t^{\frac{1}{3}} \right\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{1 + \frac{16}{9} t^{\frac{2}{3}}}$$

$$\rho(\mathbf{c}(t)) = \frac{x}{y} = \frac{t}{t^{\frac{4}{3}}}$$

Therefore the total charge will be

$$\int_{\mathcal{C}} \frac{x}{y} \, ds = \int_1^8 \frac{t}{t^{\frac{4}{3}}} \sqrt{1 + \frac{16}{9} t^{\frac{2}{3}}} \, dt = \int_1^8 \sqrt{1 + \frac{16}{9} t^{\frac{2}{3}}} \, t^{-\frac{1}{3}} \, dt$$

Using the substitution $u = 1 + \frac{16}{9} t^{\frac{2}{3}} \Rightarrow du = \frac{32}{27} t^{-\frac{1}{3}} \, dt$, we calculate the total charge as

$$\int_{\frac{25}{9}}^{\frac{73}{9}} \sqrt{u} \, \frac{27}{32} \, du = \frac{27}{32} \cdot \frac{2}{3} u^{\frac{3}{2}} \Big|_{\frac{25}{9}}^{\frac{73}{9}} = \frac{1}{48} \left(73^{\frac{3}{2}} - 25^{\frac{3}{2}} \right) \approx 10.39$$

Thus the total charge is 10.39×10^{-6} C.

46. Find the total charge on the curve $\mathbf{c}(t) = (\sin t, \cos t, \sin^2 t)$ in centimeters for $0 \le t \le \frac{\pi}{8}$ assuming a charge density of $\rho(x, y, z) = xy(y^2 - z)$ (in units of 10^{-6} C/cm).

SOLUTION Using the trigonometric identities $\sin 2t = 2 \sin t \cos t$ and $\cos 2t = \cos^2 t - \sin^2 t$, we first calculate the integrand

$$\mathbf{c}'(t) = \langle \cos t, -\sin t, 2\sin t \cos t\rangle = \langle \cos t, -\sin t, \sin 2t\rangle$$

$$\|\mathbf{c}'(t)\| = \sqrt{\cos^2 t + \sin^2 t + \sin^2 2t} = \sqrt{1 + \sin^2 2t}$$

$$\rho(\mathbf{c}(t)) = xy(y^2 - z) = \sin t \cos t(\cos^2 t - \sin^2 t) = \frac{1}{2}\sin 2t \cos 2t$$

Total charge is thus,

$$\int_{\mathcal{C}} xy(y^2 - z)\, ds = \int_0^{\frac{\pi}{8}} \frac{1}{2}\sin 2t \cos 2t\sqrt{1 + \sin^2 2t}\, dt$$

Using the substitution $u = 1 + \sin^2 2t \Rightarrow du = 4 \sin 2t \cos 2t\, dt$, we have $u(0) = 1 + \sin 0 = 1$ and $u(\frac{\pi}{8}) = 1 + \sin^2(2\frac{\pi}{8}) = \frac{3}{2}$. Thus,

$$\int_{\mathcal{C}} xy(y^2 - z)\, ds = \int_1^{\frac{3}{2}} \sqrt{u}\frac{1}{8}\, du = \frac{1}{8} \cdot \frac{2}{3} u^{\frac{3}{2}}\Big|_1^{\frac{3}{2}} = \frac{1}{12}\left(\left(\frac{3}{2}\right)^{\frac{3}{2}} - 1\right) \approx 0.0698$$

Thus the total charge is 0.0698×10^{-6} C.

In Exercises 47–50, use Eq. (6) to compute the electric potential $V(P)$ at the point P for the given charge density (in units of 10^{-6} C).

47. Calculate $V(P)$ at $P = (0, 0, 12)$ if the electric charge is distributed along the quarter circle of radius 4 centered at the origin with charge density $\rho(x, y, z) = xy$.

SOLUTION We parametrize the curve by $\mathbf{c}(t) = (4\cos t, 4\sin t, 0)$, $(0 \le t \le \frac{\pi}{2})$. Then $\mathbf{c}'(t) = (-4\sin t, 4\cos t, 0) \Rightarrow \|\mathbf{c}'(t)\| = 4$. The distance from the point $(0, 0, 12)$ to $\mathbf{c}(t)$ is

$$r_P(t) = \sqrt{(0 - 4\cos t)^2 + (0 - 4\sin t)^2 + (12 - 0)^2} = \sqrt{16 + 144} = 4\sqrt{10}$$

while the charge density along the curve is

$$\rho(\mathbf{c}(t)) = xy = 4\cos t\, 4\sin t = 16 \sin t \cos t = 8 \sin 2t$$

Therefore

$$V(P) = k\int_{\mathcal{C}} \frac{\rho}{r_P}\, ds = k\int_0^{\frac{\pi}{2}} \frac{8\sin 2t}{4\sqrt{10}} 4\, dt = \frac{8k}{\sqrt{10}} \cdot \frac{-\cos 2t}{2}\Big|_0^{\frac{\pi}{2}}$$
$$= \frac{4k}{\sqrt{10}}(-\cos\pi + \cos 0) = \frac{8k}{\sqrt{10}}$$

Thus the electric potential is $\frac{8k}{\sqrt{10}} \times 10^{-6}$ C ≈ 22743.1 volts

48. Calculate $V(P)$ at the origin $P = (0, 0)$ if the negative charge is distributed along $y = x^2$ for $1 \le x \le 2$ with charge density $\rho(x, y) = -y\sqrt{x^2 + 1}$.

SOLUTION A parametrization for the curve is $\mathbf{c}(t) = (t, t^2)$ $(1 \le t \le 2)$. Then

$$\mathbf{c}'(t) = \langle 1, 2t\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{1 + 4t^2}$$

The charge density along the curve is

$$\rho(\mathbf{c}(t)) = -y\sqrt{x^2 + 1} = -t^2\sqrt{t^2 + 1}$$

The distance from the origin to $\mathbf{c}(t)$ is

$$r_P(t) = \sqrt{(t - 0)^2 + (t^2 - 0)^2} = \sqrt{t^2 + t^4} = |t|\sqrt{1 + t^2}$$

Therefore,

$$V(P) = k\int_{\mathcal{C}} \frac{\rho}{r_P}\, ds = k\int_1^2 \frac{-t^2\sqrt{t^2 + 1}}{|t|\sqrt{1 + t^2}}\sqrt{1 + 4t^2}\, dt = -k\int_1^2 t\sqrt{1 + 4t^2}\, dt$$

Using the substitution $u = 4t^2 + 1 \Rightarrow du = 8t\,dt$, we have

$$V(P) = -\frac{k}{8}\int_5^{17} \sqrt{u}\,du = -\frac{k}{8}\cdot\frac{2}{3}u^{\frac{3}{2}}\Big|_5^{17} = -\frac{k}{12}\left(17^{\frac{3}{2}} - 5^{\frac{3}{2}}\right)$$

Thus the electric potential is $-\frac{k}{12}\left(17^{\frac{3}{2}} - 5^{\frac{3}{2}}\right) \times 10^{-6}$ C ≈ -44135 volts

49. Calculate $V(P)$ at $P = (2, 0, 2)$ if the negative charge is distributed along the y-axis for $1 \le y \le 3$ with charge density $\rho(x, y, z) = -y$.

SOLUTION A parametrization for the curve is $\mathbf{c}(t) = (0, t, 0)$ $(1 \le t \le 3)$. Then $\mathbf{c}'(t) = \langle 0, 1, 0\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = 1$, and the charge density along the curve is $\rho(\mathbf{c}(t)) = -y = -t$. The distance from the origin to $\mathbf{c}(t)$ is

$$r_P(t) = \sqrt{(2-0)^2 + (0-t)^2 + (2-0)^2} = \sqrt{8 + t^2}$$

Therefore,

$$V(P) = k\int_{\mathcal{C}} \frac{\rho}{r_P}\,ds = k\int_1^3 \frac{-t}{\sqrt{8+t^2}}\cdot 1\,dt$$

Using the substitution $u = 8 + t^2 \Rightarrow du = 2t\,dt$, we have

$$V(P) = -k\int_9^{17} u^{-\frac{1}{2}}\frac{1}{2}\,du = -\frac{k}{2}\cdot 2u^{\frac{1}{2}}\Big|_9^{17} = -\frac{k}{2}\left(17^{\frac{1}{2}} - 9^{\frac{1}{2}}\right)$$

Thus the electric potential is $-\frac{k}{2}\left(17^{\frac{1}{2}} - 9^{\frac{1}{2}}\right) \times 10^{-6}$ C ≈ -10097 volts

50. Calculate $V(P)$ at the origin $P = (0, 0)$ if the electric charge is distributed along $y = x^{-1}$ for $\frac{1}{2} \le x \le 2$ with charge density $\rho(x, y) = x^3 y$.

SOLUTION A parametrization for the curve is $\mathbf{c}(t) = (t, t^{-1})$ $(\frac{1}{2} \le t \le 2)$. Then

$$\mathbf{c}'(t) = \left\langle 1, -t^{-2}\right\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{1 + t^{-4}} = \frac{1}{t^2}\sqrt{1 + t^4}$$

The charge density along the curve is

$$\rho(\mathbf{c}(t)) = x^3 y = t^3 t^{-1} = t^2$$

The distance from the origin to $\mathbf{c}(t)$ is

$$r_P(t) = \sqrt{(t-0)^2 + (t^{-1} - 0)^2} = \sqrt{t^2 + t^{-2}} = \frac{1}{|t|}\sqrt{1 + t^4}$$

Therefore,

$$V(P) = k\int_{\mathcal{C}} \frac{\rho}{r_P}\,ds = k\int_{\frac{1}{2}}^2 \frac{t^2}{\frac{1}{|t|}\sqrt{1+t^4}}\frac{1}{t^2}\sqrt{1+t^4}\,dt = k\int_{\frac{1}{2}}^2 t\,dt$$

$$= k\cdot\frac{t^2}{2}\Big|_{\frac{1}{2}}^2 = \frac{k}{2}\left(4 - \frac{1}{4}\right) = \frac{15k}{8}$$

Thus the electric potential is $\frac{15k}{8} \times 10^{-6}$ C ≈ 16856 volts

51. Calculate the work done by a field $\mathbf{F} = \langle x + y, x - y\rangle$ when an object moves from $(0, 0)$ to $(1, 1)$ along each of the paths $y = x^2$ and $x = y^2$.

SOLUTION We calculate the work done by $\mathbf{F} = \langle x + y, x - y\rangle$ along the path $y = x^2$ from $(0, 0)$ to $(1, 1)$. We use the parametrization:

$$\mathbf{c}_1(t) = (t, t^2), \quad 0 \le t \le 1$$

We have

$$\mathbf{F}(\mathbf{c}_1(t)) = \left\langle t + t^2, t - t^2\right\rangle$$

$$\mathbf{c}_1'(t) = \langle 1, 2t\rangle$$

$$\mathbf{F}(\mathbf{c}(t))\cdot\mathbf{c}'(t) = \left\langle t + t^2, t - t^2\right\rangle\cdot\langle 1, 2t\rangle = t + t^2 + 2t^2 - 2t^3 = -2t^3 + 3t^2 + t$$

The work is the following line integral:

$$W = \int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}_1(t)) \cdot \mathbf{c}_1'(t)\, dt = \int_0^1 \left(-2t^3 + 3t^2 + t\right) dt = -\frac{1}{2}t^4 + t^3 + \frac{1}{2}t^2 \Big|_0^1 = 1$$

We now compute the work along the path $x = y^2$. We parametrize the path by:

$$\mathbf{c}_2(t) = (t^2, t), \quad 0 \le t \le 1$$

Then

$$\begin{aligned} \mathbf{F}(\mathbf{c}_2(t)) &= \left\langle t^2 + t, t^2 - t \right\rangle \\ \mathbf{c}_2'(t) &= \langle 2t, 1 \rangle \\ \mathbf{F}(\mathbf{c}_2(t)) \cdot \mathbf{c}_2'(t) &= \left\langle t^2 + t, t^2 - t \right\rangle \cdot \langle 2t, 1 \rangle = 2t^3 + 2t^2 + t^2 - t = 2t^3 + 3t^2 - t \end{aligned}$$

The work is the line integral

$$W = \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}_2(t)) \cdot \mathbf{c}_2'(t)\, dt = \int_0^1 \left(2t^3 + 3t^2 - t\right) dt = \frac{1}{2}t^4 + t^3 - \frac{1}{2}t^2 \Big|_0^1 = \frac{1}{2} + 1 - \frac{1}{2} = 1$$

We obtain the same work along the two paths.

52. Calculate the work done by the force field $\mathbf{F} = \langle x, y, z \rangle$ along the path $(\cos t, \sin t, t)$ for $0 \le t \le 3\pi$.

SOLUTION The work done by the force field $\mathbf{F}$ is the line integral:

$$W = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$$

We compute the integrand:

$$\begin{aligned} \mathbf{F}(\mathbf{c}(t)) &= \langle x, y, z \rangle = \langle \cos t, \sin t, t \rangle \\ \mathbf{c}'(t) &= \frac{d}{dt} \langle \cos t, \sin t, t \rangle = \langle -\sin t, \cos t, 1 \rangle \\ \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) &= \langle \cos t, \sin t, t \rangle \cdot \langle -\sin t, \cos t, 1 \rangle = -\cos t \sin t + \sin t \cos t + t = t \end{aligned}$$

We obtain the following integral:

$$W = \int_0^{3\pi} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^{3\pi} t\, dt = \frac{t^2}{2}\Big|_0^{3\pi} = \frac{9\pi^2}{2}$$

53. Figure 21 shows a force field $\mathbf{F}$.

(a) Over which of the two paths, ADC or ABC, does $\mathbf{F}$ perform less work?

(b) If you have to work against $\mathbf{F}$ to move an object from C to A, which of the paths, CBA or CDA, requires less work?

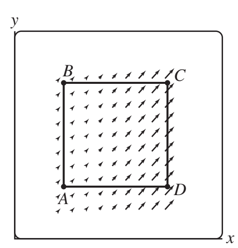


FIGURE 21

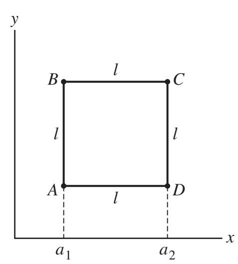
SOLUTION

(a) Since x is constant on $\overline{AB}$ and $\overline{DC}$, $\mathbf{F}(x, y) = \langle x, x \rangle$ is also constant on these segments.



Let a_1 and a_2 denote the constant values of x on the segments $\overline{AB}$ and $\overline{DC}$ respectively, and l denote the lengths of these segments. By Exercise 55 we have

$$\int_{AB} \mathbf{F} \cdot d\mathbf{s} = \langle a_1, a_1 \rangle \cdot \langle 0, l \rangle = a_1 \cdot 0 + a_1 \cdot l = a_1 l$$
$$\int_{DC} \mathbf{F} \cdot d\mathbf{s} = \langle a_2, a_2 \rangle \cdot \langle 0, l \rangle = a_2 \cdot 0 + a_2 \cdot l = a_2 l$$

Since $a_1 < a_2$ we have $\int_{AB} \mathbf{F} \cdot d\mathbf{s} < \int_{DC} \mathbf{F} \cdot d\mathbf{s}$.

(b) We compute the integral over BC. This segment is parametrized by:

$$\mathbf{c}(t) = (a_1 + lt, b)\,,\ 0 \le t \le 1.$$

Hence,

$$\mathbf{F}(\mathbf{c}(t)) = \langle x, x \rangle = \langle a_1 + lt, a_1 + lt \rangle\,,\ \mathbf{c}'(t) = \langle l, 0 \rangle$$
$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \langle a_1 + lt, a_1 + lt \rangle \cdot \langle l, 0 \rangle = a_1 l + l^2 t$$

Thus,

$$\int_{BC} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \left(a_1 l + l^2 t \right) dt = a_1 lt + \frac{l^2 t^2}{2} \bigg|_{t=0}^{1} = a_1 l + \frac{l^2}{2}$$

We see that the line integral does not depend on b, therefore,

$$\int_{AD} \mathbf{F} \cdot d\mathbf{s} = \int_{BC} \mathbf{F} \cdot d\mathbf{s} \qquad (1)$$

In part (a) we showed that:

$$\int_{AB} \mathbf{F} \cdot d\mathbf{s} < \int_{DC} \mathbf{F} \cdot d\mathbf{s} \qquad (2)$$

Combining (1) and (2) gives:

$$\int_{ABC} \mathbf{F} \cdot d\mathbf{s} = \int_{AB} \mathbf{F} \cdot d\mathbf{s} + \int_{BC} \mathbf{F} \cdot d\mathbf{s} < \int_{DC} \mathbf{F} \cdot d\mathbf{s} + \int_{AD} \mathbf{F} \cdot d\mathbf{s} = \int_{ADC} \mathbf{F} \cdot d\mathbf{s}$$

54. Verify that the work performed along the segment $\overline{PQ}$ by the constant vector field $\mathbf{F} = \langle 2, -1, 4 \rangle$ is equal to $\mathbf{F} \cdot \overrightarrow{PQ}$ in these cases:

(a) $P = (0, 0, 0)$, $Q = (4, 3, 5)$

(b) $P = (3, 2, 3)$, $Q = (4, 8, 12)$

SOLUTION

(a) The segment $\overline{PQ}$, where $P = (0, 0, 0)$ and $Q = (4, 3, 5)$ has the parametrization,

$$\mathbf{c}(t) = (4t, 3t, 5t), \quad 0 \le t \le 1$$

Therefore, $\mathbf{c}'(t) = \langle 4, 3, 5 \rangle$ and we obtain the following integral:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^1 \langle 2, -1, 4 \rangle \cdot \langle 4, 3, 5 \rangle\, dt = \int_0^1 25\, dt = 25$$

This equals $\mathbf{F} \cdot \overrightarrow{PQ} = \langle 2, -1, 4 \rangle \cdot \langle 4, 3, 5 \rangle = 25$.

(b) The segment $\overline{PQ}$, where $P = (3, 2, 3)$ and $Q = (4, 8, 12)$ has the parametrization,

$$\mathbf{c}(t) = (3 + t, 2 + 6t, 3 + 9t), \quad 0 \le t \le 1$$

Therefore, $\mathbf{c}'(t) = \langle 1, 6, 9 \rangle$ and we obtain the line integral

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^1 \langle 2, -1, 4 \rangle \cdot \langle 1, 6, 9 \rangle\, dt = \int_0^1 32\, dt = 32$$

Note that $\overrightarrow{PQ} = \langle 1, 6, 9 \rangle$, so $\mathbf{F} \cdot \overrightarrow{PQ} = \langle 2, -1, 4 \rangle \cdot \langle 1, 6, 9 \rangle = 32$.

55. Show that work performed by a constant force field $\mathbf{F}$ over any path $\mathcal{C}$ from P to Q is equal to $\mathbf{F} \cdot \overrightarrow{PQ}$.

SOLUTION We denote by $\mathbf{c}(t) = (x(t), y(t), c(t))$, $t_0 \le t \le t_1$ a parametrization of the oriented path from P to Q (then $\mathbf{c}(t_0) = P$ and $\mathbf{c}(t_1) = Q$). Let $\mathbf{F} = \langle a, b, c \rangle$ be a constant vector field. Then,

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \langle a, b, c \rangle \cdot \left\langle x'(t), y'(t), z'(t) \right\rangle = ax'(t) + by'(t) + cz'(t)$$

The vector line integral is, thus,

$$\begin{aligned}
\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} &= \int_{t_0}^{t_1} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_{t_0}^{t_1} \left(ax'(t) + by'(t) + cz'(t)\right) dt \\
&= a \int_{t_0}^{t_1} x'(t)\, dt + b \int_{t_0}^{t_1} y'(t)\, dt + c \int_{t_0}^{t_1} z'(t)\, dt = ax(t)\Big|_{t=t_0}^{t_1} + by(t)\Big|_{t=t_0}^{t_1} + cz(t)\Big|_{t=t_0}^{t_1} \\
&= a\,(x(t_1) - x(t_0)) + b\,(y(t_1) - y(t_0)) + c\,(z(t_1) - z(t_0)) \\
&= \langle a, b, c \rangle \cdot \langle x(t_1) - x(t_0), y(t_1) - y(t_0), z(t_1) - z(t_0) \rangle
\end{aligned}$$

Since $P = \langle x(t_0), y(t_0), z(t_0) \rangle$ and $Q = \langle x(t_1), y(t_1), z(t_1) \rangle$ we conclude that,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \langle a, b, c \rangle \cdot \overrightarrow{PQ} = \mathbf{F} \cdot \overrightarrow{PQ}.$$

56. Note that a curve $\mathcal{C}$ in polar form $r = f(\theta)$ is parametrized by $\mathbf{c}(\theta) = (f(\theta)\cos\theta, f(\theta)\sin\theta)$ because the x- and y-coordinates are given by $x = r\cos\theta$ and $y = r\sin\theta$.

(a) Show that $\|\mathbf{c}'(\theta)\| = \sqrt{f(\theta)^2 + f'(\theta)^2}$.

(b) Evaluate $\int_{\mathcal{C}} (x - y)^2\, ds$, where $\mathcal{C}$ is the semicircle in Figure 22 with polar equation $r = 2\cos\theta$, $0 \le \theta \le \frac{\pi}{2}$.

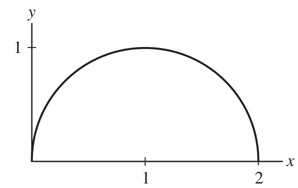


FIGURE 22 Semicircle $r = 2\cos\theta$.

SOLUTION

(a) Finding the magnitude of the tangent vector

$$\begin{aligned}
\mathbf{c}(\theta) &= \langle f(\theta)\cos(\theta), f(\theta)\sin(\theta) \rangle \\
\Rightarrow \quad \mathbf{c}'(\theta) &= \left\langle f'(\theta)\cos(\theta) - f(\theta)\sin(\theta), f'(\theta)\sin(\theta) + f(\theta)\cos(\theta) \right\rangle \\
\Rightarrow \quad \|\mathbf{c}'(\theta)\|^2 &= (f'(\theta)\cos(\theta) - f(\theta)\sin(\theta))^2 + (f'(\theta)\sin(\theta) + f(\theta)\cos(\theta))^2 \\
&= (f'(\theta))^2\cos^2(\theta) - 2f'(\theta)f(\theta)\cos(\theta)\sin(\theta) + (f(\theta))^2\sin^2(\theta) \\
&\quad + (f'(\theta))^2\sin^2(\theta) + 2f'(\theta)f(\theta)\cos(\theta)\sin(\theta) + (f(\theta))^2\cos^2(\theta) \\
&= (f'(\theta))^2 + (f(\theta))^2 \\
\Rightarrow \quad \|\mathbf{c}'(\theta)\| &= \sqrt{(f'(\theta))^2 + (f(\theta))^2}
\end{aligned}$$

(b) Using the previous part we have $f(\theta) = 2\cos(\theta)$ and $f'(\theta) = -2\sin(\theta)$. And so

$$\|\mathbf{c}'(\theta)\| = \sqrt{(2\cos(\theta))^2 + (-2\sin(\theta))^2} = 2$$

We have that $x = f(\theta)\cos(\theta) = 2\cos(\theta)\cos(\theta)$ and $y = f(\theta)\sin(\theta) = 2\cos(\theta)\sin(\theta)$. Integrating,

$$\begin{aligned}
\int_{\mathcal{C}} (x - y)^2\, ds &= \int_0^{\frac{\pi}{2}} (2\cos^2(\theta) - 2\cos(\theta)\sin(\theta))^2 2\, d\theta \\
&= 8 \int_0^{\frac{\pi}{2}} \cos^4(\theta) - 2\cos^3(\theta)\sin(\theta) + \sin^2(\theta)\cos^2(\theta)\, d\theta \\
&= 8 \int_0^{\frac{\pi}{2}} \cos^4(\theta) - 2\cos^3(\theta)\sin(\theta) + (1 - \cos^2(\theta))\cos^2(\theta)\, d\theta
\end{aligned}$$

$$= 8\int_0^{\frac{\pi}{2}} \cos^2(\theta) - 2\cos^3(\theta)\sin(\theta)\,d\theta$$
$$= 8\int_0^{\frac{\pi}{2}} \left(\frac{1+\cos(2\theta)}{2}\right) d\theta - 16\int_0^{\frac{\pi}{2}} \cos^3(\theta)\sin(\theta)\,d\theta$$
$$= 4\theta + 2\sin(2\theta)\Big|_0^{\frac{\pi}{2}} + 4\cos^4(\theta)\Big|_0^{\frac{\pi}{2}} = 2\pi - 4$$

57. Charge is distributed along the spiral with polar equation $r = \theta$ for $0 \le \theta \le 2\pi$. The charge density is $\rho(r,\theta) = r$ (assume distance is in centimeters and charge in units of 10^{-6} C/cm). Use the result of Exercise 56(a) to compute the total charge.

SOLUTION Following Exercise 56(a), $f(\theta) = \theta$, and $f'(\theta) = 1$. Thus $\|\mathbf{c}'(\theta)\| = \sqrt{\theta^2+1}$. The total charge will be

$$\int_{\mathcal{C}} \rho\,ds = \int_0^{2\pi} \theta\sqrt{\theta^2+1}\,d\theta$$

Substituting $u = \theta^2 + 1 \Rightarrow du = 2\theta\,d\theta$, we have

$$\int_{\mathcal{C}} \rho\,ds = \int_1^{4\pi^2+1} \sqrt{u}\,\frac{1}{2}\,du = \frac{1}{2}\cdot\frac{2}{3}u^{\frac{3}{2}}\Big|_1^{4\pi^2+1}$$
$$= \frac{1}{2}\left((4\pi^2+1)^{\frac{3}{2}} - 1\right) \approx 85.5$$

Thus the total charge is 85.5×10^{-6} C.

In Exercises 58–61, let **F** *be the* **vortex field** *(so-called because it swirls around the origin as in Figure 23):*

$$\mathbf{F} = \left\langle \frac{-y}{x^2+y^2}, \frac{x}{x^2+y^2} \right\rangle$$

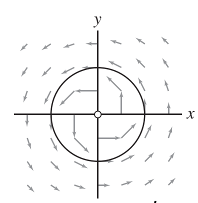

FIGURE 23 Vortex field $\mathbf{F} = \left\langle \frac{-y}{x^2+y^2}, \frac{x}{x^2+y^2} \right\rangle$.

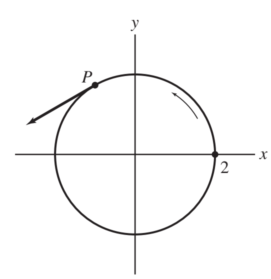
58. Calculate $I = \int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s}$, where $\mathcal{C}$ is the circle of radius 2 centered at the origin. Verify that I changes sign when $\mathcal{C}$ is oriented in the clockwise direction.

SOLUTION

(a)



The circle of radius 2 oriented counterclockwise has the parametrization:

$$\mathbf{c}(t) = (2\cos t, 2\sin t), \quad 0 \le t \le 2\pi$$

Hence,

$$\mathbf{F}(\mathbf{c}(t)) = \left\langle \frac{-2\sin t}{4\cos^2 t + 4\sin^2 t}, \frac{2\cos t}{4\cos^2 t + 4\sin^2 t} \right\rangle = \frac{1}{2}\langle -\sin t, \cos t\rangle$$

$$\mathbf{c}'(t) = \langle -2\sin t, 2\cos t\rangle$$

Therefore, the integrand is the dot product,

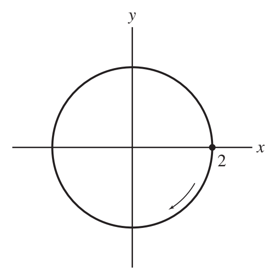
$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \frac{1}{2}\langle -\sin t, \cos t\rangle \cdot \langle -2\sin t, 2\cos t\rangle = \sin^2 t + \cos^2 t = 1$$

We obtain the following integral:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{2\pi} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^{2\pi} 1\, dt = 2\pi$$

(b) When $\mathcal{C}$ is oriented in the clockwise direction, the parameter t is changing from 2π to 0, therefore, the line integral is,

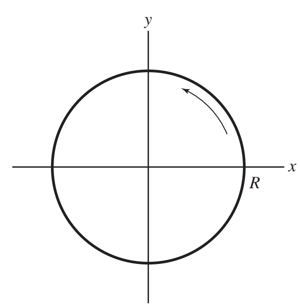
$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{2\pi}^{0} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = -\int_0^{2\pi} 1\, dt = -2\pi$$



59. Show that the value of $\int_{\mathcal{C}_R} \mathbf{F} \cdot d\mathbf{s}$, where $\mathcal{C}_R$ is the circle of radius R centered at the origin and oriented counterclockwise, does not depend on R.

SOLUTION We parametrize $\mathcal{C}_R$ by:

$$\mathbf{c}(t) = (R\cos t, R\sin t), \quad 0 \le t < 2\pi.$$



Step 1. Calculate the integrand:

$$\mathbf{F}(\mathbf{c}(t)) = \left\langle -\frac{y}{x^2+y^2}, \frac{x}{x^2+y^2}\right\rangle = \left\langle -\frac{R\sin t}{R^2}, \frac{R\cos t}{R^2}\right\rangle = \frac{1}{R}\langle -\sin t, \cos t\rangle$$

$$\mathbf{c}'(t) = \frac{d}{dt}\langle R\cos t, R\sin t\rangle = \langle -R\sin t, R\cos t\rangle = R\langle -\sin t, \cos t\rangle$$

The integrand is the dot product:

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \frac{1}{R}\langle -\sin t, \cos t\rangle \cdot R\langle -\sin t, \cos t\rangle = \sin^2 t + \cos^2 t = 1$$

Step 2. Evaluate the integral.

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{2\pi} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^{2\pi} 1\, dt = 2\pi$$

60. Let $a > 0$, $b < c$. Show that the integral of $\mathbf{F}$ along the segment [Figure 24(A)] from $P = (a, b)$ to $Q = (a, c)$ is equal to the angle $\angle POQ$.

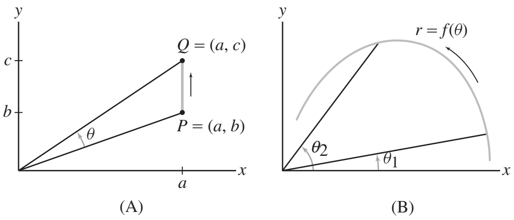


FIGURE 24

SOLUTION Note that the points P and Q are on the vertical line $x = a$. Now, a nice parametrization of this line would be $\mathbf{c}(t) = \langle a, b + (c - b)t \rangle$ for t from 0 to 1, with $\mathbf{c}'(t) = \langle 0, c - b \rangle$. We find that:

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \frac{a(c - b)}{a^2 + (b + (c - b)t)^2}$$

and so our integral becomes:

$$\int_0^1 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\,dt = \int_0^1 \frac{a(c - b)}{a^2 + (b + (c - b)t)^2}\,dt = a \int_b^c \frac{du}{a^2 + u^2}\,du$$

where the last integral was done with the substitution $u = b + (c - b)t$. This gives us:

$$\int_0^1 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\,dt = \tan^{-1} \frac{u}{a}\Big|_b^c = \tan^{-1} \frac{c}{a} - \tan^{-1} \frac{b}{a}$$

Of course, $\tan^{-1} \frac{c}{a} - \tan^{-1} \frac{b}{a}$ is just the angle $\angle POQ$.

61. Let $\mathcal{C}$ be a curve in polar form $r = f(\theta)$ for $\theta_1 \le \theta \le \theta_2$ [Figure 24(B)], parametrized by $\mathbf{c}(\theta) = (f(\theta)\cos\theta, f(\theta)\sin\theta))$ as in Exercise 56.

(a) Show that the vortex field in polar coordinates is written $\mathbf{F} = r^{-1}\langle -\sin\theta, \cos\theta \rangle$.

(b) Show that $\mathbf{F} \cdot \mathbf{c}'(\theta)\,d\theta = d\theta$.

(c) Show that $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \theta_2 - \theta_1$.

SOLUTION

(a) Letting $x = r\cos(\theta)$ and $y = r\sin(\theta)$ we have

$$\mathbf{F} = \left\langle \frac{-y}{x^2 + y^2}, \frac{x}{x^2 + y^2} \right\rangle = \left\langle \frac{-r\sin(\theta)}{(r\cos(\theta))^2 + (r\sin(\theta))^2}, \frac{r\cos(\theta)}{(r\cos(\theta))^2 + (r\sin(\theta))^2} \right\rangle$$
$$= \frac{r}{r^2}\left\langle \frac{-\sin(\theta)}{\cos^2(\theta) + \sin^2(\theta)}, \frac{\cos(\theta)}{\cos^2(\theta) + \sin^2(\theta)} \right\rangle = r^{-1}\langle -\sin\theta, \cos\theta \rangle$$

(b) From the solution to Exercise 56(a) we have

$$\mathbf{c}'(\theta) = \langle f'(\theta)\cos(\theta) - f(\theta)\sin(\theta), f'(\theta)\sin(\theta) + f(\theta)\cos(\theta) \rangle$$

Substituting $r = f(\theta)$ into the previous part, we have

$$\mathbf{F} \cdot \mathbf{c}'(\theta)\,d\theta = \frac{1}{f(\theta)}\langle -\sin(\theta), \cos(\theta) \rangle \cdot \langle f'(\theta)\cos(\theta) - f(\theta)\sin(\theta), f'(\theta)\sin(\theta) + f(\theta)\cos(\theta) \rangle\,d\theta$$
$$= \frac{1}{f(\theta)}(-f'(\theta)\sin(\theta)\cos(\theta) + f(\theta)\sin^2(\theta) + f'(\theta)\cos(\theta)\sin(\theta) + f(\theta)\cos^2(\theta))\,d\theta$$
$$= \frac{1}{f(\theta)} f(\theta)(\sin^2(\theta) + \cos^2(\theta))\,d\theta = d\theta$$

(c)

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{\theta_1}^{\theta_2} \mathbf{F} \cdot \mathbf{c}'(\theta)\,d\theta = \int_{\theta_1}^{\theta_2} d\theta = \theta_2 - \theta_1$$

In Exercises 62–65, use Eq. (10) to calculate the flux of the vector field across the curve specified.

62. $\mathbf{F} = \langle -y, x \rangle$; upper half of the unit circle, oriented clockwise

SOLUTION The curve is parametrized by $\mathbf{c}(t) = (-\cos t, \sin t)$ $(0 \le t \le \pi)$. Then

$$\mathbf{c}'(t) = \langle \sin t, \cos t \rangle$$

$$\mathbf{F}(\mathbf{c}(t)) = \langle -y, x \rangle = \langle -\sin t, -\cos t \rangle$$

Therefore the flux is

$$\int_{\mathcal{C}} F_1\,dy - F_2\,dx = \int_0^{\pi} (-\sin t)(\cos t) - (-\cos t)(\sin t)\,dt = 0$$

63. $\mathbf{F} = \left\langle x^2, y^2 \right\rangle$; segment from $(3, 0)$ to $(0, 3)$, oriented upward

SOLUTION The curve is parametrized by $\mathbf{c}(t) = (3 - t, t)$ $(0 \le t \le 3) \Rightarrow \mathbf{c}'(t) = \langle -1, 1 \rangle$. Then

$$\mathbf{F}(\mathbf{c}(t)) = \left\langle x^2, y^2 \right\rangle = \left\langle (3-t)^2, t^2 \right\rangle$$

Therefore the flux is

$$\int_{\mathcal{C}} F_1\,dy - F_2\,dx = \int_0^3 (3-t)^2(1) - (t^2)(-1)\,dt$$

$$= \int_0^3 2t^2 - 6t + 9\,dt = \frac{2t^3}{3} - 3t^2 + 9t\Big|_0^3 = 18$$

64. $\mathbf{v} = \left\langle \frac{x+1}{(x+1)^2 + y^2}, \frac{y}{(x+1)^2 + y^2} \right\rangle$; segment $1 \le y \le 4$ along the y-axis, oriented upward

SOLUTION The curve is parametrized by $\mathbf{c}(t) = (0, t)$ $(1 \le t \le 4) \Rightarrow \mathbf{c}'(t) = \langle 0, 1 \rangle$. Then

$$\mathbf{v}(\mathbf{c}(t)) = \left\langle \frac{x+1}{(x+1)^2 + y^2}, \frac{y}{(x+1)^2 + y^2} \right\rangle = \left\langle \frac{1}{1+t^2}, \frac{t}{1+t^2} \right\rangle$$

Therefore the flux is

$$\int_{\mathcal{C}} v_1\,dy - v_2\,dx = \int_1^4 \left(\frac{1}{1+t^2}\right)(1) - \left(\frac{t}{1+t^2}\right)(0)\,dt = \tan^{-1} t\Big|_1^4 = \tan^{-1}(4) - \tan^{-1}(1)$$

65. $\mathbf{v} = \left\langle e^y, 2x - 1 \right\rangle$; parabola $y = x^2$ for $0 \le x \le 1$, oriented left to right

SOLUTION The curve is parametrized by $\mathbf{c}(t) = (t, t^2)$ $(0 \le t \le 1) \Rightarrow \mathbf{c}'(t) = \langle 1, 2t \rangle$. Then

$$\mathbf{v}(\mathbf{c}(t)) = \left\langle e^y, 2x - 1 \right\rangle = \left\langle e^{t^2}, 2t - 1 \right\rangle$$

Therefore the flux is

$$\int_{\mathcal{C}} v_1\,dy - v_2\,dx = \int_0^1 \left(e^{t^2}\right)(2t) - (2t-1)(1)\,dt = e^{t^2} - t^2 + t\Big|_0^1 = e - 1$$

66. Let $I = \int_{\mathcal{C}} f(x, y, z)\,ds$. Assume that $f(x, y, z) \ge m$ for some number m and all points (x, y, z) on $\mathcal{C}$. Which of the following conclusions is correct? Explain.

(a) $I \ge m$

(b) $I \ge mL$, where L is the length of $\mathcal{C}$

SOLUTION Since $f(\mathbf{c}(t)) \ge m$ for all points on $\mathcal{C}$, also $f(\mathbf{c}(t))\,\|\mathbf{c}'(t)\| \ge m\|\mathbf{c}'(t)\|$. By properties of integrals we have

$$I = \int_a^b f(\mathbf{c}(t)) \cdot \|\mathbf{c}'(t)\|\,dt \ge \int_a^b m\|\mathbf{c}'(t)\|\,dt = m\int_a^b \|\mathbf{c}'(t)\|\,dt$$

Since $L = \int_a^b \|\mathbf{c}'(t)\|\,dt$, we get:

$$I \ge mL$$

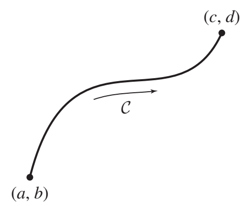
Therefore conclusion (b) is correct.

Further Insights and Challenges

67. Let $\mathbf{F} = \langle x, 0 \rangle$. Prove that if $\mathcal{C}$ is any path from (a, b) to (c, d), then

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \frac{1}{2}(c^2 - a^2)$$

SOLUTION



We denote the parametrization of the path by,

$$\mathbf{c}(t) = (x(t), y(t)), \quad t_0 \le t \le t_1, \quad \mathbf{c}(t_0) = (a, b), \quad \mathbf{c}(t_1) = (c, d)$$

By the Theorem on vector line integrals we have,

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = \int_{t_0}^{t_1} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_{t_0}^{t_1} \langle x(t), 0 \rangle \cdot \langle x'(t), y'(t) \rangle\, dt = \int_{t_0}^{t_1} x(t)x'(t)\, dt$$

We use the hint to compute the integral, obtaining

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = \frac{1}{2} x(t)^2 \Big|_{t_0}^{t_1} = \frac{1}{2}\left(x(t_1)^2 - x(t_0)^2\right) = \frac{1}{2}\left(c^2 - a^2\right)$$

Proof of the hint: By the Chain Rule for differentiation we have

$$\frac{d}{dt} f^2(t) = 2f(t)f'(t) \quad \Rightarrow \quad f(t)f'(t) = \frac{1}{2}\frac{d}{dt} f^2(t)$$

Applying the Fundamental Theorem of calculus we obtain

$$\int_{t_0}^{t_1} f(t)f'(t)\, dt = \frac{1}{2}\int_{t_0}^{t_1} \frac{d}{dt}\left(f^2(t)\right) dt = \frac{1}{2}\left(f^2(t_1) - f^2(t_0)\right)$$

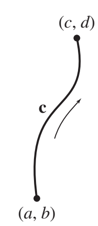
Alternatively we can evaluate the integral $\int f(t)f'(t)\, dt$ using the substitution $u = f(t)$, $du = f'(t)\, dt$. We get

$$\int f(t)f'(t)\, dt = \int u\, du = \frac{1}{2}u^2 + c = \frac{1}{2} f^2(t) + c.$$

68. Let $\mathbf{F} = \langle y, x \rangle$. Prove that if $\mathcal{C}$ is any path from (a, b) to (c, d), then

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = cd - ab$$

SOLUTION



We denote a parametrization of the path by:

$$\mathbf{c}(t) = (x(t), y(t)), \quad t_0 \le t \le t_1$$
$$\mathbf{c}(t_0) = (a, b), \quad \mathbf{c}(t_1) = (c, d)$$

By the Theorem on vector line integrals we have

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = \int_{t_0}^{t_1} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_{t_0}^{t_1} \langle y(t), x(t) \rangle \cdot \langle x'(t), y'(t) \rangle\, dt$$

$$= \int_{t_0}^{t_1} \left(y(t)x'(t) + x(t)y'(t) \right) dt = \int_{t_0}^{t_1} \frac{d}{dt} \left(x(t)y(t) \right) dt$$

The last equality follows from the Product Rule for differentiation. We now use the Fundamental Theorem of Calculus to obtain:

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = x(t)y(t) \Big|_{t=t_0}^{t_1} = x(t_1)\, y(t_1) - x(t_0)\, y(t_0) = cd - ab$$

69. We wish to define the **average value** $\mathrm{Av}(f)$ of a continuous function f along a curve $\mathcal{C}$ of length L. Divide $\mathcal{C}$ into N consecutive arcs $\mathcal{C}_1, \ldots, \mathcal{C}_N$, each of length L/N, and let P_i be a sample point in $\mathcal{C}_i$ (Figure 25). The sum

$$\frac{1}{N} \sum_{i=1} f(P_i)$$

may be considered an approximation to $\mathrm{Av}(f)$, so we define

$$\mathrm{Av}(f) = \lim_{N \to \infty} \frac{1}{N} \sum_{i=1} f(P_i)$$

Prove that

$$\mathrm{Av}(f) = \frac{1}{L} \int_{\mathcal{C}} f(x, y, z)\, ds \qquad \boxed{11}$$

Hint: Show that $\frac{L}{N} \sum_{i=1} f(P_i)$ is a Riemann sum approximation to the line integral of f along $\mathcal{C}$.

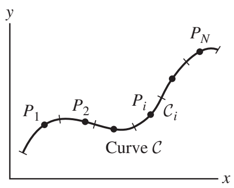


FIGURE 25

SOLUTION The Riemann sum approximation to the line integral is:

$$\sum_{i=1}^{N} f(P_i)\, \Delta S_i$$

If the consecutive arcs $\mathcal{C}_1, \ldots, \mathcal{C}_2$ have equal lengths $\frac{L}{N}$, the corresponding Riemann sum is,

$$\sum_{i=1}^{N} f(P_i) \cdot \frac{L}{N} = \frac{L}{N} \sum_{i=1}^{N} f(P_i)$$

We let $N \to \infty$,

$$\int_{\mathcal{C}} f(x, y, z)\, ds = \lim_{N \to \infty} \frac{L}{N} \sum_{i=1}^{N} f(P_i) = L \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} f(P_i) = L\mathrm{Av}(f)$$

That is,

$$\mathrm{Av}(f) = \frac{1}{L} \int_{\mathcal{C}} f(x, y, z)\, ds.$$

70. Use Eq. (11) to calculate the average value of $f(x, y) = x - y$ along the segment from $P = (2, 1)$ to $Q = (5, 5)$.

SOLUTION We can parametrize this line segment by

$$\mathbf{c}(t) = (2 + 3t, 1 + 4t), \quad 0 \le t \le 1$$

Therefore,

$$\mathbf{c}'(t) = \langle 3, 4 \rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{9 + 16} = 5$$

We compute the length of the curve,

$$L = \int_0^1 \|\mathbf{c}'(t)\|\,dt = \int_0^1 5\,dt = 5$$

Thus, using our values for x and y given above, we find that

$$\mathrm{Av}(f) = \frac{1}{L}\int_{\mathcal{C}} x - y\,dt = \frac{1}{5}\int_0^1 (2+3t) - (1+4t)\,dt = \frac{1}{5}\int_0^1 1 - t\,dt = \frac{1}{10}$$

71. Use Eq. (11) to calculate the average value of $f(x, y) = x$ along the curve $y = x^2$ for $0 \le x \le 1$.

SOLUTION The average value is

$$\mathrm{Av}(f) = \frac{1}{L}\int_{\mathbf{c}} x\,ds \tag{1}$$

We parametrize the curve by the parametrization,

$$\mathbf{c}(t) = \left(t, t^2\right), \quad 0 \le t \le 1.$$

Hence,

$$\mathbf{c}'(t) = \langle 1, 2t\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{1+4t^2}$$

We first must calculate the length of the path. That is,

$$L = \int_{\mathbf{c}} \|\mathbf{c}'(t)\|\,dt = \int_0^1 \sqrt{1+4t^2}\,dt = \frac{1}{2}t\sqrt{1+4t^2} + \frac{1}{4}\ln\left(2t + \sqrt{1+4t^2}\right)\Big|_0^1$$

$$= \frac{\sqrt{5}}{2} + \frac{1}{4}\ln\left(2+\sqrt{5}\right) = \frac{2\sqrt{5} + \ln\left(2+\sqrt{5}\right)}{4}$$

We compute the line integral in (1):

$$\int_{\mathbf{c}} x\,ds = \int_0^1 t\|\mathbf{c}'(t)\|\,dt = \int_0^1 t\sqrt{1+4t^2}\,dt$$

We compute the integral using the substitution $u = 1 + 4t^2$, $du = 8t\,dt$.

$$\int_{\mathbf{c}} x\,ds = \int_0^1 \sqrt{1+4t^2}\cdot t\,dt = \int_1^5 u^{1/2}\cdot\frac{du}{8}$$

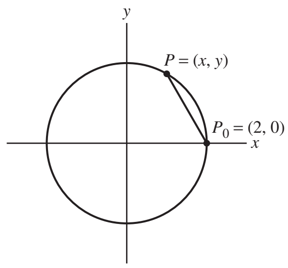
$$= \frac{1}{8}\cdot\frac{2}{3}u^{\frac{3}{2}}\Big|_1^5 = \frac{1}{12}\left(5^{\frac{3}{2}} - 1\right)$$

Combining gives the following solution:

$$\mathrm{Av}(f) = \frac{4}{2\sqrt{5} + \ln\left(2+\sqrt{5}\right)}\cdot\frac{5^{\frac{3}{2}} - 1}{12} = \frac{5\sqrt{5} - 1}{\left(6\sqrt{5} + 3\ln\left(2+\sqrt{5}\right)\right)}$$

72. The temperature (in degrees centigrade) at a point P on a circular wire of radius 2 cm centered at the origin is equal to the square of the distance from P to $P_0 = (2, 0)$. Compute the average temperature along the wire.

SOLUTION



The temperature at a point $P(x, y)$ on the wire is given by the function,

$$T(x, y) = (x-2)^2 + y^2$$

The length of the wire is the length of the circle of radius 2, $L = 2\pi \cdot 2 = 4\pi$. Therefore, the average temperature along the wire is,

$$\text{Av}(T) = \frac{1}{L}\int_{\mathcal{C}} T\,ds = \frac{1}{4\pi}\int_{\mathcal{C}} \left((x-2)^2 + y^2\right) ds$$

To compute the line integral, we parametrize the circle by:

$$\mathbf{c}(t) = (2\cos t, 2\sin t), \quad 0 \le t \le 2\pi.$$

Then,

$$\mathbf{c}(t) = \langle -2\sin t, 2\cos t\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{4\sin^2 t + 4\cos^2 t} = 2$$

We express T in terms of the parameter:

$$\begin{aligned} T\left(\mathbf{c}(t)\right) &= (x-2)^2 + y^2 = (2\cos t - 2)^2 + (2\sin t)^2 = 4\cos^2 t - 8\cos t + 4 + 4\sin^2 t \\ &= 4\left(\cos^2 + \sin^2 t\right) + 4 - 8\cos t = 8(1-\cos t) \end{aligned}$$

We obtain the integral,

$$\text{Av}(T) = \frac{1}{4\pi}\int_0^{2\pi} T\left(\mathbf{c}(t)\right)\|\mathbf{c}'(t)\|\,dt = \frac{1}{4\pi}\int_0^{2\pi} 16(1-\cos t)\,dt = \frac{4}{\pi}\left(t - \sin t\Big|_0^{2\pi}\right) = \frac{4\cdot 2\pi}{\pi} = 8$$

73. The value of a scalar line integral does not depend on the choice of parametrization (because it is defined without reference to a parametrization). Prove this directly. That is, suppose that $\mathbf{c}_1(t)$ and $\mathbf{c}(t)$ are two parametrizations such that $\mathbf{c}_1(t) = \mathbf{c}(\varphi(t))$, where $\varphi(t)$ is an increasing function. Use the Change of Variables Formula to verify that

$$\int_c^d f(\mathbf{c}_1(t))\|\mathbf{c}_1'(t)\|\,dt = \int_a^b f(\mathbf{c}(t))\|\mathbf{c}'(t)\|\,dt$$

where $a = \varphi(c)$ and $b = \varphi(d)$.

SOLUTION We compute the integral $\int_a^b f\left(\mathbf{c}(t)\right)\|\mathbf{c}'(t)\|\,dt$ using the substitution $t = \varphi(u)$, $a = \varphi(c)$, $b = \varphi(d)$. We get:

$$\int_a^b f\left(\mathbf{c}_1(t)\right)\|\mathbf{c}'(t)\|\,dt = \int_{\varphi^{-1}(a)}^{\varphi^{-1}(b)} f\left(\mathbf{c}\left(\varphi(t)\right)\right)\|\mathbf{c}'\left(\varphi(t)\right)\|\varphi'(u)\,du \tag{1}$$

Since φ is an increasing function, $\varphi'(u) > 0$ for all u, therefore:

$$\left\|\mathbf{c}'\left(\varphi(u)\right)\right\|\varphi'(u) = \left\|\mathbf{c}'\left(\varphi(u)\right)\varphi'(u)\right\| \tag{2}$$

By the Chain Rule for vector valued functions, we have,

$$\frac{d}{du}\mathbf{c}\left(\varphi(u)\right) = \varphi'(u)\mathbf{c}'\left(\varphi(u)\right) \tag{3}$$

Combining (2) and (3) gives:

$$\left\|\mathbf{c}'\left(\varphi(u)\right)\right\|\varphi'(u) = \left\|\frac{d}{du}\mathbf{c}\left(\varphi(u)\right)\right\| = \left\|\frac{d}{du}\mathbf{c}_1(u)\right\| = \|\mathbf{c}_1'(u)\| \tag{4}$$

We substitute (4) in (1) to obtain:

$$\int_a^b f\left(\mathbf{c}(t)\right)\|\mathbf{c}'(t)\|\,dt = \int_c^d f\left(\mathbf{c}_1(u)\right)\|\mathbf{c}_1'(u)\|\,du = \int_c^d f\left(\mathbf{c}_1(t)\right)\|\mathbf{c}_1'(t)\|\,dt$$

The last step is simply replacing the dummy variable of integration u by t.

16.3 Conservative Vector Fields (LT Section 17.3)

Preliminary Questions

1. The following statement is false. *If* **F** *is a gradient vector field, then the line integral of* **F** *along every curve is zero.* Which single word must be added to make it true?

SOLUTION The missing word is "closed" (curve). The line integral of a gradient vector field along every closed curve is zero.

2. Which of the following statements are true for all vector fields, and which are true only for conservative vector fields?

(a) The line integral along a path from P to Q does not depend on which path is chosen.

(b) The line integral over an oriented curve $\mathcal{C}$ does not depend on how $\mathcal{C}$ is parametrized.

(c) The line integral around a closed curve is zero.

(d) The line integral changes sign if the orientation is reversed.

(e) The line integral is equal to the difference of a potential function at the two endpoints.

(f) The line integral is equal to the integral of the tangential component along the curve.

(g) The cross-partials of the components are equal.

SOLUTION

(a) This statement is true only for conservative vector fields.

(b) This statement is true for all vector fields.

(c) This statement holds only for conservative vector fields.

(d) This is a property of all vector fields.

(e) Only conservative vector fields have a potential function, and the line integral is computed by using the potential function as stated.

(f) All vector fields' line integrals share this property.

(g) The cross-partial of the components of a conservative field are equal. For other fields, the cross-partial of the components may or may not equal.

3. Let **F** be a vector field on an open, connected domain $\mathcal{D}$. Which of the following statements are always true, and which are true under additional hypotheses on $\mathcal{D}$?

(a) If **F** has a potential function, then **F** is conservative.

(b) If **F** is conservative, then the cross-partials of **F** are equal.

(c) If the cross-partials of **F** are equal, then **F** is conservative.

SOLUTION

(a) This statement is always true, since every gradient vector field is conservative.

(b) If **F** is conservative on a connected domain $\mathcal{D}$, then **F** has a potential function $\mathcal{D}$ and consequently the cross partials of **F** are equal in $\mathcal{D}$.

(c) If the cross partials of **F** are equal in a simply-connected region $\mathcal{D}$, then **F** is a gradient vector field in $\mathcal{D}$.

4. Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be the oriented curves in Figure 16 and let $\mathbf{F} = \nabla V$ be a gradient vector field such that $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = 4$. What are the values of the following integrals?

(a) $\int_{\mathcal{D}} \mathbf{F} \cdot d\mathbf{s}$ **(b)** $\int_{\mathcal{E}} \mathbf{F} \cdot d\mathbf{s}$

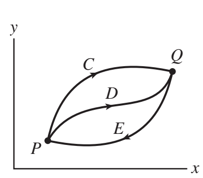


FIGURE 16

SOLUTION Since **F** is a gradient vector field the integrals over closed paths are zero. Therefore, by the equivalent conditions for path independence we have:

(a) $\int_D \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = 4$

(b) $\int_E \mathbf{F} \cdot d\mathbf{s} = \int_{-\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = -\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = -4$

Exercises

1. Let $V(x, y, z) = xy\sin(yz)$ and $\mathbf{F} = \nabla V$. Evaluate $\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s}$, where $\mathbf{c}$ is any path from $(0, 0, 0)$ to $(1, 1, \pi)$.

SOLUTION By the Fundamental Theorem for Gradient Vector Fields, we have:

$$\int_{\mathbf{c}} \nabla V \cdot d\mathbf{s} = V(1, 1, \pi) - V(0, 0, 0) = 1 \cdot 1 \sin \pi - 0 = 0$$

2. Let $\mathbf{F} = \langle x^{-1}z, y^{-1}z, \log(xy) \rangle$.

(a) Verify that $\mathbf{F} = \nabla V$, where $V(x, y, z) = z\ln(xy)$.

(b) Evaluate $\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s}$, where $\mathbf{c}(t) = \langle e^t, e^{2t}, t^2 \rangle$ for $1 \le t \le 3$.

(c) Evaluate $\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s}$ for any path $\mathbf{c}$ from $P = (\frac{1}{2}, 4, 2)$ to $Q = (2, 2, 3)$ contained in the region $x > 0$, $y > 0$.

(d) Why is it necessary to specify that the path lie in the region where x and y are positive?

SOLUTION

(a)

$$\frac{\partial V}{\partial x} = z\frac{1}{xy}y = x^{-1}z = F_1$$

$$\frac{\partial V}{\partial y} = z\frac{1}{xy}x = y^{-1}z = F_2$$

$$\frac{\partial V}{\partial z} = \ln(xy) = F_3$$

(b) $\mathbf{c}(1) = (e, e^2, 1)$, while $\mathbf{c}(3) = (e^3, e^6, 9)$. Therefore,

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = V(e^3, e^6, 9) - V(e, e^2, 1) = 9\ln(e^3 \cdot e^6) - \ln(e \cdot e^2) = 78$$

(c)

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = V(2, 2, 3) - V\left(\frac{1}{2}, 4, 2\right) = 3\ln(2 \cdot 2) - 2\ln\left(\frac{1}{2} \cdot 4\right) = 4\ln(2)$$

(d) $\mathbf{F}$ is not defined for $x = 0$ or $y = 0$. A continuous path which leaves the region $x > 0$, $y > 0$ would necessarily cross one of these lines where the line integral is not defined.

In Exercises 3–6, verify that $\mathbf{F} = \nabla V$ *and evaluate the line integral of* $\mathbf{F}$ *over the given path.*

3. $\mathbf{F} = \langle 3, 6y \rangle$, $\quad V(x, y, z) = 3x + 3y^2$; $\quad \mathbf{c}(t) = (t, 2t^{-1})$ for $1 \le t \le 4$

SOLUTION The gradient of $V = 3x + 3y^2$ is:

$$\nabla V = \left\langle \frac{\partial V}{\partial x}, \frac{\partial V}{\partial y} \right\rangle = \langle 3, 6y \rangle = \mathbf{F}$$

Using the Fundamental Theorem for Gradient Vector Fields, we have:

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = V(\mathbf{c}(4)) - V(\mathbf{c}(1)) = V\left(4, \frac{1}{2}\right) - V(1, 2) = \left(3 \cdot 4 + 3 \cdot \frac{1}{4}\right) - (3 \cdot 1 + 3 \cdot 4) = -\frac{9}{4}$$

4. $\mathbf{F} = \langle \cos y, -x\sin y \rangle$, $V(x, y) = x\cos y$; upper half of the unit circle centered at the origin, oriented counterclockwise

SOLUTION

(a) Verifying that $\mathbf{F} = \nabla V$,

$$\frac{\partial V}{\partial x} = \cos y = F_1, \quad \frac{\partial V}{\partial y} = x(-\sin y) = F_2$$

(b)

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = V(-1, 0) - V(1, 0) = -1\cos(0) - 1\cos(0) = -2$$

5. $\mathbf{F} = ye^z\mathbf{i} + xe^z\mathbf{j} + xye^z\mathbf{k}$, $V(x, y, z) = xye^z$; $\mathbf{c}(t) = (t^2, t^3, t-1)$ for $1 \le t \le 2$

SOLUTION We verify that $\mathbf{F}$ is the gradient of V:

$$\nabla V = \left\langle \frac{\partial V}{\partial x}, \frac{\partial V}{\partial y}, \frac{\partial V}{\partial z} \right\rangle = \left\langle ye^z, xe^z, xye^z \right\rangle = \mathbf{F}$$

We use the Fundamental Theorem for Gradient Vectors with the initial point $\mathbf{c}(1) = (1, 1, 0)$ and terminal point $\mathbf{c}(2) = (4, 8, 1)$, to obtain:

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = V(4, 8, 1) - V(1, 1, 0) = 32e - 1$$

6. $\mathbf{F} = \frac{z}{x}\mathbf{i} + \mathbf{j} + \ln x\mathbf{k}$, $V(x, y, z) = y + z\ln x$;
circle $(x-4)^2 + y^2 = 1$ in the clockwise direction

SOLUTION

(a) Verifying that $\mathbf{F} = \nabla V$,

$$\frac{\partial V}{\partial x} = \frac{z}{x} = F_1, \quad \frac{\partial V}{\partial y} = 1 = F_2, \quad \frac{\partial V}{\partial z} = \ln x = F_3$$

(b) Since $\mathbf{c}$ is closed curve,

$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = 0$$

In Exercises 7–16, find a potential function for $\mathbf{F}$ *or determine that* $\mathbf{F}$ *is not conservative.*

7. $\mathbf{F} = \langle z, 1, x \rangle$

SOLUTION We check whether the vector field $\mathbf{F} = \langle z, 1, x \rangle$ satisfies the cross partials condition:

$$\left.\begin{aligned} \frac{\partial F_1}{\partial y} &= \frac{\partial}{\partial y}(z) = 0 \\ \frac{\partial F_2}{\partial x} &= \frac{\partial}{\partial x}(1) = 0 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_1}{\partial y} = \frac{\partial F_2}{\partial x}$$

$$\left.\begin{aligned} \frac{\partial F_2}{\partial z} &= \frac{\partial}{\partial z}(1) = 0 \\ \frac{\partial F_3}{\partial y} &= \frac{\partial}{\partial y}(x) = 0 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_2}{\partial z} = \frac{\partial F_3}{\partial y}$$

$$\left.\begin{aligned} \frac{\partial F_3}{\partial x} &= \frac{\partial}{\partial x}(x) = 1 \\ \frac{\partial F_1}{\partial z} &= \frac{\partial}{\partial z}(z) = 1 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_3}{\partial x} = \frac{\partial F_1}{\partial z}$$

$\mathbf{F}$ satisfies the cross partials condition everywhere. Hence, $\mathbf{F}$ is conservative. We find a potential function $V(x, y, z)$.

Step 1. Use the condition $\frac{\partial V}{\partial x} = F_1$. V is an antiderivative of $F_1 = z$ when y and z are fixed, therefore:

$$V(x, y, z) = \int z\,dx = zx + g(y, z) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = F_2$. By (1) we have:

$$\frac{\partial}{\partial y}(zx + g(y, z)) = 1$$
$$g_y(y, z) = 1$$

Integrating with respect to y, while holding z fixed, gives:

$$g(y, z) = \int 1\,dy = y + h(z)$$

We substitute in (1) to obtain:

$$V(x, y, z) = zx + y + h(z) \tag{2}$$

Step 3. Use the condition $\frac{\partial V}{\partial z} = F_3$. Using (2) we get:

$$\frac{\partial}{\partial z}(zx + y + h(z)) = x$$
$$x + h'(z) = x$$
$$h'(z) = 0 \quad \Rightarrow \quad h(z) = c$$

Substituting in (2) gives the following potential functions:

$$V(x, y, z) = zx + y + c.$$

One of the potential functions is obtained by choosing $c = 0$:

$$V(x, y, z) = zx + y$$

8. $\mathbf{F} = x\mathbf{j} + y\mathbf{k}$

SOLUTION Since $\frac{\partial F_1}{\partial y} = \frac{\partial}{\partial y}(0) = 0$ and $\frac{\partial F_2}{\partial x} = \frac{\partial}{\partial x}(x) = 1$, we have $\frac{\partial F_1}{\partial y} \neq \frac{\partial F_2}{\partial x}$. Therefore **F** does not satisfy the cross-partials condition, hence **F** is not conservative.

9. $\mathbf{F} = y^2\mathbf{i} + (2xy + e^z)\mathbf{j} + ye^z\mathbf{k}$

SOLUTION We examine whether **F** satisfies the cross partials condition:

$$\left.\begin{aligned} \frac{\partial F_1}{\partial y} &= \frac{\partial}{\partial y}\left(y^2\right) = 2y \\ \frac{\partial F_2}{\partial x} &= \frac{\partial}{\partial x}\left(2xy + e^z\right) = 2y \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_1}{\partial y} = \frac{\partial F_2}{\partial x}$$

$$\left.\begin{aligned} \frac{\partial F_2}{\partial z} &= \frac{\partial}{\partial z}\left(2xy + e^z\right) = e^z \\ \frac{\partial F_3}{\partial y} &= \frac{\partial}{\partial y}\left(ye^z\right) = e^z \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_2}{\partial z} = \frac{\partial F_3}{\partial y}$$

$$\left.\begin{aligned} \frac{\partial F_3}{\partial x} &= \frac{\partial}{\partial x}\left(ye^z\right) = 0 \\ \frac{\partial F_1}{\partial z} &= \frac{\partial}{\partial z}\left(y^2\right) = 0 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_3}{\partial x} = \frac{\partial F_1}{\partial z}$$

We see that **F** satisfies the cross partials condition everywhere, hence **F** is conservative. We find a potential function for **F**.

Step 1. Use the condition $\frac{\partial V}{\partial x} = F_1$. V is an antiderivative of $F_1 = y^2$ when y and z are fixed. Hence:

$$V(x, y, z) = \int y^2\,dx = y^2x + g(y, z) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = F_2$. By (1) we have:

$$\frac{\partial}{\partial y}\left(y^2x + g(y, z)\right) = 2xy + e^z$$
$$2yx + g_y(y, z) = 2xy + e^z \quad \Rightarrow \quad g_y(y, z) = e^z$$

We integrate with respect to y, holding z fixed:

$$g(y, z) = \int e^z\,dy = e^z y + h(z)$$

Substituting in (1) gives:

$$V(x, y, z) = y^2x + e^z y + h(z) \tag{2}$$

Step 3. Use the condition $\frac{\partial V}{\partial z} = F_3$. By (2), we get:

$$\frac{\partial}{\partial z}\left(y^2x + e^z y + h(z)\right) = ye^z$$
$$e^z y + h'(z) = ye^z \quad \Rightarrow \quad h'(z) = 0$$

Therefore $h(z) = c$. Substituting in (2) we get:

$$V(x, y, z) = y^2 x + e^z y + c$$

The potential function corresponding to $c = 0$ is:

$$V(x, y, z) = y^2 x + e^z y.$$

10. $\mathbf{F} = \langle y, x, z^3 \rangle$

SOLUTION We examine whether the field $\mathbf{F} = \left\langle y, x, z^3 \right\rangle$ satisfies the cross partials condition.

$$\left.\begin{aligned} \frac{\partial F_1}{\partial y} &= \frac{\partial}{\partial y}(y) = 1 \\ \frac{\partial F_2}{\partial x} &= \frac{\partial}{\partial x}(x) = 1 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_1}{\partial y} = \frac{\partial F_2}{\partial x}$$

$$\left.\begin{aligned} \frac{\partial F_2}{\partial z} &= \frac{\partial}{\partial z}(x) = 0 \\ \frac{\partial F_3}{\partial y} &= \frac{\partial}{\partial y}\left(z^3\right) = 0 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_2}{\partial z} = \frac{\partial F_3}{\partial y}$$

$$\left.\begin{aligned} \frac{\partial F_3}{\partial x} &= \frac{\partial}{\partial x}\left(z^3\right) = 0 \\ \frac{\partial F_1}{\partial z} &= \frac{\partial}{\partial z}(y) = 0 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_3}{\partial x} = \frac{\partial F_1}{\partial z}$$

Since $\mathbf{F}$ satisfies the cross partials condition everywhere, $\mathbf{F}$ is conservative. We find a potential function for $\mathbf{F}$.

Step 1. Use the condition $\frac{\partial V}{\partial x} = F_1$. V is an antiderivative of $F_1 = y$ when y and z are fixed. Therefore:

$$V(x, y, z) = \int y\, dx = yx + g(y, z) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = F_2$. By (1) we have:

$$\frac{\partial}{\partial y}(yx + g(y, z)) = x$$

$$x + g_y(y, z) = x \quad \Rightarrow \quad g_y(y, z) = 0$$

Therefore, $g(y, z) = g(z)$. Substituting in (1) gives:

$$V(x, y, z) = yx + g(z) \tag{2}$$

Step 3. Use the condition $\frac{\partial V}{\partial z} = F_3$. Using (2) we have:

$$\frac{\partial}{\partial z}(yx + g(z)) = z^3$$

$$g'(z) = z^3 \quad \Rightarrow \quad g(z) = \frac{1}{4}z^4 + c$$

Substituting in (2) gives the following general potential function:

$$V(x, y, z) = yx + \frac{1}{4}z^4 + c$$

Choosing $c = 0$ we obtain the potential:

$$V(x, y, z) = yx + \frac{z^4}{4}.$$

11. $\mathbf{F} = \langle \cos(xz), \sin(yz), xy \sin z \rangle$

SOLUTION Since $\frac{\partial F_2}{\partial z} = \frac{\partial}{\partial z}(\sin(yz)) = y\cos(yz)$ and $\frac{\partial F_3}{\partial y} = \frac{\partial}{\partial y}(xy \sin z) = x \sin z$, we have $\frac{\partial F_2}{\partial z} \neq \frac{\partial F_3}{\partial y}$. The cross partials condition is not satisfied, therefore the vector field is not conservative.

12. $\mathbf{F} = \langle \cos z, 2y, -x \sin z \rangle$

SOLUTION We examine whether **F** satisfies the cross partials condition:

$$\left.\begin{aligned} \frac{\partial F_1}{\partial y} &= \frac{\partial}{\partial y}(\cos z) = 0 \\ \frac{\partial F_2}{\partial x} &= \frac{\partial}{\partial x}(2y) = 0 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_1}{\partial y} = \frac{\partial F_2}{\partial x}$$

$$\left.\begin{aligned} \frac{\partial F_2}{\partial z} &= \frac{\partial}{\partial z}(2y) = 0 \\ \frac{\partial F_3}{\partial y} &= \frac{\partial}{\partial y}(-x \sin z) = 0 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_2}{\partial z} = \frac{\partial F_3}{\partial y}$$

$$\left.\begin{aligned} \frac{\partial F_3}{\partial x} &= \frac{\partial}{\partial x}(-x \sin z) = -\sin z \\ \frac{\partial F_1}{\partial z} &= \frac{\partial}{\partial z}(\cos z) = -\sin z \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial F_3}{\partial x} = \frac{\partial F_1}{\partial z}$$

We see that the conditions are satisfied, therefore **F** is conservative. We find a potential function for **F**.

Step 1. Use the condition $\frac{\partial V}{\partial x} = F_1$. $V(x, y, z)$ is an antiderivative of $F_1 = \cos z$ when y and z are fixed, therefore:

$$V(x, y, z) = \int \cos z \, dx = x \cos z + g(y, z) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = F_2$. Using (1) we get:

$$\frac{\partial}{\partial y}\left(x \cos z + g(y, z)\right) = 2y$$

$$g_y(y, z) = 2y$$

We integrate with respect to y, holding z fixed:

$$g(y, z) = \int 2y \, dy = y^2 + g(z)$$

Substituting in (1) gives

$$V(x, y, z) = x \cos z + y^2 + g(z) \tag{2}$$

Step 3. Use the condition $\frac{\partial V}{\partial z} = F_3$. By (2) we have

$$\frac{\partial}{\partial z}\left(x \cos z + y^2 + g(z)\right) = -x \sin z$$

$$-x \sin z + g'(z) = -x \sin z$$

$$g'(z) = 0 \quad \Rightarrow \quad g(z) = c$$

Substituting in (2) we obtain the general potential function:

$$V(x, y, z) = x \cos z + y^2 + c$$

Choosing $c = 0$ gives the potential function:

$$V(x, y, z) = x \cos z + y^2.$$

13. $\mathbf{F} = \langle z \sec^2 x, z, y + \tan x \rangle$

SOLUTION

Step 1. Use the condition $\frac{\partial V}{\partial x} = F_1$. $V(x, y, z)$ is an antiderivative of $F_1 = z \sec^2 x$ when y and z are fixed, therefore:

$$V(x, y, z) = \int z \sec^2 x \, dx = z \tan x + g(y, z) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = F_2$. Using (1) we get:

$$\frac{\partial}{\partial y}\left(z \tan x + g(y, z)\right) = z$$

$$g_y(y, z) = z$$

We integrate with respect to y, holding z fixed:

$$g(y,z) = \int z\,dy = yz + h(z)$$

Substituting in (1) gives

$$V(x,y,z) = z\tan x + yz + h(z) \tag{2}$$

Step 3. Use the condition $\frac{\partial V}{\partial z} = F_3$. By (2) we have

$$\begin{aligned} \frac{\partial}{\partial z}\left(z\tan x + yz + h(z)\right) &= y + \tan x \\ \tan x + y + h'(z) &= y + \tan x \\ h'(z) = 0 \quad &\Rightarrow \quad h(z) = c \end{aligned}$$

Substituting in (2) we obtain the general potential function:

$$V(x,y,z) = z\tan x + yz + c$$

Choosing $c = 0$ gives the potential function:

$$V(x,y,z) = z\tan x + yz$$

14. $\mathbf{F} = \left\langle e^x(z+1), -\cos y, e^x \right\rangle$

SOLUTION

Step 1. Use the condition $\frac{\partial V}{\partial x} = F_1$. $V(x,y,z)$ is an antiderivative of $F_1 = e^x(z+1)$ when y and z are fixed, therefore:

$$V(x,y,z) = \int e^x(z+1)\,dx = e^x(z+1) + g(y,z) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = F_2$. Using (1) we get:

$$\begin{aligned} \frac{\partial}{\partial y}\left(e^x(z+1) + g(y,z)\right) &= -\cos y \\ g_y(y,z) &= -\cos y \end{aligned}$$

We integrate with respect to y, holding z fixed:

$$g(y,z) = \int -\cos y\,dy = -\sin y + h(z)$$

Substituting in (1) gives

$$V(x,y,z) = e^x(z+1) - \sin y + h(z) \tag{2}$$

Step 3. Use the condition $\frac{\partial V}{\partial z} = F_3$. By (2) we have

$$\begin{aligned} \frac{\partial}{\partial z}\left(e^x(z+1) - \sin y + h(z)\right) &= e^x \\ e^x + h'(z) &= e^x \\ h'(z) = 0 \quad &\Rightarrow \quad h(z) = c \end{aligned}$$

Substituting in (2) we obtain the general potential function:

$$V(x,y,z) = e^x(z+1) - \sin y + c$$

Choosing $c = 0$ gives the potential function:

$$V(x,y,z) = e^x(z+1) - \sin y$$

15. $\mathbf{F} = \left\langle 2xy + 5, x^2 - 4z, -4y \right\rangle$

SOLUTION We find a potential function $V(x,y,z)$ for $\mathbf{F}$, using the following steps.

Step 1. Use the condition $\frac{\partial V}{\partial x} = \mathbf{F}_1$. V is an antiderivative of $\mathbf{F}_1 = 2xy + 5$ when y and z are fixed, therefore,

$$V(x,y,z) = \int (2xy+5)\,dx = x^2y + 5x + g(y,z) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = \mathbf{F}_2$. We have,

$$\frac{\partial}{\partial y}\left(x^2 y + 5x + g(y,z)\right) = x^2 - 4z$$

$$x^2 + g_y(y,z) = x^2 - 4z \quad \Rightarrow \quad g_y(y,z) = -4z$$

We integrate with respect to y, holding z fixed:

$$g(y,z) = \int -4z\,dy = -4zy + h(z)$$

Combining with (1) gives:

$$V(x,y,z) = x^2 y + 5x - 4zy + h(z) \tag{2}$$

Step 3. Use the condition $\frac{\partial V}{\partial z} = \mathbf{F}_3$. We have,

$$\frac{\partial}{\partial z}\left(x^2 y + 5x - 4zy + h(z)\right) = -4y$$

$$-4y + h'(z) = -4y$$

$$h'(z) = 0 \quad \Rightarrow \quad h(z) = c$$

Substituting in (2) we obtain the general potential function:

$$V(x,y,z) = x^2 y + 5x - 4zy + c$$

To compute the line integral we need one of the potential functions. We choose $c = 0$ to obtain the function,

$$V(x,y,z) = x^2 y + 5x - 4zy$$

16. $\mathbf{F} = \langle yze^{xy}, xze^{xy} - z, e^{xy} - y\rangle$

SOLUTION

Step 1. Use the condition $\frac{\partial V}{\partial x} = F_1$. $V(x,y,z)$ is an antiderivative of $F_1 = yze^{xy}$ when y and z are fixed, therefore:

$$V(x,y,z) = \int yze^{xy}\,dx = ze^{xy} + g(y,z) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = F_2$. Using (1) we get:

$$\frac{\partial}{\partial y}\left(ze^{xy} + g(y,z)\right) = xze^{xy} - z$$

$$xze^{xy} + g_y(y,z) = xze^{xy} - z$$

$$g_y(y,z) = -z$$

We integrate with respect to y, holding z fixed:

$$g(y,z) = \int -z\,dy = -yz + h(z)$$

Substituting in (1) gives

$$V(x,y,z) = ze^{xy} - yz + h(z) \tag{2}$$

Step 3. Use the condition $\frac{\partial V}{\partial z} = F_3$. By (2) we have

$$\frac{\partial}{\partial z}\left(ze^{xy} - yz + h(z)\right) = e^{xy} - y$$

$$e^{xy} - y + h'(z) = e^{xy} - y$$

$$h'(z) = 0 \quad \Rightarrow \quad h(z) = c$$

Substituting in (2) we obtain the general potential function:

$$V(x,y,z) = ze^{xy} - yz + c$$

Choosing $c = 0$ gives the potential function:

$$V(x,y,z) = ze^{xy} - yz$$

17. Evaluate

$$\int_{\mathbf{c}} 2xyz\,dx + x^2z\,dy + x^2y\,dz$$

over the path $\mathbf{c}(t) = (t^2, \sin(\pi t/4), e^{t^2-2t})$ for $0 \le t \le 2$.

SOLUTION A potential function is

$$V(x, y, z) = x^2yz$$

The path begins at $\mathbf{c}(0) = (0, 0, 1)$ and ends at $\mathbf{c}(2) = (4, 1, 1)$ so the line integral is

$$V(4, 1, 1) - V(0, 0, 1) = 16 - 0 = 16$$

18. Evaluate

$$\oint_{\mathcal{C}} \sin x\,dx + z\cos y\,dy + \sin y\,dz$$

where $\mathcal{C}$ is the ellipse $4x^2 + 9y^2 = 36$, oriented clockwise.

SOLUTION First we find a potential function for the vector field $\mathbf{F} = \langle \sin x, z\cos y, \sin y\rangle$.

Step 1. Use the condition $\frac{\partial V}{\partial x} = F_1$.

$$V(x, y, z) = \int \sin x\,dx = -\cos x + g(y, z) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = F_2$. Using (1) we get:

$$\begin{aligned} \frac{\partial}{\partial y}\left(-\cos x + g(y, z)\right) &= z\cos y \\ g_y(y, z) &= z\cos y \end{aligned}$$

We integrate with respect to y, holding z fixed:

$$g(y, z) = \int z\cos y\,dy = z\sin y + h(z)$$

Substituting in (1) gives

$$V(x, y, z) = -\cos x + z\sin y + h(z) \tag{2}$$

Step 3. Use the condition $\frac{\partial V}{\partial z} = F_3$. By (2) we have

$$\begin{aligned} \frac{\partial}{\partial z}\left(-\cos x + z\sin y + h(z)\right) &= \sin y \\ \sin y + h'(z) &= \sin y \\ h'(z) &= 0 \quad \Rightarrow \quad h(z) = c \end{aligned}$$

Substituting in (2) we obtain the general potential function:

$$V(x, y, z) = -\cos x + z\sin y + c$$

Choosing $c = 0$ gives the potential function:

$$V(x, y, z) = -\cos x + z\sin y$$

Since this is a conservative vector field integrated around a closed curve we have

$$\oint_{\mathcal{C}} \sin x\,dx + z\cos y\,dy + \sin y\,dz = 0$$

19. A vector field $\mathbf{F}$ and contour lines of a potential function for $\mathbf{F}$ are shown in Figure 17. Calculate the common value of $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$ for the curves shown in Figure 17 oriented in the direction from P to Q.

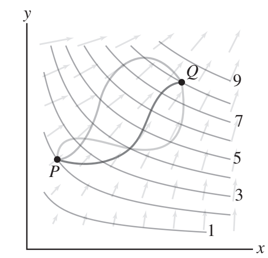

FIGURE 17

SOLUTION

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}} \nabla V \cdot d\mathbf{s} = V(Q) - V(P) = 8 - 2 = 6$$

20. Give a reason why the vector field $\mathbf{F}$ in Figure 18 is not conservative.

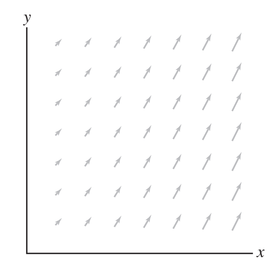

FIGURE 18

SOLUTION The line integral from the lower left corner to the upper right corner would clearly be larger if the path passed through the lower right region (where the vector field has large magnitude) than if it passed through the upper left region (where the vector field has small magnitude). If the vector field were conservative, the line integral would not depend on the path. Thus the vector field is not conservative.

21. Calculate the work expended when a particle is moved from O to Q along segments $\overline{OP}$ and $\overline{PQ}$ in Figure 19 in the presence of the force field $\mathbf{F} = \langle x^2, y^2 \rangle$. How much work is expended moving in a complete circuit around the square?

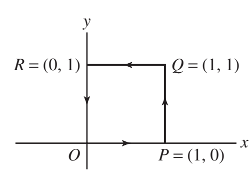

FIGURE 19

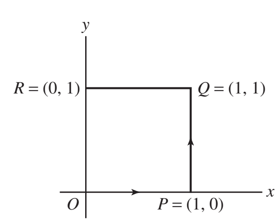
SOLUTION



Since $\frac{\partial F_1}{\partial y} = \frac{\partial}{\partial y}(x^2) = 0$ and $\frac{\partial F_2}{\partial x} = \frac{\partial}{\partial x}(y^2) = 0$, we have $\frac{\partial F_1}{\partial y} = \frac{\partial F_2}{\partial x}$. That is, $\mathbf{F}$ satisfies the cross partials condition, therefore $\mathbf{F}$ is conservative. We choose the function $\frac{x^3}{3} + \frac{y^3}{3}$, such that $\mathbf{F}$ is the gradient of the function. The potential energy is, thus, $V = -\frac{x^3}{3} - \frac{y^3}{3}$. The work done against $\mathbf{F}$ is computed by the Fundamental Theorem for Gradient vectors:

$$\text{Work against } \mathbf{F} = -\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = V(Q) - V(O) = V(1, 1) - V(0) = -\frac{2}{3} - 0 = -\frac{2}{3}$$

(The negative sign is to be expected, as our force field is actually helping us move along OP and OQ. The line integral of a conservative field along a closed curve is zero, therefore the integral of $\mathbf{F}$ along the complete square is zero, and we get:

$$W = -\int_{OPQR} \mathbf{F} \cdot d\mathbf{s} = 0$$

22. Let $\mathbf{F} = \left\langle \frac{1}{x}, \frac{-1}{y} \right\rangle$. Calculate the work against F required to move an object from $(1, 1)$ to $(3, 4)$ along any path in the first quadrant.

SOLUTION $\mathbf{F}$ is a conservative force, since $\mathbf{F} = -\nabla V$ with potential energy $V(x, y) = \ln y - \ln x$. The work required to move an object from $(1, 1)$ to $(3, 4)$ along any path $\mathcal{C}$ is equal to the change in potential energy:

$$\text{Work against } \mathbf{F} = -\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = V(3, 4) - V(1, 1) = (\ln 4 - \ln 3) - (\ln 1 - \ln 1) = \ln 4 - \ln 3$$

23. Compute the work W against the earth's gravitational field required to move a satellite of mass $m = 1000$ kg along any path from an orbit of altitude 4000 km to an orbit of altitude 6000 km.

SOLUTION Work against gravity is calculated with the integral

$$W = -\int_{\mathcal{C}} m\mathbf{F} \cdot d\mathbf{s} = 1000 \int_{\mathcal{C}} \nabla V \cdot d\mathbf{s} = 1000(V(r_2) - V(r_1))$$

Since r_1 and r_2 are measured from the center of the earth,

$$r_1 = 4 \times 10^6 + 6.4 \times 10^6 = 10.4 \times 10^6 \text{ meters}$$
$$r_2 = 6 \times 10^6 + 6.4 \times 10^6 = 12.4 \times 10^6 \text{ meters}$$

$$V(r) = -\frac{k}{r} \quad \Rightarrow \quad W = -\frac{1000k}{10^6} \left(\frac{1}{12.4} - \frac{1}{10.4} \right) \approx 6.2 \times 10^9 \text{ J}$$

24. An electric dipole with dipole moment $p = 4 \times 10^{-5}$ C-m sets up an electric field (in newtons per coulomb)

$$\mathbf{F}(x, y, z) = \frac{kp}{r^5} \left\langle 3xz, 3yz, 2z^2 - x^2 - y^2 \right\rangle$$

where $r = (x^2 + y^2 + z^2)^{1/2}$ with distance in meters and $k = 8.99 \times 10^9$ N-m^2/C^2. Calculate the work against $\mathbf{F}$ required to move a particle of charge $q = 0.01$ C from $(1, -5, 0)$ to $(3, 4, 4)$. *Note:* The force on q is $q\mathbf{F}$ newtons.

SOLUTION We first calculate the potential function.

$$\begin{aligned} -\frac{\partial V}{\partial x} &= \frac{kpq3xz}{r^5} = qF_1 \\ \Rightarrow \quad V(x, y, z) &= -3kpqz \int \frac{x}{(x^2 + y^2 + z^2)^{\frac{5}{2}}}\, dx \\ &= -3kpqz \frac{1}{2} \left(-\frac{2}{3} \right) \frac{1}{(x^2 + y^2 + z^2)^{\frac{3}{2}}} + g(y, z) = \frac{kpqz}{r^3} + g(y, z) \end{aligned}$$

We may let $g(y, z) = 0$ since,

$$\begin{aligned} -\frac{\partial}{\partial y} \left(\frac{kpqz}{r^3} \right) &= -kpqz \left(-\frac{3}{2} \right) \frac{2y}{(x^2 + y^2 + z^2)^{\frac{5}{2}}} = \frac{kpq3yz}{r^5} = qF_2 \\ -\frac{\partial}{\partial z} \left(\frac{kpqz}{r^3} \right) &= -\frac{kpq}{(x^2 + y^2 + z^2)^{\frac{3}{2}}} - kpqz \left(-\frac{3}{2} \right) \frac{2z}{(x^2 + y^2 + z^2)^{\frac{5}{2}}} \\ &= kpq \frac{-(x^2 + y^2 + z^2) + 3z^2}{(x^2 + y^2 + z^2)^{\frac{5}{2}}} = \frac{kpq(2z^2 - x^2 - y^2)}{r^5} = qF_3 \end{aligned}$$

Hence $V = \frac{kpqz}{r^3}$, so

$$V(3,4,4) - V(1,-5,0) = V(3,4,4) = \frac{(0.01)(4\times 10^{-5})(8.99\times 10^9)(4)}{(3^2+4^2+4^2)^{\frac{3}{2}}} \approx 54.8 \text{ J}$$

25. On the surface of the earth, the gravitational field (with z as vertical coordinate measured in meters) is $\mathbf{F} = \langle 0, 0, -g\rangle$.

(a) Find a potential function for $\mathbf{F}$.

(b) Beginning at rest, a ball of mass $m = 2$ kg moves under the influence of gravity (without friction) along a path from $P = (3, 2, 400)$ to $Q = (-21, 40, 50)$. Find the ball's velocity when it reaches Q.

SOLUTION

(a) By inspection $\mathbf{F} = -\nabla V$ for $V(x, y, z) = gz$.

(b) The force of gravity is $m\mathbf{F} = \langle 0, 0, -mg\rangle$, therefore $m\mathbf{F} = -\nabla V$ for $V(x, y, z) = mgz$. The work performed moving the ball from P to Q is the line integral of $m\mathbf{F}$ over the path. Since $m\mathbf{F}$ is conservative, the energy is independent of the path connecting the two points. Using the Fundamental Theorem for Gradient Vector Fields we have:

$$W = -\int_{\mathbf{c}} m\mathbf{F}\cdot d\mathbf{s} = V(-21,40,50) - V(3,2,400) = 2\cdot 9.8(50-400) = -6860 \text{ joules}$$

By conservation of energy, the kinetic energy of the ball will be 6860 joules, so

$$\frac{mv^2}{2} = 6860 \Rightarrow v = \sqrt{\frac{2\cdot 6860}{2}} \approx 82.8 \text{ m/s}$$

26. An electron at rest at $P = (5, 3, 7)$ moves along a path ending at $Q = (1, 1, 1)$ under the influence of the electric field (in newtons per coulomb)

$$\mathbf{F}(x, y, z) = 400(x^2 + z^2)^{-1}\langle x, 0, z\rangle$$

(a) Find a potential function for $\mathbf{F}$.

(b) What is the electron's speed at point Q? Use Conservation of Energy and the value $q_e/m_e = -1.76\times 10^{11}$ C/kg, where q_e and m_e are the charge and mass on the electron, respectively.

SOLUTION

(a)

$$\begin{aligned}\frac{\partial V}{\partial x} &= \frac{400x}{x^2+z^2} = F_1\\ \Rightarrow \quad V(x,y,z) &= \int \frac{400x}{x^2+z^2}\,dx\\ &= 200\ln(x^2+z^2) + g(y,z)\end{aligned}$$

We may let $g(y, z) = 0$ since,

$$\begin{aligned}\frac{\partial}{\partial y}(200\ln(x^2+z^2)) &= 0 = F_2\\ \frac{\partial}{\partial z}(200\ln(x^2+z^2)) &= \frac{400z}{x^2+z^2} = F_3\end{aligned}$$

Hence $V = 200\ln(x^2 + z^2)$ volts.

(b) The energy at the point Q will be $q_e(V(1, 1, 1) - V(5, 3, 7))$. By conservation of energy,

$$\begin{aligned}\frac{m_e v^2}{2} &= q_e(V(1,1,1) - V(5,3,7))\\ \Rightarrow \quad v &= \sqrt{\frac{2q_e(V(1,1,1)-V(5,3,7))}{m_e}} = \sqrt{400\frac{q_e}{m_e}(\ln(1^2+1^2) - \ln(5^2+7^2))} \approx 1.59\times 10^7 \text{ m/s}\end{aligned}$$

27. Let $\mathbf{F} = \left\langle \dfrac{-y}{x^2+y^2}, \dfrac{x}{x^2+y^2} \right\rangle$ be the vortex field. Determine $\displaystyle\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s}$ for each of the paths in Figure 20.

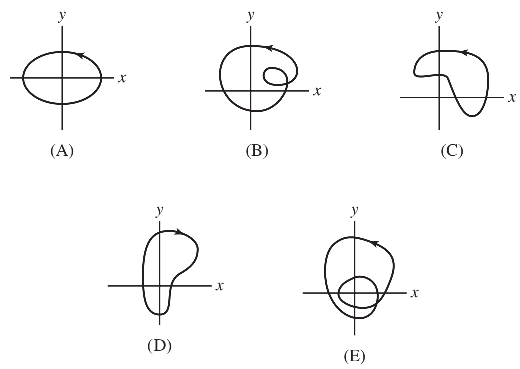


FIGURE 20

SOLUTION Since the cross partials of **F** are equal, **F** has the property,

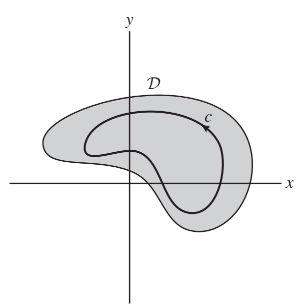
$$\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = 2\pi n$$

where **c** is a closed curve not passing through the origin, and n is the number of times **c** winds around the origin (n is negative if n winds in the clockwise direction). We use this property to compute the line integrals of **F** over the paths in Figure 18:

(A) The path (A) winds around the origin one time in the counterclockwise direction hence the line integral is $2\pi \cdot 1 = 2\pi$.

(B) The point (B) winds around the origin one time in the counterclockwise direction hence the line integral is $2\pi \cdot 1 = 2\pi$.

(C) The path (C) does not encounter the origin, hence the line integral is $2\pi \cdot 0 = 0$. Notice that there exists a simply connected domain $\mathcal{D}$, not including the origin, so that the path c and the region inside **c** are in $\mathcal{D}$. Therefore, Theorem 4 applies in $\mathcal{D}$ and **F** is a gradient vector in $\mathcal{D}$. Consequently, the line integral of **F** over **c** is zero.



(D) This path winds around the origin one time in the clockwise direction, hence $\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = 2\pi \cdot (-1) = -2\pi$.

(E) The path winds around the origin twice in the counterclockwise direction, hence the line integral is $2\pi \cdot 2 = 4\pi$.

28. The vector field $\mathbf{F} = \left\langle \dfrac{x}{x^2+y^2}, \dfrac{y}{x^2+y^2} \right\rangle$ is defined on the domain $\mathcal{D} = \{(x, y) \neq (0, 0)\}$.

(a) Is $\mathcal{D}$ simply-connected?

(b) Show that **F** satisfies the cross-partial condition. Does this guarantee that **F** is conservative?

(c) Show that **F** is conservative on $\mathcal{D}$ by finding a potential function.

(d) Do these results contradict Theorem 4?

SOLUTION

(a) $\mathcal{D}$ is not simply-connected since it has a “hole" at the origin.

(b) We compute the partials of **F**:

$$\frac{\partial F_2}{\partial x} = \frac{\partial}{\partial x}\left(\frac{y}{x^2+y^2}\right) = \frac{-2xy}{\left(x^2+y^2\right)^2}$$

$$\frac{\partial F_1}{\partial y} = \frac{\partial}{\partial y}\left(\frac{x}{x^2+y^2}\right) = \frac{-2yx}{\left(x^2+y^2\right)^2}$$

The cross partials are equal in $\mathcal{D}$, however this does not guarantee **F** is conservative since $\mathcal{D}$ is not simply connected.

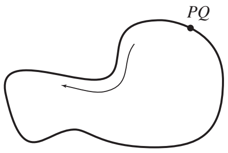
(c) We compute the gradient of $V(x, y) = \frac{1}{2}\ln\left(x^2 + y^2\right)$:

$$\nabla V = \left\langle \frac{\partial V}{\partial x}, \frac{\partial V}{\partial x} \right\rangle = \frac{1}{2}\left\langle \frac{2x}{x^2+y^2}, \frac{2y}{x^2+y^2} \right\rangle = \left\langle \frac{x}{x^2+y^2}, \frac{y}{x^2+y^2} \right\rangle = \mathbf{F}$$

(d) The requirement in Theorem 4 (that the domain be simply connected) is a sufficient condition for a vector field with equal cross-partial to have a potential function. It is not necessary, since as in our example, even if the domain is not simply-connected the field may have a gradient function. Moreover, for any closed curve in $\mathcal{D}$, V have the same value after completing one round along c. This is perhaps best seen by noting that $V = \log(r)$ in polar coordinates, which will be independent of θ. Therefore,

$$\int_c \mathbf{F} \cdot d\mathbf{s} = 0$$

Hence, **F** is conservative.



Further Insights and Challenges

29. Suppose that **F** is defined on $\mathbf{R}^3$ and that $\oint_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = 0$ for all closed paths **c** in $\mathbf{R}^3$. Prove:

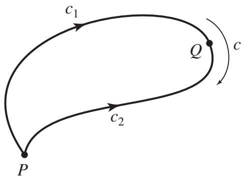
(a) **F** is path-independent; that is, for any two paths $\mathbf{c}_1$ and $\mathbf{c}_2$ in $\mathcal{D}$ with the same initial and terminal points,

$$\int_{\mathbf{c}_1} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathbf{c}_2} \mathbf{F} \cdot d\mathbf{s}$$

(b) **F** is conservative.

SOLUTION

(a) Choose two distinct points P and Q, and let $\mathbf{c}_1$ and $\mathbf{c}_2$ be paths from P to Q. We construct a path from P to P by first using $\mathbf{c}_1$ to reach Q, then using $\mathbf{c}_2$ with its orientation reversed to return to P. (This reversed path is designated $-\mathbf{c}_2$.) Such a closed path **c** can be represented as a difference $\mathbf{c} = \mathbf{c}_1 - \mathbf{c}_2$. (See figure below)



The closed loop **c** is represented as $\mathbf{c}_1 - \mathbf{c}_2$.

Thus,

$$\oint_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathbf{c}_1} \mathbf{F} \cdot d\mathbf{s} + \int_{-\mathbf{c}_2} \mathbf{F} \cdot d\mathbf{s}$$
$$= \int_{\mathbf{c}_1} \mathbf{F} \cdot d\mathbf{s} - \int_{\mathbf{c}_2} \mathbf{F} \cdot d\mathbf{s}$$

Since the problem states that the integral around any closed path is zero, we have

$$\int_{\mathbf{c}_1} \mathbf{F} \cdot d\mathbf{s} - \int_{\mathbf{c}_2} \mathbf{F} \cdot d\mathbf{s} = 0 \quad \Rightarrow \quad \int_{\mathbf{c}_1} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathbf{c}_2} \mathbf{F} \cdot d\mathbf{s}$$

(b) Since **F** is defined for all of $\mathbb{R}^3$, it is certainly defined in a simply connected domain $\mathcal{D}$. Since we have just established that **F** is also path independent, **F** is conservative by Theorem 2.

16.4 Parametrized Surfaces and Surface Integrals (LT Section 17.4)

Preliminary Questions

1. What is the surface integral of the function $f(x, y, z) = 10$ over a surface of total area 5?

SOLUTION Using Surface Integral and Surface Area we have:

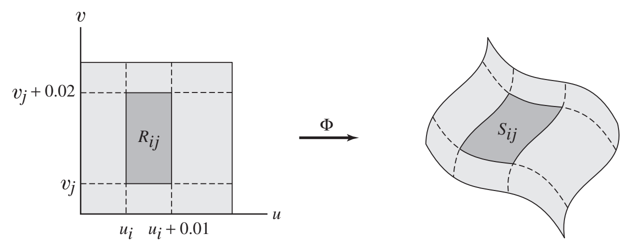
$$\iint_S f(x, y, z)\, dS = \iint_{\mathcal{D}} f(\Phi(u, v))\, \|\mathbf{n}(u, v)\|\, du\, dv = \iint_{\mathcal{D}} 10\|\mathbf{n}(u, v)\|\, du\, dv$$
$$= 10 \iint_{\mathcal{D}} \|\mathbf{n}(u, v)\|\, du\, dv = 10\,\text{Area}(S) = 10 \cdot 5 = 50$$

2. What interpretation can we give to the length $\|\mathbf{n}\|$ of the normal vector for a parametrization $G(u, v)$?

SOLUTION The approximation:

$$\text{Area}\left(S_{ij}\right) \approx \|\mathbf{n}\left(u_{ij}, v_{ij}\right)\| \text{Area}\left(R_{ij}\right)$$

tells that $\|\mathbf{n}\|$ is a distortion factor that indicates how much the area of a small rectangle R_{ij} is altered under the map ϕ.



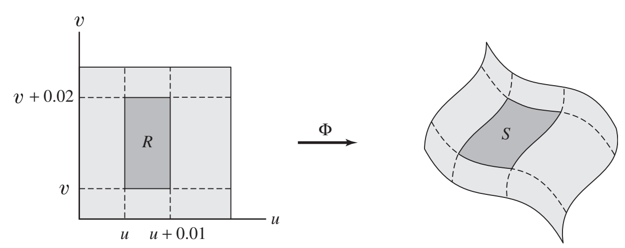
3. A parametrization maps a rectangle of size 0.01×0.02 in the uv-plane onto a small patch $\mathcal{S}$ of a surface. Estimate Area($\mathcal{S}$) if $\mathbf{T}_u \times \mathbf{T}_v = \langle 1, 2, 2\rangle$ at a sample point in the rectangle.

SOLUTION We use the estimation

$$\text{Area}(S) \approx \|\mathbf{n}(u, v)\|\text{Area}(R)$$

where $\mathbf{n}(u, v) = \mathbf{T}_u \times \mathbf{T}_v$ at a sample point in R. We get:

$$\text{Area}(S) \approx \|\,\langle 1, 2, 2\rangle\,\| \cdot 0.01 \cdot 0.02 = \sqrt{1^2 + 2^2 + 2^2} \cdot 0.0002 = 0.0006$$



4. A small surface $\mathcal{S}$ is divided into three small pieces, each of area 0.2. Estimate $\iint_{\mathcal{S}} f(x, y, z)\, dS$ if $f(x, y, z)$ takes the values 0.9, 1, and 1.1 at sample points in these three pieces.

SOLUTION We use the approximation obtained by the Riemann Sum:

$$\iint_S f(x, y, z)\, dS \approx \sum_{ij} f\left(P_{ij}\right) \text{Area}\left(S_{ij}\right) = 0.9 \cdot 0.2 + 1 \cdot 0.2 + 1.1 \cdot 0.2 = 0.6$$

5. A surface $\mathcal{S}$ has a parametrization whose domain is the square $0 \le u, v \le 2$ such that $\|\mathbf{n}(u, v)\| = 5$ for all (u, v). What is Area($\mathcal{S}$)?

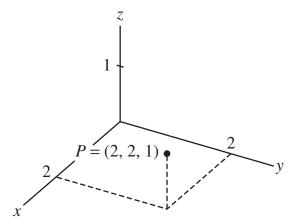
SOLUTION Writing the surface area as a surface integral where $\mathcal{D}$ is the square $[0, 2] \times [0, 2]$ in the uv-plane, we have:

$$\text{Area}(S) = \iint_{\mathcal{D}} \|\mathbf{n}(u, v)\|\, du\, dv = \iint_{\mathcal{D}} 5\, du\, dv = 5 \iint_{\mathcal{D}} 1\, du\, dv = 5\text{Area}(\mathcal{D}) = 5 \cdot 2^2 = 20$$

6. What is the outward-pointing unit normal to the sphere of radius 3 centered at the origin at $P = (2, 2, 1)$?

SOLUTION The outward-pointing normal to the sphere of radius $R = 3$ centered at the origin is the following vector:

$$\langle \cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi \rangle \qquad (1)$$



We compute the values in (1) corresponding to $P = (2, 2, 1)$: $x = y = 2$, $z = 1$ hence $0 \le \theta \le \frac{\pi}{2}$ and $0 < \phi < \frac{\pi}{2}$. We get:

$$\cos\phi = \frac{z}{\rho} = \frac{1}{3} \quad \Rightarrow \quad \sin\phi = \sqrt{1 - \left(\frac{1}{3}\right)^2} = \frac{2\sqrt{2}}{3}$$

$$\cos\theta = \frac{x}{\rho \sin\phi} = \frac{2}{3 \cdot \frac{2\sqrt{2}}{3}} = \frac{1}{\sqrt{2}} \quad \Rightarrow \quad \sin\theta = \sqrt{1 - \frac{1}{2}} = \frac{1}{\sqrt{2}}$$

Substituting in (1) we get the following unit normal:

$$\left\langle \frac{1}{\sqrt{2}} \cdot \frac{2\sqrt{2}}{3}, \frac{1}{\sqrt{2}} \cdot \frac{2\sqrt{2}}{3}, \frac{1}{3} \right\rangle = \left\langle \frac{2}{3}, \frac{2}{3}, \frac{1}{3} \right\rangle$$

Exercises

1. Match each parametrization with the corresponding surface in Figure 16.

(a) $(u, \cos v, \sin v)$
(b) $(u, u + v, v)$
(c) (u, v^3, v)
(d) $(\cos u \sin v, 3 \cos u \sin v, \cos v)$
(e) $(u, u(2 + \cos v), u(2 + \sin v))$

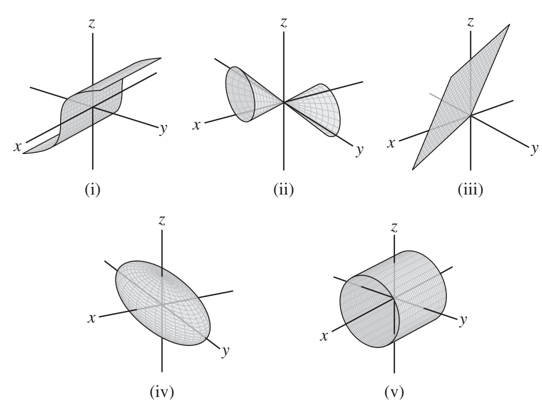


FIGURE 16

SOLUTION (a) = (v), because the y and z coordinates describe a circle with fixed radius.
(b) = (iii), because the coordinates are all linear in u and v.
(c) = (i), because the parametrization gives $y = z^3$.
(d) = (iv), an ellipsoid.
(e) = (ii), because the y and z coordinates describe a circle with varying radius.

2. Show that $G(r, \theta) = (r\cos\theta, r\sin\theta, 1 - r^2)$ parametrizes the paraboloid $z = 1 - x^2 - y^2$. Describe the grid curves of this parametrization.

SOLUTION We substitute $x = r\cos\theta$ and $y = r\sin\theta$ in the right-hand side of the equation of the cone, and verify that the result is $1 - r^2$:

$$1 - x^2 - y^2 = 1 - (r\cos\theta)^2 - (r\sin\theta)^2 = 1 - r^2\left(\cos^2\theta + \sin^2\theta\right) = 1 - r^2 \cdot 1 = 1 - r^2 = z$$

Moreover, for every x, y, z satisfying $z = 1 - x^2 - y^2$ there are suitable values of r and θ so that $x = r\cos\theta$, $y = r\sin\theta$ and $z = 1 - r^2$. We conclude that $G(r, \theta)$ parametrizes the whole paraboloid $z = 1 - x^2 - y^2$. The grid curves on the paraboloid through $P = (r_0, \theta_0)$ are:

- r-grid curve:

$$\left(r\cos\theta_0, r\sin\theta_0, 1 - r^2\right) = \text{parabola } z = 1 - r^2 \text{ in the plane } \sin(\theta_0)x - \cos(\theta_0)y = 0.$$

- θ-grid curve:

$$\left(r_0\cos\theta, r_0\sin\theta, 1 - r_0^2\right) = \text{circle of radius } r_0 \text{ at height } 1 - r_0^2.$$

3. Show that $G(u, v) = (2u + 1, u - v, 3u + v)$ parametrizes the plane $2x - y - z = 2$. Then:

(a) Calculate $\mathbf{T}_u$, $\mathbf{T}_v$, and $\mathbf{n}(u, v)$.

(b) Find the area of $\mathcal{S} = G(\mathcal{D})$, where $\mathcal{D} = \{(u, v) : 0 \le u \le 2, 0 \le v \le 1\}$.

(c) Express $f(x, y, z) = yz$ in terms of u and v, and evaluate $\iint_{\mathcal{S}} f(x, y, z)\, dS$.

SOLUTION We show that $x = 2u + 1$, $y = u - v$, and $z = 3u + v$ satisfy the equation of the plane,

$$2x - y - z = 2(2u + 1) - (u - v) - (3u + v) = 4u + 2 - u + v - 3u - v = 2$$

Moreover, for any x, y, z satisfying $2x - y - z = z$, there are values of u and v such that $x = 2u + 1$, $y = u - v$, and $z = 3u + v$, since the following equations can be solved for u and v:

$$\begin{aligned} x &= 2u + 1 \\ y &= u - v \\ z &= 3u + v \\ 2x - y - z &= 2 \end{aligned} \quad \Rightarrow \quad u = \frac{x - 1}{2}, \quad v = \frac{x - 1}{2} - y$$

We conclude that $\Phi(u, v)$ parametrizes the whole plane $2x - y - z = 2$.

(a) The tangent vectors $\mathbf{T}_u$ and $\mathbf{T}_v$ are:

$$\mathbf{T}_u = \frac{\partial\phi}{\partial u} = \frac{\partial}{\partial u}(2u + 1, u - v, 3u + v) = \langle 2, 1, 3\rangle$$

$$\mathbf{T}_v = \frac{\partial\phi}{\partial v} = \frac{\partial}{\partial v}(2u + 1, u - v, 3u + v) = \langle 0, -1, 1\rangle$$

The normal vector is the following cross product:

$$\mathbf{n}(u, v) = \mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 1 & 3 \\ 0 & -1 & 1 \end{vmatrix} = \begin{vmatrix} 1 & 3 \\ -1 & 1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2 & 3 \\ 0 & 1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2 & 1 \\ 0 & -1 \end{vmatrix}\mathbf{k}$$

$$= 4\mathbf{i} - 2\mathbf{j} - 2\mathbf{k} = \langle 4, -2, -2\rangle$$

(b) That area of $S = \Phi(\mathcal{D})$ is the following surface integral:

$$\text{Area}(S) = \iint_{\mathcal{D}} \|\mathbf{n}(u, v)\|\, du\, dv = \iint_{\mathcal{D}} \|\langle 4, -2, -2\rangle\|\, du\, dv = \sqrt{24}\iint_{\mathcal{D}} 1\, du\, dv$$

$$= \sqrt{24}\,\text{Area}(\mathcal{D}) = \sqrt{24} \cdot 2 \cdot 1 = 4\sqrt{6}$$

(c) We express $f(x, y, z) = yz$ in terms of the parameters u and v:

$$f(\phi(u, v)) = (u - v)(3u + v) = 3u^2 - 2uv - v^2$$

Using the Theorem on Surface Integrals we have:

$$\iint_S f(x, y, z)\, dS = \iint_{\mathcal{D}} f(\phi(u, v))\, \|\mathbf{n}(u, v)\|\, du\, dv = \iint_{\mathcal{D}} \left(3u^2 - 2uv - v^2\right) \|\langle 4, -2, -2\rangle\|\, du\, dv$$

$$= \sqrt{24}\int_0^1 \int_0^2 \left(3u^2 - 2uv - v^2\right) du\, dv = \sqrt{24}\int_0^1 \left(u^3 - u^2 v - v^2 u\right)\Big|_{u=0}^2 dv$$

$$= \sqrt{24}\int_0^1 \left(8 - 4v - 2v^2\right) dv = \sqrt{24}\left(8v - 2v^2 - \frac{2}{3}v^3\right)\Big|_0^1 = \frac{32\sqrt{6}}{3}$$

4. Let $\mathcal{S} = G(\mathcal{D})$, where $\mathcal{D} = \{(u, v) : u^2 + v^2 \le 1, u \ge 0, v \ge 0\}$ and G is as defined in Exercise 3.

(a) Calculate the surface area of $\mathcal{S}$.

(b) Evaluate $\iint_{\mathcal{S}} (x - y)\, dS$. *Hint:* Use polar coordinates.

SOLUTION The surface S is given by the parametrization:

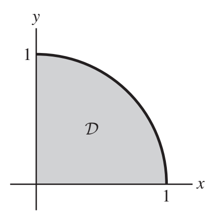
$$\Phi(u, v) = (2u + 1, u - v, 3u + v).$$

In Exercise 3 we computed the normal vector:

$$\mathbf{n}(u, v) = \langle 4, -2, 2\rangle \quad \Rightarrow \quad \|\mathbf{n}(u, v)\| = \sqrt{24}.$$

The surface area for u and v in the domain $\mathcal{D} = \left\{(u, v) : u^2 + v^2 \le 1, u \ge 0, v \ge 0\right\}$ is the surface integral:

$$\text{Area}(S) = \iint_{\mathcal{D}} \|\mathbf{n}(u, v)\|\, du\, dv = \iint_{\mathcal{D}} \sqrt{24}\, du\, dv = \sqrt{24} \iint_{\mathcal{D}} 1\, du\, dv = \sqrt{24}\, \text{Area}(\mathcal{D}) \tag{1}$$



$\mathcal{D}$ is the quarter disc $u^2 + v^2 \le 1$ in the first quadrant, hence it has the area $\frac{\pi \cdot 1^2}{4} = \frac{\pi}{4}$. Substituting in (1) gives:

$$\text{Area}(S) = \sqrt{24} \cdot \frac{\pi}{4} = \frac{\pi\sqrt{6}}{2}.$$

To compute the surface integral of $f(x, y, z) = x - y$, we first express f in terms of the parameters u and v:

$$f(\Phi(u, v)) = (2u + 1) - (u - v) = u + v + 1.$$

We now use the Theorem on surface integrals to compute the integral:

$$\iint_S f(x, y, z)\, dS = \iint_{\mathcal{D}} f(\Phi(u, v))\, \|\mathbf{n}(u, v)\|\, du\, dv = \iint_{\mathcal{D}} (u + v + 1)\sqrt{24}\, du\, dv$$

We convert the integral to polar coordinates:

$$u = r\cos\theta, \quad v = r\sin\theta$$

Then, the region of integration is:

$$0 \le r \le 1, \quad 0 \le \theta \le \frac{\pi}{2}.$$

We get:

$$\begin{aligned}
\iint_S f(x, y, z)\, dS &= \int_0^{\pi/2} \int_0^1 (r\cos\theta + r\sin\theta + 1)\sqrt{24}\, r\, dr\, d\theta = \sqrt{24} \int_0^{\pi/2} \int_0^1 \left(r^2(\cos\theta + \sin\theta) + r\right) dr\, d\theta \\
&= \sqrt{24} \int_0^{\pi/2} \frac{r^3(\cos\theta + \sin\theta)}{3} + \frac{r^2}{2}\bigg|_{r=0}^{1} d\theta = \sqrt{24} \int_0^{\pi/2} \left(\frac{\cos\theta + \sin\theta}{3} + \frac{1}{2}\right) d\theta \\
&= \sqrt{24} \left(\frac{\sin\theta - \cos\theta}{3} + \frac{\theta}{2}\right)\bigg|_0^{\pi/2} = \sqrt{24}\left(\frac{2}{3} + \frac{\pi}{4}\right) = \frac{8 + 3\pi}{\sqrt{6}}
\end{aligned}$$

5. Let $G(x, y) = (x, y, xy)$.

(a) Calculate $\mathbf{T}_x$, $\mathbf{T}_y$, and $\mathbf{n}(x, y)$.

(b) Let S be the part of the surface with parameter domain $\mathcal{D} = \{(x, y) : x^2 + y^2 \le 1, x \ge 0, y \ge 0\}$. Verify the following formula and evaluate using polar coordinates:

$$\iint_S 1\, dS = \iint_{\mathcal{D}} \sqrt{1 + x^2 + y^2}\, dx\, dy$$

(c) Verify the following formula and evaluate:

$$\iint_S z\,dS = \int_0^{\pi/2}\int_0^1 (\sin\theta\cos\theta) r^3\sqrt{1+r^2}\,dr\,d\theta$$

SOLUTION

(a) The tangent vectors are:

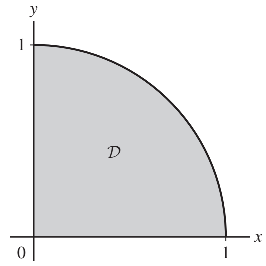
$$\mathbf{T}_x = \frac{\partial\phi}{\partial x} = \frac{\partial}{\partial x}(x, y, xy) = \langle 1, 0, y\rangle$$
$$\mathbf{T}_y = \frac{\partial\phi}{\partial y} = \frac{\partial}{\partial y}(x, y, xy) = \langle 0, 1, x\rangle$$

The normal vector is the cross product:

$$\mathbf{n}(x,y) = \mathbf{T}_x \times \mathbf{T}_y = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & y \\ 0 & 1 & x \end{vmatrix} = \begin{vmatrix} 0 & y \\ 1 & x \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & y \\ 0 & x \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix}\mathbf{k}$$
$$= -y\mathbf{i} - x\mathbf{j} + \mathbf{k} = \langle -y, -x, 1\rangle$$

(b) Using the Theorem on evaluating surface integrals we have:

$$\iint_S 1\,dS = \iint_{\mathcal{D}} \|\mathbf{n}(x,y)\|\,dx\,dy = \iint_{\mathcal{D}} \|\langle -y, -x, 1\rangle\|\,dx\,dy = \iint_{\mathcal{D}} \sqrt{y^2+x^2+1}\,dx\,dy$$



We convert the integral to polar coordinates $x = r\cos\theta$, $y = r\sin\theta$. The new region of integration is:

$$0 \le r \le 1, \quad 0 \le \theta \le \frac{\pi}{2}.$$

We get:

$$\iint_S 1\,dS = \int_0^{\pi/2}\int_0^1 \sqrt{r^2+1}\cdot r\,dr\,d\theta = \int_0^{\pi/2}\left(\int_0^1 \sqrt{r^2+1}\cdot r\,dr\right)d\theta$$
$$= \int_0^{\pi/2}\left(\int_1^2 \frac{\sqrt{u}}{2}\,du\right)d\theta = \int_0^{\pi/2}\frac{2\sqrt{2}-1}{3}\,d\theta = \frac{\left(2\sqrt{2}-1\right)\pi}{6}$$

(c) The function z expressed in terms of the parameters x, y is $f(\Phi(x,y)) = xy$. Therefore,

$$\iint_S z\,dS = \iint_{\mathcal{D}} xy\cdot\|\mathbf{n}(x,y)\|\,dx\,dy = \iint_{\mathcal{D}} xy\sqrt{1+x^2+y^2}\,dx\,dy$$

We compute the double integral by converting it to polar coordinates. We get:

$$\iint_S z\,dS = \int_0^{\pi/2}\int_0^1 (r\cos\theta)(r\sin\theta)\sqrt{1+r^2}\cdot r\,dr\,d\theta = \int_0^{\pi/2}\int_0^1 (\sin\theta\cos\theta) r^3\sqrt{1+r^2}\,dr\,d\theta$$
$$= \left(\int_0^{\pi/2}(\sin\theta\cos\theta)\,d\theta\right)\left(\int_0^1 r^3\sqrt{1+r^2}\,dr\right) \tag{1}$$

We compute each integral in (1). Using the substitution $u = 1+r^2$, $du = 2r\,dr$ we get:

$$\int_0^1 r^3\sqrt{1+r^2}\,dr = \int_0^1 r^2\sqrt{1+r^2}\cdot r\,dr = \int_1^2 \left(u^{3/2}-u^{1/2}\right)\frac{du}{2} = \frac{u^{5/2}}{5} - \frac{u^{3/2}}{3}\Big|_1^2 = \frac{2\left(\sqrt{2}+1\right)}{15}$$

Also,

$$\int_0^{\pi/2} \sin\theta\cos\theta\, d\theta = \int_0^{\pi/2} \frac{\sin 2\theta}{2}\, d\theta = -\frac{\cos 2\theta}{4}\bigg|_0^{\pi/2} = \frac{1}{2}$$

We substitute the integrals in (1) to obtain the following solution:

$$\iint_S z\, dS = \frac{1}{2} \cdot \frac{2\left(\sqrt{2}+1\right)}{15} = \frac{\sqrt{2}+1}{15}$$

6. A surface $\mathcal{S}$ has a parametrization $G(u,v)$ whose domain $\mathcal{D}$ is the square in Figure 17. Suppose that G has the following normal vectors:

$$\mathbf{n}(A) = \langle 2, 1, 0\rangle, \quad \mathbf{n}(B) = \langle 1, 3, 0\rangle$$
$$\mathbf{n}(C) = \langle 3, 0, 1\rangle, \quad \mathbf{n}(D) = \langle 2, 0, 1\rangle$$

Estimate $\iint_{\mathcal{S}} f(x,y,z)\, dS$, where f is a function such that $f(G(u,v)) = u + v$.

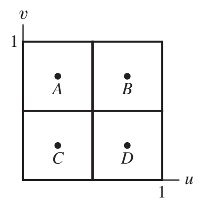


FIGURE 17

SOLUTION We estimate the surface integral by the following Riemann sum:

$$\iint_S f(x,y,z)\, dS = \Delta u \Delta v\, (f(A)\|\mathbf{n}(A)\| + f(B)\|\mathbf{n}(B)\| + f(C)\|\mathbf{n}(C)\| + f(D)\|\mathbf{n}(D)\|) \tag{1}$$

In the given grid, we have $\Delta u = \Delta v = \frac{1}{2}$. We compute the lengths of the normal vectors:

$$\|\mathbf{n}(A)\| = \|\langle 2,1,0\rangle\| = \sqrt{4+1+0} = \sqrt{5}$$
$$\|\mathbf{n}(B)\| = \|\langle 1,3,0\rangle\| = \sqrt{1+9+0} = \sqrt{10}$$
$$\|\mathbf{n}(C)\| = \|\langle 3,0,1\rangle\| = \sqrt{9+0+1} = \sqrt{10}$$
$$\|\mathbf{n}(D)\| = \|\langle 2,0,1\rangle\| = \sqrt{4+0+1} = \sqrt{5}$$

The sample points are $A = \left(\frac{1}{4}, \frac{3}{4}\right)$, $B = \left(\frac{3}{4}, \frac{3}{4}\right)$, $C = \left(\frac{1}{4}, \frac{1}{4}\right)$, $D = \left(\frac{3}{4}, \frac{1}{4}\right)$, hence the values of f at the sample points are:

$$f(A) = \frac{1}{4} + \frac{3}{4} = 1, \quad f(B) = \frac{3}{4} + \frac{3}{4} = \frac{3}{2}, \quad f(C) = \frac{1}{4} + \frac{1}{4} = \frac{1}{2}, \quad f(D) = \frac{3}{4} + \frac{1}{4} = 1$$

Substituting the values in (1) gives the following estimation:

$$\iint_S f(x,y,z)\, dS = \frac{1}{2} \cdot \frac{1}{2}\left(1 \cdot \sqrt{5} + \frac{3}{2} \cdot \sqrt{10} + \frac{1}{2} \cdot \sqrt{10} + 1 \cdot \sqrt{5}\right) = \frac{\sqrt{5}+\sqrt{10}}{2}$$

In Exercises 7–10, calculate $\mathbf{T}_u$, $\mathbf{T}_v$, and $\mathbf{n}(u,v)$ for the parametrized surface at the given point. Then find the equation of the tangent plane to the surface at that point.

7. $G(u,v) = (2u+v, u-4v, 3u)$; $\quad u = 1, \quad v = 4$

SOLUTION The tangent vectors are the following vectors,

$$\mathbf{T}_u = \frac{\partial \Phi}{\partial u} = \frac{\partial}{\partial u}(2u+v, u-4v, 3u) = \langle 2, 1, 3\rangle$$
$$\mathbf{T}_v = \frac{\partial \Phi}{\partial v} = \frac{\partial}{\partial v}(2u+v, u-4v, 3u) = \langle 1, -4, 0\rangle$$

The normal is the cross product:

$$\mathbf{n}(u,v) = \mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 1 & 3 \\ 1 & -4 & 0 \end{vmatrix} = \begin{vmatrix} 1 & 3 \\ -4 & 0 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2 & 3 \\ 1 & 0 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2 & 1 \\ 1 & -4 \end{vmatrix}\mathbf{k}$$

$$= 12\mathbf{i} + 3\mathbf{j} - 9\mathbf{k} = 3\langle 4, 1, -3\rangle$$

The equation of the plane passing through the point $P : \Phi(1, 4) = (6, -15, 3)$ with the normal vector $\langle 4, 1, -3\rangle$ is:

$$\langle x - 6, y + 15, z - 3\rangle \cdot \langle 4, 1, -3\rangle = 0$$

or

$$\begin{aligned} 4(x - 6) + y + 15 - 3(z - 3) &= 0 \\ 4x + y - 3z &= 0 \end{aligned}$$

8. $G(u, v) = (u^2 - v^2, u + v, u - v);\qquad u = 2,\quad v = 3$

SOLUTION We compute the tangent vectors:

$$\begin{aligned} \mathbf{T}_u &= \frac{\partial \Phi}{\partial u} = \frac{\partial}{\partial u}\left(u^2 - v^2, u + v, u - v\right) = \langle 2u, 1, 1\rangle \\ \mathbf{T}_v &= \frac{\partial \Phi}{\partial v} = \frac{\partial}{\partial v}\left(u^2 - v^2, u + v, u - v\right) = \langle -2v, 1, -1\rangle \end{aligned}$$

The normal is the cross product of $\mathbf{T}_u$ and $\mathbf{T}_v$. That is:

$$\begin{aligned} \mathbf{n}(u, v) = \mathbf{T}_u \times \mathbf{T}_v &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2u & 1 & 1 \\ -2v & 1 & -1 \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ 1 & -1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2u & 1 \\ -2v & -1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2u & 1 \\ -2v & 1 \end{vmatrix}\mathbf{k} \\ &= -2\mathbf{i} - 2(v - u)\mathbf{j} + 2(u + v)\mathbf{k} = 2\langle -1, u - v, v + u\rangle \end{aligned}$$

We compute the tangency point and the normal $\mathbf{n}(u, v)$ at this point:

$$\begin{aligned} P = \Phi(2, 3) &= \left(2^2 - 3^2, 2 + 3, 2 - 3\right) = (-5, 5, -1) \\ \mathbf{n}(2, 3) &= 2\langle -1, 2 - 3, 3 + 2\rangle = 2\langle -1, -1, 5\rangle \end{aligned}$$

The equation of the plane passing through the point $P = (-5, 5, -1)$ with the normal vector $\langle -1, -1, 5\rangle$ is:

$$\langle x + 5, y - 5, z + 1\rangle \cdot \langle -1, -1, 5\rangle = 0$$

or

$$\begin{aligned} -(x + 5) - (y - 5) + 5(z + 1) &= 0 \\ -x - y + 5z + 5 &= 0 \end{aligned}$$

9. $G(\theta, \phi) = (\cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi);\qquad \theta = \frac{\pi}{2},\quad \phi = \frac{\pi}{4}$

SOLUTION We compute the tangent vectors:

$$\begin{aligned} \mathbf{T}_\theta &= \frac{\partial \Phi}{\partial \theta} = \frac{\partial}{\partial \theta}(\cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi) = \langle -\sin\theta \sin\phi, \cos\theta \sin\phi, 0\rangle \\ \mathbf{T}_\phi &= \frac{\partial \Phi}{\partial \phi} = \frac{\partial}{\partial \phi}(\cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi) = \langle \cos\theta \cos\phi, \sin\theta \cos\phi, -\sin\phi\rangle \end{aligned}$$

The normal vector is the cross product:

$$\begin{aligned} \mathbf{n}(\theta, \phi) = \mathbf{T}_\theta \times \mathbf{T}_\phi &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin\theta \sin\phi & \cos\theta \sin\phi & 0 \\ \cos\theta \cos\phi & \sin\theta \cos\phi & -\sin\phi \end{vmatrix} \\ &= \left(-\cos\theta\ \sin^2\phi\right)\mathbf{i} - \left(\sin\theta\ \sin^2\phi\right)\mathbf{j} + \left(-\sin^2\theta \sin\phi \cos\phi - \cos^2\theta \cos\phi \sin\phi\right)\mathbf{k} \\ &= -\left(\cos\theta\ \sin^2\phi\right)\mathbf{i} - \left(\sin\theta\ \sin^2\phi\right)\mathbf{j} - (\sin\phi \cos\phi)\mathbf{k} \end{aligned}$$

The tangency point and the normal at this point are,

$$\begin{aligned} P = \Phi\left(\frac{\pi}{2}, \frac{\pi}{4}\right) &= \left(\cos\frac{\pi}{2} \sin\frac{\pi}{4}, \sin\frac{\pi}{2} \sin\frac{\pi}{4}, \cos\frac{\pi}{4}\right) = \left(0, \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right) \\ \mathbf{n}\left(\frac{\pi}{2}, \frac{\pi}{4}\right) &= -\frac{1}{2}\mathbf{j} - \frac{1}{2}\mathbf{k} = -\frac{1}{2}(\mathbf{j} + \mathbf{k}) = -\frac{1}{2}\langle 0, 1, 1\rangle \end{aligned}$$

The equation of the plane orthogonal to the vector $\langle 0,1,1\rangle$ and passing through $P=\left(0,\frac{\sqrt{2}}{2},\frac{\sqrt{2}}{2}\right)$ is:

$$\left\langle x, y-\frac{\sqrt{2}}{2}, z-\frac{\sqrt{2}}{2}\right\rangle\cdot\langle 0,1,1\rangle=0$$

or

$$y-\frac{\sqrt{2}}{2}+z-\frac{\sqrt{2}}{2}=0$$
$$y+z=\sqrt{2}$$

10. $G(r,\theta)=(r\cos\theta, r\sin\theta, 1-r^2);\qquad r=\frac{1}{2},\quad \theta=\frac{\pi}{4}$

SOLUTION The tangent vectors are:

$$\mathbf{T}_r=\frac{\partial\Phi}{\partial r}=\frac{\partial}{\partial r}\left(r\cos\theta, r\sin\theta, 1-r^2\right)=\langle\cos\theta,\sin\theta,-2r\rangle$$
$$\mathbf{T}_\theta=\frac{\partial\Phi}{\partial\theta}=\frac{\partial}{\partial\theta}\left(r\cos\theta, r\sin\theta, 1-r^2\right)=\langle -r\sin\theta, r\cos\theta, 0\rangle$$

The normal vector is the cross product of $\mathbf{T}_r$ and $\mathbf{T}_\theta$. That is,

$$\mathbf{n}(r,\theta)=\mathbf{T}_r\times\mathbf{T}_\theta=\begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ \cos\theta & \sin\theta & -2r\\ -r\sin\theta & r\cos\theta & 0\end{vmatrix}=\left(2r^2\cos\theta\right)\mathbf{i}+\left(2r^2\sin\theta\right)\mathbf{j}+\left(r\cos^2\theta+r\sin^2\theta\right)\mathbf{k}$$
$$=\left(2r^2\cos\theta\right)\mathbf{i}+\left(2r^2\sin\theta\right)\mathbf{j}+r\mathbf{k}=r\,\langle 2r\cos\theta, 2r\sin\theta, 1\rangle$$

We compute the tangency point and the normal vector at this point. We get:

$$P=\Phi\left(\frac{1}{2},\frac{\pi}{4}\right)=\left(\frac{1}{2}\cos\frac{\pi}{4},\frac{1}{2}\sin\frac{\pi}{4},1-\left(\frac{1}{2}\right)^2\right)=\left(\frac{1}{2\sqrt{2}},\frac{1}{2\sqrt{2}},\frac{3}{4}\right)$$
$$\mathbf{N}\left(\frac{1}{2},\frac{\pi}{4}\right)=\frac{1}{2}\left\langle 2\cdot\frac{1}{2}\cos\frac{\pi}{4}, 2\cdot\frac{1}{2}\sin\frac{\pi}{4}, 1\right\rangle=\frac{1}{2}\left\langle\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}},1\right\rangle$$

The equation of the plane through P, with normal vector $\left\langle\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}},1\right\rangle$ is:

$$\left\langle x-\frac{1}{2\sqrt{2}}, y-\frac{1}{2\sqrt{2}}, z-\frac{3}{4}\right\rangle\cdot\left\langle\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}},1\right\rangle=0$$

or

$$\frac{1}{\sqrt{2}}\left(x-\frac{1}{2\sqrt{2}}\right)+\frac{1}{\sqrt{2}}\left(y-\frac{1}{2\sqrt{2}}\right)+z-\frac{3}{4}=0$$
$$\frac{1}{\sqrt{2}}x+\frac{1}{\sqrt{2}}y+z=\frac{5}{4}$$
$$2\sqrt{2}x+2\sqrt{2}y+4=5$$

11. Use the normal vector computed in Exercise 8 to estimate the area of the small patch of the surface $G(u,v)=(u^2-v^2, u+v, u-v)$ defined by

$$2\le u\le 2.1,\qquad 3\le v\le 3.2$$

SOLUTION We denote the rectangle $\mathcal{D}=\{(u,v): 2\le u\le 2.1,\ 3\le v\le 3.2\}$. Using the sample point corresponding to $u=2$, $v=3$ we obtain the following estimation for the area of $S=\Phi(\mathcal{D})$:

$$\text{Area}(S)\approx\|\mathbf{n}(2,3)\|\text{Area}(\mathcal{D})=\|\mathbf{n}(2,3)\|\cdot 0.1\cdot 0.2=0.02\|\mathbf{n}(2,3)\| \tag{1}$$

In Exercise 8 we found that $\mathbf{n}(2,3)=2\,\langle -1,-1,5\rangle$. Therefore,

$$\|\mathbf{n}(2,3)\|=2\sqrt{1^2+1^2+5^2}=2\sqrt{27}$$

Substituting in (1) gives the following estimation:

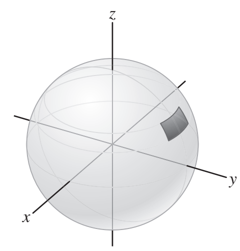
$$\text{Area}(S)\approx 0.02\cdot 2\cdot\sqrt{27}\approx 0.2078.$$

12. Sketch the small patch of the sphere whose spherical coordinates satisfy

$$\frac{\pi}{2} - 0.15 \le \theta \le \frac{\pi}{2} + 0.15, \qquad \frac{\pi}{4} - 0.1 \le \phi \le \frac{\pi}{4} + 0.1$$

Use the normal vector computed in Exercise 9 to estimate its area.

SOLUTION The small patch of the sphere is shown in the following figure:



Let $\mathcal{D}$ denote the rectangle in the (θ, ϕ)-plane. Using the sample point corresponding to the parameters $\theta = \frac{\pi}{2}, \phi = \frac{\pi}{4}$, we obtain the following estimation for the area of $S = \phi(\mathcal{D})$:

$$\text{Area}(S) = \left\| \mathbf{n}\left(\frac{\pi}{2}, \frac{\pi}{4}\right) \right\| \cdot \text{Area}(\mathcal{D}) = \left\| \mathbf{n}\left(\frac{\pi}{2}, \frac{\pi}{4}\right) \right\| \cdot 0.3 \cdot 0.2 = \left\| \mathbf{n}\left(\frac{\pi}{2}, \frac{\pi}{4}\right) \right\| \cdot 0.06 \tag{1}$$

In Exercise 9 we found that:

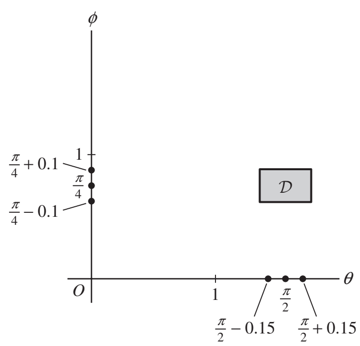
$$\mathbf{n}\left(\frac{\pi}{2}, \frac{\pi}{4}\right) = -\frac{1}{2}\langle 0, 1, 1\rangle$$

hence:

$$\left\| \mathbf{n}\left(\frac{\pi}{2}, \frac{\pi}{4}\right) \right\| = \frac{1}{2}\sqrt{0+1+1} = \frac{1}{\sqrt{2}}$$

Substituting in (1) gives the following estimation:

$$\text{Area}(S) \approx \frac{1}{\sqrt{2}} \cdot 0.06 \approx 0.0424$$



In Exercises 13–26, calculate $\iint_S f(x, y, z)\, dS$ *for the given surface and function.*

13. $G(u, v) = (u\cos v, u\sin v, u), \quad 0 \le u \le 1, \qquad 0 \le v \le 1;\ f(x, y, z) = z(x^2 + y^2)$

SOLUTION

Step 1. Compute the tangent and normal vectors. We have:

$$\mathbf{T}_u = \frac{\partial \Phi}{\partial u} = \frac{\partial}{\partial u}(u\cos v, u\sin v, u) = \langle \cos v, \sin v, 1\rangle$$
$$\mathbf{T}_v = \frac{\partial \Phi}{\partial v} = \frac{\partial}{\partial v}(u\cos v, u\sin v, u) = \langle -u\sin v, u\cos v, 0\rangle$$

The normal vector is the cross product:

$$\mathbf{n} = \mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos v & \sin v & 1 \\ -u\sin v & u\cos v & 0 \end{vmatrix}$$
$$= (-u\cos v)\mathbf{i} - (u\sin v)\mathbf{j} + \left(u\ \cos^2 v + u\ \sin^2 v\right)\mathbf{k}$$
$$= (-u\cos v)\mathbf{i} - (u\sin v)\mathbf{j} + u\mathbf{k} = \langle -u\cos v, -u\sin v, u\rangle$$

We compute the length of $\mathbf{n}$:

$$\|\mathbf{n}\| = \sqrt{(-u\cos v)^2 + (-u\sin v)^2 + u^2} = \sqrt{u^2\left(\cos^2 v + \sin^2 v + 1\right)} = \sqrt{u^2 \cdot 2} = \sqrt{2}|u| = \sqrt{2}u$$

Notice that in the region of integration $u \ge 0$, therefore $|u| = u$.

Step 2. Calculate the surface integral. We express the function $f(x, y, z) = z\left(x^2 + y^2\right)$ in terms of the parameters u, v:

$$f(\Phi, (u, v)) = u\left(u^2 \cos^2 v + u^2 \sin^2 v\right) = u \cdot u^2 = u^3$$

We obtain the following integral:

$$\iint_S f(x, y, z)\,dS = \int_0^1 \int_0^1 f(\Phi, (u, v))\,\|\mathbf{n}\|\,du\,dv = \int_0^1 \int_0^1 u^3 \cdot \sqrt{2}u\,du\,dv$$
$$= \left(\int_0^1 \sqrt{2}\,dv\right)\left(\int_0^1 u^4\,du\right) = \sqrt{2} \cdot \left.\frac{u^5}{5}\right|_0^1 = \frac{\sqrt{2}}{5}$$

14. $G(r, \theta) = (r\cos\theta, r\sin\theta, \theta), \quad 0 \le r \le 1, \quad 0 \le \theta \le 2\pi; \qquad f(x, y, z) = \sqrt{x^2 + y^2}$

SOLUTION

Step 1. Compute the tangent and normal vectors. We have:

$$\mathbf{T}_r = \frac{\partial \Phi}{\partial r} = \frac{\partial}{\partial r}(r\cos\theta, r\sin\theta, \theta) = \langle \cos\theta, \sin\theta, 0\rangle$$
$$\mathbf{T}_\theta = \frac{\partial \Phi}{\partial \theta} = \frac{\partial}{\partial \theta}(r\cos\theta, r\sin\theta, \theta) = \langle -r\sin\theta, r\cos\theta, 1\rangle$$

The normal vector is their cross product:

$$\mathbf{n} = \mathbf{T}_r \times \mathbf{T}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos\theta & \sin\theta & 0 \\ -r\sin\theta & r\cos\theta & 1 \end{vmatrix} = (\sin\theta)\mathbf{i} - (\cos\theta)\mathbf{j} + \left(r\cos^2\theta + r\sin^2\theta\right)\mathbf{k}$$
$$= (\sin\theta)\mathbf{i} - (\cos\theta)\mathbf{j} + r\mathbf{k} = \langle \sin\theta, -\cos\theta, r\rangle$$

We compute the length of $\mathbf{n}$:

$$\|\mathbf{n}\| = \sqrt{\sin^2\theta + \cos^2\theta + r^2} = \sqrt{1 + r^2}$$

Step 2. Calculate the surface integral. The surface integral is computed by the following double integral:

$$\iint_S f(x, y, z)\,dS = \iint_{\mathcal{D}} f(\Phi(r, \theta))\,\|\mathbf{n}\|\,dr\,d\theta = \int_0^{2\pi} \int_0^1 \sqrt{r^2\cos^2\theta + r^2\sin^2\theta}\sqrt{1 + r^2}\,dr\,d\theta$$
$$= \int_0^{2\pi} \int_0^1 r\sqrt{1 + r^2}\,dr\,d\theta = \left(\int_0^{2\pi} 1\,d\theta\right)\left(\int_0^1 r\sqrt{1 + r^2}\,dr\right) = 2\pi \int_0^1 r\sqrt{1 + r^2}\,dr$$

We compute the integral using the substitution $t = 1 + r^2, \quad dt = 2r\,dr$. We get:

$$\iint_S f(x, y, z)\,dS = 2\pi \int_1^2 \frac{1}{2} t^{1/2}\,dt = \frac{2\pi\left(2\sqrt{2} - 1\right)}{3}$$

15. $y = 9 - z^2, \quad 0 \le x \le 3, 0 \le z \le 3; \qquad f(x, y, z) = z$

SOLUTION We use the formula for the surface integral over a graph $y = g(x, z)$:

$$\iint_S f(x, y, z)\,dS = \iint_{\mathcal{D}} f(x, g(x, z), z)\sqrt{1 + g_x^2 + g_z^2}\,dx\,dz \tag{1}$$

Since $y = g(x, z) = 9 - z^2$, we have $g_x = 0$, $g_z = -2z$, hence:

$$\sqrt{1 + g_x^2 + g_z^2} = \sqrt{1 + 4z^2}$$
$$f(x, g(x, z), z) = z$$

The domain of integration is the square $[0, 3] \times [0, 3]$ in the xz-plane. By (1) we get:

$$\iint_S f(x, y, z)\, dS = \int_0^3 \int_0^3 z\sqrt{1+4z^2}\, dz\, dx = \left(\int_0^3 1\, dx\right)\left(\int_0^3 z\sqrt{1+4z^2}\, dz\right) = 3\int_0^3 z\sqrt{1+4z^2}\, dz$$

We use the substitution $u = 1 + 4z^2,\ du = 8z\, dz$ to compute the integral. This gives:

$$\iint_S f(x, y, z)\, dS = 3\int_0^3 z\sqrt{1+4z^2}\, dz = 3\int_1^{37} \frac{u^{1/2}}{8}\, du = \frac{37\sqrt{37}-1}{4} \approx 56$$

16. $y = 9 - z^2, \quad 0 \le x \le z \le 3; \qquad f(x, y, z) = 1$

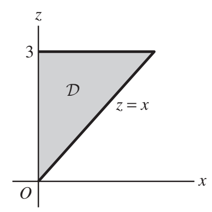
SOLUTION We use the formula for the surface integral over a graph $y = g(x, z)$:

$$\iint_S f(x, y, z)\, dS = \iint_{\mathcal{D}} f\,(x, g(x, z), z)\sqrt{1 + g_x^2 + g_z^2}\, dx\, dz \tag{1}$$

Since $y = g(x, z) = 9 - z^2$ we have $g_x = 0$, $g_z = -2z$, hence:

$$\sqrt{1 + g_x^2 + g_z^2} = \sqrt{1+4z^2}$$

The domain of integration $\mathcal{D}$ is the triangle in the xz-plane shown in the figure.



By (1) we get:

$$\begin{aligned}\iint_S f(x, y, z)\, dS &= \iint_{\mathcal{D}} \sqrt{1+4z^2}\, dx\, dz = \int_0^3 \int_0^z \sqrt{1+4z^2}\, dx\, dz \\ &= \int_0^3 \sqrt{1+4z^2}\, x\Big|_{x=0}^{z} dz = \int_0^3 \sqrt{1+4z^2} \cdot z\, dz\end{aligned}$$

We compute the integral using the substitution $u = 1 + 4z^2,\ du = 8z\, dz$. This gives:

$$\iint_S f(x, y, z)\, dS = \int_0^3 \sqrt{1+4z^2} \cdot z\, dz = \int_1^{37} \frac{u^{1/2}}{8}\, du = \frac{37\sqrt{37}-1}{12} \approx 18.672$$

17. $x^2 + y^2 + z^2 = 1,\ \ x, y, z \ge 0; \quad f(x, y, z) = x^2.$

SOLUTION The octant of the unit sphere centered at the origin, where $x, y, z \ge 0$ has the following parametrization in spherical coordinates:

$$\Phi(\theta, \phi) = (\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi), \quad 0 \le \theta \le \frac{\pi}{2}, \quad 0 \le \phi \le \frac{\pi}{2}$$

The length of the normal vector is:

$$\|\mathbf{n}\| = \sin\phi$$

The function x^2 expressed in terms of the parameters is $\cos^2\theta\ \sin^2\phi$. Using the theorem on computing surface integrals we obtain,

$$\begin{aligned}\iint_S x^2\, dS &= \int_0^{\pi/2}\int_0^{\pi/2} \left(\cos^2\theta\ \sin^2\phi\right)(\sin\phi)\, d\phi\, d\theta = \int_0^{\pi/2}\int_0^{\pi/2} \cos^2\theta\ \sin^3\phi\, d\phi\, d\theta \\ &= \left(\int_0^{\pi/2} \cos^2\theta\, d\theta\right)\left(\int_0^{\pi/2} \sin^3\phi\, d\phi\right) = \left(\frac{\theta}{2} + \frac{\sin 2\theta}{4}\right)\Big|_{\theta=0}^{\pi/2} \cdot \left(-\frac{\sin^2\phi\cos\phi}{3} - \frac{2}{3}\cos\phi\right)\Big|_{\phi=0}^{\pi/2} \\ &= \frac{\pi}{4} \cdot \frac{2}{3} = \frac{\pi}{6}\end{aligned}$$

18. $z = 4 - x^2 - y^2, \quad 0 \le z \le 3; \qquad f(x, y, z) = x^2/(4 - z)$

SOLUTION Use the formula for the surface integral over the graph of $z = g(x, y)$.

$$\begin{aligned} z &= g(x, y) = 4 - x^2 - y^2 \\ \Rightarrow \quad g_x(x, y) &= -2x \quad g_y(x, y) = -2y \\ \|\mathbf{n}\| &= \sqrt{1 + (-2x)^2 + (-2y)^2} = \sqrt{1 + 4(x^2 + y^2)} \end{aligned}$$

The domain of integration, $\mathcal{D}$, can be determined by the restrictions on z,

$$\begin{aligned} 0 \le z \le 3 \quad &\Rightarrow \quad 0 \le 4 - x^2 - y^2 \le 3 \\ &\Rightarrow \quad x^2 + y^2 \le 4 \text{ and } 4 - 3 \le x^2 + y^2 \\ &\Rightarrow \quad 1 \le x^2 + y^2 \le 4 \end{aligned}$$

$\mathcal{D}$ is the annulus for $1 \le r \le 2$. Changing into polar coordinates, the integral may be written,

$$\begin{aligned} \iint_S \frac{x^2}{4 - z}\, dS &= \iint_{\mathcal{D}} \frac{x^2}{x^2 + y^2} \sqrt{1 + 4(x^2 + y^2)}\, dx\, dy \\ &= \int_0^{2\pi} \int_1^2 \frac{r^2 \cos^2\theta}{r^2} \sqrt{1 + 4r^2}\, r\, dr\, d\theta = \left(\int_0^{2\pi} \cos^2\theta\, d\theta \right) \left(\int_1^2 \sqrt{1 + 4r^2}\, r\, dr \right) \end{aligned}$$

Substituting $u = 1 + 4r^2 \Rightarrow du = 8r\, dr$ into the second integral, we have

$$\begin{aligned} &= \left(\int_0^{2\pi} \frac{1 + \cos 2\theta}{2}\, d\theta \right) \left(\int_1^{17} \frac{\sqrt{u}}{8}\, du \right) \\ &= \pi \cdot \frac{1}{8} \cdot \frac{2}{3} \cdot u^{\frac{3}{2}} \Big|_5^{17} = \frac{\pi}{12}(17\sqrt{17} - 5\sqrt{5}) \end{aligned}$$

19. $x^2 + y^2 = 4, \quad 0 \le z \le 4; \qquad f(x, y, z) = e^{-z}$

SOLUTION The cylinder has the following parametrization in cylindrical coordinates:

$$\Phi(\theta, z) = (2\cos\theta, 2\sin\theta, z), \; 0 \le \theta \le 2\pi, \; 0 \le z \le 4$$

Step 1. Compute the tangent and normal vectors. The tangent vectors are the partial derivatives:

$$\begin{aligned} \mathbf{T}_\theta &= \frac{\partial \Phi}{\partial \theta} = \frac{\partial}{\partial \theta}(2\cos\theta, 2\sin\theta, z) = \langle -2\sin\theta, 2\cos\theta, 0 \rangle \\ \mathbf{T}_z &= \frac{\partial}{\partial z}(2\cos\theta, 2\sin\theta, z) = \langle 0, 0, 1 \rangle \end{aligned}$$

The normal vector is their cross product:

$$\mathbf{n}(\theta, z) = \mathbf{T}_\theta \times \mathbf{T}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2\sin\theta & 2\cos\theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = (2\cos\theta)\mathbf{i} + (2\sin\theta)\mathbf{j} = \langle 2\cos\theta, 2\sin\theta, 0 \rangle$$

The length of the normal vector is thus

$$\|\mathbf{n}(\theta, z)\| = \sqrt{(2\cos\theta)^2 + (2\sin\theta)^2 + 0} = \sqrt{4\left(\cos^2\theta + \sin^2\theta\right)} = \sqrt{4} = 2$$

Step 2. Calculate the surface integral. The surface integral equals the following double integral:

$$\begin{aligned} \iint_S f(x, y, z)\, dS &= \iint_{\mathcal{D}} f\left(\Phi(\theta, z)\right) \|\mathbf{n}\|\, d\theta\, dz = \int_0^{2\pi} \int_0^4 e^{-z} \cdot 2\, d\theta\, dz \\ &= \left(\int_0^{2\pi} 2\, d\theta \right) \left(\int_0^4 e^{-z}\, dz \right) = 4\pi \cdot \left(-e^{-z}\right) \Big|_0^4 = 4\pi\left(1 - e^{-4}\right) \end{aligned}$$

20. $G(u,v) = (u, v^3, u+v), \quad 0 \le u \le 1, 0 \le v \le 1; \qquad f(x,y,z) = y$

SOLUTION

Step 1. Compute the tangent and normal vectors. We have:

$$\mathbf{T}_u = \frac{\partial \Phi}{\partial u} = \frac{\partial}{\partial u}\left(u, v^3, u+v\right) = \langle 1, 0, 1\rangle$$
$$\mathbf{T}_v = \frac{\partial \Phi}{\partial v} = \frac{\partial}{\partial v}\left(u, v^3, u+v\right) = \left\langle 0, 3v^2, 1\right\rangle$$

The normal vector is their cross product:

$$\mathbf{n} = \mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 1 \\ 0 & 3v^2 & 1 \end{vmatrix} = \left(-3v^2\right)\mathbf{i} - \mathbf{j} + \left(3v^2\right)\mathbf{k} = \left\langle -3v^2, -1, 3v^2\right\rangle$$

The length of the normal vector is, thus:

$$\|\mathbf{n}\| = \sqrt{9v^4 + 1 + 9v^4} = \sqrt{1 + 18v^4}$$

Step 2. Calculate the surface integral. We express $f(x,y,z) = y$ in terms of the parameters:

$$f\left(\Phi(u,v)\right) = v^3$$

We compute the surface integral by the following double integral:

$$\iint_S f(x,y,z)\,dS = \int_0^1 \int_0^1 f\left(\Phi(u,v)\right)\|\mathbf{n}\|\,dv\,du = \int_0^1 \int_0^1 v^3\sqrt{1+18v^4}\,dv\,du$$
$$= \left(\int_0^1 du\right)\left(\int_0^1 v^3\sqrt{1+18v^4}\,dv\right) = \int_0^1 v^3\sqrt{1+18v^4}\,dv$$

We compute the integral using the substitution $t = 1 + 18v^4, \quad dt = 72v^3\,dv$. We get:

$$\iint_S f(x,y,z)\,dS = \int_0^1 \sqrt{1+18v^4}\cdot v^3\,dv = \int_1^{19} \frac{t^{1/2}}{72}\,dt = \frac{19\sqrt{19}-1}{108} \approx 0.758$$

21. Part of the plane $x + y + z = 1$, where $x, y, z \ge 0$;
$f(x,y,z) = z$

SOLUTION We let $z = g(x,y) = 1 - x - y$ and use the formula for the surface integral over the graph of $z = g(x,y)$, where $\mathcal{D}$ is the parameter domain in the xy-plane. That is:

$$\iint_S f(x,y,z)\,dS = \iint_{\mathcal{D}} f\left(x,y,g(x,y)\right)\sqrt{1+g_x^2+g_y^2}\,dx\,dy \tag{1}$$

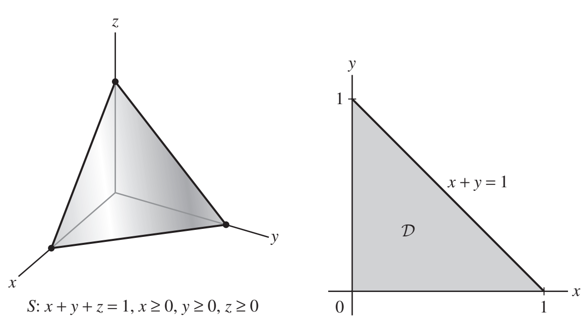
We have, $g_x = -1$ and $g_y = -1$ therefore:

$$\sqrt{1+g_x^2+g_y^2} = \sqrt{1+(-1)^2+(-1)^2} = \sqrt{3}$$

We express the function $f(x,y,z) = z$ in terms of the parameters x and y:

$$f\left(x,y,g(x,y)\right) = z = 1 - x - y$$

The domain of integration is the triangle $\mathcal{D}$ in the xy-plane shown in the figure.



By (1) we get:

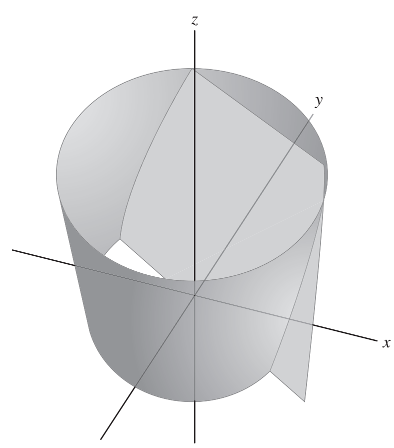
$$\iint_S f(x,y,z)\,dS = \int_0^1 \int_0^{1-y} (1-x-y)\sqrt{3}\,dx\,dy = \sqrt{3}\int_0^1 x - \frac{x^2}{2} - yx\Big|_{x=0}^{1-y} dy$$
$$= \sqrt{3}\int_0^1 \left((1-y)^2 - \frac{(1-y)^2}{2}\right) dy = \frac{\sqrt{3}}{2}\int_0^1 \left(1-2y+y^2\right) dy$$
$$= \frac{\sqrt{3}}{2}\left(y - y^2 + \frac{y^3}{3}\right)\Big|_0^1 = \frac{\sqrt{3}}{6}$$

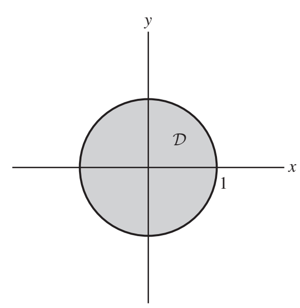
22. Part of the plane $x+y+z=0$ contained in the cylinder $x^2+y^2=1$; $\quad f(x,y,z)=z^2$

SOLUTION We let $z=-x-y$ and use the formula for the surface integral over the graph of $z=g(x,y)$. We have, $g_x=-1$ and $g_y=-1$ therefore:

$$\|\mathbf{n}\| = \sqrt{1+g_x^2+g_y^2} = \sqrt{1+(-1)^2+(-1)^2} = \sqrt{3}$$

The domain of integration, $\mathcal{D}: x^2+y^2 \le 1$, is the unit disk.





Changing to polar coordinates the integral may be evaluated

$$\iint_S z^2\,dS = \iint_{\mathcal{D}} (-x-y)^2\sqrt{3}\,dx\,dy = \int_0^{2\pi}\int_0^1 (-r\cos\theta - r\sin\theta)^2\sqrt{3}\,r\,dr\,d\theta$$
$$= \int_0^{2\pi}\int_0^1 (r^2)(\cos^2\theta + 2\sin\theta\cos\theta + \sin^2\theta)\cdot\sqrt{3}\,r\,dr\,d\theta$$
$$= \left(\int_0^{2\pi} 1+\sin(2\theta)\,d\theta\right)\left(\sqrt{3}\int_0^1 r^3\,dr\right)$$
$$= \left(\theta - \frac{\cos(2\theta)}{2}\Big|_0^{2\pi}\right)\left(\sqrt{3}\frac{r^4}{4}\Big|_0^1\right) = \frac{\pi\sqrt{3}}{2}$$

23. $x^2 + y^2 + z^2 = 4$, $1 \le z \le 2$; $\quad f(x, y, z) = z^2(x^2 + y^2 + z^2)^{-1}$

SOLUTION We use spherical coordinates to parametrize the cap S.

$$\Phi(\theta, \phi) = (2\cos\theta \sin\phi, 2\sin\theta\sin\phi, 2\cos\phi)$$
$$\mathcal{D} : 0 \le \theta \le 2\pi,\ 0 \le \phi \le \phi_0$$

The angle ϕ_0 is determined by $\cos\phi_0 = \frac{1}{2}$, that is, $\phi_0 = \frac{\pi}{3}$. The length of the normal vector in spherical coordinates is:

$$\|\mathbf{n}\| = R^2 \sin\phi = 4\sin\phi$$

We express the function $f(x, y, z) = z^2\left(x^2 + y^2 + z^2\right)^{-1}$ in terms of the parameters:

$$f(\Phi(\theta, \phi)) = (2\cos\phi)^2 4^{-1} = \cos^2\phi$$

Using the theorem on computing the surface integral we get:

$$\begin{aligned}\iint_S f(x, y, z)\, dS &= \iint_{\mathcal{D}} f(\Phi(\theta, \phi))\, \|\mathbf{n}\|\, d\phi\, d\theta = \int_0^{2\pi}\int_0^{\pi/3} \left(\cos^2\phi\right) \cdot 4\sin\phi\, d\phi\, d\theta \\ &= \left(\int_0^{2\pi} 4\, d\theta\right)\left(\int_0^{\pi/3} \cos^2\phi \sin\phi\, d\phi\right) = 8\pi\left(-\frac{\cos\phi}{3}\right)\Big|_0^{\pi/3} \\ &= \frac{8\pi}{3}\left(-\left(\frac{1}{2}\right)^3 - (-1)\right) = \frac{8\pi}{3} \cdot \frac{7}{8} = \frac{7\pi}{3}\end{aligned}$$

24. $x^2 + y^2 + z^2 = 4$, $0 \le y \le 1$; $\quad f(x, y, z) = y$

SOLUTION Since $y \ge 0$, we may consider the surface the graph $y = \sqrt{4 - x^2 - z^2}$. Using the formula for the surface integral over the graph

$$\begin{aligned} y = g(x, z) &= \sqrt{4 - x^2 - z^2} \\ \Rightarrow \quad g_x(x, z) &= \frac{-x}{\sqrt{4 - x^2 - z^2}} \\ \Rightarrow \quad g_z(x, z) &= \frac{-z}{\sqrt{4 - x^2 - z^2}} \\ \|\mathbf{n}\| &= \sqrt{1 + \left(\frac{-x}{\sqrt{4 - x^2 - z^2}}\right)^2 + \left(\frac{-z}{\sqrt{4 - x^2 - z^2}}\right)^2} \\ &= \sqrt{1 + \frac{x^2 + z^2}{4 - x^2 - z^2}} = \frac{2}{\sqrt{4 - x^2 - z^2}}\end{aligned}$$

The domain of integration, $\mathcal{D}$, can be determined by the restrictions on y,

$$\begin{aligned} 0 \le y \le 1 \quad &\Rightarrow \quad 0 \le \sqrt{4 - x^2 - z^2} \le 1 \\ &\Rightarrow \quad x^2 + z^2 \le 4 \text{ and } 4 - 1 \le x^2 + z^2 \\ &\Rightarrow \quad 3 \le x^2 + z^2 \le 4\end{aligned}$$

$\mathcal{D}$ is the annulus for $\sqrt{3} \le r \le 2$. Changing into polar coordinates, the integral may be written,

$$\begin{aligned}\iint_S y\, dS &= \iint_{\mathcal{D}} \sqrt{4 - x^2 - z^2}\, \frac{2}{\sqrt{4 - x^2 - z^2}}\, dx\, dz \\ &= \int_0^{2\pi}\int_{\sqrt{3}}^2 2r\, dr\, d\theta = 2\pi \cdot r^2\Big|_{\sqrt{3}}^2 = 2\pi(4 - 3) = 2\pi\end{aligned}$$

25. Part of the surface $z = x^3$, where $0 \le x \le 1$, $0 \le y \le 1$; $\quad f(x, y, z) = z$

SOLUTION Use the formula for the surface integral over the graph of $z = g(x, y)$. We have, $g_x = 3x^2$ and $g_y = 0$ therefore:

$$\|\mathbf{n}\| = \sqrt{1 + g_x^2 + g_y^2} = \sqrt{1 + (3x^2)^2 + (0)^2} = \sqrt{1 + 9x^4}$$

The integral then is

$$\iint_S z\,dS = \int_0^1 \int_0^1 x^3\sqrt{1+9x^4}\,dx\,dy = \left(\int_0^1 dy\right)\left(\int_0^1 x^3\sqrt{1+9x^4}\,dx\right)$$

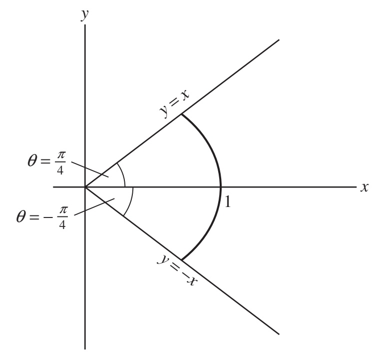
Substituting $u = 1 + 9x^4$, $du = 36x^3\,dx$

$$= 1 \cdot \int_1^{10} u^{\frac{1}{2}} \frac{du}{36} = \frac{1}{36} \cdot \frac{2}{3} \cdot u^{\frac{3}{2}}\Big|_1^{10} = \frac{1}{54}(10\sqrt{10} - 1)$$

26. Part of the unit sphere centered at the origin, where $x \ge 0$ and $|y| \le x$; $\quad f(x, y, z) = x$

SOLUTION We parametrize the surface as follows:

$$\Phi(\theta, \phi) = (\cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi), \quad -\frac{\pi}{4} \le \theta \le \frac{\pi}{4}, \quad 0 \le \phi \le \pi$$



The length of the normal vector is:

$$\|\mathbf{n}\| = 1^2 \sin\phi = \sin\phi$$

The function expressed in terms of the parameters is:

$$f\left(\Phi(\theta, \phi)\right) = x = \cos\theta \sin\phi$$

We obtain the following integral:

$$\iint_S f(x, y, z)\,dS = \iint_{\mathcal{D}} f\left(\Phi(\theta, \phi)\right) \|\mathbf{n}\|\,d\theta\,d\phi = \int_0^{\pi} \int_{-\pi/4}^{\pi/4} (\cos\theta \sin\phi) \sin\phi\,d\theta\,d\phi$$

$$= \int_0^{\pi} \int_{-\pi/4}^{\pi/4} \cos\theta\, \sin^2\phi\,d\theta\,d\phi = \left(\int_0^{\pi} \sin^2\phi\,d\phi\right)\left(\int_{-\pi/4}^{\pi/4} \cos\theta\,d\theta\right)$$

$$= \left(\frac{\phi}{2} - \frac{\sin 2\phi}{4}\Big|_{\phi=0}^{\pi}\right)\left(\sin\theta\Big|_{\theta=-\frac{\pi}{4}}^{\pi/4}\right) = \frac{\pi}{2} \cdot \sqrt{2} = \frac{\pi}{\sqrt{2}}$$

27. A surface $\mathcal{S}$ has a parametrization $G(u, v)$ with domain $0 \le u \le 2$, $0 \le v \le 4$ such that the following partial derivatives are constant:

$$\frac{\partial G}{\partial u} = \langle 2, 0, 1 \rangle, \qquad \frac{\partial G}{\partial v} = \langle 4, 0, 3 \rangle$$

What is the surface area of $\mathcal{S}$?

SOLUTION Since the partial derivatives are constant, the normal vector is also constant. We find it by computing the cross product:

$$\mathbf{n} = \mathbf{T}_u \times \mathbf{T}_v = \frac{\partial \Phi}{\partial u} \times \frac{\partial \Phi}{\partial v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 0 & 1 \\ 4 & 0 & 3 \end{vmatrix} = -2\mathbf{j} = \langle 0, -2, 0 \rangle \quad \Rightarrow \quad \|\mathbf{n}\| = 2$$

We denote the rectangle $\mathcal{D} = \{(u, v) : 0 \le u \le 2,\ 0 \le v \le 4\}$, and use the surface area to compute the area of $S = \Phi(\mathcal{D})$. We obtain:

$$\text{Area}(S) = \iint_{\mathcal{D}} \|\mathbf{n}\|\,du\,dv = \iint_{\mathcal{D}} 2\,du\,dv = 2\iint_{\mathcal{D}} 1\,du\,dv = 2 \cdot \text{Area}(\mathcal{D}) = 2 \cdot 2 \cdot 4 = 16$$

28. Let S be the sphere of radius R centered at the origin. Explain using symmetry:

$$\iint_S x^2\,dS = \iint_S y^2\,dS = \iint_S z^2\,dS$$

Then show that $\iint_S x^2\,dS = \frac{4}{3}\pi R^4$ by adding the integrals.

SOLUTION

(a) Since the sphere is symmetric with respect to the yz-plane, the surface integrals of x over the hemispheres on the two sides of the plane cancel each other and the result is zero. The two other integrals are zero due to the symmetry of the sphere with respect to the xz and xy-planes.

(b) Since the sphere is symmetric with respect to the xy, xz and yz-planes, interchanging x and y in the integral for $\iint_S x^2\,dS$ does not change the value of the integral and the result is $\iint_S y^2\,dS$. The equality for $\iint_S z^2\,dS$ is explained similarly.

On the sphere, we have $x^2 + y^2 + z^2 = R^2$ so, using properties of integrals, the integral for surface area, and the surface area of the sphere of radius R we obtain:

$$\begin{aligned}\iint_S x^2\,dS + \iint_S y^2\,dS + \iint_S z^2\,dS &= \iint_S \left(x^2 + y^2 + z^2\right)\,dS = R^2 \iint_S 1\,dS \\ &= R^2 \cdot \text{Area}(S) = R^2 \cdot 4\pi R^2 = 4\pi R^4\end{aligned}$$

Combining with (b) we conclude that the value of each of the integrals is $\frac{4}{3}\pi R^4$. That is:

$$\iint_S x^2\,dS = \iint_S y^2\,dS = \iint_S z^2\,dS = \frac{4}{3}\pi R^4.$$

29. Calculate $\iint_{\mathcal{S}} (xy + e^z)\,dS$, where $\mathcal{S}$ is the triangle in Figure 18 with vertices $(0, 0, 3)$, $(1, 0, 2)$, and $(0, 4, 1)$.

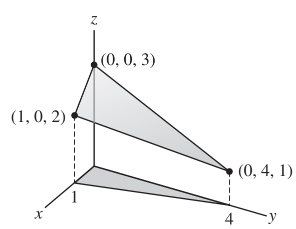


FIGURE 18

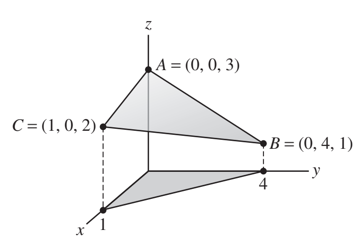
SOLUTION We find the equation of the plane through the points $A = (0, 0, 3)$, $B = (0, 4, 1)$ and $C = (1, 0, 2)$.



A normal to the plane is the cross product:

$$\overrightarrow{AB} \times \overrightarrow{AC} = \langle 0, 4, -2\rangle \times \langle 1, 0, -1\rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 4 & -2 \\ 1 & 0 & -1 \end{vmatrix} = -4\mathbf{i} - 2\mathbf{j} - 4\mathbf{k} = -2\langle 2, 1, 2\rangle$$

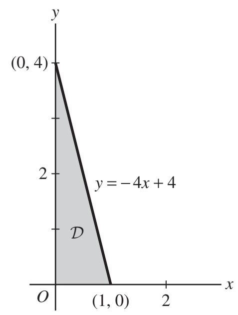
The equation of the plane passing through $A = (0, 0, 3)$ and perpendicular to the vector $\langle 2, 1, 2\rangle$ is:

$$\begin{aligned}\langle x - 0, y - 0, z - 3\rangle \cdot \langle 2, 1, 2\rangle &= 0 \\ 2x + y + 2(z - 3) &= 0 \\ 2x + y + 2z &= 6\end{aligned}$$

or

$$z = g(x, y) = -x - \frac{1}{2}y + 3$$

We compute the surface integral of $f(x, y, z) = xy + e^z$ over the triangle ABC using the formula for the surface integral over a graph. The parameter domain $\mathcal{D}$ is the projection of the triangle ABC onto the xy-plane (see figure).



We have:

$$\iint_S f(x, y, z)\, dS = \iint_{\mathcal{D}} f\big(x, y, g(x, y)\big)\sqrt{1 + g_x^2 + g_z^2}\, dx\, dy \tag{1}$$

We compute the functions in the integrand. Since $z = g(x, y) = -x - \frac{y}{2} + 3$, we have:

$$g_x = -1,\ g_y = -\frac{1}{2} \quad \Rightarrow \quad \sqrt{1 + g_x^2 + g_z^2} = \sqrt{1 + (-1)^2 + \left(-\frac{1}{2}\right)^2} = \frac{3}{2}$$

$$f\big(x, y, g(x, y, z)\big) = xy + e^z = xy + e^{-x-\frac{y}{2}+3}$$

Substituting in (1) gives:

$$\iint_S f(x, y, z)\, dS = \int_0^1 \int_0^{-4x+4} \left(xy + e^{-x-y/2+3}\right) \cdot \frac{3}{2}\, dy\, dx = \int_0^1 \frac{3xy^2}{4} - 3e^{-x-y/2+3}\Big|_{y=0}^{-4x+4} dx$$

$$= \int_0^1 \left(\frac{3x(-4x+4)^2}{4} - 3e^{-x-(-4x+4)/2+3} + 3e^{-x+3}\right) dx$$

$$= \int_0^1 \left(12x^3 - 24x^2 + 12x - 3e^{x+1} + 3e^{-x+3}\right) dx = 3x^4 - 8x^3 + 6x^2 - 3e^{x+1} - 3e^{-x+3}\Big|_0^1$$

$$= (1 - 3e^2 - 3e^2) - (-3e - 3e^3) = 3e^3 - 6e^2 + 3e + 1 \approx 25.08$$

30. Use spherical coordinates to compute the surface area of a sphere of radius R.

SOLUTION The sphere of radius R centered at the origin has the following parametrization in spherical coordinates:

$$\Phi(\theta, \phi) = (R\cos\theta\sin\phi,\ R\sin\theta\sin\phi,\ R\cos\phi), \quad 0 \le \theta \le 2\pi, \quad 0 \le \phi \le \pi$$

The length of the normal vector is:

$$\|\mathbf{n}\| = R^2 \sin\phi$$

Using the integral for surface area gives:

$$\text{Area}(S) = \iint_{\mathcal{D}} \|\mathbf{n}\|\, d\theta\, d\phi = \int_0^{2\pi}\int_0^{\pi} R^2 \sin\phi\, d\phi\, d\theta = \left(\int_0^{2\pi} R^2\, d\theta\right)\left(\int_0^{\pi} \sin\phi\, d\phi\right)$$

$$= 2\pi R^2 \cdot \left(-\cos\phi\Big|_0^{\pi}\right) = 2\pi R^2 \cdot 2 = 4\pi R^2$$

31. Use cylindrical coordinates to compute the surface area of a sphere of radius R.

SOLUTION As $z = \pm\sqrt{R^2 - (x^2 + y^2)}$ we may parametrize the upper hemisphere by the map

$$G(r, \theta) = (r\cos\theta, r\sin\theta, \sqrt{R^2 - r^2})$$

To compute the surface area of the hemisphere S, we first must find the tangent vectors and the normal vector. That is,

$$\mathbf{T}_r = \frac{\partial G}{\partial r} = \frac{\partial}{\partial r}\left\langle r\cos\theta, r\sin\theta, \sqrt{R^2-r^2}\right\rangle = \left\langle \cos\theta, \sin\theta, -\frac{r}{\sqrt{R^2-r^2}}\right\rangle$$

$$\mathbf{T}_\theta = \frac{\partial G}{\partial \theta} = \frac{\partial}{\partial \theta}\left\langle r\cos\theta, r\sin\theta, \sqrt{R^2-r^2}\right\rangle = \langle -r\sin\theta, r\cos\theta, 0\rangle$$

The normal vector is the cross product:

$$\begin{aligned}
\mathbf{n} = \mathbf{T}_r \times \mathbf{T}_\theta &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos\theta & \sin\theta & \frac{-r}{\sqrt{R^2-r^2}} \\ -r\sin\theta & r\cos\theta & 0 \end{vmatrix} \\
&= \left(\frac{r^2\cos\theta}{\sqrt{R^2-r^2}}\right)\mathbf{i} + \left(\frac{r^2\sin\theta}{\sqrt{R^2-r^2}}\right)\mathbf{j} + \left(r\cos^2\theta + r\sin^2\theta\right)\mathbf{k} \\
&= \left(\frac{r^2\cos\theta}{\sqrt{R^2-r^2}}\right)\mathbf{i} + \left(\frac{r^2\sin\theta}{\sqrt{R^2-r^2}}\right)\mathbf{j} + r\mathbf{k}
\end{aligned}$$

The length of the normal vector is thus

$$\|\mathbf{n}\| = \sqrt{\frac{r^4\cos^2\theta}{R^2-r^2} + \frac{r^4\sin^2\theta}{R^2-r^2} + r^2} = \sqrt{\frac{r^4}{R^2-r^2}\left(\cos^2\theta + \sin^2\theta\right) + r^2} = \sqrt{\frac{r^4}{R^2-r^2} + r^2} = \frac{rR}{\sqrt{R^2-r^2}}$$

We now compute the surface area as the following surface integral:

$$\begin{aligned}
\text{Area}(S) &= \iint_{\mathcal{D}} \|\mathbf{n}\|\,dr\,d\theta = \int_0^{2\pi}\int_0^R \frac{rR}{\sqrt{R^2-r^2}}\,dr\,d\theta \\
&= \left(\int_0^{2\pi} R\,d\theta\right)\left(\int_0^R \frac{r}{\sqrt{R^2-r^2}}\,dr\right) = 2\pi R\int_0^R \frac{r}{\sqrt{R^2-r^2}}\,dr
\end{aligned}$$

We compute the integral using the substitution $t = R^2 - r^2$, $dt = -2r\,dr$. We get:

$$\text{Area}(S) = 2\pi R\int_{R^2}^0 \frac{-1}{2t^{1/2}}\,dt = 2\pi R^2$$

The area of the entire sphere is twice this or $4\pi R^2$.

32. CAS Let $\mathcal{S}$ be the surface with parametrization

$$G(u, v) = \big((3+\sin v)\cos u,\ (3+\sin v)\sin u,\ v\big)$$

for $0 \le u \le 2\pi$, $0 \le v \le 2\pi$. Using a computer algebra system:

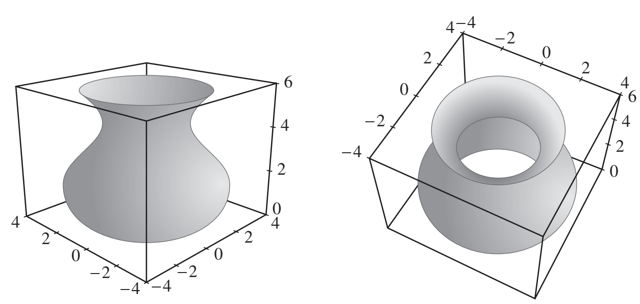
(a) Plot $\mathcal{S}$ from several different viewpoints. Is $\mathcal{S}$ best described as a "vase that holds water" or a "bottomless vase"?

(b) Calculate the normal vector $\mathbf{n}(u, v)$.

(c) Calculate the surface area of $\mathcal{S}$ to four decimal places.

SOLUTION

(a) We show the graph of $\mathcal{S}$ here.



Note that it is best described as a "bottomless vase."

(b) We compute the tangent and normal vectors:

$$\mathbf{T}_u = \frac{\partial \Phi}{\partial u} = \langle (3+\sin v)(-\sin u), (3+\sin v)(\cos u), 0\rangle$$
$$\mathbf{T}_v = \frac{\partial \Phi}{\partial v} = \langle \cos v \cos u, \cos v \sin u, 1\rangle$$

The normal vector is the cross product:

$$\mathbf{n}(u,v) = \mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ (3+\sin v)(-\sin u) & (3+\sin v)(\cos u) & 0 \\ \cos v \cos u & \cos v \sin u & 1 \end{vmatrix}$$
$$= ((3+\sin v)\cos u)\mathbf{i} + ((3+\sin v)\sin u)\mathbf{j} - ((3+\sin v)\cos v)\mathbf{k}$$

Hence,

$$\|\mathbf{n}(u,v)\| = (3+\sin v)\sqrt{1+\cos^2 v}$$

We obtain the following area:

$$\text{Area}(S) = \iint_{\mathcal{D}} \|\mathbf{n}\|\, du\, dv = \int_0^{2\pi}\int_0^{2\pi} (3+\sin v)\sqrt{1+\cos^2 v}\, du\, dv \approx 144.0181$$

33. CAS Let $\mathcal{S}$ be the surface $z = \ln(5 - x^2 - y^2)$ for $0 \le x \le 1$, $0 \le y \le 1$. Using a computer algebra system:
(a) Calculate the surface area of $\mathcal{S}$ to four decimal places.
(b) Calculate $\iint_{\mathcal{S}} x^2 y^3\, dS$ to four decimal places.

SOLUTION
(a) Using that $z_x = -2x/(5-x^2-y^2)$ and $z_y = -2y/(5-x^2-y^2)$, we calculate $\|n\|$ to be

$$\|n\| = \sqrt{1+(z_x)^2+(z_y)^2} = \frac{\sqrt{(5-x^2-y^2)^2+4x^2+4y^2}}{5-x^2-y^2}$$

Thus, the surface area is

$$\text{Area}(S) = \int_0^1\int_0^1 \frac{\sqrt{(5-x^2-y^2)^2+4x^2+4y^2}}{5-x^2-y^2}\, dx\, dy \approx 1.078$$

(b) We calculate $\iint_{\mathcal{S}} x^2 y^3\, dS$ as follows:

$$\iint_{\mathcal{S}} x^2 y^3\, dS = \int_0^1\int_0^1 x^2 y^3 \frac{\sqrt{(5-x^2-y^2)^2+4x^2+4y^2}}{5-x^2-y^2}\, dx\, dy \approx 0.09814$$

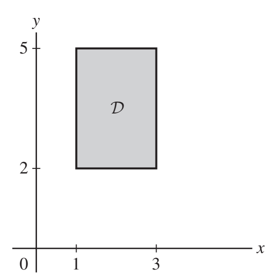
34. Find the area of the portion of the plane $2x + 3y + 4z = 28$ lying above the rectangle $1 \le x \le 3$, $2 \le y \le 5$ in the xy-plane.

SOLUTION We rewrite the equation of the plane as:

$$z = g(x,y) = -\frac{x}{2} - \frac{3}{4}y + 7 \tag{1}$$

The domain of the parameters is the rectangle $\mathcal{D} = [1,3] \times [2,5]$ in the xy-plane. Using the integral for surface area and the surface integral over a graph we have:

$$\text{Area}(S) = \iint_S 1\, dS = \iint_{\mathcal{D}} \sqrt{1+g_x^2+g_z^2}\, dx\, dy \tag{2}$$



By (1) we have:

$$g_x = -\frac{1}{2},\, g_y = -\frac{3}{4} \quad \Rightarrow \quad \sqrt{1 + g_x^2 + g_z^2} = \sqrt{1 + \frac{1}{4} + \frac{9}{16}} = \frac{\sqrt{29}}{4}$$

We substitute in (2) to obtain:

$$\text{Area}(S) = \iint_{\mathcal{D}} \frac{\sqrt{29}}{4}\, dx\, dy = \frac{\sqrt{29}}{4} \iint_{\mathcal{D}} 1\, dx\, dy = \frac{\sqrt{29}}{4}\text{Area}(\mathcal{D}) = \frac{\sqrt{29}}{4} \cdot 3 \cdot 2 = \frac{3\sqrt{29}}{2}$$

35. What is the area of the portion of the plane $2x + 3y + 4z = 28$ lying above the domain $\mathcal{D}$ in the xy-plane in Figure 19 if $\text{Area}(\mathcal{D}) = 5$?

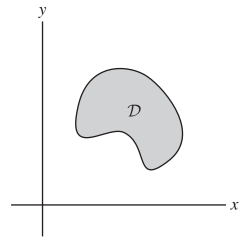


FIGURE 19

SOLUTION We rewrite the equation of the plane as:

$$z = g(x, y) = -\frac{x}{2} - \frac{3}{4}y + 7$$

Hence:

$$\sqrt{1 + g_x^2 + g_y^2} = \sqrt{1 + \left(-\frac{1}{2}\right)^2 + \left(-\frac{3}{4}\right)^2} = \frac{\sqrt{29}}{4}$$

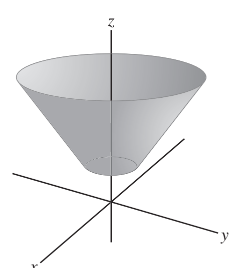
We use the integral for surface area and the surface integral over a graph to write:

$$\text{Area}(S) = \iint_S 1\, dS = \iint_{\mathcal{D}} \sqrt{1 + g_x^2 + g_y^2}\, dx\, dy = \iint_{\mathcal{D}} \frac{\sqrt{29}}{4}\, dx\, dy$$

$$= \frac{\sqrt{29}}{4} \iint_{\mathcal{D}} 1\, dx\, dy = \frac{\sqrt{29}}{4}\text{Area}(\mathcal{D}) = \frac{\sqrt{29}}{4} \cdot 5 = \frac{5\sqrt{29}}{4} \approx 6.73$$

36. Find the surface area of the part of the cone $x^2 + y^2 = z^2$ between the planes $z = 2$ and $z = 5$.

SOLUTION



We use the following parametrization of the surface S:

$$\Phi(u, v) = (u \cos v, u \sin v, u)$$

$$\mathcal{D} : \; 0 \le v \le 2\pi, \; 2 \le u \le 5$$

Step 1. Compute the tangent and normal vectors. We have,

$$\mathbf{T}_u = \frac{\partial \varphi}{\partial u} = \frac{\partial}{\partial u}(u \cos v, u \sin v, u) = \langle \cos v, \sin v, 1 \rangle$$

$$\mathbf{T}_v = \frac{\partial \varphi}{\partial v} = \frac{\partial}{\partial v}(u \cos v, u \sin v, u) = \langle -u \sin v, u \cos v, 0 \rangle$$

The normal vector is their cross product:

$$\mathbf{n} = \mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos v & \sin v & 1 \\ -u\sin v & u\cos v & 0 \end{vmatrix} = (-u\cos v)\mathbf{i} - (u\sin v)\mathbf{j} + \left(u\cos^2 v + u\sin^2 v\right)\mathbf{k}$$

$$= (-u\cos v)\mathbf{i} - (u\sin v)\mathbf{j} + u\mathbf{k} = \langle -u\cos v, -u\sin v, u\rangle$$

We compute the length of $\mathbf{n}$:

$$\|\mathbf{n}\| = \sqrt{u^2\cos^2 v + u^2\sin^2 v + u^2} = \sqrt{u^2\left(\cos^2 v + \sin^2 v\right) + u^2} = \sqrt{2u^2} = u\sqrt{2}$$

Step 2. Calculate the surface area. Using the formula for the surface area as a double integral gives:

$$\text{Area}(S) = \iint_{\mathcal{D}} \|\mathbf{n}\|\,du\,dv = \int_0^{2\pi}\int_2^5 \sqrt{2}u\,du\,dv = \left(\int_0^{2\pi}\sqrt{2}\,dv\right)\left(\int_2^5 u\,du\right)$$

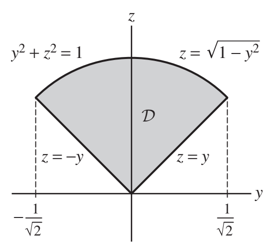
$$= 2\sqrt{2}\pi\left(\frac{u^2}{2}\Big|_2^5\right) = 2\sqrt{2}\pi\,\frac{25-4}{2} = 21\sqrt{2}\pi \approx 93.3$$

37. Find the surface area of the portion S of the cone $z^2 = x^2 + y^2$, where $z \ge 0$, contained within the cylinder $y^2 + z^2 \le 1$.

SOLUTION We rewrite the equation of the cone as $x = \pm\sqrt{z^2 - y^2}$. The projection of the cone onto the yz-plane is obtained by setting $x = 0$ in the equation of the cone, that is,

$$x = 0 = \sqrt{z^2 - y^2} \quad\Rightarrow\quad z = \pm y$$

Since on S, $z \ge 0$, we get $z = |y|$. We conclude that the projection of the upper part of the cone $x^2 + y^2 = z^2$ onto the yz-plane is the region between the lines $z = y$ and $z = -y$ on the upper part of the yz-plane. Therefore, the projection $\mathcal{D}$ of S onto the yz-plane is the region shown in the figure:



There are two identical portions of the surface parametrized by this region—one for $x \ge 0$, and one for $x \le 0$. Therefore the area of S is twice the integral over the domain $\mathcal{D}$:

$$\text{Area}(S) = \iint_S dS = 2\iint_{\mathcal{D}} \sqrt{1 + g_y^2 + g_z^2}\,dy\,dz$$

We compute the integral using a surface integral over a graph. Since $x = g(y,z) = \pm\sqrt{z^2 - y^2}$ we have,

$$g_z = \pm\frac{z}{\sqrt{z^2 - y^2}}, \quad g_y = \pm\frac{y}{\sqrt{z^2 - y^2}}$$

Hence, (notice that $z \ge 0$ on S):

$$\sqrt{1 + g_y^2 + g_z^2} = \sqrt{1 + \frac{z^2}{z^2 - y^2} + \frac{y^2}{z^2 - y^2}} = \sqrt{\frac{2z^2}{z^2 - y^2}} = \frac{z\sqrt{2}}{\sqrt{z^2 - y^2}}$$

We obtain the following integral:

$$\text{Area}(S) = 2\iint_{\mathcal{D}} \sqrt{1 + g_y^2 + g_z^2}\,dy\,dz = 2\iint_{\mathcal{D}} \frac{z\sqrt{2}}{\sqrt{z^2 - y^2}}\,dz\,dy$$

Using symmetry gives:

$$\text{Area}(S) = 4\int_0^{1/(\sqrt{2})}\int_y^{\sqrt{1-y^2}} \frac{z\sqrt{2}}{\sqrt{z^2 - y^2}}\,dz\,dy = 4\sqrt{2}\int_0^{1/(\sqrt{2})}\left(\int_y^{\sqrt{1-y^2}} \frac{z\,dz}{\sqrt{z^2 - y^2}}\right)dy \qquad (1)$$

We compute the inner integral using the substitution $u = \sqrt{z^2 - y^2}$, $du = \frac{z}{u}\,dz$. We get:

$$\int_y^{\sqrt{1-y^2}} \frac{z\,dz}{\sqrt{z^2 - y^2}} = \int_0^{\sqrt{1-y^2}} \frac{u\,du}{u} = \int_0^{\sqrt{1-2y^2}} du = \sqrt{1 - 2y^2}$$

We substitute in (1) and compute the resulting integral using the substitution $t = \sqrt{2}y$. We get:

$$\text{Area}(S) = 4\sqrt{2}\int_0^{1/(\sqrt{2})} \sqrt{1 - 2y^2}\,dy = 4\sqrt{2}\int_0^1 \sqrt{1 - t^2}\,\frac{dt}{\sqrt{2}} = 4\int_0^1 \sqrt{1 - t^2}\,dt = 4 \cdot \frac{\pi}{4} = \pi$$

38. Calculate the integral of ze^{2x+y} over the surface of the box in Figure 20.

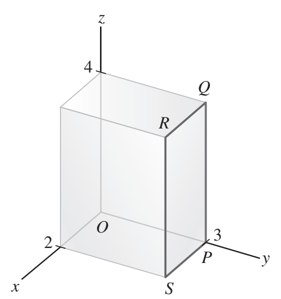


FIGURE 20

SOLUTION The cube may be parametrized by six functions for the six faces of the cube.

$$\phi_1(x, y) = (x, y, 0)\ \phi_2(x, y) = (x, y, 4)\ (0 \le x \le 3)(0 \le y \le 2)$$
$$\phi_3(x, z) = (x, 0, z)\ \phi_4(x, z) = (x, 2, z)\ (0 \le x \le 3)(0 \le z \le 4)$$
$$\phi_5(y, z) = (0, y, z)\ \phi_6(x, y) = (3, y, z)\ (0 \le y \le 2)(0 \le z \le 4)$$

We calculate the outward normal vector for the face parametrized by ϕ_1.

$$\frac{\partial \phi_1}{\partial x} = \langle 1, 0, 0\rangle, \frac{\partial \phi_1}{\partial y} = \langle 0, 1, 0\rangle \Rightarrow \mathbf{n}_1 = -\langle 1, 0, 0\rangle \times \langle 0, 1, 0\rangle = \langle 0, 0, -1\rangle$$

We have that $\|\mathbf{n}_1\| = 1$. Clearly this will be true for all the other normal vectors, $\|n_i\|$. The integrals over the six faces proceed as follows

$$\iint_{S_1} ze^{2x+y}\,dS_1 = \int_0^3\int_0^2 0 \cdot e^{2x+y}\,dx\,dy = 0$$
$$\iint_{S_2} ze^{2x+y}\,dS_2 = \int_0^2\int_0^3 4 \cdot e^{2x+y}\,dx\,dy = 4\frac{e^{2x}}{2}\bigg|_0^3 e^y\bigg|_0^2 = 2(e^6 - 1)(e^2 - 1)$$
$$\iint_{S_3} ze^{2x+y}\,dS_3 = \int_0^4\int_0^3 z \cdot e^{2x}\,dx\,dz = \frac{e^{2x}}{2}\bigg|_0^3 \frac{z^2}{2}\bigg|_0^4 = 4(e^6 - 1)$$
$$\iint_{S_4} ze^{2x+y}\,dS_4 = \int_0^4\int_0^3 z \cdot e^{2x+2}\,dx\,dz = \frac{e^{2x+2}}{2}\bigg|_0^3 \frac{z^2}{2}\bigg|_0^4 = 4(e^8 - e^2)$$
$$\iint_{S_5} ze^{2x+y}\,dS_5 = \int_0^4\int_0^2 z \cdot e^y\,dy\,dz = e^y\bigg|_0^2 \frac{z^2}{2}\bigg|_0^4 = 8(e^2 - 1)$$
$$\iint_{S_6} ze^{2x+y}\,dS_6 = \int_0^4\int_0^2 z \cdot e^{6+y}\,dy\,dz = e^{y+6}\bigg|_0^2 \frac{z^2}{2}\bigg|_0^4 = 8(e^8 - e^6)$$

The integral over the surface is just the sum of the integrals over the faces.

$$\iint_S ze^{2x+y}\,dS = 0 + 2(e^6 - 1)(e^2 - 1) + 4(e^6 - 1) + 4(e^8 - e^2) + 8(e^2 - 1) + 8(e^8 - e^6)$$
$$= 14e^8 - 6e^6 + 2e^2 - 10$$

39. Calculate $\iint_G x^2 z\, dS$, where G is the cylinder (including the top and bottom) $x^2 + y^2 = 4$, $0 \le z \le 3$.

SOLUTION We calculate the surface integral for each of the three surfaces. We begin with the bottom.

$$S_1 : \phi(x, y) = (x, y, 0)$$

$$\iint_{S_1} x^2 z\, dS_1 = \iint_{\mathcal{D}} x^2(0)\|\mathbf{n}_1\|\, dx\, dy = 0$$

Then the top

$$S_2 : \phi(x, y) = (x, y, 3)$$

$$\mathbf{T}_x = \langle 1, 0, 0\rangle, \mathbf{T}_y\ \langle 0, 1, 0\rangle \Rightarrow \mathbf{n}_2 = \langle 0, 0, 1\rangle$$

$$\iint_{S_2} x^2 z\, dS_2 = \iint_{\mathcal{D}} x^2(3)\|\mathbf{n}_2\|\, dx\, dy = 3\iint_{\mathcal{D}} x^2\, dx\, dy$$

The domain, $\mathcal{D}$, is the disk of radius 2. Changing to polar coordinates,

$$= 3\int_0^{2\pi}\int_0^2 (r\cos\theta)^2\, r\, dr\, d\theta = 3\int_0^{2\pi}\cos^2\theta\, d\theta \cdot \int_0^2 r^3\, dr$$

$$= 3\left(\frac{1}{2} + \frac{\sin 2\theta}{2}\right)\Big|_0^{2\pi} \cdot \frac{r^4}{4}\Big|_0^2 = 12\pi$$

Finally the side,

$$S_3 : \phi(r, \theta) = (2\cos\theta, 2\sin\theta, z)$$

$$\mathbf{T}_\theta = \langle -2\sin\theta, 2\cos\theta, 0\rangle, \mathbf{T}_z\ \langle 0, 0, 1\rangle$$

$$\Rightarrow \quad \mathbf{n}_3 = \langle 2\cos\theta, 2\sin\theta, 0\rangle \Rightarrow \quad \|\mathbf{n}_3\| = 2$$

$$\iint_{S_3} x^2 z\, dS_2 = \int_0^{2\pi}\int_0^3 (2\cos\theta)^2\, z\, 2\, dz\, d\theta$$

$$= 8\int_0^{2\pi}\cos^2\theta\, d\theta \cdot \int_0^3 z\, dz = 8\left(\frac{1}{2} + \frac{\sin 2\theta}{2}\right)\Big|_0^{2\pi} \cdot \frac{z^2}{2}\Big|_0^3 = 36\pi$$

The total surface integral is thus

$$\iint_G x^2 z\, dS = 0 + 12\pi + 36\pi = 48\pi$$

40. Let S be the portion of the sphere $x^2 + y^2 + z^2 = 9$, where $1 \le x^2 + y^2 \le 4$ and $z \ge 0$ (Figure 21). Find a parametrization of S in polar coordinates and use it to compute:

(a) The area of S **(b)** $\iint_S z^{-1}\, dS$

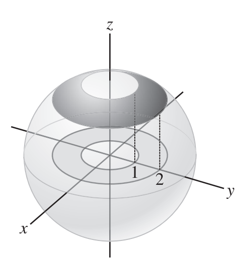

FIGURE 21

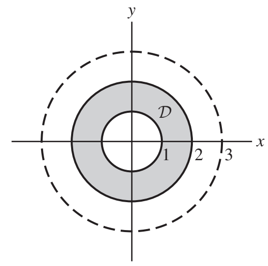
SOLUTION

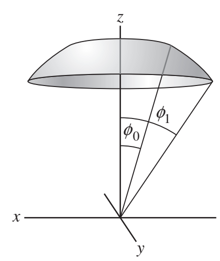


We parametrize S by spherical coordinates as follows:

$$\Phi(\theta,\phi) = (3\cos\theta\sin\phi, 3\sin\theta\sin\phi, 3\cos\phi)$$
$$\mathcal{D}:\ 0 \le \theta \le 2\pi,\ \phi_0 \le \phi \le \phi_1$$

The angles ϕ_0 and ϕ_1 are determined by,

$$\sin\phi_0 = \frac{1}{3} \quad\Rightarrow\quad \phi_0 = \sin^{-1}\frac{1}{3}$$
$$\sin\phi_1 = \frac{2}{3} \quad\Rightarrow\quad \phi_1 = \sin^{-1}\frac{2}{3}$$

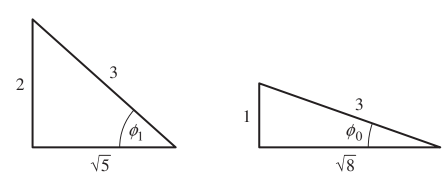


The length of the normal is:

$$\|\mathbf{n}\| = R^2\sin\phi = 9\sin\phi$$

(a) Using the integral for the surface area we have,

$$\text{Area}(S) = \iint_{\mathcal{D}} \|\mathbf{n}\|\,d\phi\,d\theta = \int_0^{2\pi}\int_{\sin^{-1}(1/3)}^{\sin^{-1}(2/3)} 9\sin\phi\,d\phi\,d\theta = \left(\int_0^{2\pi} 9\,d\phi\right)\left(\int_{\sin^{-1}(1/3)}^{\sin^{-1}(2/3)}\sin\phi\,d\phi\right)$$
$$= 18\pi\left(-\cos\phi\Big|_{\phi_0=\sin^{-1}(1/3)}^{\phi_1=\sin^{-1}(2/3)}\right) = 18\pi\left(-\frac{\sqrt{5}}{3}+\frac{\sqrt{8}}{3}\right) = 6\pi\left(\sqrt{8}-\sqrt{5}\right) \approx 11.166$$



(b) We express the function $f(x,y,z) = z^{-1}$ in the terms of the parameters:

$$f(\Phi(\theta,\phi)) = (3\cos\phi)^{-1} = \frac{\sec\phi}{3}$$

Using the surface integral as a double integral we obtain:

$$\iint_S z^{-1}\,dS = \iint_{\mathcal{D}} f(\Phi(\theta,\phi))\,\|\mathbf{n}\|\,d\phi\,d\theta = \int_0^{2\pi}\int_{\phi_0}^{\phi_1}\frac{\sec\phi}{3}\cdot 9\sin\phi\,d\phi\,d\theta = \int_0^{2\pi}\int_{\phi_0}^{\phi_1} 3\tan\phi\,d\phi\,d\theta$$
$$= \left(\int_0^{2\pi} 3\,d\theta\right)\left(\int_{\phi_0}^{\phi_1}\tan\phi\,d\phi\right) = 6\pi\left(\ln(\sec\phi)\Big|_{\phi_0=\sin^{-1}(1/3)}^{\phi_1=\sin^{-1}(2/3)}\right)$$
$$= 6\pi\left(\ln\frac{3}{\sqrt{5}} - \ln\frac{3}{\sqrt{8}}\right) = 6\pi\ln\sqrt{\frac{8}{5}} = 3\pi\ln 1.6 \approx 4.43$$

41. Prove a famous result of Archimedes: The surface area of the portion of the sphere of radius R between two horizontal planes $z = a$ and $z = b$ is equal to the surface area of the corresponding portion of the circumscribed cylinder (Figure 22).

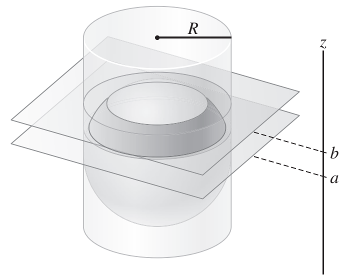


FIGURE 22

SOLUTION We compute the area of the portion of the sphere between the planes a and b. The portion S_1 of the sphere has the parametrization,

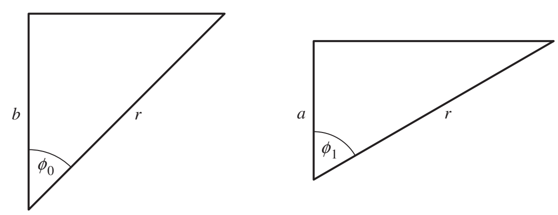
$$\Phi(\theta, \phi) = (r\cos\theta\sin\phi, r\sin\theta\sin\phi, r\cos\phi)$$

where,

$$\mathcal{D}_1 : 0 \le \theta \le 2\pi,\ \phi_0 \le \phi \le \phi_1$$

If we assume $0 < a < b$, then the angles ϕ_0 and ϕ_1 are determined by,

$$\cos\phi_0 = \frac{b}{r} \quad \Rightarrow \quad \phi_0 = \cos^{-1}\frac{b}{r}$$
$$\cos\phi_1 = \frac{a}{r} \quad \Rightarrow \quad \phi_1 = \cos^{-1}\frac{a}{r}$$



The length of the normal vector is $\|\mathbf{n}\| = r^2\sin\phi$. We obtain the following integral:

$$\text{Area }(S_1) = \iint_{\mathcal{D}_1} \|\mathbf{n}\| d\phi\, d\theta = \int_0^{2\pi}\int_{\phi_0}^{\phi_1} r^2\sin\phi\, d\phi\, d\theta = \left(\int_0^{2\pi} r^2 d\phi\right)\left(\int_{\phi_1}^{\phi_2}\sin\phi\, d\phi\right)$$
$$= 2\pi r^2\left(-\cos\phi\Big|_{\phi=\cos^{-1}\frac{b}{r}}^{\cos^{-1}\frac{a}{r}}\right) = 2\pi r^2\left(-\frac{a}{r}+\frac{b}{r}\right) = 2\pi r(b-a)$$

The area of the part S_2 of the cylinder of radius r between the planes $z = a$ and $z = b$ is:

$$\text{Area }(S_2) = 2\pi r \cdot (b-a)$$

We see that the two areas are equal:

$$\text{Area }(S_1) = \text{Area }(S_2)$$

Further Insights and Challenges

42. Surfaces of Revolution Let $\mathcal{S}$ be the surface formed by rotating the region under the graph $z = g(y)$ in the yz-plane for $c \le y \le d$ about the z-axis, where $c \ge 0$ (Figure 23).

(a) Show that the circle generated by rotating a point $(0, a, b)$ about the z-axis is parametrized by

$$(a\cos\theta, a\sin\theta, b), \quad 0 \le \theta \le 2\pi$$

(b) Show that $\mathcal{S}$ is parametrized by

$$G(y, \theta) = (y\cos\theta, y\sin\theta, g(y))$$ 13

for $c \le y \le d$, $0 \le \theta \le 2\pi$.

(c) Use Eq. (13) to prove the formula

$$\text{Area}(\mathcal{S}) = 2\pi \int_c^d y\sqrt{1 + g'(y)^2}\,dy \qquad \boxed{14}$$

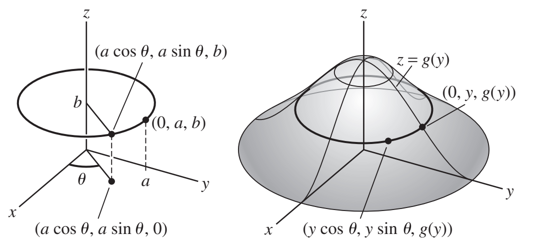


FIGURE 23

SOLUTION

(a) The circle generated by rotating a point $(0, a, b)$ about the z-axis is a circle of radius a centered at the point $(0, 0, b)$ on the z-axis. Therefore it is parametrized by,

$$(a\cos\theta, a\sin\theta, b), \quad 0 \le \theta \le 2\pi$$

(b) An arbitrary point $(x, y, g(y))$ on the surface S lies on the circle generated by rotating the point $(0, y, g(y))$ about the z-axis. Using part (a), a parametrization of this circle is:

$$(y\cos\theta, y\sin\theta, g(y)), \quad 0 \le \theta \le 2\pi$$

Therefore, the following parametrization parametrizes the surface S:

$$\Phi(y, \theta) = (y\cos\theta, y\sin\theta, g(y)), \quad 0 \le \theta \le 2\pi, \quad c \le y \le d.$$

(c) To compute the area of S we first find the tangent and normal vectors. We have:

$$\mathbf{T}_y = \frac{\partial\Phi}{\partial y} = \frac{\partial}{\partial y}(y\cos\theta, y\sin\theta, g(y)) = \langle \cos\theta, \sin\theta, g'(y)\rangle$$
$$\mathbf{T}_\theta = \frac{\partial\Phi}{\partial\theta} = \frac{\partial}{\partial\theta}(y\cos\theta, y\sin\theta, g(y)) = \langle -y\sin\theta, y\cos\theta, 0\rangle$$

The normal vector is their cross product:

$$\mathbf{n} = \mathbf{T}_y \times \mathbf{T}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos\theta & \sin\theta & g'(y) \\ -y\sin\theta & y\cos\theta & 0 \end{vmatrix}$$
$$= \left(-y\cos\theta g'(y)\right)\mathbf{i} - \left(y\sin\theta g'(y)\right)\mathbf{j} + \left(y\ \cos^2\theta + y\ \sin^2\theta\right)\mathbf{k}$$
$$= y\left\langle -\cos\theta g'(y), -\sin\theta g'(y), 1\right\rangle$$

We compute the length of $\mathbf{n}$:

$$\|\mathbf{n}\| = |y|\sqrt{\cos^2\theta g'(y)^2 + \sin^2\theta g'(y)^2 + 1} = |y|\sqrt{g'(y)^2\left(\cos^2\theta + \sin^2\theta\right) + 1} = |y|\sqrt{1 + g'(y)^2}$$

We obtain the following integral for the surface area:

$$\text{Area}(S) = \iint_{\mathcal{D}} 1\,dS = \iint_{\mathcal{D}} \|\mathbf{n}\|\,dy\,d\theta = \int_0^{2\pi}\int_c^d |y|\sqrt{1 + g'(y)^2}\,dy\,d\theta$$
$$= \left(\int_0^{2\pi} 1\,d\theta\right)\left(\int_c^d |y|\sqrt{1 + g'(y)^2}\,dy\right) = 2\pi\int_c^d |y|\sqrt{1 + g'(y)^2}\,dy$$

43. Use Eq. (14) to compute the surface area of $z = 4 - y^2$ for $0 \le y \le 2$ rotated about the z-axis.

SOLUTION Since $g(y) = 4 - y^2$, we have $g'(y) = -2y$. By Eq. (14) we obtain the following integral,

$$\text{Area}(S) = 2\pi\int_0^2 |y|\sqrt{1 + (-2y)^2}\,dy = 2\pi\int_0^2 y\cdot\sqrt{1 + 4y^2}\,dy$$

We compute the integral using the substitution $u = 1 + 4y^2$, $du = 8y\,dy$. We get:

$$\text{Area}(S) = 2\pi \int_1^{17} u^{1/2} \cdot \frac{du}{8} = 2\pi \frac{2}{3} \cdot \frac{u^{3/2}}{8}\bigg|_1^{17} = \frac{\pi}{6}\left(17\sqrt{17} - 1\right) \approx 36.18$$

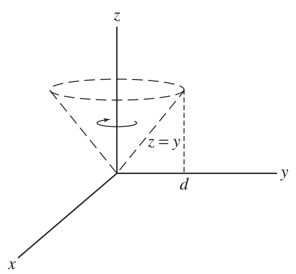
44. Describe the upper half of the cone $x^2 + y^2 = z^2$ for $0 \le z \le d$ as a surface of revolution (Figure 2) and use Eq. (14) to compute its surface area.

SOLUTION We find the graph $z = g(y)$ in the (yz)-plane that when revolved about the z-axis describes the upper part of the cone. Substituting $x = 0$ in the equation of the cone we have,

$$0^2 + y^2 = z^2 \quad \Rightarrow \quad z = \pm y$$

The generating curve is $z = g(y) = y$ for $0 \le y \le d$. Therefore $g'(y) = 1$ and Eq. (14) gives:

$$\text{Area}(S) = 2\pi \int_0^d |y|\sqrt{1 + g'(y)^2}\,dy = 2\pi \int_0^d y\sqrt{1 + 1^2}\,dy = 2\pi\sqrt{2}\int_0^d y\,dy = 2\pi\sqrt{2} \cdot \frac{y^2}{2}\bigg|_0^d = \sqrt{2}\pi d^2$$



45. Area of a Torus Let T be the torus obtained by rotating the circle in the yz-plane of radius a centered at $(0, b, 0)$ about the z-axis (Figure 24). We assume that $b > a > 0$.

(a) Use Eq. (14) to show that

$$\text{Area(T)} = 4\pi \int_{b-a}^{b+a} \frac{ay}{\sqrt{a^2 - (b - y)^2}}\,dy$$

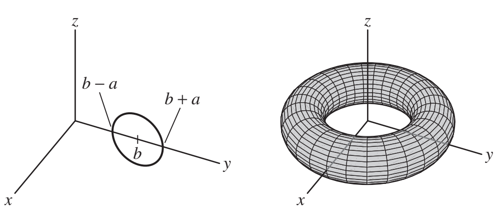


FIGURE 24 The torus obtained by rotating a circle of radius a.

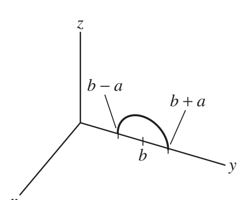
(b) Show that $\text{Area(T)} = 4\pi^2 ab$.

SOLUTION

(a) Using symmetry, the area of the surface obtained by rotating the upper part of the circle is half the area of the torus.



The rotated graph is $z = g(y) = \sqrt{a^2 - (y - b)^2}$, $b - a \le y \le b + a$. So, we have,

$$g'(y) = \frac{-2(y - b)}{2\sqrt{a^2 - (y - b)^2}} = -\frac{y - b}{\sqrt{a^2 - (y - b)^2}}$$

$$\sqrt{1 + g'(y)^2} = \sqrt{1 + \frac{(y - b)^2}{a^2 - (y - b)^2}} = \sqrt{\frac{a^2 - (y - b)^2 + (y - b)^2}{a^2 - (y - b)^2}} = \frac{a}{\sqrt{a^2 - (y - b)^2}}$$

We now use symmetry and Eq. (14) to obtain the following area of the torus (we assume that $b-a>0$, hence $y>0$):

$$\text{Area}\,(\mathbf{T}) = 2\cdot 2\pi \int_{b-a}^{b+a} |y|\sqrt{1+g'(y)^2}\,dy = 4\pi \int_{b-a}^{b+a} \frac{ay}{\sqrt{a^2-(y-b)^2}}\,dy \tag{1}$$

(b) We compute the integral using the substitution $u=\frac{y-b}{a}$, $du=\frac{1}{a}\,dy$. We get:

$$\int_{b-a}^{b+a} \frac{ay}{\sqrt{a^2-(y-b)^2}}\,dy = \int_{-1}^{1} \frac{a^2u+ab}{\sqrt{a^2-a^2u^2}}a\,du = \int_{-1}^{1} \frac{a^2u+ab}{\sqrt{1-u^2}}\,du = \int_{-1}^{1} \frac{a^2u}{\sqrt{1-u^2}}\,du + \int_{-1}^{1} \frac{ab}{\sqrt{1-u^2}}\,du$$

The first integral is zero since the integrand is an odd function. We get:

$$\int_{b-a}^{b+a} \frac{ay}{\sqrt{a^2-(y-b)^2}}\,dy = 2\int_{0}^{1} \frac{ab}{\sqrt{1-u^2}}\,du = 2ab\sin^{-1}u\Big|_0^1 = 2ab\left(\frac{\pi}{2}-0\right) = \pi ab$$

Substituting in (1) gives the following area:

$$\text{Area}\,(\mathbf{T}) = 4\pi\cdot\pi ab = 4\pi^2 ab$$

46. Pappus's Theorem (also called **Guldin's Rule**) states that the area of a surface of revolution $\mathcal{S}$ is equal to the length L of the generating curve times the distance traversed by the center of mass. Use Eq. (14) to prove Pappus's Theorem. If $\mathcal{C}$ is the graph $z=g(y)$ for $c\le y\le d$, then the center of mass is defined as the point $(\overline{y},\overline{z})$ with

$$\overline{y} = \frac{1}{L}\int_{\mathcal{C}} y\,ds, \qquad \overline{z} = \frac{1}{L}\int_{\mathcal{C}} z\,ds$$

SOLUTION We may assume that the generating curve $z=g(y)$ lies in the region $y\ge 0$ (otherwise we translate the axes so that this condition is satisfied). The curve $z=g(y)$, $c\le y\le d$ is parametrized by:

$$\mathcal{C}:\ \mathbf{c}(y) = (y, g(y)), \quad c\le y\le d$$

Hence,

$$\mathbf{c}'(y) = \langle 1, g'(y)\rangle \quad\Rightarrow\quad \|\mathbf{c}'(y)\| = \sqrt{1+g'(y)^2}$$

Using the theorem on computing scalar line integrals, we obtain:

$$\int_{\mathcal{C}} y\,ds = \int_c^d y\|\mathbf{c}'(y)\|\,dy = \int_c^d y\sqrt{1+g'(y)^2}\,dy \tag{1}$$

The center of mass $(\overline{y},\overline{z})$ of the generating curve traverses a circle of radius $\overline{y}$. Therefore the distance traversed by the center of mass is $2\pi\overline{y}$. The length L of the generating curve, times the distance traversed by the center of mass, is:

$$L\cdot 2\pi\overline{y} = L\cdot 2\pi\cdot\frac{1}{L}\int_{\mathcal{C}} y\,ds = 2\pi\int_{\mathcal{C}} y\,ds$$

Combining with (1) we get:

$$L\cdot 2\pi\overline{y} = 2\pi\cdot\int_c^d y\sqrt{1+g'(y)^2}\,dy$$

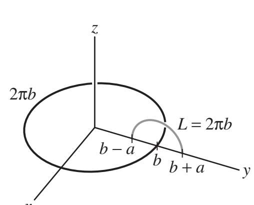
Since $y\ge 0$, the right hand-side is the area of the surface of revolution S, as stated in Eq. (14). Therefore we get:

$$L\cdot 2\pi\overline{y} = \text{Area}(S)$$

This proves Pappus' Theorem.

47. Compute the surface area of the torus in Exercise 45 using Pappus's Theorem.

SOLUTION The generating curve is the circle of radius a in the (y,z)-plane centered at the point $(0,b,0)$. The length of the generating curve is $L=\pi a$.



The center of mass of the circle is at the center $(\overline{y}, \overline{z}) = (b, 0)$, and it traverses a circle of radius b centered at the origin. Therefore, the center of mass makes a distance of $2\pi b$. Using Pappus' Theorem, the area of the torus is:

$$L \cdot 2\pi a = 2\pi a \cdot 2\pi b = 4\pi^2 ab.$$

48. **Potential Due to a Uniform Sphere** Let $\mathcal{S}$ be a hollow sphere of radius R with center at the origin with a uniform mass distribution of total mass m [since $\mathcal{S}$ has surface area $4\pi R^2$, the mass density is $\rho = m/(4\pi R^2)$]. The gravitational potential $V(P)$ due to $\mathcal{S}$ at a point $P = (a, b, c)$ is equal to

$$-G \iint_{\mathcal{S}} \frac{\rho \, dS}{\sqrt{(x-a)^2 + (y-b)^2 + (z-c)^2}}$$

(a) Use symmetry to conclude that the potential depends only on the distance r from P to the center of the sphere. Therefore, it suffices to compute $V(P)$ for a point $P = (0, 0, r)$ on the z-axis (with $r \neq R$).

(b) Use spherical coordinates to show that $V(0, 0, r)$ is equal to

$$\frac{-Gm}{4\pi} \int_0^{\pi} \int_0^{2\pi} \frac{\sin\phi \, d\theta \, d\phi}{\sqrt{R^2 + r^2 - 2Rr\cos\phi}}$$

(c) Use the substitution $u = R^2 + r^2 - 2Rr\cos\phi$ to show that

$$V(0, 0, r) = \frac{-mG}{2Rr}\big(|R + r| - |R - r|\big)$$

(d) Verify Eq. (12) for V.

SOLUTION

(a) The gravitational potential due to S at a point $P = (a, b, c)$ is given by:

$$\varphi(P) = -G \iint_S \frac{\rho \, dS}{\sqrt{(x-a)^2 + (y-b)^2 + (z-c)^2}}$$

Due to the symmetry of the sphere, the "sum" of the distances of a point $P = (a, b, c)$ from the points $Q = (x, y, z)$ on the sphere is equal for all the points P located at the same distance r from the center of the sphere. That is, the integral $\iint_S \frac{dS}{|Q-P|}$ depends only on r. Since ρ is constant, the integral for $\varphi(P)$ also depends only on r. Thus, we might as well assume that P is on the z-axis at the point $(0, 0, r)$, with r being $\sqrt{a^2 + b^2 + c^2}$.

(b) For $a = b = 0$, and $c = r$ we have,

$$\varphi(0, 0, r) = -G \iint_S \frac{\rho \, dS}{\sqrt{x^2 + y^2 + (z-r)^2}} \tag{1}$$

We parametrize the sphere S by the spherical parametrization:

$$\Phi(\theta, \phi) = (R\cos\theta\sin\phi, R\sin\theta\sin\phi, R\cos\phi), \quad 0 \le \theta \le 2\pi, \quad 0 \le \phi \le \pi$$

Then, the length of the normal vector is:

$$\|\mathbf{n}\| = R^2 \sin\phi$$

We express the function in the integrand in terms of the parameters:

$$\begin{aligned} x^2 + y^2 + (z-r)^2 &= R^2\cos^2\theta\sin^2\phi + R^2\sin^2\theta\sin^2\phi + (R\cos\phi - r)^2 \\ &= R^2\sin^2\phi + R^2\cos^2\phi - 2Rr\cos\phi + r^2 = R^2 - 2Rr\cos\phi + r^2 \end{aligned}$$

The surface integral in (1) is equal to the following double integral:

$$\begin{aligned} \varphi(0, 0, r) &= -G \int_0^{\pi} \int_0^{2\pi} \frac{\rho \|\mathbf{n}\| \, d\theta \, d\phi}{\sqrt{R^2 - 2Rr\cos\phi + r^2}} = -G \int_0^{\pi} \int_0^{2\pi} \frac{\frac{m}{4\pi R^2} \cdot R^2 \sin\phi \, d\theta \, d\phi}{\sqrt{R^2 - 2Rr\cos\phi + r^2}} \\ &= -\frac{Gm}{4\pi} \int_0^{\pi} \int_0^{2\pi} \frac{\sin\phi \, d\theta \, d\phi}{\sqrt{R^2 - 2Rr\cos\phi + r^2}} \end{aligned}$$

(c) We compute the double integral for $\varphi(0, 0, r)$. Since the integrand does not depend on θ, we have,

$$\varphi(0, 0, r) = -\frac{Gm}{4\pi} \cdot 2\pi \int_0^{\pi} \frac{\sin\phi \, d\phi}{\sqrt{R^2 + r^2 - 2Rr\cos\phi}} = -\frac{Gm}{2} \int_0^{\pi} \frac{\sin\phi \, d\phi}{\sqrt{R^2 + r^2 - 2Rr\cos\phi}}$$

We compute the integral using the substitution $u = R^2 + r^2 - 2Rr\cos\phi$, $du = 2Rr\sin\phi\, d\phi$. We obtain:

$$\varphi(0,0,r) = -\frac{Gm}{2}\int_{(R-r)^2}^{(R+r)^2} \frac{\frac{du}{2Rr}}{\sqrt{u}} = -\frac{Gm}{4Rr}\int_{(R-r)^2}^{(R+r)^2} u^{-1/2}\,du = -\frac{Gm}{4Rr}\cdot 2u^{1/2}\Big|_{u=(R-r)^2}^{(R+r)^2}$$

$$= -\frac{Gm}{2Rr}\left(\left((R+r)^2\right)^{1/2} - \left((R-r)^2\right)^{1/2}\right) = -\frac{Gm}{2Rr}(|R+r| - |R-r|)$$

(d) For $r > R$:

$$|R+r| - |R-r| = R + r - (r - R) = 2R$$

Thus,

$$\phi(0,0,r) = -\frac{Gm}{2Rr}\cdot 2R = -\frac{Gm}{r}.$$

Similarly, for $r < R$ we obtain,

$$\phi(0,0,r) = -\frac{Gm}{2Rr}\cdot 2r = -\frac{Gm}{R}.$$

49. Calculate the gravitational potential V for a hemisphere of radius R with uniform mass distribution.

SOLUTION In Exercise 48(b) we expressed the potential φ for a sphere of radius R. To find the potential for a hemisphere of radius R, we need only to modify the limits of the angle ϕ to $0 \le \phi \le \frac{\pi}{2}$. This gives the following integral:

$$\varphi(0,0,r) = \varphi(r) = -\frac{Gm}{4\pi}\int_0^{\pi/2}\int_0^{2\pi}\frac{\sin\phi\, d\theta\, d\phi}{\sqrt{R^2 + r^2 - 2Rr\cos\phi}} = -\frac{Gm}{4\pi}\cdot 2\pi\int_0^{\pi/2}\frac{\sin\phi\, d\phi}{\sqrt{R^2 + r^2 - 2Rr\cos\phi}}$$

$$= -\frac{Gm}{2}\int_0^{\pi/2}\frac{\sin\phi\, d\phi}{\sqrt{R^2 + r^2 - 2Rr\cos\phi}}$$

We compute the integral using the substitution $u = R^2 + r^2 - 2Rr\cos\phi$, $du = 2Rr\sin\phi\, d\phi$. We obtain:

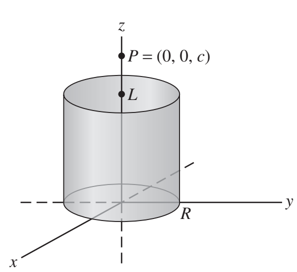
$$\varphi(r) = -\frac{Gm}{2}\int_{(R-r)^2}^{R^2+r^2}\frac{\frac{du}{2Rr}}{\sqrt{u}} = -\frac{Gm}{4Rr}\int_{(R-r)^2}^{R^2+r^2} u^{-1/2}\,du = -\frac{Gm}{4Rr}\cdot 2u^{1/2}\Big|_{u=(R-r)^2}^{R^2+r^2}$$

$$= -\frac{Gm}{2Rr}\left(\left(R^2 + r^2\right)^{1/2} - \left((R-r)^2\right)^{1/2}\right) = -\frac{Gm}{2Rr}\left(\sqrt{R^2 + r^2} - |R - r|\right)$$

50. The surface of a cylinder of radius R and length L has a uniform mass distribution ρ (the top and bottom of the cylinder are excluded). Use Eq. (11) to find the gravitational potential at a point P located along the axis of the cylinder.

SOLUTION By Eq. (11) the gravitational potential at a point $P = (0,0,c)$ along the axis of the cylinder is:

$$\varphi(0,0,c) = -G\iint_S \frac{\rho\, dS}{\sqrt{x^2 + y^2 + (z-c)^2}}$$



We parametrize the cylinder S by the following parametrization:

$$\Phi(\theta, z) = (R\cos\theta, R\sin\theta, z), \quad 0 \le \theta \le 2\pi, \quad 0 \le z \le L$$

We compute the tangent and normal vectors:

$$\mathbf{T}_\theta = \frac{\partial\Phi}{\partial\theta} = \langle -R\sin\theta, R\cos\theta, 0\rangle$$

$$\mathbf{T}_z = \frac{\partial\Phi}{\partial z} = \langle 0, 0, 1\rangle$$

Hence,

$$\mathbf{n} = \mathbf{T}_\theta \times \mathbf{T}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -R\sin\theta & R\cos\theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = (R\cos\theta)\mathbf{i} + (R\sin\theta)\mathbf{j} = R\,\langle\cos\theta, \sin\theta, 0\rangle$$

Hence,

$$\|\mathbf{n}\| = R\sqrt{\cos^2\theta + \sin^2\theta} = R$$

We express the function in the integrand in terms of the parameters:

$$\sqrt{x^2 + y^2 + (z-c)^2} = \sqrt{R^2\,\cos^2\theta + R^2\,\sin^2\theta + (z-c)^2} = \sqrt{R^2 + (z-c)^2}$$

We obtain the following integral:

$$\varphi(0,0,c) = -G\int_0^{2\pi}\int_0^L \frac{\rho\|\mathbf{n}\|\,dz\,d\theta}{\sqrt{R^2+(z-c)^2}} = -G\int_0^{2\pi}\int_0^L \frac{\rho R\,dz\,d\theta}{\sqrt{R^2+(z-c)^2}} = -G\rho R\int_0^{2\pi}\int_0^L \frac{dz\,d\theta}{\sqrt{R^2+(z-c)^2}}$$

$$= -G\rho R\cdot 2\pi\int_0^L \frac{dz}{\sqrt{R^2+(z-c)^2}} = -2G\rho R\pi\,\ln\left|z-c+\sqrt{(z-c)^2+R^2}\right|\Big|_{z=0}^{L}$$

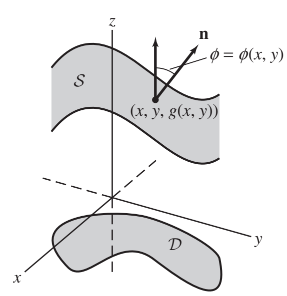
$$= -2G\rho R\pi\left(\ln\left(L-c+\sqrt{(L-c)^2+R^2}\right)\right) - \ln\left(-c+\sqrt{c^2+R^2}\right)$$

$$= -2G\rho R\pi\,\ln\left(\frac{L-c+\sqrt{(L-c)^2+R^2}}{-c+\sqrt{c^2+R^2}}\right)$$

51. Let S be the part of the graph $z = g(x,y)$ lying over a domain $\mathcal{D}$ in the xy-plane. Let $\phi = \phi(x,y)$ be the angle between the normal to S and the vertical. Prove the formula

$$\text{Area}(S) = \iint_{\mathcal{D}} \frac{dA}{|\cos\phi|}$$

SOLUTION



Using the Surface Integral over a Graph we have:

$$\text{Area}(S) = \iint_S 1\,dS = \iint_{\mathcal{D}} \sqrt{1 + g_x^2 + g_y^2}\,dA \tag{1}$$

In parametrizing the surface by $\phi(x,y) = (x, y, g(x,y))$, $(x,y) = \mathcal{D}$, we have:

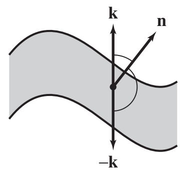
$$\mathbf{T}_x = \frac{\partial\Phi}{\partial x} = \langle 1, 0, g_x\rangle$$

$$\mathbf{T}_y = \frac{\partial\Phi}{\partial y} = \langle 0, 1, g_y\rangle$$

Hence,

$$\mathbf{n} = \mathbf{T}_x \times \mathbf{T}_y = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & g_x \\ 0 & 1 & g_y \end{vmatrix} = -g_x\mathbf{i} - g_y\mathbf{j} + \mathbf{k} = \langle -g_x, -g_y, 1\rangle$$

$$\|\mathbf{n}\| = \sqrt{g_x^2 + g_y^2 + 1}$$



There are two adjacent angles between the normal **n** and the vertical, and the cosines of these angles are opposite numbers. Therefore we take the absolute value of $\cos\phi$ to obtain a positive value for Area(S). Using the Formula for the cosine of the angle between two vectors we get:

$$|\cos\phi| = \frac{|\mathbf{n}\cdot\mathbf{k}|}{\|\mathbf{n}\|\|\mathbf{k}\|} = \frac{|\langle -g_x, -g_y, 1\rangle \cdot \langle 0,0,1\rangle|}{\sqrt{1+g_x^2+g_y^2}\cdot 1} = \frac{1}{\sqrt{1+g_x^2+g_y^2}}$$

Substituting in (1) we get:

$$\text{Area}(S) = \iint_{\mathcal{D}} \frac{dA}{|\cos\phi|}$$

16.5 Surface Integrals of Vector Fields (LT Section 17.5)

Preliminary Questions

1. Let **F** be a vector field and $G(u,v)$ a parametrization of a surface $\mathcal{S}$, and set $\mathbf{n} = \mathbf{T}_u \times \mathbf{T}_v$. Which of the following is the normal component of **F**?

(a) $\mathbf{F}\cdot\mathbf{n}$ **(b)** $\mathbf{F}\cdot\mathbf{e_n}$

SOLUTION The normal component of **F** is $\mathbf{F}\cdot\mathbf{e}_n$ rather than $\mathbf{F}\cdot\mathbf{n}$.

2. The vector surface integral $\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S}$ is equal to the scalar surface integral of the function (choose the correct answer):

(a) $\|\mathbf{F}\|$

(b) $\mathbf{F}\cdot\mathbf{n}$, where **n** is a normal vector

(c) $\mathbf{F}\cdot\mathbf{e_n}$, where $\mathbf{e_n}$ is the unit normal vector

SOLUTION The vector surface integral $\iint_S \mathbf{F}\cdot d\mathbf{S}$ is defined as the scalar surface integral of the normal component of **F** on the oriented surface. That is, $\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_S (\mathbf{F}\cdot\mathbf{e}_n)\, dS$ as stated in (c).

3. $\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S}$ is zero if (choose the correct answer):

(a) **F** is tangent to $\mathcal{S}$ at every point.

(b) **F** is perpendicular to $\mathcal{S}$ at every point.

SOLUTION Since $\iint_S \mathbf{F}\cdot d\mathbf{S}$ is equal to the scalar surface integral of the normal component of **F** on S, this integral is zero when the normal component is zero at every point, that is, when **F** is tangent to S at every point as stated in (a).

4. If $\mathbf{F}(P) = \mathbf{e_n}(P)$ at each point on $\mathcal{S}$, then $\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S}$ is equal to (choose the correct answer):

(a) Zero **(b)** Area$(\mathcal{S})$ **(c)** Neither

SOLUTION If $\mathbf{F}(P) = \mathbf{e}_n(P)$ at each point on S, then,:

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_S (\mathbf{e}_n\cdot\mathbf{e}_n)\, dS = \iint_S \|\mathbf{e}_n\|^2\, dS = \iint_S 1\, dS = \text{Area}(S)$$

Therefore, (b) is the correct answer.

5. Let $\mathcal{S}$ be the disk $x^2+y^2 \le 1$ in the xy-plane oriented with normal in the positive z-direction. Determine $\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S}$ for each of the following vector constant fields:

(a) $\mathbf{F} = \langle 1,0,0\rangle$ **(b)** $\mathbf{F} = \langle 0,0,1\rangle$ **(c)** $\mathbf{F} = \langle 1,1,1\rangle$

SOLUTION The unit normal vector to the oriented disk is $\mathbf{e}_n = \langle 0,0,1\rangle$.

(a) Since $\mathbf{F}\cdot\mathbf{e}_n = \langle 1,0,0\rangle\cdot\langle 0,0,1\rangle = 0$, **F** is perpendicular to the unit normal vector at every point on S, therefore $\iint_S \mathbf{F}\cdot d\mathbf{S} = 0$.

(b) Since $\mathbf{F} = \mathbf{e}_n$ at every point on S, we have:

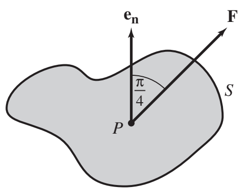
$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_S (\mathbf{e}_n\cdot\mathbf{e}_n)\, dS = \iint_S \|\mathbf{e}_n\|^2\, dS = \iint_S 1\, dS = \text{Area}(S) = \pi$$

(c) For $\mathbf{F} = \langle 1, 1, 1 \rangle$ we have:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_S (\mathbf{F} \cdot \mathbf{e}_n)\, dS = \iint_S \langle 1, 1, 1 \rangle \cdot \langle 0, 0, 1 \rangle\, dS = \iint_S 1\, dS = \text{Area}(S) = \pi$$

6. Estimate $\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S}$, where $\mathcal{S}$ is a tiny oriented surface of area 0.05 and the value of $\mathbf{F}$ at a sample point in $\mathcal{S}$ is a vector of length 2 making an angle $\frac{\pi}{4}$ with the normal to the surface.

SOLUTION



Since S is a tiny surface, we may assume that the dot product $\mathbf{F} \cdot \mathbf{e}_n$ on S is equal to the dot product at the sample point. This gives the following approximation:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_S (\mathbf{F} \cdot \mathbf{e}_n)\, d\mathbf{S} \approx \iint_S (\mathbf{F}(P) \cdot \mathbf{e}_n(P))\, d\mathbf{S} = \mathbf{F}(P) \cdot \mathbf{e}_n(P) \iint_S 1 d\mathbf{S} = \mathbf{F}(P) \cdot \mathbf{e}_n \text{Area}(S)$$

That is,

$$\iint_S \mathbf{F} \cdot d\mathbf{S} \approx \mathbf{F}(P) \cdot \mathbf{e}_n(P)\text{Area}(S) \tag{1}$$

We are given that $\text{Area}(S) = 0.05$. We compute the dot product:

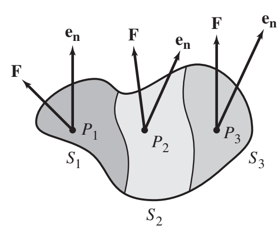
$$\mathbf{F}(P) \cdot \mathbf{e}_n(P) = \|\mathbf{F}(P)\| \|\mathbf{e}_n(P)\| \cos\frac{\pi}{4} = 2 \cdot 1 \cdot \frac{1}{\sqrt{2}} = \sqrt{2}$$

Combining with (1) gives the following estimation:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} \approx 0.05\sqrt{2} \approx 0.0707.$$

7. A small surface $\mathcal{S}$ is divided into three pieces of area 0.2. Estimate $\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S}$ if $\mathbf{F}$ is a unit vector field making angles of $85°$, $90°$, and $95°$ with the normal at sample points in these three pieces.

SOLUTION



We estimate the vector surface integral by the following sum:

$$\begin{aligned}\iint_S \mathbf{F} \cdot d\mathbf{S} &= \mathbf{F}(P_1) \cdot \mathbf{e}_n(P_1)\,\text{Area}(S_1) + \mathbf{F}(P_2) \cdot \mathbf{e}_n(P_2)\,\text{Area}(S_2) + \mathbf{F}(P_3) \cdot \mathbf{e}_n(P_3)\,\text{Area}(S_3) \\ &= 0.2\,(\mathbf{F}(P_1) \cdot \mathbf{e}_n(P_1) + \mathbf{F}(P_2) \cdot \mathbf{e}_n(P_2) + \mathbf{F}(P_3) \cdot \mathbf{e}_n(P_3))\end{aligned}$$

We compute the dot product. Since $\mathbf{F}$ and $\mathbf{e}_n$ are unit vectors, we have:

$$\begin{aligned}\mathbf{F}(P_1) \cdot \mathbf{e}_n(P_1) &= \cos 85° \approx 0.0872 \\ \mathbf{F}(P_2) \cdot \mathbf{e}_n(P_2) &= \cos 90° = 0 \\ \mathbf{F}(P_3) \cdot \mathbf{e}_n(P_3) &= \cos 95° \approx -0.0872\end{aligned}$$

Substituting gives the following estimation:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} \approx 0.2(0.0872 + 0 - 0.0872) = 0.$$

Exercises

1. Let $\mathbf{F} = \langle z, 0, y\rangle$ and let $\mathcal{S}$ be the oriented surface parametrized by $G(u, v) = (u^2 - v, u, v^2)$ for $0 \le u \le 2$, $-1 \le v \le 4$. Calculate:

(a) $\mathbf{n}$ and $\mathbf{F}\cdot\mathbf{n}$ as functions of u and v

(b) The normal component of $\mathbf{F}$ to the surface at $P = (3, 2, 1) = G(2, 1)$

(c) $\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S}$

SOLUTION

(a) The tangent vectors are,

$$\mathbf{T}_u = \frac{\partial \mathrm{G}}{\partial u} = \frac{\partial}{\partial u}\left(u^2 - v, u, v^2\right) = \langle 2u, 1, 0\rangle$$
$$\mathbf{T}_v = \frac{\partial \mathrm{G}}{\partial v} = \frac{\partial}{\partial v}\left(u^2 - v, u, v^2\right) = \langle -1, 0, 2v\rangle$$

The normal vector is their cross product:

$$\mathbf{n} = \mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2u & 1 & 0 \\ -1 & 0 & 2v \end{vmatrix} = v\mathbf{i} - 4uv\mathbf{j} + \mathbf{k} = \langle 2v, -4uv, 1\rangle$$

We write $\mathbf{F} = \langle z, 0, y\rangle$ in terms of the parameters $x = u^2 - v$, $y = u$, $z = v^2$ and then compute $\mathbf{F}\cdot\mathbf{n}$:

$$\mathbf{F}(\Phi(u, v)) = \langle z, 0, y\rangle = \left\langle v^2, 0, u\right\rangle$$
$$\mathbf{F}(\Phi(u, v))\cdot\mathbf{n}(u, v) = \left\langle v^2, 0, u\right\rangle\cdot\langle 2v, -4uv, 1\rangle$$
$$= 2v^3 + u$$

(b) At the point $P = (3, 2, 1) = \Phi(2, 1)$ we have:

$$\mathbf{F}(P) = \langle 1, 0, 2\rangle$$
$$\mathbf{n}(P) = \langle 2, -8, 1\rangle$$
$$\mathbf{e}_n(P) = \frac{\mathbf{n}(P)}{\|\mathbf{n}(P)\|} = \frac{\langle 2, -8, 1\rangle}{\sqrt{4 + 64 + 1}} = \frac{1}{\sqrt{69}}\langle 2, -8, 1\rangle$$

Hence, the normal component of $\mathbf{F}$ to the surface at P is the dot product:

$$\mathbf{F}(P)\cdot\mathbf{e}_n(P) = \langle 1, 0, 2\rangle\cdot\frac{1}{\sqrt{69}}\langle 2, -8, 1\rangle = \frac{4}{\sqrt{69}}$$

(c) Using the definition of the vector surface integral and the dot product in part (a), we have:

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\phi(u, v))\cdot\mathbf{n}(u, v)\, du\, dv = \int_0^2\int_{-1}^4 \left(2v^3 + u\right) dv\, du$$
$$= \int_0^2 \frac{2v^4}{4} + uv\Big|_{v=-1}^{4} du$$
$$= \int_0^2 \left(128 - \frac{1}{2}\right) + (4 - (-1))u\, du$$
$$= \int_0^2 \frac{255}{2} + 5u\, du = \frac{255u}{2} + \frac{5u^2}{2}\Big|_0^2 = 265$$

2. Let $\mathbf{F} = \langle y, -x, x^2 + y^2\rangle$ and let $\mathcal{S}$ be the portion of the paraboloid $z = x^2 + y^2$ where $x^2 + y^2 \le 3$.

(a) Show that if $\mathcal{S}$ is parametrized in polar variables $x = r\cos\theta$, $y = r\sin\theta$, then $\mathbf{F}\cdot\mathbf{n} = r^3$.

(b) Show that $\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^{\sqrt{3}} r^3\, dr\, d\theta$ and evaluate.

SOLUTION

(a) The parametrization of this surface in these coordinates is:

$$\phi(r, \theta) = (x, y, x^2 + y^2) = (r\cos\theta, r\sin\theta, r^2) \quad (0 \le \theta \le 2\pi,\ 0 \le r \le \sqrt{3})$$

Calculating the normal vector,

$$\mathbf{T}_r = \langle \cos\theta, \sin\theta, 2r \rangle$$
$$\mathbf{T}_\theta = \langle -r\sin\theta, r\cos\theta, 0 \rangle$$
$$\Rightarrow \quad \mathbf{n} = \left\langle -2r^2\cos\theta, -2r^2\sin\theta, r \right\rangle$$

Then

$$\begin{aligned}\mathbf{F}\cdot\mathbf{n} &= \left\langle y, -x, x^2+y^2 \right\rangle \cdot \mathbf{n} = \left\langle r\sin\theta, -r\cos\theta, r^2 \right\rangle \cdot \left\langle -2r^2\cos\theta, -2r^2\sin\theta, r \right\rangle \\ &= -2r^3\sin\theta\cos\theta + 2r^3\cos\theta\sin\theta + r^3 = r^3\end{aligned}$$

(b) The integral over this surface is

$$\begin{aligned}\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} &= \int_0^{2\pi}\int_0^{\sqrt{3}} \mathbf{F}\cdot\mathbf{n}\,dr\,d\theta = \int_0^{2\pi}\int_0^{\sqrt{3}} r^3\,dr\,d\theta \\ &= \int_0^{2\pi} d\theta \cdot \int_0^{\sqrt{3}} r^3\,dr = 2\pi \left.\frac{r^4}{4}\right|_0^{\sqrt{3}} = \frac{9\pi}{2}\end{aligned}$$

3. Let $\mathcal{S}$ be the unit square in the xy-plane shown in Figure 14, oriented with the normal pointing in the positive z-direction. Estimate

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S}$$

where $\mathbf{F}$ is a vector field whose values at the labeled points are

$$\mathbf{F}(A) = \langle 2, 6, 4 \rangle, \qquad \mathbf{F}(B) = \langle 1, 1, 7 \rangle$$
$$\mathbf{F}(C) = \langle 3, 3, -3 \rangle, \qquad \mathbf{F}(D) = \langle 0, 1, 8 \rangle$$

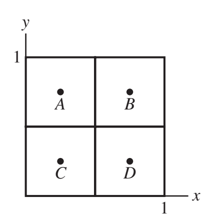


FIGURE 14

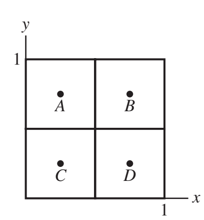
SOLUTION The unit normal vector to S is $\mathbf{e}_n = \langle 0, 0, 1 \rangle$. We estimate the vector surface integral $\iint_S \mathbf{F}\cdot d\mathbf{S}$ using the division and sample points given in Figure 12.



Each subsquare has area $\frac{1}{4}$, therefore we obtain the following estimation:

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{S} &\approx (\mathbf{F}(A)\cdot\mathbf{e}_n + \mathbf{F}(B)\cdot\mathbf{e}_n + \mathbf{F}(C)\cdot\mathbf{e}_n + \mathbf{F}(D)\cdot\mathbf{e}_n)\cdot\frac{1}{4} \\ &= (\langle 2,6,4\rangle\cdot\langle 0,0,1\rangle + \langle 1,1,7\rangle\cdot\langle 0,0,1\rangle + \langle 3,3,-3\rangle\cdot\langle 0,0,1\rangle + \langle 0,1,8\rangle\cdot\langle 0,0,1\rangle)\cdot\frac{1}{4} \\ &= (4+7-3+8)\cdot\frac{1}{4} = 4\end{aligned}$$

4. Suppose that $\mathcal{S}$ is a surface in $\mathbf{R}^3$ with a parametrization G whose domain $\mathcal{D}$ is the square in Figure 14. The values of a function f, a vector field $\mathbf{F}$, and the normal vector $\mathbf{n} = \mathbf{T}_u \times \mathbf{T}_v$ at $G(P)$ are given for the four sample points in $\mathcal{D}$ in the following table. Estimate the surface integrals of f and $\mathbf{F}$ over $\mathcal{S}$.

Point P in $\mathcal{D}$	f	$\mathbf{F}$	$\mathbf{n}$
A	3	$\langle 2, 6, 4\rangle$	$\langle 1, 1, 1\rangle$
B	1	$\langle 1, 1, 7\rangle$	$\langle 1, 1, 0\rangle$
C	2	$\langle 3, 3, -3\rangle$	$\langle 1, 0, -1\rangle$
D	5	$\langle 0, 1, 8\rangle$	$\langle 2, 1, 0\rangle$

SOLUTION The area of each subrectangle is $\frac{1}{4}$. We estimate the surface integral of f over $\mathcal{S}$ by the following sum:

$$\iint_{\mathcal{S}} f(x, y, z)\, dS = (f(A)\|\mathbf{n}(A)\| + f(B)\|\mathbf{n}(B)\| + f(C)\|\mathbf{n}(C)\| + f(D)\|\mathbf{n}(D)\|) \cdot \frac{1}{4} \tag{1}$$

We use the given data to compute the length of the normal vectors:

$$\|\mathbf{n}(A)\| = \|\,\langle 1, 1, 1\rangle\,\| = \sqrt{3}$$
$$\|\mathbf{n}(B)\| = \|\,\langle 1, 1, 0\rangle\,\| = \sqrt{2}$$
$$\|\mathbf{n}(C)\| = \|\,\langle 1, 0, -1\rangle\,\| = \sqrt{2}$$
$$\|\mathbf{n}(D)\| = \|\,\langle 2, 1, 0\rangle\,\| = \sqrt{5}$$

Substituting the values in (1) we obtain the following estimation:

$$\iint_{\mathcal{S}} f(x, y, z)\, dS = \left(3\sqrt{3} + 1 \cdot \sqrt{2} + 2\sqrt{2} + 5\sqrt{5}\right) \cdot \frac{1}{4} = \frac{3\sqrt{3} + 3\sqrt{2} + 5\sqrt{5}}{4} \approx 5.155$$

We now estimate the vector surface integral $\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S}$ by the following sum:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = (\mathbf{F}(A) \cdot \mathbf{n} + \mathbf{F}(B) \cdot \mathbf{n} + \mathbf{F}(C) \cdot \mathbf{n} + \mathbf{F}(D) \cdot \mathbf{n}) \cdot \frac{1}{4}$$
$$= (\langle 2, 6, 4\rangle \cdot \langle 1, 1, 1\rangle + \langle 1, 1, 7\rangle \cdot \langle 1, 1, 0\rangle + \langle 3, 3, -3\rangle \cdot \langle 1, 0, -1\rangle + \langle 0, 1, 8\rangle \cdot \langle 2, 1, 0\rangle) \cdot \frac{1}{4}$$
$$= (12 + 2 + 6 + 1) \cdot \frac{1}{4} = \frac{21}{4}$$

In Exercises 5–17, compute $\iint_{\mathcal{S}} \mathbf{F} \cdot\, d\mathbf{S}$ *for the given oriented surface.*

5. $\mathbf{F} = \langle y, z, x\rangle$, plane $3x - 4y + z = 1$, $0 \le x \le 1$, $0 \le y \le 1$, upward-pointing normal

SOLUTION We rewrite the equation of the plane as $z = 1 - 3x + 4y$, and parametrize the plane by:

$$\Phi(x, y) = (x, y, 1 - 3x + 4y)$$

Here, the parameter domain is the square $\mathcal{D} = \{(x, y) : 0 \le x,\ y \le 1\}$ in the xy-plane.

Step 1. Compute the tangent and normal vectors.

$$\mathbf{T}_x = \frac{\partial \Phi}{\partial x} = \frac{\partial}{\partial x}(x, y, 1 - 3x + 4y) = \langle 1, 0, -3\rangle$$
$$\mathbf{T}_y = \frac{\partial \Phi}{\partial y} = \frac{\partial}{\partial y}(x, y, 1 - 3x + 4y) = \langle 0, 1, 4\rangle$$
$$\mathbf{T}_x \times \mathbf{T}_y = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -3 \\ 0 & 1 & 4 \end{vmatrix} = 3\mathbf{i} - 4\mathbf{j} + \mathbf{k} = \langle 3, -4, 1\rangle$$

Since the plane is oriented with upward pointing normal, the normal vector $\mathbf{n}$ is:

$$\mathbf{n} = \langle 3, -4, 1\rangle$$

Step 2. Evaluate the dot product $\mathbf{F} \cdot \mathbf{n}$. We write $\mathbf{F}$ in terms of the parameters:

$$\mathbf{F}(\Phi(x, y)) = \langle y, z, x\rangle = \langle y, 1 - 3x + 4y, x\rangle$$

The dot product $\mathbf{F} \cdot \mathbf{n}$ is thus

$$\mathbf{F}(\Phi(x, y)) \cdot \mathbf{n} = \langle y, 1 - 3x + 4y, x\rangle \cdot \langle 3, -4, 1\rangle = 3y - 4(1 - 3x + 4y) + x = 13x - 13y - 4$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(x,y))\cdot \mathbf{n}(x,y)\,dx\,dy = \int_0^1\int_0^1 (13x - 13y - 4)\,dx\,dy$$
$$= \int_0^1 \frac{13x^2}{2} - 13yx - 4x\Big|_{x=0}^1 dy = \int_0^1 \left(\frac{13}{2} - 13y - 4\right) dy = \frac{5y}{2} - \frac{13y^2}{2}\Big|_0^1 = -4$$

6. $\mathbf{F} = \langle e^z, z, x\rangle$, $\quad G(r,s) = (rs, r+s, r), 0 \le r \le 1, 0 \le s \le 1,\quad$ oriented by $\mathbf{T}_r \times \mathbf{T}_s$

SOLUTION

Step 1. Compute the tangent and normal vectors. We have:

$$\mathbf{T}_r = \frac{\partial \Phi}{\partial r} = \frac{\partial}{\partial r}(rs, r+s, r) = \langle s, 1, 1\rangle$$
$$\mathbf{T}_s = \frac{\partial \Phi}{\partial s} = \frac{\partial}{\partial s}(rs, r+s, r) = \langle r, 1, 0\rangle$$
$$\mathbf{n} = \mathbf{T}_r \times \mathbf{T}_s = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ s & 1 & 1 \\ r & 1 & 0 \end{vmatrix} = -\mathbf{i} + r\mathbf{j} + (s-r)\mathbf{k} = \langle -1, r, s-r\rangle$$

Step 2. Evaluate the dot product $\mathbf{F}\cdot\mathbf{n}$. We write $\mathbf{F}$ in terms of the parameters $x = rs$, $y = r+s$, $z = r$:

$$\mathbf{F}(\phi(r,s)) = \langle e^z, z, x\rangle = \langle e^r, r, rs\rangle$$

We compute the dot product $\mathbf{F}\cdot\mathbf{n}$:

$$\mathbf{F}(\phi(r,s))\cdot \mathbf{n}(r,s) = \langle e^r, r, rs\rangle \cdot \langle -1, r, s-r\rangle = -e^r + r^2 + rs(s-r) = -e^r + r^2(1-s) + rs^2$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(r,s))\cdot\mathbf{n}(r,s)\,dr\,ds = \int_0^1\int_0^1 \left(-e^r + r^2(1-s) + rs^2\right) dr\,ds$$
$$= \int_0^1 -e^r + \frac{r^3(1-s)}{3} + \frac{r^2s^2}{2}\Big|_{r=0}^1 ds = \int_0^1 \left(-e + \frac{1-s}{3} + \frac{s^2}{2} + 1\right) ds$$
$$= (1-e)s + \frac{s - \frac{s^2}{2}}{3} + \frac{s^3}{6}\Big|_0^1 = 1 - e + \frac{1}{6} + \frac{1}{6} = \frac{4}{3} - e \approx -1.385$$

7. $\mathbf{F} = \langle 0, 3, x\rangle$, $\quad$ part of sphere $x^2 + y^2 + z^2 = 9$, where $x \ge 0$, $y \ge 0$, $z \ge 0$ $\quad$ outward-pointing normal

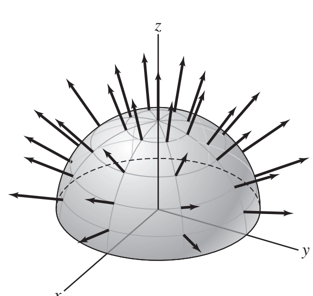
SOLUTION We parametrize the octant S by:

$$\Phi(\theta,\phi) = (3\cos\theta\sin\phi, 3\sin\theta\sin\phi, 3\cos\phi),\ 0 \le \theta \le \frac{\pi}{2},\ 0 \le \phi \le \frac{\pi}{2}$$

Step 1. Compute the normal vector. As seen in the text, the normal vector that points to the outside of the sphere is:

$$\mathbf{n} = \mathbf{T}_\phi \times \mathbf{T}_\theta = 9\sin\phi\,\langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle$$

For $0 \le \theta \le \frac{\pi}{2}$, $0 \le \phi \le \frac{\pi}{2}$, all trigonometric functions are positive. Therefore all components of $\mathbf{n}$ are positive, so $\mathbf{n}$ points to the outside of the sphere.



Step 2. Evaluate the dot product $\mathbf{F}\cdot\mathbf{n}$. We express the vector field in terms of the parameters:

$$\mathbf{F}(\Phi(\theta,\phi)) = \langle 0, 3, x\rangle = \langle 0, 3, 3\cos\theta\sin\phi\rangle$$

Hence:

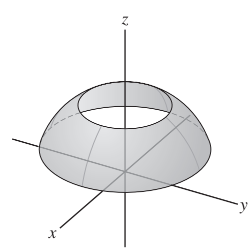
$$\begin{aligned}\mathbf{F}(\Phi(\theta,\phi))\cdot\mathbf{n}(\theta,\phi) &= \langle 0, 3, 3\cos\theta\sin\phi\rangle \cdot 9\sin\phi\,\langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle\\ &= 27\sin\theta\sin^2\phi + 27\cos\theta\sin^2\phi\cos\phi\end{aligned}$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{S} &= \iint_{\mathcal{D}} \mathbf{F}(\Phi(\theta,\phi))\cdot\mathbf{n}(\theta,\phi)\,d\theta\,d\phi\\ &= \int_0^{\frac{\pi}{2}}\int_0^{\frac{\pi}{2}} \left(27\sin\theta\sin^2\phi + 27\cos\theta\sin^2\phi\cos\phi\right)d\theta\,d\phi\\ &= 27\left(\int_0^{\frac{\pi}{2}}\sin\theta\,d\theta\cdot\int_0^{\frac{\pi}{2}}\sin^2\phi\,d\phi + \int_0^{\frac{\pi}{2}}\cos\theta\,d\theta\cdot\int_0^{\frac{\pi}{2}}\sin^2\phi\cos\phi\,d\phi\right)\\ &= 27\left(-\cos\theta\Big|_0^{\frac{\pi}{2}}\cdot\left(\frac{\phi}{2}-\frac{\sin 2\phi}{4}\right)\Big|_0^{\frac{\pi}{2}} + \sin\theta\Big|_0^{\frac{\pi}{2}}\cdot\frac{\sin^3\phi}{3}\Big|_0^{\frac{\pi}{2}}\right)\\ &= 27\left(\frac{\pi}{4}\cdot 1 + \frac{1}{3}\cdot 1\right) = \frac{27}{12}(3\pi+4)\end{aligned}$$

8. $\mathbf{F} = \langle x, y, z\rangle$, part of sphere $x^2+y^2+z^2=1$, where $\frac{1}{2}\le z\le\frac{\sqrt{3}}{2}$, inward-pointing normal

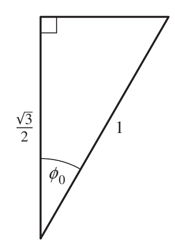
SOLUTION



We parametrize S by the following parametrization:

$$\Phi(\theta,\phi) = (\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi)$$

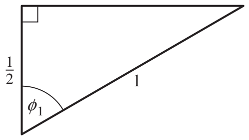
$$\mathcal{D}\,:\,0\le\theta\le 2\pi,\ \phi_0\le\phi\le\phi_1$$



The angles ϕ_0 and ϕ_1 are determined by:

$$\cos\phi_0 = \frac{\sqrt{3}}{2} \quad\Rightarrow\quad \phi_0 = \frac{\pi}{6}$$

$$\cos\phi_1 = \frac{1}{2} \quad\Rightarrow\quad \phi_1 = \frac{\pi}{3}$$



Step 1. Determine the normal vector. The normal vector pointing to the inside of the sphere is:

$$\mathbf{n} = \mathbf{T}_\theta\times\mathbf{T}_\phi = -\sin\phi\,\langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle$$

(Notice that for $\frac{\pi}{6}\le\phi\le\frac{\pi}{3}$, $-\sin\phi\cos\phi < 0$, therefore the z-component is negative and the normal points to the inside of the sphere).

Step 2. Evaluate the dot product $\mathbf{F}\cdot\mathbf{n}$. We express $\mathbf{F}$ in terms of the parameters:

$$\mathbf{F}(\Phi(\theta,\phi)) = \langle x, y, z\rangle = (\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi)$$

Hence:

$$\begin{aligned}\mathbf{F}(\Phi(\theta,\phi))\cdot\mathbf{n}(\theta,\phi) &= \langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle\cdot(-\sin\phi)\langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle\\ &= -\sin\phi\left(\cos^2\phi\sin^2\phi + \sin^2\theta\sin^2\phi + \cos^2\phi\right)\\ &= -\sin\phi\cdot 1 = -\sin\phi\end{aligned}$$

Step 3. Evaluate the surface integral. We have:

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{S} &= \iint_{\mathcal{D}} \mathbf{F}(\Phi(\theta,\phi))\cdot\mathbf{n}(\theta,\phi)\,d\theta\,d\phi = \int_0^{2\pi}\int_{\pi/6}^{\pi/3} -\sin\phi\,d\theta\,d\phi = 2\pi\int_{\pi/6}^{\pi/3} -\sin\phi\,d\theta\\ &= 2\pi(\cos\phi)\Big|_{\phi=\pi/6}^{\pi/3} = 2\pi\left(\cos\frac{\pi}{3} - \cos\frac{\pi}{6}\right) = 2\pi\left(\frac{1}{2} - \frac{\sqrt{3}}{2}\right) = \pi\left(1-\sqrt{3}\right) \approx -2.3\end{aligned}$$

9. $\mathbf{F} = \langle z, z, x\rangle$, $\quad z = 9 - x^2 - y^2$, $x \ge 0$, $y \ge 0$, $z \ge 0$ upward-pointing normal

SOLUTION

Step 1. Find a parametrization. We use x and y as parameters and parametrize the surface by:

$$\Phi(x,y) = \left(x, y, 9 - x^2 - y^2\right)$$

The parameter domain $\mathcal{D}$ is determined by the conditions $z = 9 - x^2 - y^2 \ge 0 \Rightarrow x^2 + y^2 \le 9$ and $x, y \ge 0$. That is:

$$\mathcal{D} = \left\{(x,y) : x^2 + y^2 \le 9,\ x, y \ge 0\right\}$$

$\mathcal{D}$ is the portion of the disk of radius 3 in the first quadrant.

Step 2. Compute the tangent and normal vectors. We have:

$$\begin{aligned}\mathbf{T}_x &= \frac{\partial\Phi}{\partial x} = \frac{\partial}{\partial x}\left(x, y, 9 - x^2 - y^2\right) = \langle 1, 0, -2x\rangle\\ \mathbf{T}_y &= \frac{\partial\Phi}{\partial y} = \frac{\partial}{\partial y}\left(x, y, 9 - x^2 - y^2\right) = \langle 0, 1, -2y\rangle\end{aligned}$$

We compute the cross product of the tangent vectors:

$$\mathbf{T}_x\times\mathbf{T}_y = \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 1 & 0 & -2x\\ 0 & 1 & -2y\end{vmatrix} = (2x)\mathbf{i} + (2y)\mathbf{j} + \mathbf{k} = \langle 2x, 2y, 1\rangle$$

Since the z-component is positive, the vector points upward, and we have:

$$\mathbf{n} = \langle 2x, 2y, 1\rangle$$

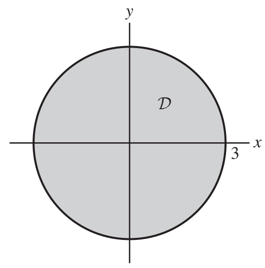
Step 3. Evaluate the dot product $\mathbf{F}\cdot\mathbf{n}$. We first express the vector field in terms of the parameters x and y, by setting $z = 9 - x^2 - y^2$. We get:

$$\mathbf{F}(\Phi(x,y)) = \langle z, z, x\rangle = \left\langle 9 - x^2 - y^2, 9 - x^2 - y^2, x\right\rangle$$

We now compute the dot product:

$$\begin{aligned}\mathbf{F}(\Phi(x,y))\cdot\mathbf{n}(x,y) &= \left\langle 9 - x^2 - y^2, 9 - x^2 - y^2, x\right\rangle\cdot\langle 2x, 2y, 1\rangle\\ &= 2x(9 - x^2 - y^2) + 2y(9 - x^2 - y^2) + x\\ &= 19x + 18y - 2xy(x^2 + y^2)\end{aligned}$$

Step 4. Evaluate the surface integral.



The surface integral is equal to the following double integral:

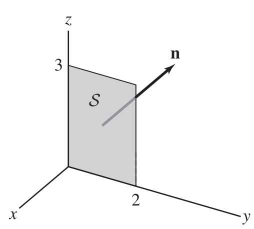
$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(x, y)) \cdot \mathbf{n}(x, y)\, dx\, dy = \iint_{\mathcal{D}} \left(19x + 18y - 2xy(x^2 + y^2)\right) dx\, dy$$

We convert the integral to polar coordinates and use the identity $\sin 2\theta = 2\cos\theta \sin\theta$ to obtain:

$$\begin{aligned}
\iint_S \mathbf{F} \cdot d\mathbf{S} &= \int_0^3 \int_0^{\pi/2} \left(19r\cos\theta + 18r\sin\theta - 2r^2\cos\theta\sin\theta\right) r\, d\theta\, dr \\
&= \left(\int_0^3 r^2\, dr\right) \cdot \left(\int_0^{\pi/2} 19\cos\theta + 18\sin\theta\, d\theta\right) + \left(\int_0^3 -r^3\, dr\right) \cdot \left(\int_0^{\pi/2} \sin 2\theta\, d\theta\right) \\
&= \left(\frac{r^3}{3}\bigg|_0^3\right) \cdot \left(19\sin\theta - 18\cos\theta\bigg|_0^{\pi/2}\right) + \left(-\frac{r^4}{4}\bigg|_0^3\right) \cdot \left(-\frac{1}{2}\cos 2\theta\bigg|_0^{\pi/2}\right) \\
&= 9 \cdot 37 - \frac{81}{4} \cdot (1) = 312.75
\end{aligned}$$

10. $\mathbf{F} = \langle \sin y, \sin z, yz \rangle$, rectangle $0 \le y \le 2$, $0 \le z \le 3$ in the (y, z)-plane, normal pointing in negative x-direction

SOLUTION



The surface is the plane $x = 0$ over the rectangle $0 \le y \le 2$, $0 \le z \le 3$ in the (y, z)-plane, hence it is parametrized by:

$$\Phi(y, z) = (0, y, z), \quad 0 \le y \le 2, \quad 0 \le z \le 3$$

Step 1. Compute the tangent and normal vectors. We have:

$$\mathbf{T}_y = \frac{\partial \Phi}{\partial y} = \frac{\partial}{\partial y}(0, y, z) = \langle 0, 1, 0 \rangle = \mathbf{j}$$

$$\mathbf{T}_z = \frac{\partial \Phi}{\partial z} = \frac{\partial}{\partial z}(0, y, z) = \langle 0, 0, 1 \rangle = \mathbf{k}$$

$$\mathbf{T}_y \times \mathbf{T}_z = \mathbf{j} \times \mathbf{k} = \mathbf{i} = \langle 1, 0, 0 \rangle$$

Since the normal points to the negative x-direction, the x-component must be negative. Hence:

$$\mathbf{n} = \langle -1, 0, 0 \rangle$$

Step 2. Evaluate the dot product $\mathbf{F} \cdot \mathbf{n}$. We compute the dot product:

$$\mathbf{F}(\Phi(y, z)) \cdot \mathbf{n} = \langle \sin y, \sin z, yz \rangle \cdot \langle -1, 0, 0 \rangle = -\sin y$$

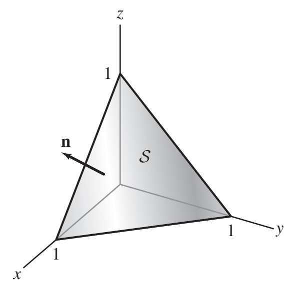
Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(y, z)) \cdot \mathbf{n}\, dy\, dz = \int_0^3 \int_0^2 (-\sin y)\, dy\, dz = \int_0^2 \int_0^3 -\sin y\, dz\, dy$$

$$= 3\int_0^2 (-\sin y)\, dy = 3\cos y\bigg|_0^2 = 3(\cos 2 - 1) \approx -4.25$$

11. $\mathbf{F} = y^2\mathbf{i} + 2\mathbf{j} - x\mathbf{k}$, portion of the plane $x + y + z = 1$ in the octant $x, y, z \geq 0$, upward-pointing normal

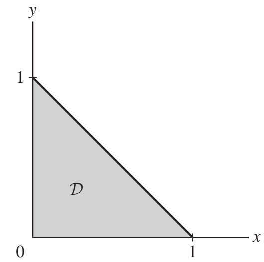
SOLUTION



We parametrize the surface by:

$$\Phi(x, y) = (x, y, 1 - x - y),$$

using the parameter domain $\mathcal{D}$ shown in the figure.



Step 1. Compute the tangent and normal vectors. We have:

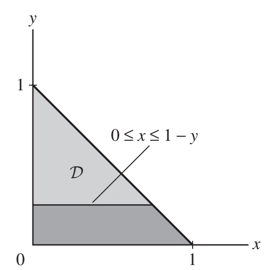
$$\mathbf{T}_x = \frac{\partial \Phi}{\partial x} = \frac{\partial}{\partial x}(x, y, 1 - x - y) = \langle 1, 0, -1 \rangle$$

$$\mathbf{T}_y = \frac{\partial \Phi}{\partial y} = \frac{\partial}{\partial y}(x, y, 1 - y) = \langle 0, 1, -1 \rangle$$

$$\mathbf{n} = \mathbf{T}_x \times \mathbf{T}_y = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -1 \\ 0 & 1 & -1 \end{vmatrix} = \mathbf{i} + \mathbf{j} + \mathbf{k} = \langle 1, 1, 1 \rangle$$

Note that $\mathbf{n}$ points upward.

Step 2. Evaluate the dot product $\mathbf{F} \cdot \mathbf{n}$.



We compute the dot product:

$$\mathbf{F}(\Phi(x, y)) \cdot \mathbf{n} = \left\langle y^2, 2, -x \right\rangle \cdot \langle 1, 1, 1 \rangle = y^2 + 2 - x$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(x, y)) \cdot \mathbf{n}\, dx\, dy = \int_0^1 \int_0^{1-y} \left(y^2 + 2 - x\right) dx\, dy = \int_0^1 y^2 x + 2x - \frac{x^2}{2} \bigg|_{x=0}^{1-y} dy$$

$$= \int_0^1 \left(y^2(1 - y) + 2(1 - y) - \frac{(1 - y)^2}{2}\right) dy = \int_0^1 \left(y^2 - y^3 + 2(1 - y) - \frac{(y - 1)^2}{2}\right) dy$$

$$= \frac{y^3}{3} - \frac{y^4}{4} - (1 - y)^2 - \frac{(y - 1)^3}{6} \bigg|_0^1 = \left(\frac{1}{3} - \frac{1}{4}\right) + \left(1 - \frac{1}{6}\right) = \frac{11}{12}$$

12. $\mathbf{F} = \langle x, y, e^z \rangle$, cylinder $x^2 + y^2 = 4$, $1 \le z \le 5$, outward-pointing normal

SOLUTION We parametrize the surface by

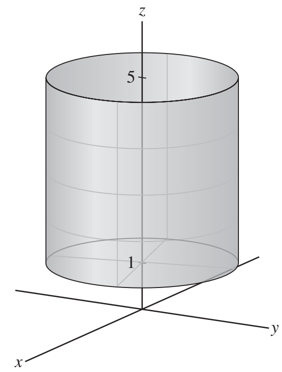
$$\Phi(\theta, z) = (2\cos\theta, 2\sin\theta, z)$$

where the parameter domain is:

$$\mathcal{D}: \ 0 \le \theta \le 2\pi, \ 1 \le z \le 5$$

For this parametrization it holds that:

$$\mathbf{T}_\theta \times \mathbf{T}_z = \langle 2\cos\theta, 2\sin\theta, 0\rangle$$

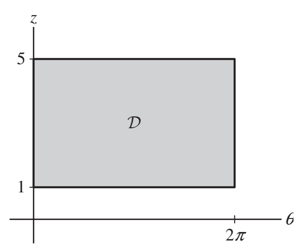


This vector is horizontal and points out of the cylinder (this can be verified by setting $\theta = 0$; the vector $\langle 2, 0, 0\rangle$ points out of the cylinder). Therefore:

$$\mathbf{n} = \langle 2\cos\theta, 2\sin\theta, 0\rangle$$

We compute the dot product $\mathbf{F} \cdot \mathbf{n}$:

$$\mathbf{F}(\Phi(\theta, z)) \cdot \mathbf{n}(\theta, z) = \left\langle 2\cos\theta, 2\sin\theta, e^z \right\rangle \cdot \langle 2\cos\theta, 2\sin\theta, 0\rangle = 4\cos^2\theta + 4\sin^2\theta = 4$$

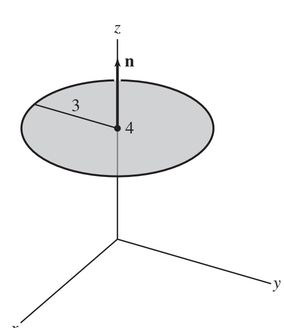


The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(\theta, z)) \cdot \mathbf{n}(\theta, z)\, dz\, d\theta = \iint_{\mathcal{D}} 4\, dz\, d\theta = 4\text{Area}(\mathcal{D}) = 4 \cdot 4 \cdot 2\pi = 32\pi$$

13. $\mathbf{F} = \left\langle xz, yz, z^{-1} \right\rangle$, disk of radius 3 at height 4 parallel to the xy-plane, upward-pointing normal

SOLUTION



We parametrize the surface S by:

$$\Phi(\theta, r) = (r\cos\theta, r\sin\theta, 4)$$

with the parameter domain:

$$\mathcal{D} = \{(\theta, r) : 0 \le \theta \le 2\pi, 0 \le r \le 3\}$$

Step 1. Compute the tangent and normal vectors. We have:

$$\mathbf{T}_\theta = \frac{\partial \Phi}{\partial \theta} = \frac{\partial}{\partial \theta}(r\cos\theta, r\sin\theta, 4) = \langle -r\sin\theta, r\cos\theta, 0\rangle$$
$$\mathbf{T}_r = \frac{\partial \Phi}{\partial r} = \frac{\partial}{\partial r}(r\cos\theta, r\sin\theta, 4) = \langle \cos\theta, \sin\theta, 0\rangle$$
$$\mathbf{T}_\theta \times \mathbf{T}_r = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -r\sin\theta & r\cos\theta & 0 \\ \cos\theta & \sin\theta & 0 \end{vmatrix} = \left(-r\ \sin^2\theta - r\cos^2\theta\right)\mathbf{k} = -r\mathbf{k} = \langle 0, 0, -r\rangle$$

Since the orientation of S is with an upward pointing normal, the z-coordinate of $\mathbf{n}$ must be positive. Hence:

$$\mathbf{n} = \langle 0, 0, r\rangle$$

Step 2. Evaluate the dot product $\mathbf{F} \cdot \mathbf{n}$. We first express $\mathbf{F}$ in terms of the parameters:

$$\mathbf{F}(\Phi(\theta, r)) = \left\langle xz, yz, z^{-1}\right\rangle = \left\langle r\cos\theta \cdot 4, r\sin\theta \cdot 4, 4^{-1}\right\rangle = \left\langle 4r\cos\theta, 4r\sin\theta, \frac{1}{4}\right\rangle$$

We now compute the dot product:

$$\mathbf{F}(\Phi(\theta, r)) \cdot \mathbf{n}(\theta, r) = \left\langle 4r\cos\theta, 4r\sin\theta, \frac{1}{4}\right\rangle \cdot \langle 0, 0, r\rangle = \frac{r}{4}$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(\theta, r)) \cdot \mathbf{n}(\theta, r)\, dr\, d\theta = \int_0^{2\pi} \int_0^3 \frac{r}{4}\, dr\, d\theta = 2\pi \int_0^3 \frac{r}{4}\, dr = 2\pi \cdot \left.\frac{r^2}{8}\right|_0^3 = \frac{9\pi}{4}$$

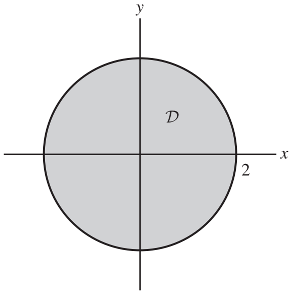
14. $\mathbf{F} = \langle xy, y, 0\rangle$, cone $z^2 = x^2 + y^2$, $x^2 + y^2 \le 4$, $z \ge 0$, downward-pointing normal

SOLUTION We parametrize the surface S by:

$$\Phi(\theta, t) = (t\cos\theta, t\sin\theta, t)$$

with the parameter domain:

$$\mathcal{D} = \{(\theta, t) : 0 \le \theta \le 2\pi,\ 0 \le t \le 2\}$$



In this parametrization it holds that (see Example 4 in Section 17.4).

$$\mathbf{T}_\theta \times \mathbf{T}_t = \langle t\cos\theta, t\sin\theta, -t\rangle$$

Since the normal is pointing downward, the z-coordinate must be negative. Therefore the normal is:

$$\mathbf{n} = \langle t\cos\theta, t\sin\theta, -t\rangle$$

We express $\mathbf{F}$ in terms of the parameters and then compute the dot product $\mathbf{F} \cdot \mathbf{n}$. We obtain:

$$\mathbf{F}(\Phi(\theta, t)) = \langle xy, y, 0 \rangle = \langle (t\cos\theta)(t\sin\theta), t\sin\theta, 0 \rangle = \left\langle t^2\cos\theta\sin\theta, t\sin\theta, 0 \right\rangle$$

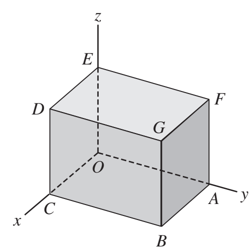
$$\mathbf{F}(\Phi(\theta, t)) \cdot \mathbf{n}(\theta, t) = t\sin\theta \langle t\cos\theta, 1, 0 \rangle \cdot t\langle \cos\theta, \sin\theta, -1 \rangle = t^2\sin\theta\left(t\cos^2\theta + \sin\theta\right)$$
$$= t^3\cos^2\theta\sin\theta + t^2\sin^2\theta$$

The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(\theta, t)) \cdot \mathbf{n}(\theta, t)\, dt\, d\theta = \int_0^{2\pi}\int_0^2 \left(t^3 \cos^2\theta\sin\theta + t^2 \sin^2\theta\right) dt\, d\theta$$
$$= \left(\int_0^2 t^3\, dt\right)\left(\int_0^{2\pi} \cos^2\theta\sin\theta\, d\theta\right) + \left(\int_0^2 t^2\, dt\right)\left(\int_0^{2\pi} \sin^2\theta\, d\theta\right)$$
$$= \left(\frac{t^4}{4}\bigg|_{t=0}^{2}\right)\left(-\frac{\cos^3\theta}{3}\bigg|_{\theta=0}^{2\pi}\right) + \left(\frac{t^3}{3}\bigg|_{t=0}^{2}\right)\left(\frac{\theta}{2} - \frac{\sin 2\theta}{4}\bigg|_{\theta=0}^{2\pi}\right) = 4 \cdot 0 + \frac{8}{3} \cdot \pi = \frac{8\pi}{3}$$

15. $\mathbf{F} = \left\langle 0, 0, e^{y+z} \right\rangle$, boundary of unit cube $0 \le x \le 1, 0 \le y \le 1, 0 \le z \le 1$, outward-pointing normal

SOLUTION



We denote the faces of the cube by:

$$S_1 = \text{Face } OABC \quad S_2 = \text{Face } DGEF \quad S_3 = \text{Face } ABGF$$
$$S_4 = \text{Face } OCDE \quad S_5 = \text{Face } BCDG \quad S_6 = \text{Face } OAFE$$

- On S_1

$$\Phi_1(x, y) = (x, y, 0)$$

and $\mathbf{n}_1 = \langle 0, 0, -1 \rangle$. Thus,

$$\mathbf{F}(\Phi_1(x, y)) \cdot \mathbf{n}_1 = \left\langle 0, 0, e^y \right\rangle \cdot \langle 0, 0, -1 \rangle = -e^y$$

- On S_2

$$\Phi_2(x, y) = (x, y, 1)$$

and $\mathbf{n}_2 = \langle 0, 0, 1 \rangle$. Thus,

$$\mathbf{F}(\Phi_2(x, y)) \cdot \mathbf{n}_2 = \left\langle 0, 0, e^{y+1} \right\rangle \cdot \langle 0, 0, 1 \rangle = e^{y+1}$$

- On any other surface S_i, $3 \le i \le 6$, we have

$$\mathbf{F}(\Phi_1(x, y)) \cdot \mathbf{n}_i = 0,$$

because the z-component of $\mathbf{n}_i = 0$ and the x, y components of $\mathbf{F}$ equal 0. Thus,

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{S_1} \mathbf{F} \cdot d\mathbf{S} + \iint_{S_2} \mathbf{F} \cdot d\mathbf{S} = \int_0^1\int_0^1 -e^y\, dx\, dy + \int_0^1\int_0^1 e^{y+1}\, dx\, dy$$
$$= \int_0^1\int_0^1 \left(e^{y+1} - e^y\right) dx\, dy = \int_0^1 \left(e^{y+1} - e^y\right) dy$$
$$= \int_0^1 e^y(e-1)\, dy = (e-1)e^y\bigg|_0^1 = (e-1)^2$$

16. $\mathbf{F} = \langle 0, 0, z^2 \rangle$, $G(u, v) = (u \cos v, u \sin v, v)$, $0 \le u \le 1$, $0 \le v \le 2\pi$, upward-pointing normal

SOLUTION For this parametrization it holds that (see Example 3 in Section 17.4):

$$\mathbf{T}_u \times \mathbf{T}_v = \langle \sin v, -\cos v, u \rangle$$

Since $u \ge 0$, the upward pointing normal is,

$$\mathbf{n} = \langle \sin v, -\cos v, u \rangle$$

We express $\mathbf{F}$ in terms of the parameters and then compute $\mathbf{F} \cdot \mathbf{n}$ we get:

$$\mathbf{F}(\Phi(u, v)) = \left\langle 0, 0, z^2 \right\rangle = \left\langle 0, 0, v^2 \right\rangle$$

$$\mathbf{F}(\Phi(u, v)) \cdot \mathbf{n}(u, v) = \left\langle 0, 0, v^2 \right\rangle \cdot \langle \sin v, -\cos v, u \rangle = v^2 u$$

The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(u, v)) \cdot \mathbf{n}(u, v)\, du\, dv = \int_0^{2\pi} \int_0^1 v^2 u\, du\, dv = \left(\int_0^{2\pi} v^2\, dv \right) \left(\int_0^1 u\, du \right)$$

$$= \left(\frac{v^3}{3} \bigg|_{v=0}^{2\pi} \right) \left(\frac{u^2}{2} \bigg|_{u=0}^{1} \right) = \frac{8\pi^3}{3} \cdot \frac{1}{2} = \frac{4\pi^3}{3}$$

17. $\mathbf{F} = \langle y, z, 0 \rangle$, $G(u, v) = (u^3 - v, u + v, v^2)$, $0 \le u \le 2$, $0 \le v \le 3$, downward-pointing normal

SOLUTION

Step 1. Compute the tangent and normal vectors. We have,

$$\mathbf{T}_u = \frac{\partial \Phi}{\partial u} = \frac{\partial}{\partial u} \left(u^3 - v, u + v, v^2 \right) = \left\langle 3u^2, 1, 0 \right\rangle$$

$$\mathbf{T}_v = \frac{\partial \Phi}{\partial v} = \frac{\partial}{\partial v} \left(u^3 - v, u + v, v^2 \right) = \langle -1, 1, 2v \rangle$$

$$\mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3u^2 & 1 & 0 \\ -1 & 1 & 2v \end{vmatrix} = (2v)\mathbf{i} - \left(6u^2 v\right)\mathbf{j} + \left(3u^2 + 1\right)\mathbf{k} = \left\langle 2v, -6u^2 v, 3u^2 + 1 \right\rangle$$

Since the normal is pointing downward, the z-coordinate is negative, hence,

$$\mathbf{n} = \left\langle -2v, 6u^2 v, -3u^2 - 1 \right\rangle$$

Step 2. Evaluate the dot product $\mathbf{F} \cdot \mathbf{n}$. We first express $\mathbf{F}$ in terms of the parameters:

$$\mathbf{F}(\Phi(u, v)) = \langle y, z, 0 \rangle = \left\langle u + v, v^2, 0 \right\rangle$$

We compute the dot product:

$$\mathbf{F}(\Phi(u, v)) \cdot \mathbf{n}(u, v) = \left\langle u + v, v^2, 0 \right\rangle \cdot \left\langle -2v, 6u^2 v, -3u^2 - 1 \right\rangle$$

$$= -2v(u + v) + 6u^2 v \cdot v^2 + 0 = -2vu - 2v^2 + 6u^2 v^3$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}(\Phi(u, v)) \cdot \mathbf{n}(u, v)\, du\, dv = \int_0^3 \int_0^2 \left(-2uv - 2v^2 + 6u^2 v^3 \right) du\, dv$$

$$= \int_0^3 -u^2 v - 2v^2 u + 2u^3 v^3 \bigg|_{u=0}^{2} dv = \int_0^3 \left(16v^3 - 4v^2 - 4v \right) dv = 4v^4 - \frac{4}{3}v^3 - 2v^2 \bigg|_0^3 = 270$$

18. Let $\mathcal{S}$ be the oriented half-cylinder in Figure 15. In (a)–(f), determine whether $\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S}$ is positive, negative, or zero. Explain your reasoning.

(a) $\mathbf{F} = \mathbf{i}$ **(b)** $\mathbf{F} = \mathbf{j}$

(c) $\mathbf{F} = \mathbf{k}$ **(d)** $\mathbf{F} = y\mathbf{i}$

(e) $\mathbf{F} = -y\mathbf{j}$ **(f)** $\mathbf{F} = x\mathbf{j}$

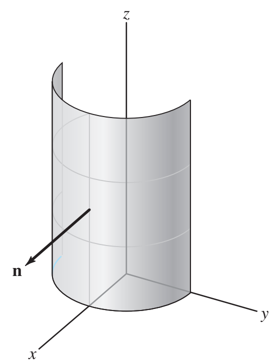


FIGURE 15

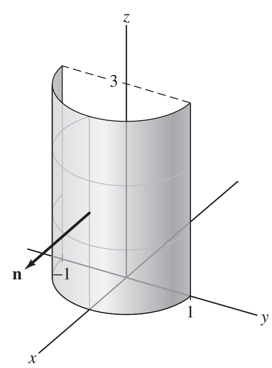
SOLUTION



S is parametrized by:

$$\Phi(\theta, z) = (\cos\theta, \sin\theta, z), \quad 0 \le z \le 3, \quad -\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$$

Hence,

$$\mathbf{T}_\theta = \frac{\partial \Phi}{\partial \theta} = \langle -\sin\theta, \cos\theta, 0\rangle$$

$$\mathbf{T}_z = \frac{\partial \Phi}{\partial z} = \langle 0, 0, 1\rangle$$

$$\mathbf{T}_\theta \times \mathbf{T}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = (\cos\theta)\mathbf{i} + (\sin\theta)\mathbf{j} = \langle \cos\theta, \sin\theta, 0\rangle$$

The normal to S is pointing in the outward direction, hence the x-coordinate of $\mathbf{n}$ is positive. Since $-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$, we have $\cos\theta \ge 0$, hence,

$$\mathbf{n} = \langle \cos\theta, \sin\theta, 0\rangle$$

(a) Since $\mathbf{F} \cdot \mathbf{n} = \langle 1, 0, 0\rangle \cdot \langle \cos\theta, \sin\theta, 0\rangle = \cos\theta$, and $-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$, we have $\mathbf{F} \cdot \mathbf{n} \ge 0$ therefore:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} > 0.$$

(b) We compute the dot product:

$$\mathbf{F} \cdot \mathbf{n} = \langle 0, 1, 0\rangle \cdot \langle \cos\theta, \sin\theta, 0\rangle = \sin\theta$$

The part of the surface integral for $-\frac{\pi}{2} \le \theta \le 0$ is canceled by the part for $0 \le \theta \le \frac{\pi}{2}$, therefore the surface integral is zero.

(c) The normal vector $\mathbf{n}$ is horizontal at each point on S, therefore it is orthogonal to the field $\mathbf{F} = \mathbf{k}$. We conclude that the surface integral is zero.
(d) We compute the dot product:

$$\mathbf{F} \cdot \mathbf{n} = \langle y, 0, 0\rangle \cdot \langle \cos\theta, \sin\theta, 0\rangle = \langle \sin\theta, 0, 0\rangle \cdot \langle \cos\theta, \sin\theta, 0\rangle = \sin\theta\cos\theta$$

The surface integral over the part of S where $-\frac{\pi}{2} \le \theta \le 0$ is canceled by the integral over the part where $0 \le \theta \le \frac{\pi}{2}$, hence the surface integral over S is zero.
(e) We have,

$$\mathbf{F} \cdot \mathbf{n} = \langle 0, -y, 0\rangle \cdot \langle \cos\theta, \sin\theta, 0\rangle = \langle 0, -\sin\theta, 0\rangle \cdot \langle \cos\theta, \sin\theta, 0\rangle = -\sin^2\theta \le 0$$

Since the dot product is nonpositive, the surface integral is negative.
(f) We compute the dot product:

$$\mathbf{F} \cdot \mathbf{n} = \langle 0, x, 0\rangle \cdot \langle \cos\theta, \sin\theta, 0\rangle = \langle 0, \cos\theta, 0\rangle \cdot \langle \cos\theta, \sin\theta, 0\rangle = \cos\theta\sin\theta$$

The surface integral is zero by the same reasoning given in part (d).

19. Let $\mathbf{e_r} = \langle x/r, y/r, z/r\rangle$ be the unit radial vector, where $r = \sqrt{x^2 + y^2 + z^2}$. Calculate the integral of $\mathbf{F} = e^{-r}\mathbf{e_r}$ over:
(a) The upper hemisphere of $x^2 + y^2 + z^2 = 9$, outward-pointing normal.
(b) The octant $x \ge 0$, $y \ge 0$, $z \ge 0$ of the unit sphere centered at the origin.

SOLUTION
(a) We parametrize the upper-hemisphere by,

$$\Phi : x = 3\cos\theta\sin\phi,\ y = 3\sin\theta\sin\phi,\ z = 3\cos\phi$$

with the parameter domain:

$$\mathcal{D} = \left\{(\theta, \phi) : 0 \le \theta < 2\pi, 0 \le \phi < \frac{\pi}{2}\right\}$$

The outward pointing normal is (see Eq. (4) in sec. 17.4):

$$\mathbf{n} = 9\sin\phi\mathbf{e}_r$$

We compute the dot product $\mathbf{F} \cdot \mathbf{n}$ on the sphere. On the sphere $r = 3$, hence,

$$\mathbf{F} \cdot \mathbf{n} = e^{-r}\,\mathbf{e}_r \cdot \mathbf{n} = e^{-3}\mathbf{e}_r \cdot 9\sin\phi\,\mathbf{e}_r = 9e^{-3}\sin\phi\,\mathbf{e}_r \cdot \mathbf{e}_r = 9\,e^{-3}\sin\phi$$

We obtain the following integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} (\mathbf{F} \cdot \mathbf{n})\ d\phi\, d\theta = \int_0^{2\pi}\int_0^{\pi/2} 9e^{-3}\sin\phi\, d\phi\, d\theta$$
$$= 18\pi e^{-3}\int_0^{\pi/2}\sin\phi\, d\phi = 18\pi e^{-3}\left(-\cos\phi\Big|_0^{\pi/2}\right) = 18\pi e^{-3}$$

(b) We parametrize the first octant of the sphere by,

$$\Phi : x = \cos\theta\sin\phi,\ y = \sin\theta\sin\phi,\ z = \cos\phi$$

with the parameter domain:

$$\mathcal{D} = \left\{(\theta, \phi) : 0 \le \theta < \frac{\pi}{2}, 0 \le \phi < \frac{\pi}{2}\right\}$$

The outward pointing normal is (as seen above):

$$\mathbf{n} = 1\sin\phi\mathbf{e}_r$$

We compute the dot product $\mathbf{F} \cdot \mathbf{n}$ on the sphere. On the sphere $r = 1$, hence,

$$\mathbf{F} \cdot \mathbf{n} = e^{-r}\,\mathbf{e}_r \cdot \mathbf{n} = e^{-1}\mathbf{e}_r \cdot \sin\phi\,\mathbf{e}_r = e^{-1}\sin\phi\,\mathbf{e}_r \cdot \mathbf{e}_r = e^{-1}\sin\phi$$

We obtain the following integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} (\mathbf{F} \cdot \mathbf{n})\ d\phi\, d\theta = \int_0^{\pi/2}\int_0^{\pi/2} e^{-1}\sin\phi\, d\phi\, d\theta$$
$$= \frac{\pi}{2}e^{-1}\int_0^{\pi/2}\sin\phi\, d\phi = \frac{\pi}{2}e^{-1}\left(-\cos\phi\Big|_0^{\pi/2}\right) = \frac{\pi}{2}e^{-1}$$

20. Show that the flux of $\mathbf{F} = \dfrac{\mathbf{e}_r}{r^2}$ through a sphere centered at the origin does not depend on the radius of the sphere.

SOLUTION We parametrize the sphere of radius R centered at the origin by,

$$\Phi : x = R\cos\theta\sin\phi,\ y = R\sin\theta\sin\phi,\ z = R\cos\phi,\ 0 \le \theta < 2\pi,\ 0 \le \phi \le \pi$$

The outward pointing normal is (See Eq. (4) in sec. 17.4):

$$\mathbf{n} = R^2 \sin\phi\, \mathbf{e}_r$$

We compute the product $\mathbf{F}\cdot\mathbf{n}$ on the sphere. On the sphere $r = R$, therefore we get:

$$\mathbf{F}\cdot\mathbf{n} = \frac{\mathbf{e}_r}{r^2}\cdot R^2\sin\phi\,\mathbf{e}_r = \frac{\mathbf{e}_r}{R^2}\cdot R^2\sin\phi\mathbf{e}_r = (\sin\phi)\mathbf{e}_r\cdot\mathbf{e}_r = \sin\phi$$

hence,

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_{\mathcal{D}} (\mathbf{F}\cdot\mathbf{n})\ d\phi\,d\theta = \int_0^{2\pi}\int_0^{\pi}(\sin\phi)d\phi\,d\theta$$
$$= 2\pi\int_0^{\pi}\sin\phi\,d\phi = 2\pi\left(-\cos\phi\big|_0^{\pi}\right) = 4\pi$$

We see that the surface integral of $\mathbf{F}$ does not depend on the radius R of the sphere.

21. The electric field due to a point charge located at the origin in $\mathbf{R}^3$ is $\mathbf{E} = k\dfrac{\mathbf{e}_r}{r^2}$, where $r = \sqrt{x^2+y^2+z^2}$ and k is a constant. Calculate the flux of $\mathbf{E}$ through the disk D of radius 2 parallel to the xy-plane with center $(0, 0, 3)$.

SOLUTION Let $r = \sqrt{x^2+y^2+z^2}$ and $\hat{r} = \sqrt{x^2+y^2}$. We parametrize the disc by:

$$\Phi(\hat{r},\theta) = (\hat{r}\cos\theta, \hat{r}\sin\theta, 3)$$
$$\mathbf{T}_{\hat{r}} = \frac{\partial\Phi}{\partial\hat{r}} = \langle\cos\theta, \sin\theta, 0\rangle$$
$$\mathbf{T}_{\theta} = \frac{\partial\Phi}{\partial\theta} = \left\langle -\hat{r}\sin\theta, \hat{r}\cos\theta, 0\right\rangle$$
$$\mathbf{n} = \mathbf{T}_{\hat{r}}\times\mathbf{T}_{\theta} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos\theta & \sin\theta & 0 \\ -\hat{r}\sin\theta & \hat{r}\cos\theta & 0 \end{vmatrix} = \left\langle 0, 0, \hat{r}\right\rangle$$

Now,

$$\mathbf{E}\cdot\mathbf{n} = k\frac{\mathbf{e}_r}{r^2}\cdot\left\langle 0,0,\hat{r}\right\rangle = \frac{k\hat{r}}{r^3}\langle x,y,z\rangle\cdot\langle 0,0,1\rangle = \frac{zk\hat{r}}{r^3}$$

Since on the disk $z = 3$, we get:

$$\mathbf{E}\cdot\mathbf{n} = 3k\frac{\hat{r}}{r^3} \text{ and } r = \sqrt{\hat{r}^2+9}$$

so $\mathbf{E}\cdot\mathbf{n} = 3k\dfrac{\hat{r}}{\left(\sqrt{\hat{r}^2+9}\right)^3}$.

$$\iint_{\mathcal{D}} \mathbf{E}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^2 \frac{3k\hat{r}}{(\hat{r}^2+9)^{3/2}}\,d\hat{r}\,d\theta = 6\pi k\int_0^2\frac{\hat{r}}{(\hat{r}^2+9)^{3/2}}\,d\hat{r}$$

Substituting $u = \hat{r}^2 + 9$ and $\frac{1}{2}\,du = \hat{r}\,d\hat{r}$, we get:

$$\iint_{\mathcal{D}} \mathbf{E}\cdot d\mathbf{S} = 3\pi k\int_9^{13}\frac{du}{u^{3/2}} = -6\pi k u^{-1/2}\Big|_9^{13} = \left(2 - \frac{6}{\sqrt{13}}\right)\pi k$$

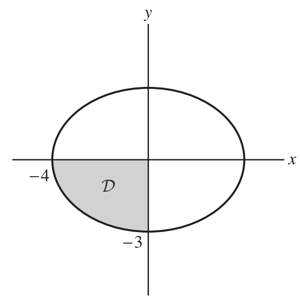
22. Let $\mathcal{S}$ be the ellipsoid $\left(\frac{x}{4}\right)^2 + \left(\frac{y}{3}\right)^2 + \left(\frac{z}{2}\right)^2 = 1$. Calculate the flux of $\mathbf{F} = z\mathbf{i}$ over the portion of $\mathcal{S}$ where $x, y, z \le 0$ with upward-pointing normal. *Hint:* Parametrize $\mathcal{S}$ using a modified form of spherical coordinates (θ, ϕ).

SOLUTION We parametrize the ellipsoid by a modified form of spherical coordinates. That is,

$$\Phi(\theta,\phi) = (4\cos\theta\sin\phi, 3\sin\theta\sin\phi, 2\cos\phi)$$

with the parameter domain

$$\mathcal{D} = \left\{(\theta,\phi) : \pi \le \theta < \frac{3\pi}{2}, \frac{\pi}{2} \le \phi < \pi\right\}$$



One can easily verify that $\Phi(u, v)$ satisfies the equation of the ellipsoid.

Step 1. Compute the tangent and normal vectors. We have,

$$\mathbf{T}_\theta = \frac{\partial \Phi}{\partial \theta} = \langle -4\sin\theta\sin\phi, 3\cos\theta\sin\phi, 0\rangle$$

$$\mathbf{T}_\phi = \frac{\partial \Phi}{\partial \phi} = \langle 4\cos\theta\cos\phi, 3\sin\theta\cos\phi, -2\sin\phi\rangle$$

$$\begin{aligned}\mathbf{T}_\theta \times \mathbf{T}_\phi &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -4\sin\theta\sin\phi & 3\cos\theta\sin\phi & 0 \\ 4\cos\theta\cos\phi & 3\sin\theta\cos\phi & -2\sin\phi \end{vmatrix} \\ &= \left(-6\cos\theta\sin^2\phi\right)\mathbf{i} - \left(8\sin\theta\sin^2\phi\right)\mathbf{j} - \left(12\ \sin^2\theta\cos\phi\sin\phi + 12\ \cos^2\theta\cos\phi\sin\phi\right)\mathbf{k} \\ &= \left\langle -6\cos\theta\sin^2\phi, -8\sin\theta\sin^2\phi, -12\cos\phi\sin\phi\right\rangle\end{aligned}$$

In $\mathcal{D}$, $\frac{\pi}{2} \le \phi < \pi$ hence $-12\cos\phi\sin\phi \ge 0$. This is the upward pointing normal on this portion of the ellipse since the z-coordinate is positive. Therefore,

$$\mathbf{n} = \left\langle -6\cos\theta\sin^2\phi, -8\sin\theta\sin^2\phi, -12\cos\phi\sin\phi\right\rangle = -2\sin\phi\,\langle 3\cos\theta\sin\phi, 4\sin\theta\sin\phi, 6\cos\phi\rangle$$

Step 2. Compute the dot product $\mathbf{F}\cdot\mathbf{n}$. We first express $\mathbf{F}$ in terms of the parameters:

$$\mathbf{F}\left(\Phi(\theta, \phi)\right) = \langle z, 0, 0\rangle = \langle 2\cos\phi, 0, 0\rangle$$

Hence,

$$\begin{aligned}\mathbf{F}\left(\Phi(\theta, \phi)\right)\cdot\mathbf{n}(\theta, \phi) &= -2\sin\phi(6\cos\theta\sin\phi\cos\phi) \\ &= -4\ \sin^2\phi(3\cos\theta\cos\phi)\end{aligned}$$

Step 3. Calculate the surface integral. The surface integral is equal to the following double integral:

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{F}\left(\Phi(\theta, \phi)\right)\cdot\mathbf{n}(\theta, \phi)\,d\phi\,d\theta &= -\int_\pi^{3\pi/2}\int_{\pi/2}^{\pi}\left(12\sin^2\phi\cos\phi\cos\theta\right)d\phi\,d\theta \\ &= -\left(\int_\pi^{3\pi/2} 12\ \cos\theta\,d\theta\right)\left(\int_{\pi/2}^{\pi}\sin^2\phi\cos\phi\,d\phi\right) \\ &= -\left(12\sin\theta\Big|_{\theta=\pi}^{3\pi/2}\right)\left(\frac{\sin^3\phi}{3}\Big|_{\phi=\pi/2}^{\pi}\right) \\ &= 12\cdot\left(-\frac{1}{3}\right) = -4\end{aligned}$$

23. Let $\mathbf{v} = z\mathbf{k}$ be the velocity field (in meters per second) of a fluid in $\mathbf{R}^3$. Calculate the flow rate (in cubic meters per second) through the upper hemisphere ($z \ge 0$) of the sphere $x^2 + y^2 + z^2 = 1$.

SOLUTION We use the spherical coordinates:

$$x = \cos\theta\sin\phi, \quad y = \sin\theta\sin\phi, \quad z = \cos\phi$$

with the parameter domain

$$0 \le \theta < 2\pi, \quad 0 \le \phi \le \frac{\pi}{2}$$

The normal vector is (see Eq. (4) in Section 17.4):

$$\mathbf{n} = \mathbf{T}_\phi \times \mathbf{T}_\theta = \sin\phi \,\langle \cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi \rangle$$

We express the function in terms of the parameters:

$$\mathbf{v} = \langle 0, 0, z \rangle = \langle 0, 0, \cos\phi \rangle$$

Hence,

$$\mathbf{v} \cdot \mathbf{n} = \langle 0, 0, \cos\phi \rangle \cdot \sin\phi \,\langle \cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi \rangle = \sin\phi \cos^2\phi$$

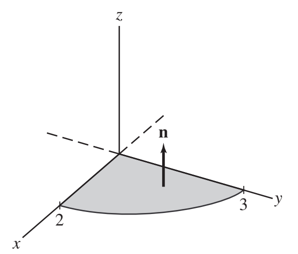
The flow rate of the fluid through the upper hemisphere S is equal to the flux of the velocity vector through S. That is,

$$\begin{aligned}\iint_S \mathbf{v} \cdot d\mathbf{S} &= \int_0^{\frac{\pi}{2}} \int_0^{2\pi} \sin\phi \cos^2\phi \, d\theta \, d\phi \\ &= \int_0^{2\pi} d\theta \cdot \int_0^{\frac{\pi}{2}} \sin\phi \cos^2\phi \, d\phi = 2\pi \cdot \frac{-\cos^3\phi}{3}\Big|_0^{\frac{\pi}{2}} \\ &= \frac{2\pi}{3} \mathrm{m}^3/\mathrm{s}\end{aligned}$$

24. Calculate the flow rate of a fluid with velocity field $\mathbf{v} = \langle x, y, x^2 y \rangle$ (in m/s) through the portion of the ellipse $\left(\frac{x}{2}\right)^2 + \left(\frac{y}{3}\right)^2 = 1$ in the xy-plane, where $x, y \geq 0$, oriented with the normal in the positive z-direction.

SOLUTION We use the following parametrization for the surface (see remark at the end of the solution):

$$\begin{aligned}&\Phi : x = 2r\cos\theta, \; y = 3r\sin\theta, \; z = 0 \\ &0 \leq \theta \leq \frac{\pi}{2}, \quad 0 \leq r \leq 1\end{aligned} \qquad (1)$$



Step 1. Compute the tangent and normal vectors. We have,

$$\mathbf{T}_r = \frac{\partial \Phi}{\partial r} = \frac{\partial}{\partial r}(2r\cos\theta, 3r\sin\theta, 0) = \langle 2\cos\theta, 3\sin\theta, 0 \rangle$$

$$\mathbf{T}_\theta = \frac{\partial \Phi}{\partial \theta} = \frac{\partial}{\partial \theta}(2r\cos\theta, 3r\sin\theta, 0) = \langle -2r\sin\theta, 3r\cos\theta, 0 \rangle$$

$$\mathbf{T}_r \times \mathbf{T}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2\cos\theta & 3\sin\theta & 0 \\ -2r\sin\theta & 3r\cos\theta & 0 \end{vmatrix} = \left(6r\,\cos^2\theta + 6r\sin^2\theta\right)\mathbf{k} = 6r\mathbf{k}$$

Since the normal points to the positive z-direction, the normal vector is,

$$\mathbf{n} = 6r\mathbf{k} = \langle 0, 0, 6r \rangle$$

Step 2. Compute the dot product $\mathbf{v} \cdot \mathbf{n}$. We write the velocity vector in terms of the parameters:

$$\begin{aligned}\mathbf{v} &= \left\langle x, y, x^2 y \right\rangle = \left\langle 2r\cos\theta, 3r\sin\theta, 4r^2\cos^2\theta \cdot 3r\sin\theta \right\rangle \\ &= \left\langle 2r\cos\theta, 3r\sin\theta, 12r^3\cos^2\theta\sin\theta \right\rangle\end{aligned}$$

Hence,

$$\mathbf{v} \cdot \mathbf{n} = 12r^3\cos^2\theta\sin\theta \cdot 6r = 72r^4\cos^2\theta\sin\theta$$

Step 3. Compute the flux. The flow rate of the fluid is the flux of the velocity vector through S. That is,

$$\iint_S \mathbf{v}\cdot d\mathbf{S} = \int_0^{\pi/2}\int_0^1 72r^4\cos^2\theta\sin\theta\,dr\,d\theta = \left(\int_0^1 72r^4\,dr\right)\left(\int_0^{\pi/2}\cos^2\theta\sin\theta\,d\theta\right)$$

$$= \left(\frac{72}{5}r^5\Big|_0^1\right)\left(-\frac{\cos^3\theta}{3}\Big|_{\theta=0}^{\pi/2}\right) = \frac{72}{5}\cdot\left(0+\frac{1}{3}\right) = \frac{24}{5} = 4.8\ \text{ft}^3/\text{s}$$

Remark: We explain why (1) parametrizes the given portion of the ellipse. At any point (x, y) which satisfies (1) we have,

$$\left(\frac{x}{2}\right)^2 + \left(\frac{y}{3}\right)^3 = r^2\cos^2\theta + r^2\sin^2\theta = r^2 \le 1$$

Therefore (x, y) is inside the ellipse $\left(\frac{x}{2}\right)^2 + \left(\frac{y}{2}\right)^2 = 1$. The limits of θ determine the part of the region inside the ellipse in the first quadrant.

In Exercises 25–26, let $\mathcal{T}$ be the triangular region with vertices $(1, 0, 0)$, $(0, 1, 0)$, *and* $(0, 0, 1)$ *oriented with upward-pointing normal vector (Figure 16). Assume distances are in meters.*

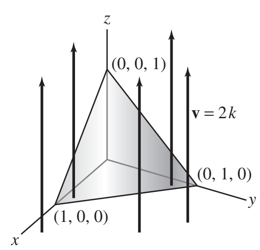


FIGURE 16

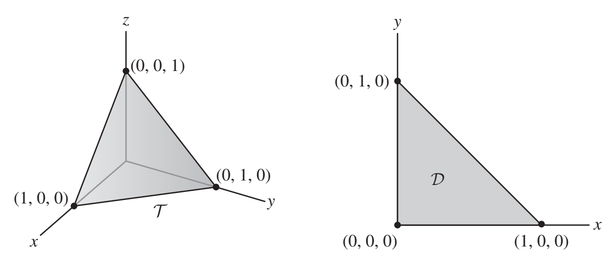
25. A fluid flows with constant velocity field $\mathbf{v} = 2\mathbf{k}$ (m/s). Calculate:
(a) The flow rate through $\mathcal{T}$
(b) The flow rate through the projection of $\mathcal{T}$ onto the xy-plane [the triangle with vertices (0, 0, 0), (1, 0, 0), and (0, 1, 0)]

SOLUTION



The equation of the plane through the three vertices is $x + y + z = 1$, hence the upward pointing normal vector is:

$$\mathbf{n} = \langle 1, 1, 1\rangle$$

and the unit normal is:

$$\mathbf{e_n} = \left\langle \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right\rangle$$

We compute the dot product $\mathbf{v}\cdot\mathbf{e_n}$:

$$\mathbf{v}\cdot\mathbf{e_n} = \langle 0, 0, 2\rangle\cdot\left\langle \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right\rangle = \frac{2}{\sqrt{3}}$$

The flow rate through $\mathcal{T}$ is equal to the flux of $\mathbf{v}$ through $\mathcal{T}$. That is,

$$\iint_S \mathbf{v}\cdot d\mathbf{S} = \iint_S (\mathbf{v}\cdot\mathbf{e_n})\,dS = \iint_S \frac{2}{\sqrt{3}}\,dS = \frac{2}{\sqrt{3}}\iint_S 1\,dS = \frac{2}{\sqrt{3}}\cdot\text{Area}(S)$$

The area of the equilateral triangle $\mathcal{T}$ is $\frac{\left(\sqrt{2}\right)^2\cdot\sqrt{3}}{4} = \frac{\sqrt{3}}{2}$. Therefore,

$$\iint_S \mathbf{v}\cdot d\mathbf{S} = \frac{2}{\sqrt{3}}\cdot\frac{\sqrt{3}}{2} = 1$$

Let $\mathcal{D}$ denote the projection of $\mathcal{T}$ onto the xy-plane. Then the upward pointing normal is $\mathbf{n} = \langle 0, 0, 1\rangle$. We compute the dot product $\mathbf{v} \cdot \mathbf{n}$:

$$\mathbf{v} \cdot \mathbf{n} = \langle 0, 0, 2\rangle \cdot \langle 0, 0, 1\rangle = 2$$

The flow rate through $\mathcal{D}$ is equal to the flux of $\mathbf{v}$ through $\mathcal{D}$. That is,

$$\iint_{\mathcal{D}} \mathbf{v} \cdot d\mathbf{S} = \iint_{\mathcal{D}} (\mathbf{v} \cdot \mathbf{n})\, dS = \iint_{\mathcal{D}} 2\, dS = 2 \iint_{\mathcal{D}} 1\, dS = 2 \cdot \text{Area}(\mathcal{D}) = 2 \cdot \frac{1 \cdot 1}{2} = 1$$

26. Calculate the flow rate through $\mathcal{T}$ if $\mathbf{v} = -\mathbf{j}$ m/s.

SOLUTION We compute the flow rate through $\mathcal{T}$. Since the unit normal vector is $\mathbf{e_n} = \left\langle \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}} \right\rangle$ we have,

$$\mathbf{v} \cdot \mathbf{e_n} = \langle 0, -1, 0\rangle \cdot \left\langle \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}} \right\rangle = \frac{-1}{\sqrt{3}}$$

Therefore, the flow rate through $\mathcal{T}$ is the following flux:

$$\iint_S \mathbf{v} \cdot d\mathbf{S} = \iint_S (\mathbf{v} \cdot \mathbf{e_n})\, dS = \iint_S \frac{-1}{\sqrt{3}}\, dS = -\text{Area}(S)/\sqrt{3} = -\frac{\sqrt{3}}{2}\frac{1}{\sqrt{3}} = \frac{-1}{2}$$

The upward pointing normal to the projection $\mathcal{D}$ of $\mathcal{T}$ onto the xy-plane is $\mathbf{n} = \langle 0, 0, 1\rangle$. Since $\mathbf{v} = \langle 0, -1, 0\rangle$ is orthogonal to $\mathbf{n}$, the flux of $\mathbf{v}$ through $\mathcal{D}$ is zero.

27. Prove that if $\mathcal{S}$ is the part of a graph $z = g(x, y)$ lying over a domain $\mathcal{D}$ in the xy-plane, then

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \left(-F_1 \frac{\partial g}{\partial x} - F_2 \frac{\partial g}{\partial y} + F_3 \right) dx\, dy$$

SOLUTION

Step 1. Find a parametrization. We parametrize the surface by

$$\Phi(x, y) = (x, y, g(x, y)), \ (x, y) \in \mathcal{D}$$

Step 2. Compute the tangent and normal vectors. We have,

$$\mathbf{T}_x = \frac{\partial \Phi}{\partial x} = \frac{\partial}{\partial x}(x, y, g(x, y)) = \left\langle 1, 0, \frac{\partial g}{\partial x} \right\rangle$$

$$\mathbf{T}_y = \frac{\partial \Phi}{\partial y} = \frac{\partial}{\partial y}(x, y, g(x, y)) = \left\langle 0, 1, \frac{\partial g}{\partial y} \right\rangle$$

$$\mathbf{n} = \mathbf{T}_x \times \mathbf{T}_y = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & \frac{\partial g}{\partial x} \\ 0 & 1 & \frac{\partial g}{\partial y} \end{vmatrix} = -\frac{\partial g}{\partial x}\mathbf{i} - \frac{\partial g}{\partial x}\mathbf{j} + \mathbf{k} = \left\langle -\frac{\partial g}{\partial x}, -\frac{\partial g}{\partial y}, 1 \right\rangle$$

Step 3. Evaluate the dot product $\mathbf{F} \cdot \mathbf{n}$.

$$\mathbf{F} \cdot \mathbf{n} = \langle F_1, F_2, F_3\rangle \cdot \left\langle -\frac{\partial g}{\partial x}, -\frac{\partial g}{\partial y}, 1 \right\rangle = -F_1 \frac{\partial g}{\partial x} - F_2 \frac{\partial g}{\partial y} + F_3$$

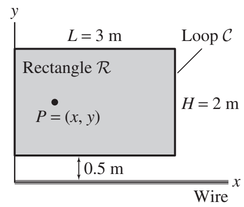
Step 4. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} (\mathbf{F} \cdot \mathbf{n})\, dx\, dy = \iint_{\mathcal{D}} \left(-F_1 \frac{\partial g}{\partial x} - F_2 \frac{\partial g}{\partial y} + F_3 \right) dx\, dy$$

In Exercises 28–29, a varying current $i(t)$ flows through a long straight wire in the xy-plane as in Example 5. The current produces a magnetic field $\mathbf{B}$ *whose magnitude at a distance r from the wire is $B = \frac{\mu_0 i}{2\pi r}$ T, where $\mu_0 = 4\pi \cdot 10^{-7}$* T-m/A. *Furthermore,* $\mathbf{B}$ *points into the page at points P in the xy-plane.*

28. Assume that $i(t) = t(12 - t)$ A (t in seconds). Calculate the flux $\Phi(t)$, at time t, of $\mathbf{B}$ through a rectangle of dimensions $L \times H = 3 \times 2$ m whose top and bottom edges are parallel to the wire and whose bottom edge is located $d = 0.5$ m above the wire, similar to Figure 13(B). Then use Faraday's Law to determine the voltage drop around the rectangular loop (the boundary of the rectangle) at time t.

SOLUTION



We choose the coordinate system as shown in the figure. Therefore the rectangle $\mathcal{R}$ is the region:

$$\mathcal{R} = \{(x, y) : 0 \le x \le 3, 0.5 \le y \le 2.5\}$$

Since the magnetic field points into the page and $\mathcal{R}$ is oriented with normal vector pointing out of the page (as in Example 5) we have $\mathbf{B} = -\|\mathbf{B}\|\mathbf{k}$ and $\mathbf{n} = \mathbf{e_n} = \mathbf{k}$. Hence:

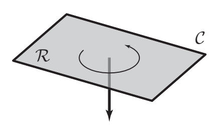
$$\mathbf{B} \cdot \mathbf{n} = \|\mathbf{B}\| (-\mathbf{k}) \cdot \mathbf{k} = -\|\mathbf{B}\| = -\frac{\mu_0 i}{2\pi r}$$

The distance from $P = (x, y)$ in $\mathcal{R}$ to the wire is $r = y$, hence, $\mathbf{B} \cdot \mathbf{n} = -\frac{\mu_0 i}{2\pi y}$. We now compute the flux $\Phi(t)$ of $\mathbf{B}$ through the rectangle $\mathcal{R}$, by evaluating the following double integral:

$$\begin{aligned}\Phi(t) &= \iint_{\mathcal{R}} \mathbf{B} \cdot d\mathbf{S} = \iint_{\mathcal{R}} \mathbf{B} \cdot \mathbf{n}\, dy\, dx = \int_0^3 \int_{0.5}^{2.5} -\frac{\mu_0 i}{2\pi y}\, dy\, dx = -\frac{\mu_0 i}{2\pi} \int_0^3 \int_{0.5}^{2.5} \frac{1}{y}\, dy\, dx \\ &= -\frac{3\mu_0 i}{2\pi} \int_{0.5}^{2.5} \frac{dy}{y} = -\frac{3\mu_0 i}{2\pi} (\ln 2.5 - \ln 0.5) = -\frac{3\mu_0 i}{2\pi} \ln \frac{2.5}{0.5} \\ &= \frac{-3 \cdot 4\pi \cdot 10^{-7} \ln 5}{2\pi} t(12 - t) = -9.65 \times 10^{-7} t(12 - t) \text{ T/m}^2\end{aligned}$$

We now use Faraday's Law to determine the voltage drop around the boundary $\mathcal{C}$ of the rectangle. By Faraday's Law, the voltage drop around $\mathcal{C}$, when $\mathcal{C}$ is oriented according to the orientation of $\mathcal{R}$ and the Right Hand Rule (that is, counterclockwise) is,

$$\int_{\mathcal{C}} \mathbf{E} \cdot d\mathbf{S} = -\frac{d\Phi}{dt} = -\frac{d}{dt}\left(-9.65 \cdot 10^{-7} t(12 - t)\right) = 9.65 \cdot 10^{-7} \cdot 2(6 - t) = 1.93 \cdot 10^{-6}(6 - t) \text{ volts}$$



29. Assume that $i = 10e^{-0.1t}$ A (t in seconds). Calculate the flux $\Phi(t)$, at time t, of $\mathbf{B}$ through the isosceles triangle of base 12 cm and height 6 cm whose bottom edge is 3 cm from the wire, as in Figure 17. Assume the triangle is oriented with normal vector pointing out of the page. Use Faraday's Law to determine the voltage drop around the triangular loop (the boundary of the triangle) at time t.

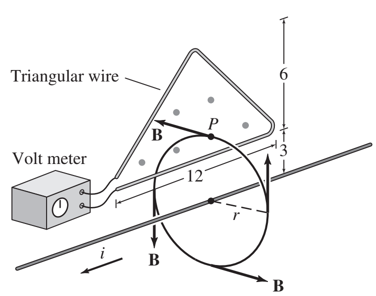


FIGURE 17

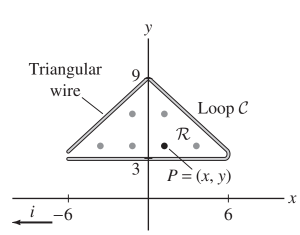
SOLUTION The magnetic field is $\mathbf{B} = \frac{-\mu_0 i}{2\pi r}\mathbf{k}$ and the unit normal on the triangle points out of the page, hence $\mathbf{n} = \mathbf{e_n} = \mathbf{k}$.

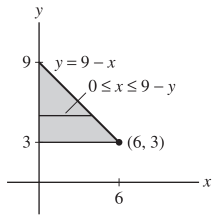


Also, the distance from a point $P = (x, y)$ in $\mathcal{R}$ to the wire is $r = y$. Hence:

$$\mathbf{B} \cdot \mathbf{n} = \frac{-\mu_0 i}{2\pi y}\mathbf{k} \cdot \mathbf{k} = \frac{-\mu_0 i}{2\pi y}$$

The flux $\Phi(t)$ of $\mathbf{B}$ through $\mathcal{R}$ is the following integral:

$$\Phi(t) = \iint_{\mathcal{R}} \mathbf{B} \cdot \mathbf{n}\, dx\, dy = \frac{-\mu_0 i}{2\pi} \iint_{\mathcal{R}} \frac{1}{y}\, dx\, dy$$



Using symmetry we have:

$$\Phi(t) = \frac{-\mu_0 i}{\pi} \int_3^9 \int_0^{9-y} \frac{1}{y}\, dx\, dy = \frac{-\mu_0 i}{\pi} \int_3^9 \left.\frac{x}{y}\right|_{x=0}^{9-y} dy = \frac{-\mu_0 i}{\pi} \int_3^9 \frac{9-y}{y}\, dy$$

$$= \frac{-\mu_0 i}{\pi} \int_3^9 \left(\frac{9}{y} - 1\right) dy = \frac{-\mu_0 i}{\pi} \left(9 \ln y - y\Big|_{y=3}^{9}\right) = \frac{-\mu_0 i}{\pi} \left((9 \ln 9 - 9) - (9 \ln 3 - 3)\right)$$

$$= \frac{-\mu_0 i}{\pi}(9 \ln 3 - 6) = \frac{-4\pi \cdot 10^{-7}}{\pi}(9 \ln 3 - 6) i = -1.56 \cdot 10^{-6} i = -1.56 \cdot 10^{-5} \cdot e^{-0.1t}$$

Using Faraday's Law, the voltage drop around the triangular loop $\mathcal{C}$ (oriented counterclockwise):

$$\int_{\mathcal{C}} \mathbf{E} \cdot d\mathbf{S} = -\frac{d\phi}{dt} = -\frac{d}{dt}\left(-1.56 \cdot 10^{-5} \cdot e^{-0.1t}\right) = -1.56 \cdot 10^{-6} \cdot e^{-0.1t} \text{ Volts}$$

Further Insights and Challenges

30. A point mass m is located at the origin. Let Q be the flux of the gravitational field $\mathbf{F} = -Gm\dfrac{\mathbf{e}_r}{r^2}$ through the cylinder $x^2 + y^2 = R^2$ for $a \le z \le b$, including the top and bottom (Figure 18). Show that $Q = -4\pi Gm$ if $a < 0 < b$ (m lies inside the cylinder) and $Q = 0$ if $0 < a < b$ (m lies outside the cylinder).

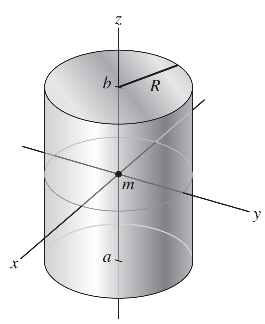


FIGURE 18

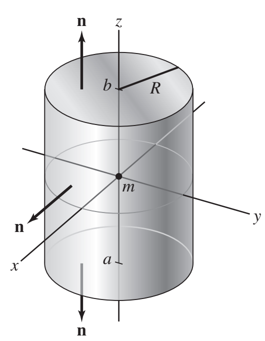
SOLUTION Let the surface be oriented with normal vector pointing outward.



We denote by S_1, S_2 and S_3 the cylinder, the top and the bottom respectively. These surfaces are parametrized by:

- S_1:

$$\Phi_1(\theta, z) = (R\cos\theta, R\sin\theta, z),\ 0 \le \theta < 2\pi,\ a \le z \le b,\ \mathbf{n} = R\langle\cos\theta, \sin\theta, 0\rangle$$

- S_2:

$$\Phi_2(\theta, r) = (r\cos\theta, r\sin\theta, b),\ 0 \le \theta < 2\pi,\ 0 \le r \le R,\ \mathbf{n} = \langle 0, 0, r\rangle$$

- S_3:

$$\Phi_3(\theta, r) = (r\cos\theta, r\sin\theta, a),\ 0 \le \theta < 2\pi,\ 0 \le r \le R,\ \mathbf{n} = \langle 0, 0, -r\rangle$$

Using properties of integrals we have,

$$Q = \iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_{S_1} \mathbf{F}\cdot d\mathbf{S} + \iint_{S_2} \mathbf{F}\cdot d\mathbf{S} + \iint_{S_3} \mathbf{F}\cdot d\mathbf{S} \tag{1}$$

Let us assume that $a < 0$. We compute the integrals over each part of the surface S separately.

- S_1: On S_1, we have:

$$\mathbf{F}(\Phi_1(\theta, z)) = -Gm\frac{\mathbf{e}_r}{r^2} = -\frac{Gm}{\left(R^2+z^2\right)^{3/2}}\langle R\cos\theta, R\sin\theta, z\rangle$$

Hence,

$$\mathbf{F}(\Phi_1(\theta, z))\cdot\mathbf{n}(\theta, z) = -\frac{Gm}{\left(R^2+z^2\right)^{3/2}}\langle R\cos\theta, R\sin\theta, z\rangle\cdot R\langle\cos\theta, \sin\theta, 0\rangle = -\frac{GmR^2}{\left(R^2+z^2\right)^{3/2}}$$

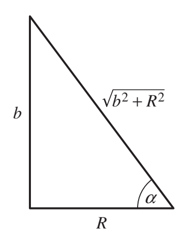
We obtain the following integral:

$$\iint_{S_1} \mathbf{F}\cdot d\mathbf{S} = \int_0^{2\pi}\int_a^b -\frac{GmR^2}{\left(R^2+z^2\right)^{3/2}}\,dz\,d\theta = -2\pi GmR^2\int_a^b \frac{dz}{\left(R^2+z^2\right)^{3/2}}$$

We compute the integral using the substitution $z = R\tan t$. This gives:

$$\iint_{S_1} \mathbf{F}\cdot d\mathbf{S} = -2\pi GmR^2\int_{\tan^{-1}\frac{a}{R}}^{\tan^{-1}\frac{b}{R}} \frac{\cos t}{R^2}\,dt = -2\pi Gm\sin t\Big|_{t=\tan^{-1}\frac{a}{R}}^{\tan^{-1}\frac{b}{R}}$$

$$= -2\pi Gm\left(\frac{b}{\sqrt{b^2+R^2}} - \frac{a}{\sqrt{a^2+R^2}}\right) \tag{2}$$



$\sin\left(\tan^{-1}\frac{b}{R}\right) = \frac{b}{\sqrt{b^2+R^2}}$

- S_2:

$$\mathbf{F}(\Phi_2(\theta, r)) = -Gm\frac{\mathbf{e}_r}{r^2} = -\frac{Gm}{\left(r^2+b^2\right)^{3/2}}\langle r\cos\theta, r\sin\theta, b\rangle$$

Hence,

$$\mathbf{F}(\Phi_2(\theta, r))\cdot\mathbf{n}(\theta, r) = -\frac{Gm}{\left(r^2+b^2\right)^{3/2}}\langle r\cos\theta, r\sin\theta, b\rangle\cdot\langle 0, 0, r\rangle = -\frac{Gmbr}{\left(r^2+b^2\right)^{3/2}}$$

We obtain the following integral:

$$\iint_{S_2} \mathbf{F}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^R -\frac{Gmbr}{\left(r^2+b^2\right)^{3/2}}\,dr\,d\theta = -2\pi Gmb\int_0^R \frac{r\,dr}{\left(r^2+b^2\right)^{3/2}}$$

We compute the integral using the substitution $t = r^2 + b^2$, $dt = 2r\,dr$, and we get:

$$\iint_{S_2} \mathbf{F} \cdot d\mathbf{S} = -\pi Gmb \int_{b^2}^{R^2+b^2} \frac{dt}{t^{3/2}} = 2\pi Gmb \frac{1}{\sqrt{t}}\bigg|_{t=b^2}^{R^2+b^2} = 2\pi Gmb \left(\frac{1}{\sqrt{b^2+R^2}} - \frac{1}{b} \right) \tag{3}$$

- S_3:

$$\mathbf{F}\left(\Phi_3(\theta, r)\right) = -Gm\frac{\mathbf{e}_r}{r^2} = -\frac{Gm}{\left(r^2+a^2\right)^{3/2}} \langle r\cos\theta, r\sin\theta, a\rangle$$

$$\mathbf{F}\left(\Phi_3(\theta, r)\right) \cdot \mathbf{n}(\theta, r) = -\frac{Gm}{\left(r^2+a^2\right)^{3/2}} \langle r\cos\theta, r\sin\theta, a\rangle \cdot \langle 0, 0, -r\rangle = \frac{Gmar}{\left(r^2+a^2\right)^{3/2}}$$

Hence, by the same computation as for S_2 we get (notice that since $a < 0$, we have $\sqrt{a^2} = -a$):

$$\iint_{S_3} \mathbf{F} \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^R \frac{Gmar}{\left(r^2+a^2\right)^{3/2}}\,dr\,d\theta = -2\pi Gma \frac{1}{\sqrt{t}}\bigg|_{t=a^2}^{R^2+a^2}$$

$$= -2\pi Gma \left(\frac{1}{\sqrt{R^2+a^2}} - \frac{1}{\sqrt{a^2}} \right) = -2\pi Gma \left(\frac{1}{\sqrt{R^2+a^2}} + \frac{1}{a} \right) \tag{4}$$

Substituting (2), (3), and (4) in (1) we get:

$$Q = -2\pi Gm \left(\frac{b}{\sqrt{b^2+R^2}} - \frac{a}{\sqrt{a^2+R^2}} \right) + 2\pi Gmb \left(\frac{1}{\sqrt{b^2+R^2}} - \frac{1}{b} \right) - 2\pi Gma \left(\frac{1}{\sqrt{R^2+a^2}} + \frac{1}{a} \right)$$
$$= -2\pi Gm - 2\pi Gm = -4\pi Gm$$

If $0 < a < b$ the only difference is in the integral in (4). In this case $\sqrt{a} = a$ therefore,

$$\iint_{S_3} \mathbf{F} \cdot d\mathbf{S} = -2\pi Gma \left(\frac{1}{\sqrt{R^2+a^2}} - \frac{1}{\sqrt{a^2}} \right) = -2\pi Gma \left(\frac{1}{\sqrt{R^2+a^2}} - \frac{1}{a} \right).$$

Therefore, adding the integrals gives:

$$Q = -2\pi Gm \left(\frac{b}{\sqrt{b^2+R^2}} - \frac{a}{\sqrt{a^2+R^2}} \right) + 2\pi Gmb \left(\frac{1}{\sqrt{b^2+R^2}} - \frac{1}{b} \right) - 2\pi Gma \left(\frac{1}{\sqrt{R^2+a^2}} - \frac{1}{a} \right)$$
$$= -2\pi Gm + 2\pi Gm = 0$$

In Exercises 31 and 32, let $\mathcal{S}$ be the surface with parametrization

$$G(u, v) = \left(\left(1 + v\cos\frac{u}{2}\right)\cos u, \left(1 + v\cos\frac{u}{2}\right)\sin u, v\sin\frac{u}{2} \right)$$

for $0 \le u \le 2\pi$, $-\frac{1}{2} \le v \le \frac{1}{2}$.

31. CAS Use a computer algebra system.

(a) Plot $\mathcal{S}$ and confirm visually that $\mathcal{S}$ is a Möbius strip.

(b) The intersection of $\mathcal{S}$ with the xy-plane is the unit circle $G(u, 0) = (\cos u, \sin u, 0)$. Verify that the normal vector along this circle is

$$\mathbf{n}(u, 0) = \left\langle \cos u \sin\frac{u}{2}, \sin u \sin\frac{u}{2}, -\cos\frac{u}{2} \right\rangle$$

(c) As u varies from 0 to 2π, the point $G(u, 0)$ moves once around the unit circle, beginning and ending at $G(0, 0) = G(2\pi, 0) = (1, 0, 0)$. Verify that $\mathbf{n}(u, 0)$ is a unit vector that varies continuously but that $\mathbf{n}(2\pi, 0) = -\mathbf{n}(0, 0)$. This shows that $\mathcal{S}$ is not orientable—that is, it is not possible to choose a nonzero normal vector at each point on $\mathcal{S}$ in a continuously varying manner (if it were possible, the unit normal vector would return to itself rather than to its negative when carried around the circle).

SOLUTION

(a) We use a computer algebra system to graph the plot of $\mathcal{S}$, and it is indeed a Möbius strip.

(b) To find the normal vector along the unit circle, we use our computer to first find the cross product $\frac{\partial \mathbf{n}}{\partial u} \times \frac{\partial \mathbf{n}}{\partial v}$ and simplify, we get the very ugly expression

$$\begin{aligned}\mathbf{n}(u, v) = \frac{\partial \mathbf{n}}{\partial u} \times \frac{\partial \mathbf{n}}{\partial v} = \Bigg\langle & \frac{1}{2}\left(-v\cos\left(\frac{u}{2}\right) + 2\cos u + v\cos\left(\frac{3u}{2}\right)\right)\sin\left(\frac{u}{2}\right), \\ & \frac{1}{4}\left(v + 2\cos\left(\frac{u}{2}\right) + 2v\cos(u) - 2\cos\left(\frac{3u}{2}\right) - v\cos(2u)\right), \\ & -\cos\left(\frac{u}{2}\right)\left(1 + v\cos\left(\frac{u}{2}\right)\right)\Bigg\rangle\end{aligned}$$

(Different computer algebra systems may produce different simplifications.) When we replace v with 0 and simplify, we find that:

$$\mathbf{n}(u, 0) = \left\langle \cos u \sin\frac{u}{2}, \frac{1}{2}\left(\cos\frac{u}{2} - \cos\frac{3u}{2}\right), -\cos\frac{u}{2}\right\rangle$$

This is almost, but not quite, what we want. Let's examine that middle term a bit more.

$$\begin{aligned}\frac{1}{2}\left(\cos\frac{u}{2} - \cos\frac{3u}{2}\right) &= \frac{1}{2}\left(\cos\frac{u}{2} - (\cos u \cos\frac{u}{2} - \sin u \sin\frac{u}{2})\right) = \frac{1}{2}\left(\cos\frac{u}{2}(1 - \cos u) + \sin u \sin\frac{u}{2}\right) \\ &= \frac{1}{2}\left(\cos\frac{u}{2}\cdot 2\sin^2\frac{u}{2} + \sin u \sin\frac{u}{2}\right) = \frac{1}{2}\sin\frac{u}{2}\left(2\sin\frac{u}{2}\cos\frac{u}{2} + \sin u\right) \\ &= \frac{1}{2}\sin\frac{u}{2}(\sin u + \sin u) = \sin u \sin\frac{u}{2}\end{aligned}$$

which is what we expect. Thus, we see that

$$\mathbf{n}(u, 0) = \left\langle \cos u \sin\frac{u}{2}, \sin u \sin\frac{u}{2}, -\cos\frac{u}{2}\right\rangle$$

(c) To verify that $\mathbf{n}(u, 0)$ is a unit vector, we note that

$$\begin{aligned}\|\mathbf{n}(u, 0)\| &= \sqrt{\left(\cos u \sin\frac{u}{2}\right)^2 + \left(\sin u \sin\frac{u}{2}\right)^2 + \left(\cos\frac{u}{2}\right)^2} \\ &= \sqrt{\cos^2 u \sin^2\frac{u}{2} + \sin^2 u \sin^2\frac{u}{2} + \cos^2\frac{u}{2}} = \sqrt{\sin^2\frac{u}{2} + \cos^2\frac{u}{2}} = \sqrt{1} = 1\end{aligned}$$

It is clear that $\mathbf{n}(u, 0)$ varies continuously with u, as each of its three components are non-constant continuous functions of u. Finally, we note that $\mathbf{n}(0, 0) = \langle 0, 0, -1\rangle$ but $\mathbf{n}(2\pi, 0) = \langle 0, 0, 1\rangle$, so indeed $\mathbf{n}(2\pi, 0) = -\mathbf{n}(0, 0)$.

32. CAS We cannot integrate vector fields over $\mathcal{S}$ because $\mathcal{S}$ is not orientable, but it is possible to integrate functions over $\mathcal{S}$. Using a computer algebra system:

(a) Verify that

$$\|\mathbf{n}(u, v)\|^2 = 1 + \frac{3}{4}v^2 + 2v\cos\frac{u}{2} + \frac{1}{2}v^2\cos u$$

(b) Compute the surface area of $\mathcal{S}$ to four decimal places.

(c) Compute $\iint_{\mathcal{S}} (x^2 + y^2 + z^2)\, dS$ to four decimal places.

SOLUTION

(a) Using a CAS, we discover that

$$\begin{aligned}\mathbf{n}(u, v) = \frac{\partial \mathbf{n}}{\partial u} \times \frac{\partial \mathbf{n}}{\partial v} = \Bigg\langle & \frac{1}{2}\left(-v\cos\left(\frac{u}{2}\right) + 2\cos u + v\cos\left(\frac{3u}{2}\right)\right)\sin\left(\frac{u}{2}\right), \\ & \frac{1}{4}\left(v + 2\cos(u/2) + 2v\cos(u) - 2\cos\left(\frac{3u}{2}\right) - v\cos(2u)\right), \\ & -\cos\left(\frac{u}{2}\right)\left(1 + v\cos\left(\frac{u}{2}\right)\right)\Bigg\rangle\end{aligned}$$

and after taking the norm of this, we find that

$$\|\mathbf{n}(u, v)\|^2 = 1 + \frac{3}{4}v^2 + 2v\cos\frac{u}{2} + \frac{1}{2}v^2\cos u$$

(b) We calculate the area of $\mathcal{S}$ as follows:

$$A(\mathcal{S}) = \int\int \|\mathbf{n}(u, v)\|\, du\, dv = \int_{-1/2}^{1/2}\int_0^{2\pi} \sqrt{1 + \frac{3}{4}v^2 + 2v\cos\frac{u}{2} + \frac{1}{2}v^2\cos u}\, du\, dv \approx 6.3533$$

(c) We proceed as follows. Since

$$x^2 + y^2 + z^2 = \left(\left(1 + v\cos\frac{u}{2}\right)\cos u\right)^2 + \left(\left(1 + v\cos\frac{u}{2}\right)\sin u\right)^2 + \left(v\sin\frac{u}{2}\right)^2$$

and

$$\|\mathbf{n}(u, v)\| = \sqrt{1 + \frac{3}{4}v^2 + 2v\cos\frac{u}{2} + \frac{1}{2}v^2\cos u}$$

then, substituting these expressions into the double integral $\iint_{\mathcal{S}}(x^2 + y^2 + z^2)\, dS = \iint_{\mathcal{S}}(x^2 + y^2 + z^2)\|\mathbf{n}(u, v)\|\, du\, dv$, and integrating over $0 \le u \le 2\pi$, $-\frac{1}{2} \le v \le \frac{1}{2}$, we find that

$$\iint_{\mathcal{S}}(x^2 + y^2 + z^2)\, dS \approx 7.4003$$

CHAPTER REVIEW EXERCISES

1. Compute the vector assigned to the point $P = (-3, 5)$ by the vector field:

(a) $\mathbf{F} = \langle xy, y - x\rangle$

(b) $\mathbf{F} = \langle 4, 8\rangle$

(c) $\mathbf{F} = \left\langle 3^{x+y}, \log_2(x + y)\right\rangle$

SOLUTION

(a) Substituting $x = -3$, $y = 5$ in $\mathbf{F} = \langle xy, y - x\rangle$ we obtain:

$$\mathbf{F} = \langle -3\cdot 5, 5 - (-3)\rangle = \langle -15, 8\rangle$$

(b) The constant vector field $\mathbf{F} = \langle 4, 8\rangle$ assigns the vector $\langle 4, 8\rangle$ to all the vectors. Thus:

$$\mathbf{F}(-3, 5) = \langle 4, 8\rangle$$

(c) Substituting $x = -3$, $y = 5$ in $\mathbf{F} = \left\langle 3^{x+y}, \log_2(x + y)\right\rangle$ we obtain

$$\mathbf{F} = \left\langle 3^{-3+5}, \log_2(-3 + 5)\right\rangle = \left\langle 3^2, \log_2(2)\right\rangle = \langle 9, 1\rangle$$

2. Find a vector field $\mathbf{F}$ in the plane such that $\|\mathbf{F}(x, y)\| = 1$ and $\mathbf{F}(x, y)$ is orthogonal to $\mathbf{G}(x, y) = \langle x, y\rangle$ for all x, y.

SOLUTION The vector field $\langle y, -x\rangle$ is orthogonal to $\mathbf{G}(x, y) = \langle x, y\rangle$ since the dot product of the two vectors is zero.

$$\langle y, -x\rangle \cdot \langle x, y\rangle = yx - xy = 0$$

We now normalize the vector $\langle y, -x\rangle$ to obtain a unit vector orthogonal to $\mathbf{G}$:

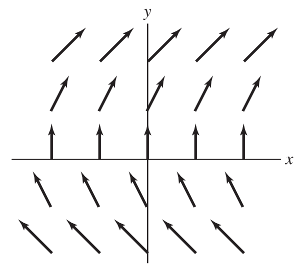
$$\mathbf{F}(x, y) = \frac{\langle y, -x\rangle}{\|\langle y, -x\rangle\|} = \frac{\langle y, -x\rangle}{\sqrt{y^2 + (-x)^2}} = \left\langle \frac{y}{\sqrt{x^2 + y^2}}, \frac{-x}{\sqrt{x^2 + y^2}}\right\rangle$$

However, this is only for $(x, y) \neq (0, 0)$! We can assign any unit vector for $\mathbf{F}(0, 0)$, as since $\mathbf{G}(0, 0) = \langle 0, 0\rangle$, then anything is perpendicular to $\mathbf{G}(0, 0)$. So, let's define $\mathbf{F}$ to be as above for $(x, y) \neq (0, 0)$, and let's define $\mathbf{F}(0, 0)$ to be, say, $\langle 1, 0\rangle$. Now we have a vector field $\mathbf{F}$ such that $\mathbf{F}(x, y)$ is always a unit vector and always perpendicular to $\mathbf{G}(x, y)$.

In Exercises 3–6, sketch the vector field.

3. $\mathbf{F}(x, y) = \langle y, 1\rangle$

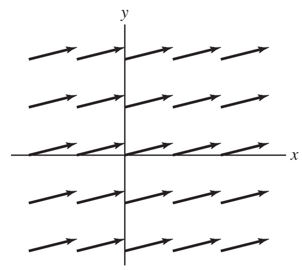
SOLUTION Notice that the vector field is constant along horizontal lines.



$\mathbf{F} = \langle y, 1\rangle$

4. $\mathbf{F}(x, y) = \langle 4, 1\rangle$

SOLUTION $\mathbf{F}$ is the constant field $\langle 4, 1\rangle$ shown in the figure.



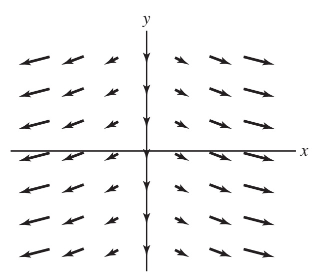
$\mathbf{F} = \langle 4, 1\rangle$

5. ∇V, where $V(x, y) = x^2 - y$

SOLUTION The gradient of $V(x, y) = x^2 - y$ is the following vector:

$$\mathbf{F}(x, y) = \left\langle \frac{\partial V}{\partial x}, \frac{\partial V}{\partial y} \right\rangle = \langle 2x, -1\rangle$$

This vector is sketched in the following figure:



$\nabla\varphi = \langle 2x, -1\rangle$

6. $\mathbf{F}(x, y) = \left\langle \dfrac{4y}{\sqrt{x^2 + 4y^2}}, \dfrac{-x}{\sqrt{x^2 + 16y^2}} \right\rangle$

Hint: Show that $\mathbf{F}$ is a unit vector field tangent to the family of ellipses $x^2 + 4y^2 = c^2$.

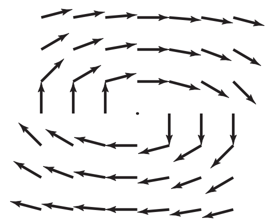
SOLUTION First, $\mathbf{F}$ is a unit vector since:

$$\|\mathbf{F}(x, y)\|^2 = \left(\frac{4y}{\sqrt{x^2 + 16y^2}}\right)^2 + \left(\frac{-x}{\sqrt{x^2 + 16y^2}}\right)^2 = \frac{16y^2}{x^2 + 16y^2} + \frac{x^2}{x^2 + 16y^2}$$
$$= \frac{16y^2 + x^2}{x^2 + 16y^2} = 1 \quad \Rightarrow \quad \|\mathbf{F}(x, y)\| = 1$$

Next, we show that $\mathbf{F}$ is tangent to the ellipses $x^2 + 4y^2 = c^2$. We find $\frac{dy}{dx}$ using implicit differentiation of $x^2 + 4y^2 = c^2$:

$$2x + 8y\frac{dy}{dx} = 0 \quad \Rightarrow \quad \frac{dy}{dx} = -\frac{x}{4y}$$

Therefore the vector $\langle 4y, -x\rangle$ is tangent to the ellipses. Since $\mathbf{F}(x, y)$ is a scalar multiple of this vector, i.e, $\mathbf{F}(x, y) = \frac{1}{\sqrt{x^2+16y^2}} \langle 4y, -x\rangle$, $\mathbf{F}$ is parallel to $\langle 4y, -x\rangle$ hence $\mathbf{F}$ is tangent to the ellipses $x^2 + 4y^2 = c^2$. We find that $\mathbf{F}$ can be sketched by first sketching ellipses in the family $x^2 + 4y^2 = c^2$, and then sketching the unit tangents at points on the ellipses. The field $\mathbf{F}(x, y)$ is shown in the figure:



In Exercises 7–15, determine whether the vector field is conservative, and if so, find a potential function.

7. $\mathbf{F}(x, y) = \langle x^2 y, y^2 x \rangle$

SOLUTION If $\mathbf{F}$ is conservative, the cross partials must be equal. We compute the cross partials:

$$\frac{\partial F_1}{\partial y} = \frac{\partial}{\partial y}\left(x^2 y\right) = x^2$$
$$\frac{\partial F_2}{\partial x} = \frac{\partial}{\partial x}\left(y^2 x\right) = y^2$$

Since the cross-partials are not equal, $\mathbf{F}$ is not conservative.

8. $\mathbf{F}(x, y) = \langle 4x^3 y^5, 5x^4 y^4 \rangle$

SOLUTION

$$\frac{\partial F_1}{\partial y} = \frac{\partial}{\partial y}\left(4x^3 y^5\right) = 20x^3 y^4$$
$$\frac{\partial F_2}{\partial x} = \frac{\partial}{\partial x}\left(5x^4 y^4\right) = 20x^3 y^4$$

Since the cross partials are equal F is conservative.

$$F_1 = \frac{\partial V}{\partial x} = 4x^3 y^5$$
$$\Rightarrow \quad V = \int 4x^3 y^5 \, dx = x^4 y^5 + h(y)$$
$$F_2 = \frac{\partial}{\partial y}(x^4 y^5 + h(y)) = 5x^4 y^4 + h'(y) = 5x^4 y^4$$
$$\Rightarrow \quad h'(y) = 0 \Rightarrow h(y) = c$$

We may choose the constant $c = 0$, giving us the potential function,

$$V(x, y) = x^4 y^5$$

9. $\mathbf{F}(x, y, z) = \langle \sin x, e^y, z \rangle$

SOLUTION We examine the cross partials of $\mathbf{F}$. Since $\mathbf{F}_1 = \sin x$, $\mathbf{F}_2 = e^y$, $\mathbf{F}_3 = z$ we have:

$$\begin{array}{lll} \dfrac{\partial \mathbf{F}_1}{\partial y} = 0 & \dfrac{\partial \mathbf{F}_2}{\partial z} = 0 & \dfrac{\partial \mathbf{F}_3}{\partial x} = 0 \\ \dfrac{\partial \mathbf{F}_2}{\partial x} = 0 & \dfrac{\partial \mathbf{F}_3}{\partial y} = 0 & \dfrac{\partial \mathbf{F}_1}{\partial z} = 0 \end{array} \quad \Rightarrow \quad \frac{\partial \mathbf{F}_1}{\partial y} = \frac{\partial \mathbf{F}_2}{\partial x}, \quad \frac{\partial \mathbf{F}_2}{\partial z} = \frac{\partial \mathbf{F}_3}{\partial y}, \quad \frac{\partial \mathbf{F}_3}{\partial x} = \frac{\partial \mathbf{F}_1}{\partial z}$$

Since the cross partials are equal, $\mathbf{F}$ is conservative. We denote the potential field by $V(x, y, z)$. So we have:

$$V_x = \sin x \quad V_y = e^y \quad V_z = z$$

By integrating we get:

$$V(x, y, z) = \int \sin x \, dx = -\cos x + C(y, z)$$
$$V_y = C_y = e^y \quad \Rightarrow \quad C(y, z) = e^y + D(z)$$
$$V(x, y, z) = -\cos x + e^y + D(z)$$
$$V_z = D_z = z \quad \Rightarrow \quad D(z) = \frac{z^2}{2}$$

We conclude that $V(x, y, z) = -\cos x + e^y + \frac{z^2}{2}$. Indeed:

$$\nabla V = \left\langle \frac{\partial V}{\partial x}, \frac{\partial V}{\partial y}, \frac{\partial V}{\partial z} \right\rangle = \langle \sin x, e^y, z \rangle = \mathbf{F}$$

10. $\mathbf{F}(x, y, z) = \langle 2, 4, e^z \rangle$

SOLUTION We examine the cross partials of $\mathbf{F}$. We have, $\mathbf{F}_1 = 2, \mathbf{F}_2 = 4, \mathbf{F}_3 = e^z$ hence:

$$\left.\begin{array}{l} \frac{\partial \mathbf{F}_1}{\partial y} = 0 \\ \frac{\partial \mathbf{F}_2}{\partial x} = 0 \end{array}\right. \quad \Rightarrow \quad \frac{\partial \mathbf{F}_1}{\partial y} = \frac{\partial \mathbf{F}_2}{\partial x}$$

$$\left.\begin{array}{l} \frac{\partial \mathbf{F}_2}{\partial z} = 0 \\ \frac{\partial \mathbf{F}_3}{\partial y} = 0 \end{array}\right. \quad \Rightarrow \quad \frac{\partial \mathbf{F}_2}{\partial z} = \frac{\partial \mathbf{F}_3}{\partial y}$$

$$\left.\begin{array}{l} \frac{\partial \mathbf{F}_3}{\partial x} = 0 \\ \frac{\partial \mathbf{F}_1}{\partial z} = 0 \end{array}\right. \quad \Rightarrow \quad \frac{\partial \mathbf{F}_3}{\partial x} = \frac{\partial \mathbf{F}_1}{\partial z}$$

Since the cross-partials are equal, $\mathbf{F}$ is conservative. We denote the potential field by $V(x, y, z)$. We have:

$$V_x = 2 \quad V_y = 4 \quad V_z = e^z$$

By integrating we get:

$$\begin{aligned} V(x, y, z) &= \int 2\, dx = 2x + C(y, z) \\ V_y = C_y &= 4 \quad \Rightarrow \quad C(y, z) = 4y + D(z) \\ V(x, y, z) &= 2x + 4y + D(z) \\ V_z = D_z &= e^z \quad \Rightarrow \quad D = e^z \end{aligned}$$

We conclude that $V(x, y, z) = 2x + 4y + e^z$. We verify:

$$\nabla V = \left\langle \frac{\partial V}{\partial x}, \frac{\partial V}{\partial y}, \frac{\partial V}{\partial z} \right\rangle = \langle 2, 4, e^z \rangle = \mathbf{F}$$

11. $\mathbf{F}(x, y, z) = \langle xyz, \frac{1}{2}x^2 z, 2z^2 y \rangle$

SOLUTION No. We show that the cross partials for x and z are not equal. Since the equality of the cross partials is a necessary condition for a field to be a gradient vector field, we conclude that $\mathbf{F}$ is not a gradient field. We have:

$$\left.\begin{array}{l} \frac{\partial F_1}{\partial z} = \frac{\partial}{\partial z}(xyz) = xy \\ \frac{\partial F_3}{\partial x} = \frac{\partial}{\partial x}(2z^2 y) = 0 \end{array}\right. \quad \Rightarrow \quad \frac{\partial F_1}{\partial z} \neq \frac{\partial F_3}{\partial x}$$

Therefore the cross partials condition is not satisfied, hence $\mathbf{F}$ is not a gradient vector field.

12. $\mathbf{F}(x, y) = \langle y^4 x^3, x^4 y^3 \rangle$

SOLUTION YES. We examine the cross-partials of $\mathbf{F}$:

$$\begin{aligned} \frac{\partial F_1}{\partial y} &= \frac{\partial}{\partial y}\left(y^4 x^3\right) = 4y^3 x^3 \\ \frac{\partial F_2}{\partial x} &= \frac{\partial}{\partial x}\left(y^4 x^3\right) = 4y^3 x^3 \end{aligned}$$

Since the cross-partials are equal, $\mathbf{F}$ is conservative. We compute the potential function $V(x, y)$ of $\mathbf{F}$.

Step 1. Use the condition $\frac{\partial V}{\partial x} = F_1$. Since V is an antiderivative of $F_1 = y^4 x^3$ when y is fixed, we have:

$$V(x, y) = \int y^4 x^3\, dx = y^4 \cdot \frac{x^4}{4} + g(y) \tag{1}$$

Step 2. Use the condition $\frac{\partial V}{\partial y} = F_2$. Differentiating V with respect to y gives:

$$4y^3 \cdot \frac{x^4}{4} + g'(y) = F_2 = x^4y^4$$
$$y^3x^4 + g'(y) = x^4y^3$$
$$g'(y) = 0 \quad \Rightarrow \quad g(y) = c$$

Substituting in (1) gives:

$$V(x, y) = \frac{1}{4}x^4y^4 + c$$

Choosing $c = 0$, we obtain one of the potential functions, which is $V(x, y) = \frac{1}{4}x^4y^4$.

13. $\mathbf{F}(x, y, z) = \left\langle \frac{y}{1+x^2}, \tan^{-1} x, 2z \right\rangle$

SOLUTION We examine the cross partials of $\mathbf{F}$. Since $\mathbf{F}_1 = \frac{y}{1+x^2}$, $\mathbf{F}_2 = \tan^{-1} x$, $\mathbf{F}_3 = 2z$ we have:

$$\left.\begin{aligned} \frac{\partial \mathbf{F}_1}{\partial y} &= \frac{1}{1+x^2} \\ \frac{\partial \mathbf{F}_2}{\partial x} &= \frac{1}{1+x^2} \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial \mathbf{F}_1}{\partial y} = \frac{\partial \mathbf{F}_2}{\partial x}$$

$$\left.\begin{aligned} \frac{\partial \mathbf{F}_2}{\partial z} &= 0 \\ \frac{\partial \mathbf{F}_3}{\partial y} &= 0 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial \mathbf{F}_2}{\partial z} = \frac{\partial \mathbf{F}_3}{\partial y}$$

$$\left.\begin{aligned} \frac{\partial \mathbf{F}_3}{\partial x} &= 0 \\ \frac{\partial \mathbf{F}_1}{\partial z} &= 0 \end{aligned}\right. \quad \Rightarrow \quad \frac{\partial \mathbf{F}_3}{\partial x} = \frac{\partial \mathbf{F}_1}{\partial z}$$

Since the cross partials are equal, $\mathbf{F}$ is conservative. We denote the potential function by $V(x, y, z)$. We have:

$$V_x = \frac{y}{1+x^2}, \quad V_y = \tan^{-1}(x), \quad V_z = 2z$$

By integrating we get:

$$V(x, y, z) = \int \frac{y}{1+x^2}\, dx = y \tan^{-1}(x) + c(y, z)$$
$$V_y = \tan^{-1}(x) + c_y(y, z) = \tan^{-1}(x) \quad \Rightarrow \quad c_y(y, z) = 0 \quad \Rightarrow \quad c(y, z) = c(z)$$

Hence $V(x, y, z) = y \tan^{-1}(x) + c(z)$. $V_z = c'(z) = 2z \Rightarrow c(z) = z^2$. We conclude that $V(x, y, z) = y \tan^{-1}(x) + z^2$. Indeed:

$$\nabla V = \left\langle \frac{\partial V}{\partial x}, \frac{\partial V}{\partial y}, \frac{\partial V}{\partial z} \right\rangle = \left\langle \frac{y}{1+x^2}, \tan^{-1} x, 2z \right\rangle = \mathbf{F}$$

14. $\mathbf{F}(x, y, z) = \left\langle \frac{2xy}{x^2+z}, \ln(x^2+z), \frac{y}{x^2+z} \right\rangle$

SOLUTION

$$\frac{\partial F_1}{\partial y} = \frac{\partial}{\partial y}\left(\frac{2xy}{x^2+z}\right) = \frac{2x}{x^2+z}$$
$$\frac{\partial F_2}{\partial x} = \frac{\partial}{\partial x}\left(\ln(x^2+z)\right) = \frac{2x}{x^2+z}$$
$$\frac{\partial F_1}{\partial z} = \frac{\partial}{\partial z}\left(\frac{2xy}{x^2+z}\right) = \frac{-2xy}{(x^2+z)^2}$$
$$\frac{\partial F_3}{\partial x} = \frac{\partial}{\partial x}\left(\frac{y}{x^2+z}\right) = \frac{-2xy}{(x^2+z)^2}$$
$$\frac{\partial F_3}{\partial y} = \frac{\partial}{\partial y}\left(\frac{y}{x^2+z}\right) = \frac{1}{x^2+z}$$
$$\frac{\partial F_2}{\partial z} = \frac{\partial}{\partial z}\left(\ln(x^2+z)\right) = \frac{1}{x^2+z}$$

Since the cross partials are equal F is conservative.

$$F_1 = \frac{\partial V}{\partial x} = \frac{2xy}{x^2+z}$$
$$\Rightarrow \quad V = \int \frac{2xy}{x^2+z}\,dx = y\ln(x^2+z) + g(y,z)$$
$$F_2 = \frac{\partial}{\partial y}(y\ln(x^2+z) + g(y,z)) = \ln(x^2+z) + g_y(y,z) = \ln(x^2+z)$$
$$\Rightarrow \quad g_y(y,z) = 0 \quad \Rightarrow \quad g(y,z) = h(z)$$
$$F_3 = \frac{\partial}{\partial z}(y\ln(x^2+z) + h(z)) = \frac{y}{x^2+z} + h'(z) = \frac{y}{x^2+z}$$
$$\Rightarrow \quad h(z) = 0 \quad \Rightarrow \quad h(y) = c$$

We may choose the constant $c = 0$, giving us the potential function,

$$V(x,y) = y\ln(x^2+z)$$

15. $\mathbf{F}(x,y,z) = \left\langle xe^{2x}, ye^{2z}, ze^{2y}\right\rangle$

SOLUTION We have:

$$\frac{\partial F_3}{\partial y} = \frac{\partial}{\partial y}\left(ze^{2y}\right) = 2ze^{2y}$$
$$\frac{\partial F_2}{\partial z} = \frac{\partial}{\partial z}\left(ye^{2z}\right) = 2ye^{2y}$$

Since $\frac{\partial F_3}{\partial y} \neq \frac{\partial F_2}{\partial z}$, the cross-partials condition is not satisfied , hence $\mathbf{F}$ is not conservative.

16. Find a conservative vector field of the form $\mathbf{F} = \langle g(y), h(x)\rangle$ such that $\mathbf{F}(0,0) = \langle 1, 1\rangle$, where $g(y)$ and $h(x)$ are differentiable functions. Determine all such vector fields.

SOLUTION We need to find a scalar function $V(x,y)$ such that $\mathbf{F} = \nabla V$. That is:

$$\frac{\partial V}{\partial x} = g(y) \tag{1}$$
$$\frac{\partial V}{\partial y} = h(x) \tag{2}$$

Integrating (1) with respect to x, treating y as a constant, we get:

$$V(x,y) = xg(y) + f(y) \tag{3}$$

We differentiate $V(x,y)$ with respect to y and equate with (2). This gives:

$$\frac{\partial V}{\partial y} = xg'(y) + f'(y) = h(x)$$

This equation can hold only when $g'(y)$ and $f'(y)$ are constants. That is, $g'(y) = c_1$ and $f'(y) = c_2$, yielding $g(y) = c_1 y + d_1$ and $f(y) = c_2 y + d_2$. Substituting in (3) gives:

$$V(x,y) = x(c_1 y + d_1) + c_2 y + d_2$$

Or

$$V(x,y) = d_1 x + c_2 y + c_1 xy + d_2 \quad \Rightarrow \quad \nabla V = \langle d_1 + c_1 y, c_2 + c_1 x\rangle$$

We conclude that $\mathbf{F} = \langle g(y), h(x)\rangle$ are gradient vector fields if and only if $g(y) = a + by$ and $h(x) = c + bx$ for any constants a, b, c. That is:

$$\mathbf{F} = \langle a + by, c + bx\rangle$$

We also want that $\mathbf{F}(0,0) = \langle 1, 1\rangle$, hence:

$$\mathbf{F}(0,0) = \langle a, c\rangle = \langle 1, 1\rangle \quad \Rightarrow \quad a = c = 1$$

Therefore, all the gradient fields of the form $\mathbf{F} = \langle g(y), h(x)\rangle$ such that $\mathbf{F}(0,0) = \langle 1, 1\rangle$ are:

$$\mathbf{F} = \langle 1 + by, 1 + bx\rangle$$

In Exercises 17–20, compute the line integral $\int_{\mathcal{C}} f(x, y)\, ds$ *for the given function and path or curve.*

17. $f(x, y) = xy$, the path $\mathbf{c}(t) = (t, 2t - 1)$ for $0 \le t \le 1$

SOLUTION

Step 1. Compute $ds = \|\mathbf{c}'(t)\|\, dt$. We differentiate $\mathbf{c}(t) = (t, 2t - 1)$ and compute the length of the derivative vector:

$$\mathbf{c}'(t) = \langle 1, 2\rangle \quad \Rightarrow \quad \|\mathbf{c}'(t)\| = \sqrt{1^2 + 2^2} = \sqrt{5}$$

Hence,

$$ds = \|\mathbf{c}'(t)\|\, dt = \sqrt{5}\, dt$$

Step 2. Write out $f(\mathbf{c}(t))$ and evaluate the line integral. We have:

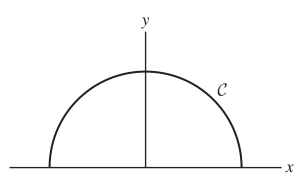
$$f(\mathbf{c}(t)) = xy = t(2t - 1) = 2t^2 - t$$

Using the Theorem on Scalar Line Integral we have:

$$\int_{\mathcal{C}} f(x, y)\, ds = \int_0^1 f(\mathbf{c}(t))\, \|\mathbf{c}'(t)\|\, dt = \int_0^1 \left(2t^2 - t\right)\sqrt{5}\, dt = \sqrt{5}\left(\frac{2}{3}t^3 - \frac{1}{2}t^2\right)\bigg|_0^1 = \sqrt{5}\left(\frac{2}{3} - \frac{1}{2}\right) = \frac{\sqrt{5}}{6}$$

18. $f(x, y) = x - y$, the unit semicircle $x^2 + y^2 = 1$, $y \ge 0$

SOLUTION



The semi unit circle above the x-axis is parametrized by:

$$c(\theta) = (\cos\theta, \sin\theta),\ 0 \le \theta \le \pi$$

Step 1. Compute $ds = \|\mathbf{c}'(\theta)\|\, d\theta$. We have:

$$\mathbf{c}'(\theta) = \frac{d}{d\theta}\langle\cos\theta, \sin\theta\rangle = \langle -\sin\theta, \cos\theta\rangle$$

$$\|\mathbf{c}'(\theta)\| = \sqrt{(-\sin\theta)^2 + \cos^2\theta} = 1$$

Hence:

$$ds = \|\mathbf{c}'(\theta)\|\, d\theta = d\theta$$

Step 2. Write out $f(\mathbf{c}(\theta))$ and evaluate the integral.

$$f(\mathbf{c}(\theta)) = x - y = \cos\theta - \sin\theta$$

We use the Theorem on Scalar Line Integrals to obtain:

$$\int_{\mathcal{C}} f(x, y)\, ds = \int_0^{\pi} f(\mathbf{c}(\theta))\, \|\mathbf{c}'(\theta)\|\, dt = \int_0^{\pi} (\cos\theta - \sin\theta)\, d\theta$$

$$= \sin\theta + \cos\theta\bigg|_0^{\pi} = (0 - 1) - (0 + 1) = -2$$

19. $f(x, y, z) = e^x - \dfrac{y}{2\sqrt{2}z}$, the path $\mathbf{c}(t) = \left(\ln t, \sqrt{2}t, \frac{1}{2}t^2\right)$ for $1 \le t \le 2$

SOLUTION

Step 1. Compute $ds = \|\mathbf{c}'(t)\|\, dt$. We have:

$$\mathbf{c}'(t) = \frac{d}{dt}\left\langle \ln t, \sqrt{2}t, \frac{1}{2}t^2\right\rangle = \left\langle \frac{1}{t}, \sqrt{2}, t\right\rangle$$

$$\|\mathbf{c}'(t)\| = \sqrt{\left(\frac{1}{t}\right)^2 + \left(\sqrt{2}\right)^2 + t^2} = \sqrt{\frac{1}{t^2} + 2 + t^2} = \sqrt{\left(\frac{1}{t} + t\right)^2} = \frac{1}{t} + t$$

Hence:

$$ds = \|\mathbf{c}'(t)\|\,dt = \left(t + \frac{1}{t}\right)dt$$

Step 2. Write out $f(\mathbf{c}(t))$ and evaluate the integral.

$$f(\mathbf{c}(t)) = e^x - \frac{y}{2\sqrt{2}z} = e^{\ln t} - \frac{\sqrt{2}t}{2\sqrt{2}\cdot\frac{1}{2}t^2} = t - \frac{1}{t}$$

We use the Theorem on Scalar Line Integrals to compute the line integral:

$$\int_{\mathcal{C}} f(x,y)\,ds = \int_1^2 f(\mathbf{c}(t))\,\|\mathbf{c}'(t)\|\,dt = \int_1^2 \left(t - \frac{1}{t}\right)\left(t + \frac{1}{t}\right)dt$$

$$= \int_1^2 \left(t^2 - \frac{1}{t^2}\right)dt = \frac{t^3}{3} + \frac{1}{t}\Big|_1^2 = \left(\frac{8}{3} + \frac{1}{2}\right) - \left(\frac{1}{3} + 1\right) = \frac{11}{6}$$

20. $f(x,y,z) = x + 2y + z$, the helix $\mathbf{c}(t) = (\cos t, \sin t, t)$ for $-1 \le t \le 3$

SOLUTION We have:

$$\mathbf{c}'(t) = \frac{d}{dt}\langle \cos t, \sin t, t\rangle = \langle -\sin t, \cos t, 1\rangle$$

$$\|\mathbf{c}'(t)\| = \sqrt{(-\sin t)^2 + \cos^2 t + 1} = \sqrt{1+1} = \sqrt{2}$$

We write out $f(\mathbf{c}(t))$:

$$f(\mathbf{c}(t)) = x + 2y + z = \cos t + 2\sin t + t$$

The scalar Line Integral is the following integral:

$$\int_{\mathcal{C}} f(x,y,z)\,ds = \int_{-1}^3 f(\mathbf{c}(t))\,\|\mathbf{c}'(t)\|\,dt = \int_{-1}^3 (\cos t + 2\sin t + t)\sqrt{2}\,dt$$

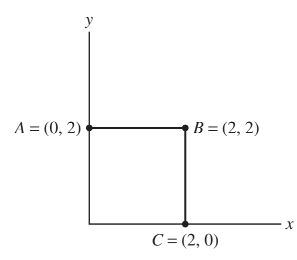
$$= \sqrt{2}\left(\sin t - 2\cos t + \frac{t^2}{2}\right)\Big|_{-1}^3$$

$$= \sqrt{2}\left(\left(\sin 3 - 2\cos 3 + \frac{9}{2}\right) - \left(\sin(-1) - 2\cos(-1) + \frac{1}{2}\right)\right)$$

$$= \sqrt{2}(\sin 3 - 2\cos 3 + \sin 1 + 2\cos 1 + 4) \approx 11.375$$

21. Find the total mass of an L-shaped rod consisting of the segments $(2t, 2)$ and $(2, 2-2t)$ for $0 \le t \le 1$ (length in centimeters) with mass density $\rho(x,y) = x^2y$ g/cm.

SOLUTION



The total mass of the rod is the following sum:

$$M = \int_{\overline{AB}} x^2y\,ds + \int_{\overline{BC}} x^2y\,ds \qquad (1)$$

The segment $\overline{AB}$ is parametrized by $\mathbf{c}_1(t) = (2t, 2)$, $0 \le t \le 1$. Hence

$$\mathbf{c}_1'(t) = \langle 2, 0\rangle, \ \|\mathbf{c}_1'(t)\| = 2$$

and

$$f(\mathbf{c}_1(t)) = x^2y = (2t)^2 \cdot 2 = 8t^2.$$

The segment $\overline{BC}$ is parametrized by $\mathbf{c}_2(t) = (2, 2-2t)$, $0 \le t \le 1$. Hence

$$\mathbf{c}_2'(t) = \langle 0, -2 \rangle, \ \|\mathbf{c}_2'(t)\| = 2$$

and

$$f(\mathbf{c}_2(t)) = x^2 y = 2^2(2-2t) = 8 - 8t.$$

Using these values, the Theorem on Scalar Line Integrals and (1) we get:

$$M = \int_0^1 8t^2 \cdot 2\,dt + \int_0^1 (8-8t)\cdot 2\,dt = \frac{16t^3}{3}\bigg|_0^1 + 16t - 8t^2\bigg|_0^1 = \frac{40}{3} = 13\frac{1}{3}$$

22. Calculate $\mathbf{F} = \nabla V$, where $V(x, y, z) = xye^z$, and compute $\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s}$, where:

(a) $\mathcal{C}$ is any curve from $(1, 1, 0)$ to $(3, e, -1)$.

(b) $\mathcal{C}$ is the boundary of the square $0 \le x \le 1$, $0 \le y \le 1$ oriented counterclockwise.

SOLUTION The gradient of $V(x, y, z) = xye^z$ is the following vector:

$$\mathbf{F} = \left\langle \frac{\partial V}{\partial x}, \frac{\partial V}{\partial y}, \frac{\partial V}{\partial z} \right\rangle = \left\langle ye^z, xe^z, xye^z \right\rangle$$

(a) By the Fundamental Theorem for Gradient Vector Fields, we have:

$$\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} = \int_{\mathcal{C}} \nabla V \cdot d\mathbf{s} = V(3, e, -1) - V(1, 1, 0) = 3\cdot e \cdot e^{-1} - 1\cdot 1e^0 = 3 - 1 = 2$$

(b) Since $\mathbf{F}$ is the gradient of a function, $\mathbf{F}$ is conservative. That is, the line integral of $\mathbf{F}$ over any closed curve is zero. Therefore, the line integral $\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s}$ is zero, where $\mathcal{C}$ is the boundary of a square.

23. Calculate $\int_{\mathcal{C}_1} y\,dx + x^2 y\,dy$, where $\mathcal{C}_1$ is the oriented curve in Figure 1(A).

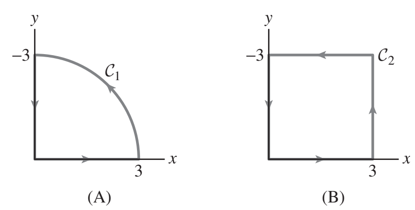


FIGURE 1

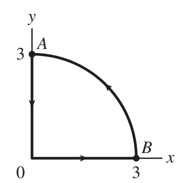
SOLUTION We compute the line integral as the sum of the line integrals over the segments $\overline{AO}$, $\overline{OB}$ and the circular arc BA.



The vector field is $\mathbf{F} = \left\langle y, x^2 y \right\rangle$. We have:

$$\int_{\mathcal{C}_1} \mathbf{F}\cdot d\mathbf{s} = \int_{\overline{AO}} \mathbf{F}\cdot d\mathbf{s} + \int_{\overline{OB}} \mathbf{F}\cdot d\mathbf{s} + \int_{\text{arc } BA} \mathbf{F}\cdot d\mathbf{s} \tag{1}$$

We compute each integral separately.

- The line integral over $\overline{AO}$. The segment $\overline{AO}$ is parametrized by $\mathbf{c}(t) = (0, -t)$, $-3 \le t \le 0$. Hence:

$$\mathbf{F}(\mathbf{c}(t)) = \left\langle y, x^2 y \right\rangle = \langle -t, 0 \rangle$$

$$\mathbf{c}'(t) = \langle 0, -1 \rangle$$

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \langle -t, 0 \rangle \cdot \langle 0, -1 \rangle = 0$$

Therefore:

$$\int_{\overline{AO}} \mathbf{F}\cdot d\mathbf{s} = \int_{-3}^{0} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\,dt = 0 \tag{2}$$

- The line integral over $\overline{OB}$. We parametrize the segment $\overline{OB}$ by $\mathbf{c}(t) = (t, 0), \quad 0 \le t \le 3$. Hence:

$$\mathbf{F}(\mathbf{c}(t)) = \left\langle y, x^2 y \right\rangle = \langle 0, 0 \rangle$$
$$\mathbf{c}'(t) = \langle 1, 0 \rangle$$
$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = 0$$

Therefore:

$$\int_{\overline{OB}} \mathbf{F} \cdot d\mathbf{s} = \int_0^3 \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = 0 \qquad (3)$$

- The line integral over the circular arc BA. We parametrize the circular arc by $\mathbf{c}(t) = (3\cos t, 3\sin t)$, $0 \le t \le \frac{\pi}{2}$. Then $\mathbf{c}'(t) = \langle -3\sin t, 3\cos t \rangle$ and $\mathbf{F}(\mathbf{c}(t)) = \left\langle y, x^2 y \right\rangle = \left\langle 3\sin t, 27\cos^2 t \sin t \right\rangle$. We compute the dot product:

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \left\langle 3\sin t, 27\cos^2 t \sin t \right\rangle \cdot \langle -3\sin t, 3\cos t \rangle = -9\sin^2 t + 81\cos^3 t \sin t$$

We obtain the integral:

$$\begin{aligned}\int_{\text{arc } BA} \mathbf{F} \cdot d\mathbf{s} &= \int_0^{\pi/2} -9\sin^2 t + 81\cos^3 t \sin t\, dt \\ &= -9\left(\frac{t}{2} - \frac{\sin 2t}{4}\right) - 81\left(\frac{\cos^4 t}{4}\right)\Bigg|_0^{\pi/2} \\ &= -\frac{9\pi}{4} + \frac{81}{4} = \frac{81 - 9\pi}{4}\end{aligned}$$

Combining (1), (2), (3), and (4) gives:

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = 0 + 0 + \frac{81 - 9\pi}{4} \approx 13.18$$

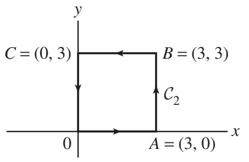
24. Let $\mathbf{F}(x, y) = \left\langle 9y - y^3, e^{\sqrt{y}}(x^2 - 3x) \right\rangle$ and let $\mathcal{C}_2$ be the oriented curve in Figure 1(B).

(a) Show that $\mathbf{F}$ is not conservative.

(b) Show that $\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = 0$ without explicitly computing the integral. *Hint:* Show that $\mathbf{F}$ is orthogonal to the edges along the square.

SOLUTION

(a) We show that the cross-partials of $\mathbf{F}(x, y) = \left\langle 9y - y^3, e^{\sqrt{y}}\left(x^2 - 3x\right) \right\rangle$ are not equal.



We have $\mathbf{F}_1 = 9y - y^3$ and $\mathbf{F}_2 = e^{\sqrt{y}}\left(x^2 - 3x\right)$, therefore:

$$\frac{\partial \mathbf{F}_1}{\partial y} = 9 - 3y^2$$
$$\frac{\partial \mathbf{F}_2}{\partial x} = e^{\sqrt{y}}(2x - 3)$$

The cross-partials are not equal, hence $\mathbf{F}$ is not conservative.

(b) On $\overline{OA}$, $y = 0$ hence

$$\mathbf{F} = \mathbf{F}(x, 0) = \left\langle 0, x^2 - 3x \right\rangle.$$

Therefore the tangential component of $\mathbf{F}$ along the segment $\overline{OA}$ is zero, resulting in $\int_{\overline{OA}} \mathbf{F} \cdot d\mathbf{s} = 0$. On $\overline{AB}$, $x = 3$ hence

$$\mathbf{F}(3, y) = \left\langle 9y - y^3, e^{\sqrt{y}}\left(3^2 - 3 \cdot 3\right) \right\rangle = \left\langle 9y - y^3, 0 \right\rangle.$$

We see that $\mathbf{F}$ is orthogonal to the segment AB, resulting in $\int_{\overline{AB}} \mathbf{F} \cdot d\mathbf{s} = 0$. On $\overline{BC}$, $y = 3$ hence

$$\mathbf{F}(x,3) = \left\langle 9 \cdot 3 - 3^3, e^{\sqrt{3}}\left(x^2 - 3x\right)\right\rangle = \left\langle 0, e^{\sqrt{3}}\left(x^2 - 3x\right)\right\rangle.$$

We see that $\mathbf{F}$ is orthogonal to the segment $\overline{BC}$, therefore $\int_{\overline{BC}} \mathbf{F} \cdot d\mathbf{s} = 0$. Finally, on CO we have $x = 0$, hence $\mathbf{F}(0, y) = \left\langle 9y - y^3, 0\right\rangle$. It follows that $\mathbf{F}$ is orthogonal to the segment $\overline{CO}$, therefore the tangential component of $\mathbf{F}$ along $\overline{CO}$ is zero. We conclude that $\int_{\overline{CO}} \mathbf{F} \cdot d\mathbf{s} = 0$. Combining these integrals we conclude that:

$$\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = \int_{\overline{OA}} \mathbf{F} \cdot d\mathbf{s} + \int_{\overline{AB}} \mathbf{F} \cdot d\mathbf{s} + \int_{\overline{BC}} \mathbf{F} \cdot d\mathbf{s} + \int_{\overline{CO}} \mathbf{F} \cdot d\mathbf{s} = 0 + 0 + 0 + 0 = 0$$

In Exercises 25–28, compute the line integral $\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s}$ *for the given vector field and path.*

25. $\mathbf{F}(x, y) = \left\langle \dfrac{2y}{x^2 + 4y^2}, \dfrac{x}{x^2 + 4y^2}\right\rangle$,

the path $\mathbf{c}(t) = \left(\cos t, \frac{1}{2}\sin t\right)$ for $0 \le t \le 2\pi$

SOLUTION

Step 1. Calculate the integrand $\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)$.

$$\mathbf{c}(t) = \left(\cos t, \frac{1}{2}\sin t\right)$$

$$\mathbf{F}(\mathbf{c}(t)) = \left\langle \frac{2y}{x^2 + 4y^2}, \frac{x}{x^2 + 4y^2}\right\rangle = \left\langle \frac{2 \cdot \frac{1}{2} \cdot \sin t}{\cos^2 t + 4 \cdot \frac{1}{4}\sin^2 t}, \frac{\cos t}{\cos^2 t + 4 \cdot \frac{1}{4}\sin^2 t}\right\rangle$$

$$= \left\langle \frac{\sin t}{\cos^2 t + \sin^2 t}, \frac{\cos t}{\cos^2 t + \sin^2 t}\right\rangle = \langle \sin t, \cos t\rangle$$

$$\mathbf{c}'(t) = \left\langle -\sin t, \frac{1}{2}\cos t\right\rangle$$

The integrand is the dot product:

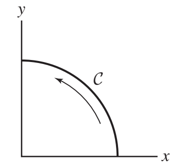
$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \langle \sin t, \cos t\rangle \cdot \left\langle -\sin t, \frac{1}{2}\cos t\right\rangle = -\sin^2 t + \frac{1}{2}\cos^2 t = \frac{1}{2}\cos 2t - \frac{1}{2}\sin^2 t$$

Step 2. Evaluate the line integral.

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{2\pi} \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t)\, dt = \int_0^{2\pi} \left(\frac{1}{2}\cos 2t - \frac{1}{2}\sin^2 t\right) dt = \left.\frac{\sin 2t}{4} - \frac{t}{4} + \frac{\sin 2t}{8}\right|_0^{2\pi} = -\frac{\pi}{2}$$

26. $\mathbf{F}(x, y) = \left\langle 2xy, x^2 + y^2\right\rangle$, the part of the unit circle in the first quadrant oriented counterclockwise.

SOLUTION



The path is parametrized by:

$$\mathbf{c}(\theta) = (\cos\theta, \sin\theta), \quad 0 \le \theta \le \frac{\pi}{2}$$

Step 1. Calculate the integrand $\mathbf{F}(\mathbf{c}(\theta)) \cdot \mathbf{c}'(\theta)$.

$$\mathbf{c}'(\theta) = \langle -\sin\theta, \cos\theta\rangle$$

$$\mathbf{F}(\mathbf{c}(\theta)) = \left\langle 2xy, x^2 + y^2\right\rangle = \left\langle 2\cos\theta\sin\theta, \cos^2\theta + \sin^2\theta\right\rangle = \langle 2\cos\theta\sin\theta, 1\rangle$$

The integrand is the dot product:

$$\mathbf{F}(\mathbf{c}(\theta)) \cdot \mathbf{c}'(\theta) = \langle 2\cos\theta\sin\theta, 1\rangle \cdot \langle -\sin\theta, \cos\theta\rangle = -2\cos\theta\sin^2\theta + \cos\theta$$

Step 2. Evaluate the line integral. The vector line integral is:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{\pi/2} \mathbf{F}\left(\mathbf{c}(\theta)\right) \cdot \mathbf{c}'(\theta)\, d\theta = \int_0^{\pi/2} \left(-2\cos\theta \sin^2\theta + \cos\theta\right) d\theta$$

$$= -2\int_0^{\pi/2} \sin^2\theta \cos\theta\, d\theta + \int_0^{\pi/2} \cos\theta\, d\theta = \frac{-2\sin^3\theta}{3}\bigg|_0^{\pi/2} + \sin\theta\bigg|_0^{\pi/2} = -\frac{2}{3} + 1 = \frac{1}{3}$$

27. $\mathbf{F}(x, y) = \langle x^2 y, y^2 z, z^2 x\rangle$, the path $\mathbf{c}(t) = \left(e^{-t}, e^{-2t}, e^{-3t}\right)$ for $0 \le t < \infty$

SOLUTION

Step 1. Calculate the integrand $\mathbf{F}\left(\mathbf{c}(t)\right) \cdot \mathbf{c}'(t)$.

$$\mathbf{c}(t) = \left(e^{-t}, e^{-2t}, e^{-3t}\right)$$

$$\mathbf{c}'(t) = \left\langle e^{-t}, -2e^{-2t}, -3e^{-3t}\right\rangle$$

$$\mathbf{F}\left(\mathbf{c}(t)\right) = \left\langle x^2 y, y^2 z, z^2 x\right\rangle = \left\langle e^{-2t}\cdot e^{-2t}, e^{-4t}\cdot e^{-3t}, e^{-6t}\cdot e^{-t}\right\rangle = \left\langle e^{-4t}, e^{-7t}, e^{-7t}\right\rangle$$

The integrand is the dot product:

$$\mathbf{F}\left(\mathbf{c}(t)\right) \cdot \mathbf{c}'(t) = \left\langle e^{-4t}, e^{-7t}, e^{-7t}\right\rangle \cdot \left\langle e^{-t}, -2e^{-2t}, -3e^{-3t}\right\rangle = -e^{-5t} - 2e^{-9t} - 3e^{-10t}$$

Step 2. Evaluate the line integral.

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{\infty} \mathbf{F}\left(\mathbf{c}(t)\right) \cdot \mathbf{c}'(t)\, dt = \int_0^{\infty} \left(-e^{-5t} - 2e^{-9t} - 3e^{-10t}\right) dt$$

$$= \lim_{R\to\infty} \left(\frac{1}{5}e^{-5R} + \frac{2}{9}e^{-9R} + \frac{3}{10}e^{-10R}\right) - \left(\frac{1}{5} + \frac{2}{9} + \frac{3}{10}\right) = 0 - \frac{13}{18} = -\frac{13}{18}$$

28. $\mathbf{F} = \nabla V$, where $V(x, y, z) = 4x^2 \ln(1 + y^4 + z^2)$, the path $\mathbf{c}(t) = \left(t^3, \ln(1 + t^2), e^t\right)$ for $0 \le t \le 1$

SOLUTION We use the Fundamental Theorem for Gradient Vector Field to write:

$$\int_c \nabla V \cdot d\mathbf{s} = V\left(c(1)\right) - V\left(c(0)\right) \tag{1}$$

We compute the values on the right-hand side:

$$c(1) = \left(1^3, \ln\left(1 + 1^2\right), e^1\right) = (1, \ln 2, e)$$

$$c(0) = \left(0^3, \ln\left(1 + 0^2\right), e^0\right) = (0, 0, 1)$$

Hence:

$$V\left(c(1)\right) = 4 \cdot 1^2 \ln\left(1 + \ln^4 2 + e^2\right) = 4\ln\left(1 + e^2 + \ln^4 2\right) \approx 8.616$$

$$V\left(c(0)\right) = 0$$

Combining with (1) gives:

$$\int_c \nabla V \cdot d\mathbf{s} = 8.616$$

29. Consider the line integrals $\int_{\mathbf{c}} \mathbf{F} \cdot d\mathbf{s}$ for the vector fields $\mathbf{F}$ and paths $\mathbf{c}$ in Figure 2. Which two of the line integrals appear to have a value of zero? Which of the other two appears to have a negative value?

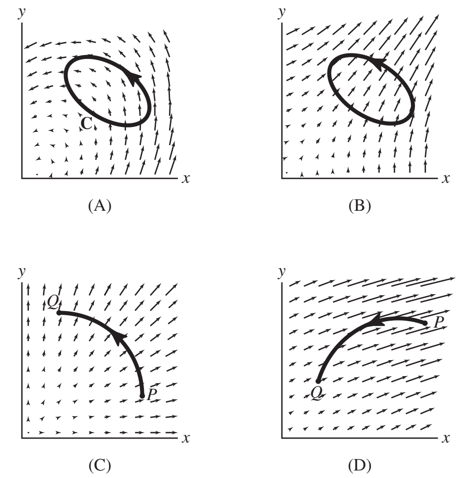


FIGURE 2

SOLUTION In (A), the line integral around the ellipse appears to be positive, because the negative tangential components from the lower part of the curve appears to be smaller than the positive contribution of the tangential components from the upper part.

In (B), the line integral around the ellipse appears to be zero, since $\mathbf{F}$ is orthogonal to the ellipse at all points except for two points where the tangential components of $\mathbf{F}$ cancel each other.

In (C), $\mathbf{F}$ is orthogonal to the path, hence the tangential component is zero at all points on the curve. Therefore the line integral $\int_C \mathbf{F} \cdot d\mathbf{s}$ is zero.

In (D), the direction of $\mathbf{F}$ is opposite to the direction of the curve. Therefore the dot product $\mathbf{F} \cdot \mathbf{T}$ is negative at each point along the curve, resulting in a negative line integral.

30. Calculate the work required to move an object from $P = (1, 1, 1)$ to $Q = (3, -4, -2)$ against the force field $\mathbf{F}(x, y, z) = -12r^{-4}\langle x, y, z\rangle$ (distance in meters, force in newtons), where $r = \sqrt{x^2 + y^2 + z^2}$. *Hint:* Find a potential function for $\mathbf{F}$.

SOLUTION The work performed against $\mathbf{F}$ is given by the line integral:

$$W = -\int_{PQ} \mathbf{F} \cdot d\mathbf{s} \tag{1}$$

We notice that $\mathbf{F} = -\frac{12}{\left(x^2+y^2+z^2\right)^2}\langle x, y, z\rangle$ is the gradient of the function $V(x, y, z) = \frac{6}{x^2+y^2+z^2}$ since:

$$\begin{aligned} \nabla V &= \left\langle \frac{\partial V}{\partial x}, \frac{\partial V}{\partial y}, \frac{\partial V}{\partial z} \right\rangle = \left\langle \frac{6 \cdot (-2x)}{\left(x^2 + y^2 + z^2\right)^2}, \frac{6 \cdot (-2y)}{\left(x^2 + y^2 + z^2\right)^2}, \frac{6 \cdot (-2z)}{\left(x^2 + y^2 + z^2\right)^2} \right\rangle \\ &= -\frac{12}{\left(x^2 + y^2 + z^2\right)^2}\langle x, y, z\rangle = \mathbf{F} \end{aligned}$$

We now use the Fundamental Theorem for Gradient vector Field to compute the line integral (1):

$$\begin{aligned} W &= -\int_{PQ} \mathbf{F} \cdot d\mathbf{s} = -\int_{PQ} \nabla V \cdot d\mathbf{s} = -\left(V(Q) - V(P)\right) = -\left(V(3, -4, -2) - V(1, 1, 1)\right) \\ &= -\left(\frac{6}{9 + 16 + 4} - \frac{6}{1 + 1 + 1}\right) = \frac{52}{29} \approx 1.79 \end{aligned}$$

31. Find constants a, b, c such that

$$G(u, v) = (u + av, bu + v, 2u - c)$$

parametrizes the plane $3x - 4y + z = 5$. Calculate $\mathbf{T}_u$, $\mathbf{T}_v$, and $\mathbf{n}(u, v)$.

SOLUTION We substitute $x = u + av$, $y = bu + v$ and $z = 2u - c$ in the equation of the plane $3x - 4y + z = 5$, to obtain:

$$5 = 3x - 4y + z = 3(u + av) - 4(bu + v) + 2u - c = (5 - 4b)u + (3a - 4)v - c$$

or

$$(5-4b)u+(3a-4)v-(5+c)=0$$

This equation must be satisfied for all u and v, therefore the following must hold:

$$\begin{aligned} 5-4b&=0 & & b=\frac{5}{4}\\ 3a-4&=0 &\Rightarrow\quad & a=\frac{4}{3}\\ 5+c&=0 & & c=-5 \end{aligned}$$

We obtain the following parametrization for the plane $3x-4y+z=5$:

$$\phi(u,v)=\left(u+\frac{4}{3}v,\ \frac{5}{4}u+v,\ 2u+5\right)$$

We compute the tangent vectors $\mathbf{T}_u$ and $\mathbf{T}_v$:

$$\mathbf{T}_u=\frac{\partial\phi}{\partial u}=\left\langle 1,\frac{5}{4},2\right\rangle;\ \mathbf{T}_v=\frac{\partial\phi}{\partial v}=\left\langle\frac{4}{3},1,0\right\rangle$$

The normal vector is their cross product:

$$\begin{aligned}\mathbf{n}=\mathbf{T}_u\times\mathbf{T}_v&=\begin{vmatrix}\mathbf{i}&\mathbf{j}&\mathbf{k}\\ 1&\frac{5}{4}&2\\ \frac{4}{3}&1&0\end{vmatrix}=\begin{vmatrix}\frac{5}{4}&2\\ 1&0\end{vmatrix}\mathbf{i}-\begin{vmatrix}1&2\\ \frac{4}{3}&0\end{vmatrix}\mathbf{j}+\begin{vmatrix}1&\frac{5}{4}\\ \frac{4}{3}&1\end{vmatrix}\mathbf{k}\\ &=-2\mathbf{i}+\frac{8}{3}\mathbf{j}+\left(1-\frac{5}{3}\right)\mathbf{k}=\left\langle -2,\frac{8}{3},-\frac{2}{3}\right\rangle\end{aligned}$$

32. Calculate the integral of $f(x,y,z)=e^z$ over the portion of the plane $x+2y+2z=3$, where $x,y,z\ge 0$.

SOLUTION We consider the surface a graph of the form $x=g(y,z)=3-2y-2z$. The requirement that $x\ge 0$ means $3-2y-2z\ge 0\Rightarrow y+z\le\frac{3}{2}$. Combined with the requirements that $y,z\ge 0$ we have that our parameter domain, $\mathcal{D}$, is the triangle bounded by the $y-$axis, the $z-$axis, and the line $y+z=\frac{3}{2}$.

Calculating the magnitude of the normal vector,

$$\begin{aligned}\Phi(y,z)&=(3-2y-2z,y,z)\ (x,y)\in\mathcal{D}\\ \mathbf{T}_y&=\langle -2,1,0\rangle\\ \mathbf{T}_z&=\langle -2,0,1\rangle\\ \mathbf{n}&=\langle 1,2,2\rangle\quad\Rightarrow\quad\|\mathbf{n}\|=\sqrt{1^2+2^2+2^2}=3\end{aligned}$$

Our integral is

$$\begin{aligned}\iint_{\mathcal{S}}f(x,y,z)\,dS&=\iint_{\mathcal{D}}e^z\|n\|\,dz\,dy=\int_0^{3/2}\int_0^{-y+3/2}e^z\,3\,dz\,dy\\ &=\int_0^{3/2}\left(e^{-y+3/2}-1\right)3\,dy=-3e^{-y+3/2}-3y\Big|_0^{3/2}\\ &=-3+3e^{3/2}-\frac{9}{2}=3e^{3/2}-\frac{15}{2}\approx 5.945\end{aligned}$$

33. Let $\mathcal{S}$ be the surface parametrized by

$$G(u,v)=\left(2u\sin\frac{v}{2},2u\cos\frac{v}{2},3v\right)$$

for $0\le u\le 1$ and $0\le v\le 2\pi$.

(a) Calculate the tangent vectors $\mathbf{T}_u$ and $\mathbf{T}_v$ and the normal vector $\mathbf{n}(u,v)$ at $P=G(1,\frac{\pi}{3})$.

(b) Find the equation of the tangent plane at P.

(c) Compute the surface area of $\mathcal{S}$.

SOLUTION

(a) The tangent vectors are the partial derivatives:

$$\mathbf{T}_u = \frac{\partial G}{\partial u} = \frac{\partial}{\partial u}\left\langle 2u\sin\frac{v}{2}, 2u\cos\frac{v}{2}, 3v\right\rangle = \left\langle 2\sin\frac{v}{2}, 2\cos\frac{v}{2}, 0\right\rangle$$
$$\mathbf{T}_v = \frac{\partial G}{\partial v} = \frac{\partial}{\partial v}\left\langle 2u\sin\frac{v}{2}, 2u\cos\frac{v}{2}, 3v\right\rangle = \left\langle u\cos\frac{v}{2}, -u\sin\frac{v}{2}, 3\right\rangle$$

The normal vector is their cross-product:

$$\mathbf{n} = \mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2\sin\frac{v}{2} & 2\cos\frac{v}{2} & 0 \\ u\cos\frac{v}{2} & -u\sin\frac{v}{2} & 3 \end{vmatrix} = \begin{vmatrix} 2\cos\frac{v}{2} & 0 \\ -u\sin\frac{v}{2} & 3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2\sin\frac{v}{2} & 0 \\ u\cos\frac{v}{2} & 3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2\sin\frac{v}{2} & 2\cos\frac{v}{2} \\ u\cos\frac{v}{2} & -u\sin\frac{v}{2} \end{vmatrix}\mathbf{k}$$
$$= \left(6\cos\frac{v}{2}\right)\mathbf{i} - \left(6\sin\frac{v}{2}\right)\mathbf{j} + \left(-2u\sin^2\frac{v}{2} - 2u\cos^2\frac{v}{2}\right)\mathbf{k}$$
$$= \left(6\cos\frac{v}{2}\right)\mathbf{i} - \left(6\sin\frac{v}{2}\right)\mathbf{j} - 2u\mathbf{k} = \left\langle 6\cos\frac{v}{2}, -6\sin\frac{v}{2}, -2u\right\rangle$$

At the point $P = G\left(1, \frac{\pi}{3}\right)$, $u = 1$ and $v = \frac{\pi}{3}$. The tangents and the normal vector at this point are,

$$\mathbf{T}_u\left(1, \frac{\pi}{3}\right) = \left\langle 2\sin\frac{\pi}{6}, 2\cos\frac{\pi}{6}, 0\right\rangle = \left\langle 1, \sqrt{3}, 0\right\rangle$$
$$\mathbf{T}_v\left(1, \frac{\pi}{3}\right) = \left\langle 1\cdot\cos\frac{\pi}{6}, -1\cdot\sin\frac{\pi}{6}, 3\right\rangle = \left\langle \frac{\sqrt{3}}{2}, -\frac{1}{2}, 3\right\rangle$$
$$\mathbf{n}\left(1, \frac{\pi}{3}\right) = \left\langle 6\cos\frac{\pi}{6}, -6\sin\frac{\pi}{6}, -2\cdot 1\right\rangle = \left\langle 3\sqrt{3}, -3, -2\right\rangle$$

(b) A normal to the plane is $\mathbf{n}\left(1, \frac{\pi}{3}\right) = \left\langle 3\sqrt{3}, -3, -2\right\rangle$ found in part (a). We find the tangency point:

$$P = \phi\left(1, \frac{\pi}{3}\right) = \left(2\cdot 1\sin\frac{\pi}{6}, 2\cdot 1\cos\frac{\pi}{6}, 3\cdot\frac{\pi}{3}\right) = \left(1, \sqrt{3}, \pi\right)$$

The equation of the tangent plane is, thus,

$$\left\langle x-1, y-\sqrt{3}, z-\pi\right\rangle \cdot \left\langle 3\sqrt{3}, -3, -2\right\rangle = 0$$

or

$$3\sqrt{3}(x-1) - 3\left(y-\sqrt{3}\right) - 2(z-\pi) = 0$$
$$3\sqrt{3}x - 3y - 2z + 2\pi = 0$$

(c) In part (a) we found the normal vector:

$$\mathbf{n} = \left\langle 6\cos\frac{v}{2}, -6\sin\frac{v}{2}, -2u\right\rangle$$

We compute the length of $\mathbf{n}$:

$$\|\mathbf{n}\| = \sqrt{36\cos^2\frac{v}{2} + 36\sin^2\frac{v}{2} + 4u^2} = \sqrt{36+4u^2} = 2\sqrt{9+u^2}$$

Using the Integral for the Surface Area we get:

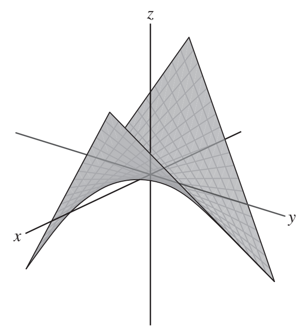
$$\text{Area}(S) = \iint_{\mathcal{D}} \|n(u,v)\|\,du\,dv = \int_0^{2\pi}\int_0^1 2\sqrt{9+u^2}\,du\,dv = 4\pi\int_0^1 \sqrt{9+u^2}\,du$$
$$= 4\pi\left(\frac{u}{2}\sqrt{u^2+9} + \frac{9}{2}\ln\left(u+\sqrt{9+u^2}\right)\Big|_{u=0}^{1}\right) = 4\pi\left(\frac{1}{2}\sqrt{10} + \frac{9}{2}\ln\left(1+\sqrt{10}\right) - \frac{9}{2}\ln 3\right)$$
$$= 2\sqrt{10}\pi + 18\pi\ln\left(1+\sqrt{10}\right) - 18\pi\ln 3 = 2\sqrt{10}\pi + 18\pi\ln\frac{1+\sqrt{10}}{3} \approx 38.4$$

34. CAS Plot the surface with parametrization

$$G(u,v) = (u+4v, 2u-v, 5uv)$$

for $-1 \le v \le 1, -1 \le u \le 1$. Express the surface area as a double integral and use a computer algebra system to compute the area numerically.

SOLUTION The surface is shown in the following plot:



We compute the area of the surface, using the Integral for the surface Area. We find the tangent and normal vectors:

$$\mathbf{T}_u = \frac{\partial \phi}{\partial u} = \frac{\partial}{\partial u}\langle u+4v, 2u-v, 5uv\rangle = \langle 1, 2, 5v\rangle$$

$$\mathbf{T}_v = \frac{\partial \phi}{\partial v} = \frac{\partial}{\partial v}\langle u+4v, 2u-v, 5uv\rangle = \langle 4, -1, 5u\rangle$$

$$\mathbf{n} = \mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 5v \\ 4 & -1 & 5u \end{vmatrix} = \begin{vmatrix} 2 & 5v \\ -1 & 5u \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 5v \\ 4 & 5u \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 2 \\ 4 & -1 \end{vmatrix}\mathbf{k}$$

$$= (10u+5v)\mathbf{i} - (5u-20v)\mathbf{j} + (-1-8)\mathbf{k} = \langle 10u+5v, -5u+20v, -9\rangle$$

Next, we calculate the length of the normal vector:

$$\|\mathbf{n}\| = \sqrt{(10u+5v)^2 + (-5u+20v)^2 + (-9)^2}$$
$$= \sqrt{100u^2 + 100uv + 25v^2 + 25u^2 - 200uv + 400v^2 + 81}$$
$$= \sqrt{125u^2 - 100uv + 425v^2 + 81}$$

We obtain the following integral, which we compute by a CAS:

$$\text{Area}(S) = \iint_{\mathcal{D}} \|\mathbf{n}(u,v)\|\,du\,dv = \int_{-1}^{1}\int_{-1}^{1}\sqrt{125u^2 - 100uv + 425v^2 + 81}\,du\,dv = 62.911$$

35. CAS Express the surface area of the surface $z = 10 - x^2 - y^2$ for $-1 \le x \le 1$, $-3 \le y \le 3$ as a double integral. Evaluate the integral numerically using a CAS.

SOLUTION We use the Surface Integral over a graph. Let $g(x,y) = 10 - x^2 - y^2$. Then $g_x = -2x$, $g_y = -2y$ hence $\sqrt{1 + {g_x}^2 + {g_y}^2} = \sqrt{1 + 4x^2 + 4y^2}$. The area at the surface is the following integral which we compute using a CAS:

$$\text{Area}(S) = \iint_{\mathcal{D}} \sqrt{1 + {g_x}^2 + {g_y}^2}\,dx\,dy = \int_{-3}^{3}\int_{-1}^{1}\sqrt{1 + 4x^2 + 4y^2}\,dx\,dy \approx 41.8525$$

36. Evaluate $\iint_{\mathcal{S}} x^2 y\,dS$, where $\mathcal{S}$ is the surface $z = \sqrt{3}x + y^2$, $-1 \le x \le 1$, $0 \le y \le 1$.

SOLUTION We use the Surface Integral over a Graph with $g(x,y) = \sqrt{3}x + y^2$. The partial derivatives are $g_x = \sqrt{3}$ and $g_y = 2y$. Therefore

$$\sqrt{1 + g_x^2 + g_y^2} = \sqrt{1 + \left(\sqrt{3}\right)^2 + (2y)^2} = \sqrt{4 + 4y^2} = 2\sqrt{1 + y^2}$$

We obtain the following integral:

$$\iint_S x^2 y \cdot dS = \iint_{\mathcal{D}} x^2 y\sqrt{1 + g_x^2 + g_y^2}\,dx\,dy = \int_0^1\int_{-1}^{1} x^2 y \cdot 2\sqrt{1+y^2}\,dx\,dy = \left(\int_{-1}^{1} x^2\,dx\right)\left(\int_0^1 \sqrt{1+y^2}\cdot 2y\,dy\right)$$

$$= \left(\frac{x^3}{3}\bigg|_{x=-1}^{1}\right)\left(\int_0^1 \sqrt{1+y^2}\cdot 2y\,dy\right) = \frac{2}{3}\int_0^1 \sqrt{1+y^2}\cdot 2y\,dy$$

We compute the integral using the substitution $u = 1 + y^2$, $du = 2y\,dy$. We get:

$$\iint_S x^2 y \cdot dS = \frac{2}{3}\int_1^2 u^{1/2} du = \frac{2}{3} \cdot \frac{2}{3} u^{3/2}\Big|_1^2 = \frac{4}{9}\left(2^{3/2} - 1\right) = \frac{4}{9}\left(2\sqrt{2} - 1\right)$$

37. Calculate $\iint_{\mathcal{S}} \left(x^2 + y^2\right) e^{-z}\, dS$, where $\mathcal{S}$ is the cylinder with equation $x^2 + y^2 = 9$ for $0 \le z \le 10$.

SOLUTION We parametrize the cylinder $\mathcal{S}$ by,

$$G(\theta, z) = (3\cos\theta, 3\sin\theta, z)$$

with the parameter domain:

$$0 \le \theta \le 2\pi, \quad 0 \le z \le 10.$$

We compute the tangent and normal vectors:

$$\mathbf{T}_\theta = \frac{\partial\phi}{\partial\theta} = \frac{\partial}{\partial\theta}\langle 3\cos\theta, 3\sin\theta, z\rangle = \langle -3\sin\theta, 3\cos\theta, 0\rangle$$
$$\mathbf{T}_z = \frac{\partial\phi}{\partial\theta} = \frac{\partial}{\partial\theta}\langle 3\cos\theta, 3\sin\theta, z\rangle = \langle 0, 0, 1\rangle$$

The normal vector is their cross product:

$$\mathbf{n} = \mathbf{T}_\theta \times \mathbf{T}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -3\sin\theta & 3\cos\theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = \begin{vmatrix} 3\cos\theta & 0 \\ 0 & 1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} -3\sin\theta & 0 \\ 0 & 1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} -3\sin\theta & 3\cos\theta \\ 0 & 0 \end{vmatrix}\mathbf{k}$$
$$= (3\cos\theta)\mathbf{i} + (3\sin\theta)\mathbf{j} = 3\langle\cos\theta, \sin\theta, 0\rangle$$

We compute the length of the normal vector:

$$\|\mathbf{n}\| = 3\sqrt{\cos^2\theta + \sin^2\theta + 0} = 3$$

We now express the function $f(x, y, z) = \left(x^2 + y^2\right) e^{-z}$ in terms of the parameters:

$$f(\phi(\theta, z)) = \left(x^2 + y^2\right) e^{-z} = \left(9\cos^2\theta + 9\sin^2\theta\right) e^{-z} = 9e^{-z}$$

Using the Theorem on Surface Integrals, we obtain:

$$\iint_{\mathcal{S}} \left(x^2 + y^2\right) e^{-z} dS = \int_0^{10}\int_0^{2\pi} 9e^{-z} 3\, d\theta\, dz = 27 \cdot 2\pi \int_0^{10} e^{-z} dz = 54\pi\left(-e^{-z}\right)\Big|_{z=0}^{10}$$
$$= 54\pi\left(-e^{-10} + 1\right) \approx 54\pi$$

38. Let $\mathcal{S}$ be the upper hemisphere $x^2 + y^2 + z^2 = 1$, $z \ge 0$. For each of the functions (a)–(d), determine whether $\iint_{\mathcal{S}} f\, dS$ is positive, zero, or negative (without evaluating the integral). Explain your reasoning.

(a) $f(x, y, z) = y^3$

(b) $f(x, y, z) = z^3$

(c) $f(x, y, z) = xyz$

(d) $f(x, y, z) = z^2 - 2$

SOLUTION

(a) Since $f(x, y, z) = y^3$ is an odd function of y, and the upper hemisphere is symmetric with respect to the (x, z)-plane, the surface integrals over the parts where $y \ge 0$ and $y \le 0$ cancel each other. Therefore the surface integral is zero.

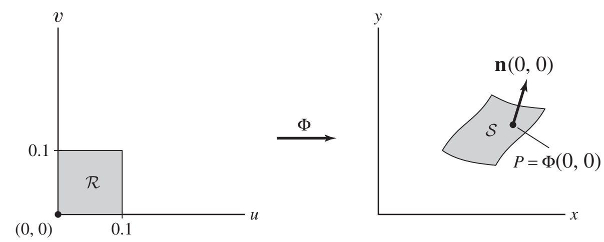
(b) The function $f(x, y, z) = z^3$ is non-negative on $\mathcal{S}$, hence the surface integral is positive.

(c) Since $f(-x, y, z) = -xyz = -f(x, y, z)$ and since the upper hemisphere is symmetric with respect to (y, z)-plane, the surface integrals over the parts of $\mathcal{S}$ where $x \ge 0$ and $x \le 0$ cancel each other to obtain a zero surface integral.

(d) On $\mathcal{S}$ we have $z^2 = 1 - x^2 - y^2 \le 1$, hence $z^2 - 2 < 0$. That is, $f(x, y, z) = z^2 - 2$ is negative on $\mathcal{S}$, therefore the surface integral is negative.

39. Let $\mathcal{S}$ be a small patch of surface with a parametrization $G(u,v)$ for $0 \le u \le 0.1$, $0 \le v \le 0.1$ such that the normal vector $\mathbf{n}(u,v)$ for $(u,v) = (0,0)$ is $\mathbf{n} = \langle 2, -2, 4\rangle$. Use Eq. (3) in Section 16.4 to estimate the surface area of $\mathcal{S}$.

SOLUTION



We use Eq. (3) in section 16.4 with $(u_{ij}, v_{ij}) = (0,0)$, $\mathcal{R}_{ij} = \mathcal{R} = [0, 0.1] \times [0, 0.1]$ in the (u,v)-plane and $\mathcal{S}_{ij} = \mathcal{S} = G(\mathcal{R})$, in the (x,y)-plane to obtain the following estimation for the area of $\mathcal{S}$:

$$\text{Area}(\mathcal{S}) \approx \|\mathbf{n}(0,0)\| \text{Area}(\mathcal{R})$$

That is:

$$\text{Area}(\mathcal{S}) \approx \|\langle 2, -2, 4\rangle\| 0.1^2 = \sqrt{2^2 + (-2)^2 + 4^2} \cdot (0.1)^2 = 0.02\sqrt{6} \approx 0.049$$

40. The upper half of the sphere $x^2 + y^2 + z^2 = 9$ has parametrization $G(r,\theta) = (r\cos\theta, r\sin\theta, \sqrt{9 - r^2})$ in cylindrical coordinates (Figure 3).

(a) Calculate the normal vector $\mathbf{n} = \mathbf{T}_r \times \mathbf{T}_\theta$ at the point $G\left(2, \frac{\pi}{3}\right)$.

(b) Use Eq. (3) in Section 16.4 to estimate the surface area of $G(\mathcal{R})$, where $\mathcal{R}$ is the small domain defined by

$$2 \le r \le 2.1, \qquad \frac{\pi}{3} \le \theta \le \frac{\pi}{3} + 0.05$$

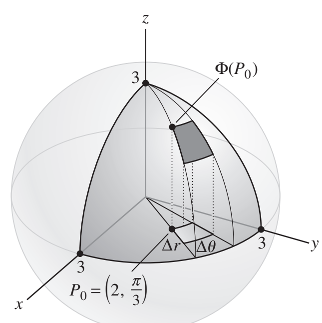


FIGURE 3

SOLUTION

(a) We first find the tangent vectors at the given point:

$$\mathbf{T}_\theta = \frac{\partial G}{\partial \theta} = \frac{\partial}{\partial \theta}\left\langle r\cos\theta, r\sin\theta, \sqrt{9 - r^2}\right\rangle = \langle -r\sin\theta, r\cos\theta, 0\rangle$$

$$\Rightarrow \quad \mathbf{T}_\theta\left(2, \frac{\pi}{3}\right) = \left\langle -2\sin\frac{\pi}{3}, 2\cos\frac{\pi}{3}, 0\right\rangle = \left\langle -\sqrt{3}, 1, 0\right\rangle$$

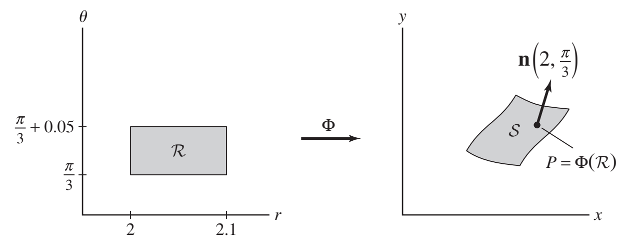
$$\mathbf{T}_r = \frac{\partial G}{\partial r} = \frac{\partial}{\partial r}\left\langle r\cos\theta, r\sin\theta, \sqrt{9 - r^2}\right\rangle = \left\langle \cos\theta, \sin\theta, -\frac{r}{\sqrt{9 - r^2}}\right\rangle$$

$$\Rightarrow \quad \mathbf{T}_r\left(2, \frac{\pi}{3}\right) = \left\langle \cos\frac{\pi}{3}, \sin\frac{\pi}{3}, -\frac{2}{\sqrt{9 - 2^2}}\right\rangle = \left\langle \frac{1}{2}, \frac{\sqrt{3}}{2}, -\frac{2}{\sqrt{5}}\right\rangle$$

The normal vector is the cross product:

$$\mathbf{n} = \mathbf{T}_r \times \mathbf{T}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{1}{2} & \frac{\sqrt{3}}{2} & -\frac{2}{\sqrt{5}} \\ -\sqrt{3} & 1 & 0 \end{vmatrix} = \frac{2}{\sqrt{5}}\mathbf{i} + \frac{2\sqrt{3}}{\sqrt{5}}\mathbf{j} + \left(\frac{1}{2} + \frac{3}{2}\right)\mathbf{k} = \left\langle \frac{2}{\sqrt{5}}, \frac{2\sqrt{3}}{\sqrt{5}}, 2\right\rangle$$

(b) We use Eq. (3) with the sample point $(u, v) = \left(2, \frac{\pi}{3}\right)$.



In part (a) we found that the normal to $G(\mathcal{R})$ at this point is $\mathbf{n} = \left\langle \frac{2}{\sqrt{5}}, \frac{2\sqrt{3}}{\sqrt{5}}, 2 \right\rangle$. Therefore, $\|\mathbf{n}\| = \sqrt{\frac{4}{5} + \frac{12}{5} + 4} = \frac{6}{\sqrt{5}}$. We get:

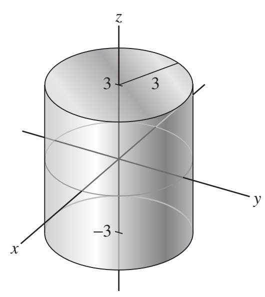
$$\text{Area}(G(\mathcal{R})) \approx \left\| \mathbf{n}\left(2, \frac{\pi}{3}\right) \right\| \text{Area}(\mathcal{R}) = \frac{6}{\sqrt{5}} \cdot 0.1 \cdot 0.05 = \frac{0.03}{\sqrt{5}} \approx 0.0134$$

In Exercises 41–46, compute $\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S}$ *for the given oriented surface or parametrized surface.*

41. $\mathbf{F}(x, y, z) = \langle y, x, e^{xz} \rangle$, $\quad x^2 + y^2 = 9$, $x \ge 0$, $y \ge 0$, $\quad -3 \le z \le 3$, $\quad$ outward-pointing normal

SOLUTION The part of the cylinder is parametrized by:

$$G(\theta, z) = (3\cos\theta, 3\sin\theta, z), \quad 0 \le \theta \le \frac{\pi}{2}, \quad -3 \le z \le 3$$



Step 1. Compute the tangent and normal vectors.

$$\mathbf{T}_\theta = \frac{\partial G}{\partial \theta} = \frac{\partial}{\partial \theta} \langle 3\cos\theta, 3\sin\theta, z \rangle = \langle -3\sin\theta, 3\cos\theta, 0 \rangle$$
$$\mathbf{T}_z = \frac{\partial G}{\partial z} = \frac{\partial}{\partial z} \langle 3\cos\theta, 3\sin\theta, z \rangle = \langle 0, 0, 1 \rangle$$

We compute the cross product:

$$\mathbf{T}_\theta \times \mathbf{T}_z = ((-3\sin\theta)\mathbf{i} + (3\cos\theta)\mathbf{j}) \times \mathbf{k} = (3\sin\theta)\mathbf{j} + (3\cos\theta)\mathbf{i} = \langle 3\cos\theta, 3\sin\theta, 0 \rangle$$

The outward pointing normal is (when $\theta = 0$, the x-component must be positive):

$$\mathbf{n} = \langle 3\cos\theta, 3\sin\theta, 0 \rangle$$

Step 2. Evaluate the dot product $\mathbf{F} \cdot \mathbf{n}$. We write $\mathbf{F}(x, y, z) = \langle y, x, e^{xz} \rangle$ in terms of the parameters by substituting $x = 3\cos\theta$, $y = 3\sin\theta$. We get:

$$\mathbf{F}(G(\theta, z)) = \left\langle 3\sin\theta, 3\cos\theta, e^{3z\cos\theta} \right\rangle$$

Hence:

$$\mathbf{F}(G(\theta, z)) \cdot \mathbf{n} = \left\langle 3\sin\theta, 3\cos\theta, e^{3z\cos\theta} \right\rangle \cdot \langle 3\cos\theta, 3\sin\theta, 0 \rangle$$
$$= 18\sin\theta\cos\theta$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral (we use the trigonometric identities $\sin\theta\cos\theta = \frac{\sin 2\theta}{2}$ and $\sin^2 2\theta = \frac{1}{2}(1-\cos 4\theta)$):

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \int_0^{\pi/2}\int_{-3}^{3} \mathbf{F}\left(G(\theta,z)\right)\cdot \mathbf{n}(\theta,z)\,dz\,d\theta = \int_0^{\pi/2}\int_{-3}^{3} 18\sin\theta\cos\theta\,d\theta$$

$$= 18\int_0^{\pi/2} \frac{\sin 2\theta}{2}\,d\theta\cdot\int_{-3}^{3} dz = -9\frac{\cos 2\theta}{2}\Big|_0^{\pi/2}\cdot z\Big|_{-3}^{3}$$

$$= -\frac{9}{2}(-1-1)\cdot(3-(-3)) = 54$$

42. $\mathbf{F}(x,y,z) = \langle -y, z, -x\rangle$, $\quad G(u,v) = (u+3v, v-2u, 2v+5), 0\le u\le 1, 0\le v\le 1$, $\quad$ upward-pointing normal

SOLUTION

Step 1. Compute the tangent and normal vectors.

$$\mathbf{T}_u = \frac{\partial G}{\partial u} = \frac{\partial}{\partial u}\langle u+3v, v-2u, 2v+5\rangle = \langle 1,-2,0\rangle$$

$$\mathbf{T}_v = \frac{\partial G}{\partial v} = \frac{\partial}{\partial v}\langle u+3v, v-2u, 2v+5\rangle = \langle 3,1,2\rangle$$

$$\mathbf{T}_u\times\mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k}\\ 1 & -2 & 0\\ 3 & 1 & 2\end{vmatrix} = \begin{vmatrix} -2 & 0\\ 1 & 2\end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 0\\ 3 & 2\end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & -2\\ 3 & 1\end{vmatrix}\mathbf{k} = -4\mathbf{i}-2\mathbf{j}+7\mathbf{k} = \langle -4,-2,7\rangle$$

Since the normal is pointing upward, the z-component is positive. Therefore the normal vector is $\mathbf{n} = \langle -4,-2,7\rangle$.

Step 2. Evaluate the dot product $\mathbf{F}\cdot\mathbf{n}$. We write $\mathbf{F}$ in terms of the parameters. Since $x = u+3v$, $\quad y = v-2u$, $z = 2v+5$, we have:

$$\mathbf{F}\left(G(u,v)\right) = \langle -y, z, -x\rangle = \langle 2u-v, 2v+5, -u-3v\rangle$$

The dot product is, thus:

$$\mathbf{F}\left(G(u,v)\right)\cdot\mathbf{n} = \langle 2u-v, 2v+5, -u-3v\rangle\cdot\langle -4,-2,7\rangle$$

$$= -4(2u-v) - 2(2v+5) + 7(-u-3v) = -15u-21v-10$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\iint_{S} \mathbf{F}\cdot d\mathbf{s} = \iint_{\mathcal{D}} \mathbf{F}\left(G(u,v)\right)\cdot\mathbf{n}\,du\,dv = \int_0^1\int_0^1 (-15u-21v-10)\,du\,dv$$

$$= \int_0^1 -\frac{15u^2}{2} - 21vu - 10u\Big|_{u=0}^{1} dv = \int_0^1\left(-\frac{35}{2}-21v\right)dv$$

$$= -\frac{35v}{2} - \frac{21v^2}{2}\Big|_0^1 = -\frac{35}{2} - \frac{21}{2} = -28$$

43. $\mathbf{F}(x,y,z) = \left\langle 0,0,x^2+y^2\right\rangle$, $\quad x^2+y^2+z^2 = 4$, $\quad z\ge 0$, outward-pointing normal

SOLUTION The upper hemisphere is parametrized by:

$$G(\theta,\phi) = (2\cos\theta\sin\phi, 2\sin\theta\sin\phi, 2\cos\phi),\quad 0\le\theta\le 2\pi,\quad 0\le\phi\le\frac{\pi}{2}$$

As seen in Section 17.4, since $0\le\phi\le\frac{\pi}{2}$ then the outward-pointing normal is:

$$\mathbf{n} = 4\sin\phi\,\langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle$$

We express $\mathbf{F}$ in terms of the parameters:

$$\mathbf{F}\left(G(\theta,\phi)\right) = \left\langle 0,0,x^2+y^2\right\rangle = \left\langle 0,0,4\sin^2\phi\left(\cos^2\theta+\sin^2\theta\right)\right\rangle$$

$$= \left\langle 0,0,4\sin^2\phi\right\rangle$$

The dot product $\mathbf{F}\cdot\mathbf{n}$ is thus

$$\mathbf{F}\left(G(\theta,\phi)\right)\cdot\mathbf{n}(\theta,\phi) = 16\sin^3\phi\,\cos\phi$$

We obtain the following integral:

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{s} &= \iint_{\mathcal{D}} \mathbf{F}\left(G(\theta,\phi)\right)\cdot \mathbf{n}(\theta,\phi)\,d\theta\,d\phi\\ &= \int_0^{\pi/2}\int_0^{2\pi} 16\sin^3\phi\cos\phi\,d\theta\,d\phi = 16\int_0^{2\pi} d\theta\cdot\int_0^{\pi/2}\sin^3\phi\cos\phi\,d\phi\\ &= 16\cdot 2\pi\cdot \frac{\sin^4\phi}{4}\bigg|_0^{\pi/2} = 8\pi\end{aligned}$$

44. $\mathbf{F}(x,y,z) = \left\langle z, 0, z^2\right\rangle$, $G(u,v) = (v\cosh u, v\sinh u, v)$, $0\le u\le 1$, $0\le v\le 1$, upward-pointing normal

SOLUTION

Step 1. Compute the tangent and normal vectors.

$$\mathbf{T}_u = \frac{\partial G}{\partial u} = \frac{\partial}{\partial u}\langle v\cosh(u), v\sinh(u), v\rangle = \langle v\sinh(u), v\cosh(u), 0\rangle$$

$$\mathbf{T}_v = \frac{\partial G}{\partial v} = \frac{\partial}{\partial v}\langle v\cosh(u), v\sinh(u), v\rangle = \langle \cosh(u), \sinh(u), 1\rangle$$

$$\begin{aligned}\mathbf{T}_u\times\mathbf{T}_v &= \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ v\sinh(u) & v\cosh(u) & 0\\ \cosh(u) & \sinh(u) & 1\end{vmatrix}\\ &= \begin{vmatrix} v\cosh(u) & 0\\ \sinh(u) & 1\end{vmatrix}\mathbf{i} - \begin{vmatrix} v\sinh(u) & 0\\ \cosh(u) & 1\end{vmatrix}\mathbf{j} + \begin{vmatrix} v\sinh(u) & v\cosh(u)\\ \cosh(u) & \sinh(u)\end{vmatrix}\mathbf{k}\\ &= (v\cosh(u))\,\mathbf{i} - (v\sinh(u))\,\mathbf{j} + \left(v\sinh^2(u) - v\cosh^2(u)\right)\mathbf{k}\\ &= \langle v\cosh(u), -v\sinh(u), -v\rangle\end{aligned}$$

Since the normal points upward, the z-component is positive. Therefore the normal vector is, (notice that $v\ge 0$):

$$\mathbf{n} = \langle -v\cosh(u), v\sinh(u), v\rangle$$

Step 2. Evaluate the dot product $\mathbf{F}\cdot\mathbf{n}$. We write $\mathbf{F}$ in terms of the parameters:

$$\mathbf{F}\left(G(u,v)\right) = \left\langle z, 0, z^2\right\rangle = \left\langle v, 0, v^2\right\rangle$$

Hence:

$$\mathbf{F}\left(G(u,v)\right)\cdot\mathbf{n}(u,v) = \left\langle v, 0, v^2\right\rangle\cdot\langle -v\cosh(u), v\sinh(u), v\rangle = -v^2\cosh(u) + v^3$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{s} &= \iint_{\mathcal{D}} \mathbf{F}\left(G(u,v)\right)\cdot\mathbf{n}\,du\,dv = \int_0^1\int_0^1\left(-v^2\cosh(u)+v^3\right)du\,dv\\ &= \int_0^1\int_0^1 -v^2\cosh(u)\,du\,dv + \int_0^1\int_0^1 v^3\,du\,dv = \left(\int_0^1 -v^2\,dv\right)\left(\int_0^1\cosh(u)\,du\right) + \int_0^1 v^3\,dv\\ &= \left(-\frac{v^3}{3}\Big|_{v=0}^1\right)\left(\sinh(u)\Big|_{u=0}^1\right) + \frac{v^4}{4}\bigg|_{v=0}^1 = -\frac{1}{3}\sinh(1) + \frac{1}{4}\approx -0.1417\end{aligned}$$

45. $\mathbf{F}(x,y,z) = \left\langle 0, 0, xze^{xy}\right\rangle$, $z = xy$, $0\le x\le 1$, $0\le y\le 1$, upward-pointing normal

SOLUTION We parametrize the surface by:

$$G(x,y) = (x, y, xy)$$

Where the parameter domain is the square:

$$\mathcal{D} = \{(x,y) : 0\le x\le 1, 0\le y\le 1\}$$

Step 1. Compute the tangent and normal vectors.

$$\mathbf{T}_x = \frac{\partial G}{\partial x} = \frac{\partial}{\partial x}\langle x, y, xy\rangle = \langle 1, 0, y\rangle$$

$$\mathbf{T}_y = \frac{\partial G}{\partial y} = \frac{\partial}{\partial y}\langle x, y, xy\rangle = \langle 0, 1, x\rangle$$

$$\mathbf{T}_x \times \mathbf{T}_y = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & y \\ 0 & 1 & x \end{vmatrix} = \begin{vmatrix} 0 & y \\ 1 & x \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & y \\ 0 & x \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix}\mathbf{k} = -y\mathbf{i} - x\mathbf{j} + \mathbf{k} = \langle -y, -x, 1\rangle$$

Since the normal points upwards, the z-coordinate is positive. Therefore the normal vector is:

$$\mathbf{n} = \langle -y, -x, 1\rangle$$

Step 2. Evaluate the dot product $\mathbf{F} \cdot \mathbf{n}$. We express $\mathbf{F}$ in terms of x and y:

$$\mathbf{F}\left(G(x, y)\right) = \left\langle 0, 0, xze^{xy}\right\rangle = \left\langle 0, 0, x(xy)e^{xy}\right\rangle = \left\langle 0, 0, x^2ye^{xy}\right\rangle$$

Hence:

$$\mathbf{F}\left(G(x, y)\right) \cdot \mathbf{n}(x, y) = \left\langle 0, 0, x^2ye^{xy}\right\rangle \cdot \langle -y, -x, 1\rangle = x^2ye^{xy}$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\begin{aligned}\iint_S \mathbf{F} \cdot d\mathbf{s} &= \iint_{\mathcal{D}} \mathbf{F}\left(G(x, y)\right) \cdot \mathbf{n}(x, y)\, dx\, dy \\ &= \int_0^1 \int_0^1 x^2ye^{xy}\, dy\, dx = \int_0^1 x^2 \left(\int_0^1 ye^{xy}\, dy\right) dx \end{aligned} \tag{1}$$

We evaluate the inner integral using integration by parts:

$$\int_0^1 ye^{xy}\, dy = \frac{y}{x}e^{xy}\Big|_{y=0}^1 - \int_0^1 \frac{1}{x}e^{xy}\, dy = \frac{e^x}{x} - \frac{1}{x^2}e^{xy}\Big|_{y=0}^1 = \frac{e^x}{x} - \frac{1}{x^2}\left(e^x - 1\right)$$

Substituting this integral in (1) gives:

$$\begin{aligned}\iint_S \mathbf{F} \cdot d\mathbf{s} &= \int_0^1 \left(xe^x - \left(e^x - 1\right)\right) dx = \int_0^1 xe^x\, dx - \int_0^1 \left(e^x - 1\right) dx \\ &= \int_0^1 xe^x\, dx - \left(e^x - x\right)\Big|_0^1 = \int_0^1 xe^x\, dx - (e - 2)\end{aligned}$$

Using integration by parts we have:

$$\iint_S F \cdot dS = xe^x - e^x\Big|_0^1 - (e - 2) = 1 - (e - 2) = 3 - e$$

46. $\mathbf{F}(x, y, z) = \langle 0, 0, z\rangle, \quad 3x^2 + 2y^2 + z^2 = 1, \quad z \geq 0,$
upward-pointing normal

SOLUTION We use modified spherical coordinates to parametrize the ellipsoid:

$$G(\theta, \phi) = \left(\frac{1}{\sqrt{3}}\cos\theta\sin\phi, \frac{1}{\sqrt{2}}\sin\theta\sin\phi, \cos\phi\right)$$

where the parameter domain is:

$$\mathcal{D} = \left\{(\theta, \phi) : 0 \leq \theta \leq 2\pi, 0 \leq \phi \leq \frac{\pi}{2}\right\}$$

Step 1. Compute the tangent and normal vectors.

$$\mathbf{T}_\theta = \frac{\partial G}{\partial \theta} = \left\langle -\frac{1}{\sqrt{3}}\sin\theta\sin\phi, \frac{1}{\sqrt{2}}\cos\theta\sin\phi, 0\right\rangle$$

$$\mathbf{T}_\phi = \frac{\partial G}{\partial \phi} = \left\langle \frac{1}{\sqrt{3}}\cos\theta\cos\phi, \frac{1}{\sqrt{2}}\sin\theta\cos\phi, -\sin\phi\right\rangle$$

$$\mathbf{T}_\theta \times \mathbf{T}_\phi = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\frac{1}{\sqrt{3}}\sin\theta\sin\phi & \frac{1}{\sqrt{2}}\cos\theta\sin\phi & 0 \\ \frac{1}{\sqrt{3}}\cos\theta\cos\phi & \frac{1}{\sqrt{2}}\sin\theta\cos\phi & -\sin\phi \end{vmatrix}$$

$$= \left(-\frac{1}{\sqrt{2}}\cos\theta\ \sin^2\phi\right)\mathbf{i} - \left(\frac{1}{\sqrt{3}}\sin\theta\ \sin^2\phi\right)\mathbf{j} - \left(\frac{1}{\sqrt{6}}\sin^2\theta\sin\phi\cos\phi + \frac{1}{\sqrt{6}}\cos^2\theta\sin\phi\cos\phi\right)\mathbf{k}$$

$$= \left(-\frac{1}{\sqrt{2}}\cos\theta\ \sin^2\phi\right)\mathbf{i} - \left(\frac{1}{\sqrt{3}}\sin\theta\ \sin^2\phi\right)\mathbf{j} - \left(\frac{1}{\sqrt{6}}\sin\phi\cos\phi\right)\mathbf{k}$$

Since the normal points upward, the z-component is positive. For $0 \le \phi \le \frac{\pi}{2}$, $\sin\phi\cos\phi \ge 0$ therefore the normal vector is:

$$\mathbf{n} = \left\langle \frac{1}{\sqrt{2}}\cos\theta\ \sin^2\phi,\ \frac{1}{\sqrt{3}}\sin\theta\ \sin^2\phi,\ \frac{1}{\sqrt{6}}\sin\phi\cos\phi \right\rangle$$

Step 2. Compute the dot product $\mathbf{F}\cdot\mathbf{n}$. We have:

$$\mathbf{F}(G(\theta,\phi)) = \langle 0, 0, \cos\phi\rangle \cdot \left\langle \frac{1}{\sqrt{2}}\cos\theta\sin^2\phi,\ \frac{1}{\sqrt{3}}\sin\theta\sin^2\phi,\ \frac{1}{\sqrt{6}}\sin\phi\cos\phi \right\rangle = \frac{1}{\sqrt{6}}\sin\phi\cos^2\phi$$

Step 3. Evaluate the surface integral. The surface integral is equal to the following double integral:

$$\iint_S \mathbf{F}\cdot d\mathbf{s} = \iint_{\mathcal{D}} \mathbf{F}(G(\theta,\phi))\cdot\mathbf{n}(\theta,\phi)\,d\phi\,d\theta = \int_0^{2\pi}\int_0^{\pi/2} \frac{1}{\sqrt{6}}\sin\phi\ \cos^2\phi\,d\phi\,d\theta$$

$$= \frac{2\pi}{\sqrt{6}}\int_0^{\pi/2}\cos^2\phi\ \sin\phi\,d\phi = \frac{2\pi}{\sqrt{6}}\left(-\frac{\cos^3\phi}{3}\Big|_{\phi=0}^{\pi/2}\right) = \frac{2\pi}{\sqrt{6}}\left(\frac{0+1}{3}\right) = \frac{2\pi}{3\sqrt{6}} = \frac{\sqrt{2}}{3\sqrt{3}}\pi$$

47. Calculate the total charge on the cylinder

$$x^2 + y^2 = R^2, \qquad 0 \le z \le H$$

if the charge density in cylindrical coordinates is $\rho(\theta, z) = Kz^2\cos^2\theta$, where K is a constant.

SOLUTION The total change on the surface $\mathcal{S}$ is $\iint_{\mathcal{S}} \rho\, dS$. We parametrize the surface by,

$$\mathrm{G}(\theta, z) = (R\cos\theta, R\sin\theta, Hz)$$

with the parameter domain,

$$0 \le \theta \le 2\pi,\ 0 \le z \le 1.$$

We compute the tangent and normal vectors:

$$\mathbf{T}_\theta = \frac{\partial G}{\partial\theta} = \frac{\partial}{\partial\theta}\langle R\cos\theta, R\sin\theta, Hz\rangle = \langle -R\sin\theta, R\cos\theta, 0\rangle$$

$$\mathbf{T}_z = \frac{\partial G}{\partial z} = \frac{\partial}{\partial z}\langle R\cos\theta, R\sin\theta, Hz\rangle = \langle 0, 0, H\rangle$$

The normal vector is their cross product:

$$\mathbf{n} = \mathbf{T}_\theta \times \mathbf{T}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -R\sin\theta & R\cos\theta & 0 \\ 0 & 0 & H \end{vmatrix}$$

$$= \begin{vmatrix} R\cos\theta & 0 \\ 0 & H \end{vmatrix}\mathbf{i} - \begin{vmatrix} -R\sin\theta & 0 \\ 0 & H \end{vmatrix}\mathbf{j} + \begin{vmatrix} -R\sin\theta & R\cos\theta \\ 0 & 0 \end{vmatrix}\mathbf{k}$$

$$= (RH\cos\theta)\mathbf{i} + (RH\sin\theta)\mathbf{j} = RH\langle\cos\theta, \sin\theta, 0\rangle$$

We find the length of $\mathbf{n}$:

$$\|\mathbf{n}\| = RH\sqrt{\cos^2\theta + \sin^2\theta} = RH$$

We compute $\rho(G(\theta, z))$:

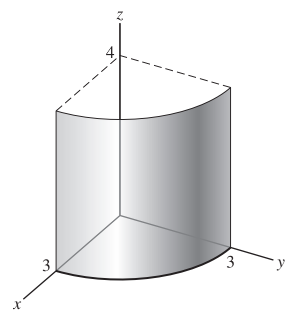
$$\rho(G(\theta, z)) = K(Hz)^2\cos^2\theta = KH^2z^2\cos^2\theta$$

Using the Theorem on Surface Integrals we obtain:

$$\iint_{\mathcal{S}} \rho \cdot dS = \iint_{\mathcal{D}} \rho\,(G(\theta, z)) \cdot \|\mathbf{n}(\theta, z)\|\, dz\, d\theta = \int_0^{2\pi} \int_0^1 KH^2 z^2 \cos^2\theta \cdot HR\, dz\, d\theta$$
$$= \left(\int_0^1 KH^3Rz^2 dz\right)\left(\int_0^{2\pi} \cos^2\theta\, d\theta\right) = \left(\frac{KH^3Rz^3}{3}\Big|_0^1\right)\left(\frac{\theta}{2} + \frac{\sin 2\theta}{4}\Big|_0^{2\pi}\right)$$
$$= \frac{KH^3R}{3} \cdot \pi = \frac{\pi}{3} KH^3R$$

48. Find the flow rate of a fluid with velocity field $\mathbf{v} = \langle 2x, y, xy\rangle$ m/s across the part of the cylinder $x^2 + y^2 = 9$ where $x \ge 0$, $y \ge 0$, and $0 \le z \le 4$ (distance in meters).

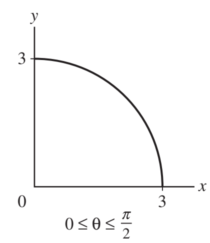
SOLUTION The flow rate of a fluid with velocity field $\mathbf{v}$ through the part $\mathcal{S}$ of the cylinder is the surface integral:



$$\iint_{\mathcal{S}} \mathbf{v} \cdot d\mathbf{S} \tag{1}$$

We parametrize $\mathcal{S}$ by,

$$G(\theta, z) = (3\cos\theta, 3\sin\theta, z), \quad 0 \le \theta \le \frac{\pi}{2}, \quad 0 \le z \le 4.$$



Step 1. Compute the tangent and normal vectors.

$$\mathbf{T}_\theta = \frac{\partial G}{\partial \theta} = \frac{\partial}{\partial \theta}\langle 3\cos\theta, 3\sin\theta, z\rangle = \langle -3\sin\theta, 3\cos\theta, 0\rangle = (-3\sin\theta)\,\mathbf{i} + (3\cos\theta)\mathbf{j}$$
$$\mathbf{T}_z = \frac{\partial G}{\partial z} = \frac{\partial}{\partial z}\langle 3\cos\theta, 3\sin\theta, z\rangle = \langle 0, 0, 1\rangle = \mathbf{k}$$
$$\mathbf{n} = \mathbf{T}_\theta \times \mathbf{T}_z = ((-3\sin\theta)\mathbf{i} + (3\cos\theta)\mathbf{j}) \times \mathbf{k} = (3\sin\theta)\mathbf{j} + (3\cos\theta)\mathbf{i} = \langle 3\cos\theta, 3\sin\theta, 0\rangle$$

Step 2. Compute the dot product $\mathbf{v} \cdot \mathbf{n}$.

$$\mathbf{v}\,(G(\theta, z)) \cdot \mathbf{n} = \langle 2 \cdot 3\cos\theta, 3\sin\theta, 9\cos\theta\sin\theta\rangle \cdot \langle 3\cos\theta, 3\sin\theta, 0\rangle$$
$$= 18\cos^2\theta + 9\sin^2\theta = 9\left(\cos^2\theta + \sin^2\theta\right) + 9\cos^2\theta = 9\cos^2\theta + 9$$

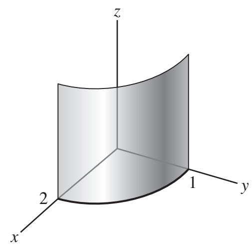
Step 3. Evaluate the flux of $\mathbf{v}$. The flux of $\mathbf{v}$ in (1) is equal to the following double integral (we use the equality $\cos^2\theta = \frac{1}{2} + \frac{1}{2}\cos 2\theta$):

$$\iint_{\mathcal{S}} \mathbf{v} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{v}\,(G(\theta, z)) \cdot \mathbf{n}\, d\theta\, dz = \int_0^4 \int_0^{\pi/2} \left(9\cos^2\theta + 9\right) d\theta\, dz$$
$$= 4\int_0^{\pi/2} \left(9\cos^2\theta + 9\right) d\theta = 36\int_0^{\pi/2} \left(\cos^2\theta + 1\right) d\theta$$
$$= 36\int_0^{\pi/2} \left(\frac{3}{2} + \frac{1}{2}\cos 2\theta\right) d\theta = 36\left(\frac{3}{2}\theta + \frac{1}{4}\sin 2\theta\Big|_{\theta=0}^{\pi/2}\right) = 27\pi$$

49. With $\mathbf{v}$ as in Exercise 48, calculate the flow rate across the part of the elliptic cylinder $\frac{x^2}{4} + y^2 = 1$ where $x \ge 0$, $y \ge 0$, and $0 \le z \le 4$.

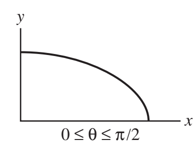
SOLUTION The flow rate of a fluid with velocity field $\mathbf{v} = \langle 2x, y, xy \rangle$ through the elliptic cylinder S is the surface integral:

$$\iint_{\mathcal{S}} \mathbf{v} \cdot d\mathbf{S} \tag{1}$$



To compute this integral, we parametrize $\mathcal{S}$ by,

$$G(\theta, z) = (2\cos\theta, \sin\theta, z), \quad 0 \le \theta \le \frac{\pi}{2}, \quad 0 \le z \le 4$$



Step 1. Compute the tangent and normal vectors.

$$\mathbf{T}_\theta = \frac{\partial G}{\partial \theta} = \frac{\partial}{\partial \theta} \langle 2\cos\theta, \sin\theta, z \rangle = \langle -2\sin\theta, \cos\theta, 0 \rangle$$

$$\mathbf{T}_z = \frac{\partial G}{\partial z} = \frac{\partial}{\partial z} \langle 2\cos\theta, \sin\theta, z \rangle = \langle 0, 0, 1 \rangle$$

$$\mathbf{n} = \mathbf{T}_\theta \times \mathbf{T}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = (\cos\theta)\mathbf{i} + (2\sin\theta)\mathbf{j} = \langle \cos\theta, 2\sin\theta, 0 \rangle$$

Step 2. Compute the dot product $\mathbf{v} \cdot \mathbf{n}$

$$\begin{aligned} \mathbf{v}(G(\theta, z)) \cdot \mathbf{n} &= \langle 4\cos\theta, \sin\theta, 2\cos\theta\sin\theta \rangle \cdot \langle \cos\theta, 2\sin\theta, 0 \rangle = 4\cos^2\theta + 2\sin^2\theta \\ &= 2\cos^2\theta + 2\left(\cos^2\theta + \sin^2\theta\right) = 2\cos^2\theta + 2 \end{aligned}$$

Step 3. Evaluate the flux of $\mathbf{v}$. The flux of $\mathbf{v}$ in (1) is equal to the following double integral (we use the equality $2\cos^2\theta = 1 + \cos 2\theta$ in our calculation):

$$\begin{aligned} \iint_{\mathcal{S}} \mathbf{v} \cdot d\mathbf{S} &= \iint_{\mathcal{D}} \mathbf{v}(G(\theta, z)) \cdot \mathbf{n}\, d\theta\, dz = \int_0^4 \int_0^{\pi/2} \left(2\cos^2\theta + 2\right) d\theta\, dz \\ &= 4\int_0^{\pi/2} \left(2\cos^2\theta + 2\right) d\theta = 4\int_0^{\pi/2} (3 + \cos 2\theta)\, d\theta = 4\left(3\theta + \frac{\sin 2\theta}{2}\Big|_{\theta=0}^{\pi/2}\right) = 6\pi \end{aligned}$$

50. Calculate the flux of the vector field $\mathbf{E}(x, y, z) = \langle 0, 0, x \rangle$ through the part of the ellipsoid

$$4x^2 + 9y^2 + z^2 = 36$$

where $z \ge 3$, $x \ge 0$, $y \ge 0$. *Hint:* Use the parametrization

$$G(r, \theta) = \left(3r\cos\theta, 2r\sin\theta, 6\sqrt{1 - r^2}\right)$$

SOLUTION The flux of the vector field $\mathbf{E}$ through the part $\mathcal{S}$ of the ellipsoid is the surface integral:

$$\iint_{\mathcal{S}} \mathbf{E} \cdot d\mathbf{S} \tag{1}$$

We use the following parametrization for $\mathcal{S}$:

$$G(\theta, r) = \left(3r\cos\theta, 2r\sin\theta, 6\sqrt{1-r^2}\right)$$

With the parameter domain:

$$\mathcal{D} = \left\{(\theta, r) : 0 \le \theta \le \frac{\pi}{2},\ 0 \le r \le \frac{\sqrt{3}}{2}\right\}$$

We justify this parametrization. First, we verify that $x = 3r\cos\theta$, $y = 2r\sin\theta$ and $z = 6\sqrt{1-r^2}$ satisfy the equation of the ellipsoid $4x^2 + 9y^2 + z^2 = 36$.

$$4x^2 + 9y^2 + z^2 = 4(3r\cos\theta)^2 + 9(2r\sin\theta)^2 + \left(6\sqrt{1-r^2}\right)^2 = 36r^2\cos^2\theta + 36r^2\sin^2\theta + 36\left(1-r^2\right)$$
$$= 36r^2\left(\cos^2\theta + \sin^2\theta\right) + 36 - 36r^2 = 36r^2 + 36 - 36r^2 = 36$$

Next, the part $z \ge 3$ of the ellipsoid corresponds to the values of r such that $6\sqrt{1-r^2} \ge 3$. We solve for $r \ge 0$:

$$6\sqrt{1-r^2} \ge 3 \quad \Rightarrow \quad \sqrt{1-r^2} \ge \frac{1}{2} \quad \Rightarrow \quad 1-r^2 \ge \frac{1}{4} \quad \Rightarrow \quad r^2 \le \frac{3}{4} \quad \Rightarrow \quad 0 \le r \le \frac{\sqrt{3}}{2}$$

Finally,

$$x \ge 0,\ y \ge 0 \quad \Rightarrow \quad \cos\theta \ge 0,\ \sin\theta \ge 0 \quad \Rightarrow \quad 0 \le \theta \le \frac{\pi}{2}$$

Step 1. Compute the tangent and normal vectors.

$$\mathbf{T}_\theta = \frac{\partial G}{\partial\theta} = \frac{\partial}{\partial\theta}\left\langle 3r\cos\theta, 2r\sin\theta, 6\sqrt{1-r^2}\right\rangle = \langle -3r\sin\theta, 2r\cos\theta, 0\rangle$$
$$\mathbf{T}_r = \frac{\partial G}{\partial r} = \frac{\partial}{\partial r}\left\langle 3r\cos\theta, 2r\sin\theta, 6\sqrt{1-r^2}\right\rangle = \left\langle 3\cos\theta, 2\sin\theta, -\frac{6r}{\sqrt{1-r^2}}\right\rangle$$

The outward pointing normal is:

$$\mathbf{n} = -\mathbf{T}_\theta \times \mathbf{T}_r = ((3r\sin\theta)\mathbf{i} - (2r\cos\theta)\mathbf{j}) \times \left((3\cos\theta)\mathbf{i} + (2\sin\theta)\mathbf{j} - \frac{6r}{\sqrt{1-r^2}}\mathbf{k}\right)$$
$$= 6r\sin^2\theta\mathbf{k} + \frac{18r^2\sin\theta}{\sqrt{1-r^2}}\mathbf{j} + \left(6r\cos^2\theta\right)\mathbf{k} + \frac{12r^2\cos\theta}{\sqrt{1-r^2}}\mathbf{i} = \frac{12r^2\cos\theta}{\sqrt{1-r^2}}\mathbf{i} + \frac{18r^2\sin\theta}{\sqrt{1-r^2}}\mathbf{j} + 6r\mathbf{k}$$

Step 2. Compute the dot product $\mathbf{E}\cdot\mathbf{n}$.

$$\mathbf{E}\left(G(\theta, r)\right)\cdot\mathbf{n} = \langle 0, 0, 3r\cos\theta\rangle \cdot \left\langle \frac{12r^2\cos\theta}{\sqrt{1-r^2}}, \frac{18r^2\sin\theta}{\sqrt{1-r^2}}, 6r\right\rangle = 18r^2\cos\theta$$

Step 3. Evaluate the flux of $\mathbf{E}$. The flux of $\mathbf{E}$ in (1) is equal to the following double integral:

$$\iint_{\mathcal{S}} \mathbf{E}\cdot d\mathbf{S} = \iint_{\mathcal{D}} \mathbf{E}\left(G(\theta, r)\right)\cdot\mathbf{n}\, dr\, d\theta = \int_0^{\pi/2}\int_0^{\sqrt{3}/2} 18r^2\cos\theta\, dr\, d\theta$$
$$= 18\int_0^{\pi/2}\cos\theta\, d\theta \cdot \int_0^{\sqrt{3}/2} r^2\, dr = 18\sin\theta\Big|_0^{\pi/2} \cdot \frac{r^3}{3}\Big|_0^{\sqrt{3}/2}$$
$$= \frac{9\sqrt{3}}{4}$$

17 FUNDAMENTAL THEOREMS OF VECTOR ANALYSIS

17.1 Green's Theorem (LT Section 18.1)

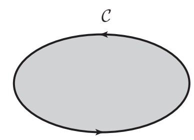
Preliminary Questions

1. Which vector field **F** is being integrated in the line integral $\oint x^2\,dy - e^y\,dx$?

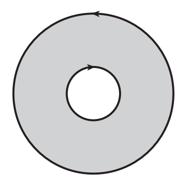
SOLUTION The line integral can be rewritten as $\oint -e^y\,dx + x^2\,dy$. This is the line integral of $\mathbf{F} = \left\langle -e^y, x^2 \right\rangle$ along the curve.

2. Draw a domain in the shape of an ellipse and indicate with an arrow the boundary orientation of the boundary curve. Do the same for the annulus (the region between two concentric circles).

SOLUTION The orientation on $\mathcal{C}$ is counterclockwise, meaning that the region enclosed by $\mathcal{C}$ lies to the left in traversing $\mathcal{C}$.



For the annulus, the inner boundary is oriented clockwise and the outer boundary is oriented counterclockwise. The region between the circles lies to the left while traversing each circle.



3. The circulation of a conservative vector field around a closed curve is zero. Is this fact consistent with Green's Theorem? Explain.

SOLUTION Green's Theorem asserts that

$$\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} = \int_{\mathcal{C}} P\,dx + Q\,dy = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dA \tag{1}$$

If **F** is conservative, the cross partials are equal, that is,

$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x} \quad \Rightarrow \quad \frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 0 \tag{2}$$

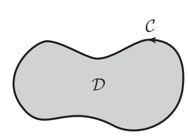
Combining (1) and (2) we obtain $\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} = 0$. That is, Green's Theorem implies that the integral of a conservative vector field around a simple closed curve is zero.

4. Indicate which of the following vector fields possess the following property: For every simple closed curve $\mathcal{C}$, $\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s}$ is equal to the area enclosed by $\mathcal{C}$.

(a) $\mathbf{F} = \langle -y, 0\rangle$ **(b)** $\mathbf{F} = \langle x, y\rangle$ **(c)** $\mathbf{F} = \left\langle \sin(x^2), x + e^{y^2}\right\rangle$

SOLUTION By Green's Theorem,

$$\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dx\,dy \tag{1}$$



(a) Here, $P = -y$ and $Q = 0$, hence $\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 0 - (-1) = 1$. Therefore, by (1),

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} 1\,dx\,dy = \text{Area}(\mathcal{D})$$

(b) We have $P = x$ and $Q = y$, therefore $\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 0 - 0 = 0$. By (1) we get

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} 0\,dx\,dy = 0 \neq \text{Area}(\mathcal{D})$$

(c) In this vector field we have $P = \sin(x^2)$ and $Q = x + e^{y^2}$. Therefore,

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 1 - 0 = 1.$$

By (1) we obtain

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} 1\,dx\,dy = \text{Area}(\mathcal{D}).$$

Exercises

1. Verify Green's Theorem for the line integral $\oint_{\mathcal{C}} xy\,dx + y\,dy$, where $\mathcal{C}$ is the unit circle, oriented counterclockwise.

SOLUTION

Step 1. Evaluate the line integral. We use the parametrization $\gamma(\theta) = \langle \cos\theta, \sin\theta \rangle$, $0 \le \theta \le 2\pi$ of the unit circle. Then

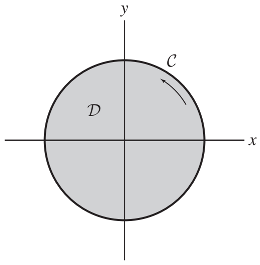
$$dx = -\sin\theta\,d\theta, \quad dy = \cos\theta\,d\theta$$

and

$$xy\,dx + y\,dy = \cos\theta\sin\theta(-\sin\theta\,d\theta) + \sin\theta\cos\theta\,d\theta = \left(-\cos\theta\sin^2\theta + \sin\theta\cos\theta\right)d\theta$$

The line integral is thus

$$\begin{aligned}\int_{\mathcal{C}} xy\,dx + y\,dy &= \int_0^{2\pi} \left(-\cos\theta\sin^2\theta + \sin\theta\cos\theta\right)d\theta \\ &= \int_0^{2\pi} -\cos\theta\sin^2\theta\,d\theta + \int_0^{2\pi} \sin\theta\cos\theta\,d\theta = -\frac{\sin^3\theta}{3}\Big|_0^{2\pi} - \frac{\cos 2\theta}{4}\Big|_0^{2\pi} = 0 \qquad (1)\end{aligned}$$



Step 2. Evaluate the double integral. Since $P = xy$ and $Q = y$, we have

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 0 - x = -x$$

We compute the double integral in Green's Theorem:

$$\iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dx\,dy = \iint_{\mathcal{D}} -x\,dx\,dy = -\iint_{\mathcal{D}} x\,dx\,dy$$

The integral of x over the disk $\mathcal{D}$ is zero, since by symmetry the positive and negative values of x cancel each other. Therefore,

$$\iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dx\,dy = 0 \qquad (2)$$

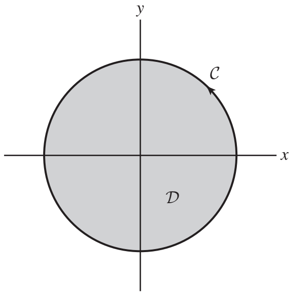
Step 3. Compare. The line integral in (1) is equal to the double integral in (2), as stated in Green's Theorem.

2. Let $I = \oint_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$, where $\mathbf{F} = \left\langle y + \sin x^2, x^2 + e^{y^2} \right\rangle$ and $\mathcal{C}$ is the circle of radius 4 centered at the origin.

(a) Which is easier, evaluating I directly or using Green's Theorem?

(b) Evaluate I using the easier method.

SOLUTION



(a) Using the parametrization $\gamma(\theta) = \langle 4\cos\theta, 4\sin\theta \rangle$ for the circle, we have

$$dx = -4\sin\theta\, d\theta, \quad dy = 4\cos\theta\, d\theta$$

and

$$(y + \sin x^2)dx + (x^2 + e^{y^2})dy = \left(4\sin\theta + \sin(16\cos^2\theta)\right)(-4\sin\theta)\,d\theta + (16\cos^2\theta + e^{16\sin^2\theta}) \cdot 4\cos\theta\, d\theta$$

$$= \left(-16\sin^2\theta - 4\sin\theta\sin(16\cos^2\theta) + 64\cos^3\theta + 4\cos\theta e^{16\sin^2\theta}\right) d\theta$$

The line integral is thus

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{2\pi} \left(-16\sin^2\theta - 4\sin\theta\sin(16\cos^2\theta) + 64\cos^3\theta + 4\cos\theta e^{16\sin^2\theta}\right) d\theta \tag{1}$$

We examine the double integral in Green's Theorem. Since $P = y + \sin x^2$ and $Q = x^2 + e^{y^2}$, we have

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 2x - 1$$

The double integral is thus

$$\iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dA = \iint_{\mathcal{D}} (2x - 1)\, dx\, dy \tag{2}$$

Clearly, the double integral in (2) is much easier to evaluate than the line integral in (1).

(b) To evaluate the double integral in (2), we notice that by symmetry the integral of $2x$ over $\mathcal{D}$ is zero, since the positive and negative values of x cancel each other. Hence,

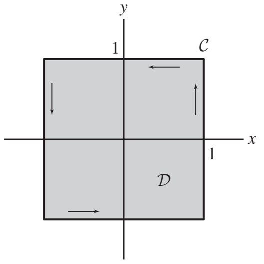
$$\iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dA = \iint_{\mathcal{D}} (2x - 1)\, dx\, dy = \iint_{\mathcal{D}} 2x\, dx\, dy - \iint_{\mathcal{D}} 1\, dx\, dy$$

$$= 0 - \text{Area}(\mathcal{D}) = -\pi \cdot 4^2 = -16\pi$$

In Exercises 3–10, use Green's Theorem to evaluate the line integral. Orient the curve counterclockwise unless otherwise indicated.

3. $\oint_{\mathcal{C}} y^2\, dx + x^2\, dy$, where $\mathcal{C}$ is the boundary of the unit square $0 \le x \le 1$, $0 \le y \le 1$

SOLUTION



We have $P = y^2$ and $Q = x^2$, therefore

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 2x - 2y$$

Using Green's Theorem we obtain

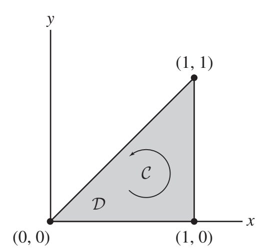
$$\int_{\mathcal{C}} y^2\,dx + x^2\,dy = \iint_{\mathcal{D}} \frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\,dA = \iint_{\mathcal{D}} (2x - 2y)\,dx\,dy = 2\iint_{\mathcal{D}} x\,dx\,dy - 2\iint_{\mathcal{D}} y\,dx\,dy$$

By symmetry, the positive and negative values of x cancel each other in the first integral, so this integral is zero. The second double integral is zero by similar reasoning. Therefore,

$$\int_{\mathcal{C}} y^2\,dx + x^2\,dy = 0 - 0 = 0$$

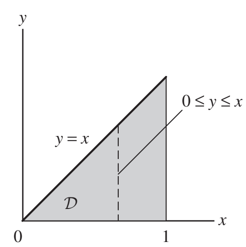
4. $\oint_{\mathcal{C}} e^{2x+y}\,dx + e^{-y}\,dy$, where $\mathcal{C}$ is the triangle with vertices $(0, 0)$, $(1, 0)$, and $(1, 1)$

SOLUTION



We have $P = e^{2x+y}$ and $Q = e^{-y}$, hence

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 0 - e^{2x+y} = -e^{2x+y}$$



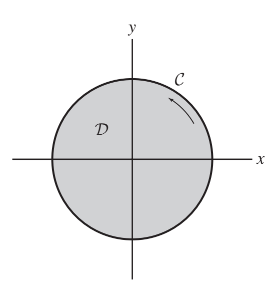
Using Green's Theorem we get

$$\int_{\mathcal{C}} e^{2x+y}\,dx + e^{-y}\,dy = \iint_{\mathcal{D}} \frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\,dA = \iint_{\mathcal{D}} -e^{2x+y}\,dA = \int_0^1 \int_0^x -e^{2x+y}\,dy\,dx$$

$$= \int_0^1 -e^{2x+y}\Big|_{y=0}^{x}\,dx = \int_0^1 \left(-e^{3x} + e^{2x}\right)\,dx = -\frac{e^{3x}}{3} + \frac{e^{2x}}{2}\Big|_0^1 = \frac{e^2}{2} - \frac{e^3}{3} - \frac{1}{6}$$

5. $\oint_{\mathcal{C}} x^2\,y\,dx$, where $\mathcal{C}$ is the unit circle centered at the origin

SOLUTION



In this function $P = x^2 y$ and $Q = 0$. Therefore,

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 0 - x^2 = -x^2$$

We obtain the following integral:

$$I = \int_{\mathcal{C}} x^2 y\, dx = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA = \iint_{\mathcal{D}} -x^2\, dA$$

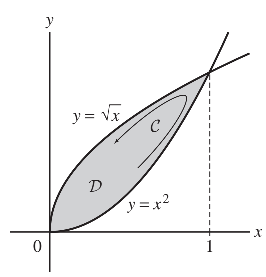
We convert the integral to polar coordinates. This gives

$$I = \int_0^{2\pi} \int_0^1 -r^2 \cos^2\theta \cdot r\, dr\, d\theta = \int_0^{2\pi} \int_0^1 -r^3 \cos^2\theta\, dr\, d\theta$$
$$= \left(\int_0^{2\pi} \cos^2\theta\, d\theta \right) \left(\int_0^1 -r^3\, dr \right) = \left(\frac{\theta}{2} + \frac{\sin 2\theta}{4} \Big|_{\theta=0}^{2\pi} \right) \left(-\frac{r^4}{4} \Big|_{r=0}^{1} \right) = \pi \cdot \left(-\frac{1}{4} \right) = -\frac{\pi}{4}$$

6. $\oint_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$, where $\mathbf{F} = \langle x + y, x^2 - y \rangle$ and $\mathcal{C}$ is the boundary of the region enclosed by $y = x^2$ and $y = \sqrt{x}$ for $0 \le x \le 1$

SOLUTION By Green's Theorem we have

$$I = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA$$



Since $P = x + y$ and $Q = x^2 - y$, we have

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 2x - 1$$

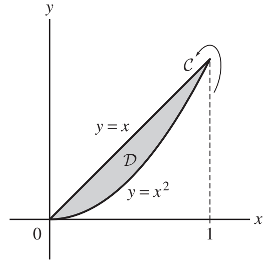
Therefore,

$$I = \iint_{\mathcal{D}} (2x - 1)\, dA = \int_0^1 \int_{x^2}^{\sqrt{x}} (2x - 1)\, dy\, dx = \int_0^1 (2x - 1) y \Big|_{y=x^2}^{\sqrt{x}} dx$$
$$= \int_0^1 (2x - 1) \left(\sqrt{x} - x^2 \right) dx = \int_0^1 \left(2x^{3/2} - 2x^3 - x^{1/2} + x^2 \right) dx$$
$$= \frac{4}{5} x^{5/2} - \frac{1}{2} x^4 - \frac{2}{3} x^{3/2} + \frac{x^3}{3} \Big|_0^1 = \frac{4}{5} - \frac{1}{2} - \frac{2}{3} + \frac{1}{3} = -\frac{1}{30}$$

7. $\oint_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$, where $\mathbf{F} = \langle x^2, x^2 \rangle$ and $\mathcal{C}$ consists of the arcs $y = x^2$ and $y = x$ for $0 \le x \le 1$

SOLUTION By Green's Theorem,

$$I = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA$$



We have $P = Q = x^2$, therefore

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 2x - 0 = 2x$$

Hence,

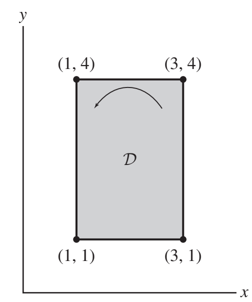
$$I = \iint_{\mathcal{D}} 2x\, dA = \int_0^1 \int_{x^2}^{x} 2x\, dy\, dx = \int_0^1 2xy \Big|_{y=x^2}^{x} dx = \int_0^1 2x(x - x^2)\, dx = \int_0^1 (2x^2 - 2x^3)\, dx$$

$$= \frac{2}{3}x^3 - \frac{1}{2}x^4 \Big|_0^1 = \frac{2}{3} - \frac{1}{2} = \frac{1}{6}$$

8. $\oint_{\mathcal{C}} (\ln x + y)\, dx - x^2\, dy$, where $\mathcal{C}$ is the rectangle with vertices $(1, 1)$, $(3, 1)$, $(1, 4)$, and $(3, 4)$

SOLUTION By Green's Theorem,

$$I = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA$$



We have $P = \ln x + y$ and $Q = -x^2$, therefore

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = -2x - 1$$

Hence,

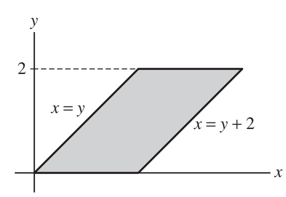
$$I = \iint_{\mathcal{D}} (-2x - 1)\, dA = \int_1^3 \int_1^4 (-2x - 1)\, dy\, dx = \int_1^3 (-2x - 1)y \Big|_{y=1}^{4} dx = \int_1^3 -3(2x + 1)\, dx$$

$$= -3(x^2 + x) \Big|_1^3 = -3(12 - 2) = -30$$

9. The line integral of $\mathbf{F} = \langle e^{x+y}, e^{x-y} \rangle$ along the curve (oriented clockwise) consisting of the line segments by joining the points $(0, 0)$, $(2, 2)$, $(4, 2)$, $(2, 0)$, and back to $(0, 0)$ (note the orientation).

SOLUTION Consider $\mathbf{F} = \langle e^{x+y}, e^{x-y} \rangle$. Here, $P = e^{x+y}$ and $Q = e^{x-y}$, hence

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = e^{x-y} - e^{x+y} = e^x(e^{-y} - e^y).$$



Using Green's Theorem we obtain

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} e^x(e^{-y} - e^y)\, dx\, dy = \int_0^2 \int_y^{y+2} e^x(e^{-y} - e^y)\, dx\, dy = \int_0^2 e^x(e^{-y} - e^y) \Big|_{x=y}^{y+2} dy$$

$$= \int_0^2 (e^{y+2} - e^y)(e^{-y} - e^y)\, dy = \int_0^2 (e^2 - 1)(1 - e^{2y})\, dy = (e^2 - 1)\left(y - \frac{e^{2y}}{2} \right) \Big|_{y=0}^{2}$$

$$= (e^2 - 1)\left(2 - \frac{e^4}{2} - \left(-\frac{1}{2} \right) \right) = \frac{(e^2 - 1)(5 - e^4)}{2}$$

10. $\int_{\mathcal{C}} xy\,dx + (x^2 + x)\,dy$, where $\mathcal{C}$ is the path in Figure 16

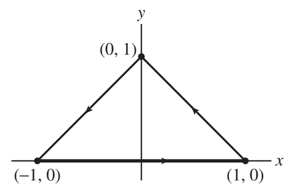


FIGURE 16

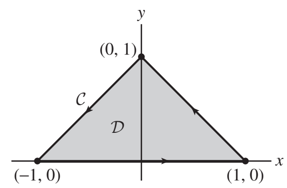
SOLUTION



In the given function, $P = xy$ and $Q = x^2 + x$. Therefore,

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 2x + 1 - x = x + 1$$

By Green's Theorem we obtain the following integral:

$$\int_{\mathcal{C}} xy\,dx + (x^2 + x)\,dy = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dA = \iint_{\mathcal{D}} (x+1)\,dA = \iint_{\mathcal{D}} x\,dA + \iint_{\mathcal{D}} 1\,dA$$

By symmetry, the positive and negative values of x cancel each other, causing the first integral to be zero. Thus,

$$\int_{\mathcal{C}} xy\,dx + (x^2 + x)\,dy = 0 + \iint_{\mathcal{D}} dA = \text{Area}(\mathcal{D}) = \frac{2 \cdot 1}{2} = 1.$$

11. Let $\mathbf{F} = \left\langle 2xe^y, x + x^2 e^y \right\rangle$ and let $\mathcal{C}$ be the quarter-circle path from A to B in Figure 17. Evaluate $I = \oint_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$ as follows:

(a) Find a function $V(x, y)$ such that $\mathbf{F} = \mathbf{G} + \nabla V$, where $\mathbf{G} = \langle 0, x \rangle$.

(b) Show that the line integrals of $\mathbf{G}$ along the segments $\overline{OA}$ and $\overline{OB}$ are zero.

(c) Evaluate I. *Hint:* Use Green's Theorem to show that

$$I = V(B) - V(A) + 4\pi$$

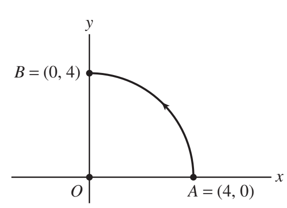


FIGURE 17

SOLUTION

(a) We need to find a potential function $V(x, y)$ for the difference

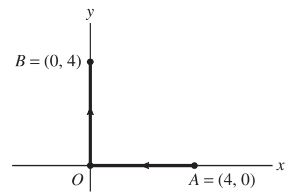
$$\mathbf{F} - \mathbf{G} = \left\langle 2xe^y, x + x^2 e^y \right\rangle - \langle 0, x \rangle = \left\langle 2xe^y, x^2 e^y \right\rangle$$

We let $V(x, y) = x^2 e^y$.

(b) We use the parametrizations $\overline{AO} : \langle t, 0 \rangle, 0 \le t \le 4$ and $\overline{OB} : \langle 0, t \rangle, 0 \le t \le 4$ to evaluate the integrals of $\mathbf{G} = \langle 0, x \rangle$. We get

$$\int_{\overline{OA}} \mathbf{G} \cdot d\mathbf{s} = \int_0^4 \langle 0, t \rangle \cdot \langle 1, 0 \rangle \; dt = \int_0^4 0\,dt = 0$$

$$\int_{\overline{OB}} \mathbf{G} \cdot d\mathbf{s} = \int_0^4 \langle 0, 0 \rangle \cdot \langle 0, 1 \rangle \; dt = \int_0^4 0\,dt = 0$$



(c) Since $\mathbf{F} - \mathbf{G} = \nabla V$, we have

$$\int_{\mathcal{C}} (\mathbf{F} - \mathbf{G}) \cdot d\mathbf{s} = V(B) - V(A) = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} - \int_{\mathcal{C}} \mathbf{G} \cdot d\mathbf{s} = I - \int_{\mathcal{C}} \mathbf{G} \cdot d\mathbf{s}$$

That is,

$$I = V(B) - V(A) + \int_{\mathcal{C}} \mathbf{G} \cdot d\mathbf{s} \tag{1}$$

To compute the line integral on the right-hand side, we rewrite it as

$$\int_{\mathcal{C}} \mathbf{G} \cdot d\mathbf{s} = \int_{\overline{BO}+\overline{OA}+C} \mathbf{G} \cdot d\mathbf{s} - \int_{\overline{BO}} \mathbf{G} \cdot d\mathbf{s} - \int_{\overline{OA}} \mathbf{G} \cdot d\mathbf{s}$$

Using part (b) we may write

$$\int_{\mathcal{C}} \mathbf{G} \cdot d\mathbf{s} = \int_{\overline{BO}+\overline{OA}+C} \mathbf{G} \cdot d\mathbf{s} \tag{2}$$

We now use Green's Theorem. Since $\mathbf{G} = \langle 0, x \rangle$, we have $P = 0$ and $Q = x$, hence $\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 1 - 0 = 1$. Thus,

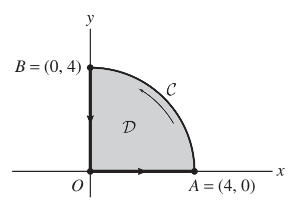
$$\int_{\overline{BO}+\overline{OA}+C} \mathbf{G} \cdot d\mathbf{s} = \iint_{\mathcal{D}} 1\, dA = \text{Area}(\mathcal{D}) = \frac{\pi \cdot 4^2}{4} = 4\pi \tag{3}$$

Combining (1), (2), and (3), we obtain

$$I = V(B) - V(A) + 4\pi$$

Since $V(x, y) = x^2 e^y$, we conclude that

$$I = V(0, 4) - V(4, 0) + 4\pi = 0 - 4^2 e^0 + 4\pi = 4\pi - 16.$$



12. Compute the line integral of $\mathbf{F} = \langle x^3, 4x \rangle$ along the path from A to B in Figure 18. To save work, use Green's Theorem to relate this line integral to the line integral along the vertical path from B to A.

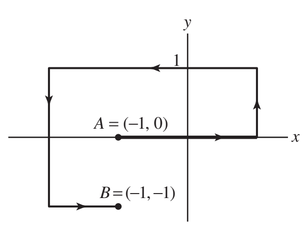


FIGURE 18

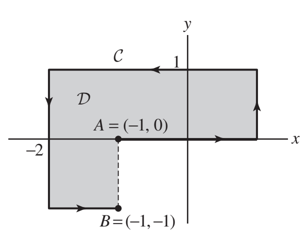
SOLUTION We denote by $\mathcal{C}$ the path from A to B, and $\mathcal{D}$ is the region enclosed by $\mathcal{C}$ and the segment $\overline{BA}$.



By Green's Theorem, we have

$$\int_{\mathcal{C}+\overline{BA}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} + \int_{\overline{BA}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA$$

or

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA + \int_{\overline{AB}} \mathbf{F} \cdot d\mathbf{s} \tag{1}$$

We compute the integrals on the right-hand side. We parametrize the segment $\overline{AB}$ by $\langle -1, t \rangle$, with t from 0 to -1. We get

$$\int_{\overline{AB}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{-1} \langle -1, -4 \rangle \cdot \langle 0, 1 \rangle \, dt = \int_0^{-1} -4 \, dt = \int_{-1}^{0} 4 \, dt = 4 \tag{2}$$

Since $Q = 4x$ and $P = x^3$, we have $\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 4 - 0 = 4$. Hence,

$$\iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA = \iint_{\mathcal{D}} 4 \, dA = 4 \iint_{\mathcal{D}} 1 \, dA = 4\text{Area}(\mathcal{D}) = 4(1 \cdot 3 + 1 \cdot 1) = 16 \tag{3}$$

Substituting (2) and (3) in (1), we get

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = 4 + 16 = 20$$

13. Evaluate $I = \int_{\mathcal{C}} (\sin x + y) \, dx + (3x + y) \, dy$ for the nonclosed path $ABCD$ in Figure 19. Use the method of Exercise 12.

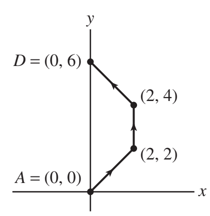


FIGURE 19

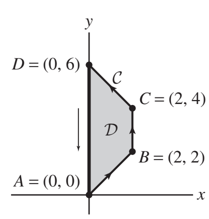
SOLUTION

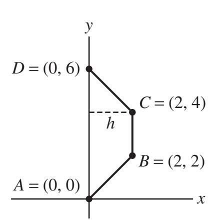


Let $\mathbf{F} = \langle \sin x + y, 3x + y \rangle$, hence $P = \sin x + y$ and $Q = 3x + y$. We denote by $\mathcal{C}_1$ the closed path determined by $\mathcal{C}$ and the segment $\overline{DA}$. Then by Green's Theorem,

$$\int_{\mathcal{C}_1} P \, dx + Q \, dy = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA = \iint_{\mathcal{D}} (3 - 1) \, dA = 2 \iint_{\mathcal{D}} dA = 2 \,\text{Area}(\mathcal{D}) \tag{1}$$

The area of $\mathcal{D}$ is the area of the trapezoid $ABCD$, that is,

$$\text{Area}(\mathcal{D}) = \frac{\left(\overline{BC} + \overline{AD}\right) h}{2} = \frac{(2+6) \cdot 2}{2} = 8.$$



Combining with (1) we get

$$\int_{\mathcal{C}_1} P\,dx + Q\,dy = 2 \cdot 8 = 16$$

Using properties of line integrals, we have

$$\int_{\mathcal{C}} P\,dx + Q\,dy + \int_{\overline{DA}} P\,dx + Q\,dy = 16 \qquad (2)$$

We compute the line integral over $\overline{DA}$, using the parametrization

$$\overline{DA} : x = 0,\ \ y = t, t \text{ varies from 6 to 0.}$$

We get

$$\int_{\overline{DA}} P\,dx + Q\,dy = \int_6^0 F(0,t) \cdot \frac{d}{dt}\langle 0, t\rangle\,dt = \int_6^0 \langle \sin 0 + t, 3 \cdot 0 + t\rangle \cdot \langle 0, 1\rangle\,dt$$
$$= \int_6^0 \langle t, t\rangle \cdot \langle 0, 1\rangle\,dt = \int_6^0 t\,dt = \left.\frac{t^2}{2}\right|_{t=6}^0 = -18$$

We substitute in (2) and solve for the required integral:

$$\int_{\mathcal{C}} P\,dx + Q\,dy - 18 = 16 \quad \text{or} \quad \int_{\mathcal{C}} P\,dx + Q\,dy = 34.$$

14. Show that if $\mathcal{C}$ is a simple closed curve, then

$$\oint_{\mathcal{C}} -y\,dx = \oint_{\mathcal{C}} x\,dy$$

and both integrals are equal to the area enclosed by $\mathcal{C}$.

SOLUTION We show that $\int_{\mathcal{C}} y\,dx + x\,dy = 0$ by showing that the vector field $\mathbf{F} = \langle y, x\rangle$ is conservative. Indeed, since $P = y$ and $Q = x$, we have $\frac{\partial Q}{\partial x} = 1$ and $\frac{\partial P}{\partial y} = 1$. Therefore, the cross partials are equal and therefore $\mathbf{F}$ is conservative. By the formula for the area enclosed by a simple closed curve, the area enclosed by $\mathcal{C}$ is

$$A = \frac{1}{2}\int_{\mathcal{C}} x\,dy - y\,dx = \frac{1}{2}\int_{\mathcal{C}} x\,dy + \frac{1}{2}\int_{\mathcal{C}} -y\,dx$$

Using the equality obtained above, we have

$$A = \frac{1}{2}\int_{\mathcal{C}} x\,dy + \frac{1}{2}\int_{\mathcal{C}} x\,dy = \int_{\mathcal{C}} x\,dy = \int_{\mathcal{C}} -y\,dx.$$

In Exercises 15–18, use Eq. (6) to calculate the area of the given region.

15. The circle of radius 3 centered at the origin

SOLUTION By Eq. (6), we have

$$A = \frac{1}{2}\int_{\mathcal{C}} x\,dy - y\,dx$$

We parametrize the circle by $x = 3\cos\theta$, $y = 3\sin\theta$, hence,

$$x\,dy - y\,dx = 3\cos\theta \cdot 3\cos\theta\,d\theta - 3\sin\theta(-3\sin\theta)\,d\theta = (9\cos^2\theta + 9\sin^2\theta)\,d\theta = 9\,d\theta$$

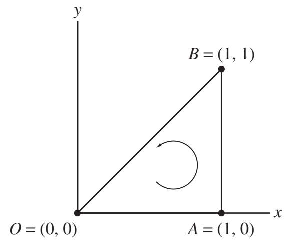
Therefore,

$$A = \frac{1}{2}\int_{\mathcal{C}} x\,dy - y\,dx = \frac{1}{2}\int_0^{2\pi} 9\,d\theta = \frac{9}{2} \cdot 2\pi = 9\pi.$$

16. The triangle with vertices (0, 0), (1, 0), and (1, 1)

SOLUTION We parametrize the segments by

$$\overline{OA} : \langle t, 0\rangle,\ \ t = 0 \text{ to } t = 1$$
$$\overline{AB} : \langle 1, t\rangle,\ \ t = 0 \text{ to } t = 1$$
$$\overline{BO} : \langle t, t\rangle,\ \ t = 1 \text{ to } t = 0$$



Using Eq. (6), we obtain the following area of the triangle:

$$\begin{aligned} A &= \frac{1}{2}\int_{\mathcal{C}} x\,dy - y\,dx = \frac{1}{2}\int_{\overline{OA}} \langle -y, x\rangle \cdot ds + \frac{1}{2}\int_{\overline{AB}} \langle -y, x\rangle \cdot ds + \frac{1}{2}\int_{\overline{BO}} \langle -y, x\rangle \cdot ds \\ &= \frac{1}{2}\int_0^1 \langle 0, t\rangle \cdot \langle 1, 0\rangle\, dt + \frac{1}{2}\int_0^1 \langle -t, 1\rangle \cdot \langle 0, 1\rangle\, dt + \frac{1}{2}\int_1^0 \langle -t, t\rangle \cdot \langle 1, 1\rangle\, dt \\ &= \frac{1}{2}\int_0^1 0\,dt + \frac{1}{2}\int_0^1 dt + \frac{1}{2}\int_1^0 0\,dt = \frac{1}{2}\int_0^1 dt = \frac{1}{2}\cdot 1 = \frac{1}{2} \end{aligned}$$

17. The region between the x-axis and the cycloid parametrized by $\mathbf{c}(t) = (t - \sin t, 1 - \cos t)$ for $0 \le t \le 2\pi$ (Figure 20)

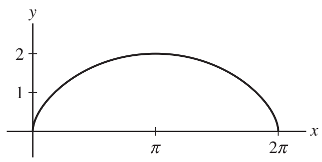


FIGURE 20 Cycloid.

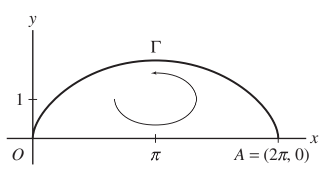
SOLUTION By Eq. (6), the area is the following integral:

$$A = \frac{1}{2}\int_{\mathcal{C}} x\,dy - y\,dx$$

where $\mathcal{C}$ is the closed curve determined by the segment OA and the cycloid Γ.



Therefore,

$$A = \frac{1}{2}\int_{\overline{OA}} x\,dy - y\,dx + \frac{1}{2}\int_{\Gamma} x\,dy - y\,dx \tag{1}$$

We compute the two integrals. The segment $\overline{OA}$ is parametrized by $\langle t, 0\rangle$, $t = 0$ to $t = 2\pi$. Hence, $x = t$ and $y = 0$. Therefore,

$$x\,dy - y\,dx = t\cdot 0\,dt - 0\cdot\,dt = 0$$

$$\int_{\overline{OA}} x\,dy - y\,dx = 0 \tag{2}$$

On Γ we have $x = t - \sin t$ and $y = 1 - \cos t$, therefore

$$\begin{aligned} x\,dy - y\,dx &= (t - \sin t)\sin t\,dt - (1 - \cos t)(1 - \cos t)\,dt \\ &= (t\sin t - \sin^2 t - 1 + 2\cos t - \cos^2 t)\,dt = (t\sin t + 2\cos t - 2)\,dt \end{aligned}$$

Hence,

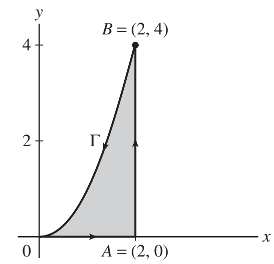
$$\begin{aligned} \int_{\Gamma} x\,dy - y\,dx &= \int_{2\pi}^0 (t\sin t + 2\cos t - 2)\,dt = \int_0^{2\pi} (2 - 2\cos t - t\sin t)\,dt \\ &= 2t - 2\sin t + t\cos t - \sin t\Big|_0^{2\pi} = 2t - 3\sin t + t\cos t\Big|_0^{2\pi} = 6\pi \end{aligned} \tag{3}$$

Substituting (2) and (3) in (1) we get

$$A = \frac{1}{2} \cdot 0 + \frac{1}{2} \cdot 6\pi = 3\pi.$$

18. The region between the graph of $y = x^2$ and the x-axis for $0 \le x \le 2$

SOLUTION The boundary of the region consists of the curve Γ and the segments $\overline{OA}$ and $\overline{AB}$ shown in the figure.



By Eq. (6), the area A of the region is given by,

$$A = \frac{1}{2} \int_{\overline{OA}} x\,dy - y\,dx + \frac{1}{2} \int_{\overline{AB}} x\,dy - y\,dx + \frac{1}{2} \int_{\Gamma} x\,dy - y\,dx \tag{1}$$

We compute each integral separately. We use the following parametrizations:

$$\overline{OA} : c_1(t) = (t, 0), \text{ for } 0 \le t \le 2 \quad \Rightarrow \quad c_1'(t) = \langle 1, 0 \rangle$$
$$\overline{AB} : c_2(t) = (2, t), \text{ for } 0 \le t \le 4 \quad \Rightarrow \quad c_2'(t) = \langle 0, 1 \rangle$$
$$\Gamma : c_3(t) = (t, t^2) \text{ for } t \text{ from 2 to 0} \quad \Rightarrow \quad c_3'(t) = \langle 1, 2t \rangle$$

The line integrals in (1) are thus

$$\int_{\overline{OA}} x\,dy - y\,dx = \int_{\overline{OA}} \langle -y, x \rangle \cdot ds = \int_0^2 \langle 0, t \rangle \cdot \langle 1, 0 \rangle \, dt = 0$$
$$\int_{\overline{AB}} x\,dy - y\,dx = \int_{\overline{AB}} \langle -y, x \rangle \cdot ds = \int_0^4 \langle -t, 2 \rangle \cdot \langle 0, 1 \rangle \, dt = \int_0^4 2\,dt = 8$$
$$\int_{\Gamma} x\,dy - y\,dx = \int_{\Gamma} \langle -y, x \rangle \cdot ds = \int_2^0 \left\langle -t^2, t \right\rangle \cdot \langle 1, 2t \rangle \, dt = \int_2^0 (-t^2 + 2t^2) \cdot dt$$
$$= \int_0^2 -t^2\,dt = -\frac{t^3}{3}\Big|_0^2 = -\frac{8}{3}$$

Substituting the integrals in (1) we obtain the following area:

$$A = \frac{1}{2} \cdot 0 + \frac{1}{2} \cdot 8 + \frac{1}{2} \cdot \left(-\frac{8}{3}\right) = \frac{8}{3}.$$

19. Let $x^3 + y^3 = 3xy$ be the **folium of Descartes** (Figure 21).

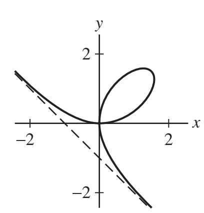


FIGURE 21 Folium of Descartes.

(a) Show that the folium has a parametrization in terms of $t = y/x$ given by

$$x = \frac{3t}{1+t^3}, \qquad y = \frac{3t^2}{1+t^3} \quad (-\infty < t < \infty) \quad (t \ne -1)$$

(b) Show that

$$x\,dy - y\,dx = \frac{9t^2}{(1+t^3)^2}\,dt$$

Hint: By the Quotient Rule,

$$x^2\,d\left(\frac{y}{x}\right) = x\,dy - y\,dx$$

(c) Find the area of the loop of the folium.

SOLUTION

(a) We show that $x = \frac{3t}{1+t^3}$, $y = \frac{3t^2}{1+t^3}$ satisfy the equation $x^3 + y^3 - 3xy = 0$ of the folium:

$$x^3 + y^3 - 3xy = \left(\frac{3t}{1+t^3}\right)^3 + \left(\frac{3t^2}{1+t^3}\right)^3 - 3\cdot\frac{3t}{1+t^3}\cdot\frac{3t^2}{1+t^3}$$

$$= \frac{27t^3 + 27t^6}{(1+t^3)^3} - \frac{27t^3(1+t^3)}{(1+t^3)^3} = \frac{27t^3\left(1+t^3-(1+t^3)\right)}{(1+t^3)^3} = \frac{0}{(1+t^3)^3} = 0$$

This proves that the curve parametrized by $x = \frac{3t}{1+t^3}$, $y = \frac{3t^2}{1+t^3}$ lies on the folium of Descartes. This parametrization parametrizes the whole folium since the two equations can be solved for t in terms of x and y. That is,

$$\left.\begin{aligned} x &= \frac{3t}{1+t^3} \\ y &= \frac{3t^2}{1+t^3} \end{aligned}\right. \quad \Rightarrow \quad t = \frac{y}{x}$$

A glance at the graph of the folium shows that any line $y = tx$, with slope t, intersects the folium exactly once. Thus, there is a one-to-one relationship between the values of t and the points on the graph.

(b) We differentiate the two sides of $t = \frac{y}{x}$ with respect to t. Using the Quotient Rule gives

$$1 = \frac{x\frac{dy}{dt} - y\frac{dx}{dt}}{x^2}$$

or

$$x\frac{dy}{dt} - y\frac{dx}{dt} = x^2 = \left(\frac{3t}{1+t^3}\right)^2$$

This equality can be written in the form

$$x\,dy - y\,dx = \frac{9t^2}{(1+t^3)^2}\,dt$$

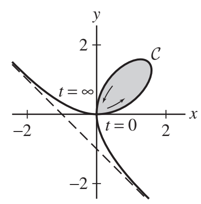
(c) We use the formula for the area enclosed by a closed curve and the result of part (b) to find the required area. That is,

$$A = \frac{1}{2}\int_{\mathcal{C}} x\,dy - y\,dx = \frac{1}{2}\int_0^{\infty} \frac{9t^2}{(1+t^3)^2}\,dt$$

From our earlier discussion on the parametrization of the folium, we see that the loop is traced when the parameter t is increasing along the interval $0 \le t < \infty$. We compute the improper integral using the substitution $u = 1 + t^3$, $du = 3t^2\,dt$. This gives

$$A = \frac{1}{2}\lim_{R\to\infty}\int_0^R \frac{9t^2}{(1+t^3)^2}\,dt = \frac{1}{2}\lim_{R\to\infty}\int_1^{1+R^3}\frac{3\,du}{u^2} = \frac{3}{2}\lim_{R\to\infty} -\frac{1}{u}\Big|_{u=1}^{1+R^3}$$

$$= \frac{3}{2}\lim_{R\to\infty}\left(1 - \frac{1}{1+R^3}\right) = \frac{3}{2}(1-0) = \frac{3}{2}$$



20. Find a parametrization of the lemniscate $(x^2 + y^2)^2 = xy$ (see Figure 22) by using $t = y/x$ as a parameter (see Exercise 19). Then use Eq. (6) to find the area of one loop of the lemniscate.

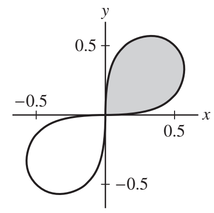


FIGURE 22 Lemniscate.

SOLUTION We first find the parametrization of the lemniscate, determined by the parameter $t = \frac{y}{x}$. We substitute $y = tx$ in the equation of the lemniscate and solve for x in terms of t. This gives

$$(x^2 + y^2)^2 = (x^2 + t^2x^2)^2 = (1 + t^2)^2 x^4$$
$$xy = x \cdot tx = tx^2$$

We obtain the equation

$$(1 + t^2)^2 x^4 = tx^2$$
$$(1 + t^2)^2 x^2 = t$$

or (taking x positive)

$$x = \frac{t^{1/2}}{1 + t^2}$$

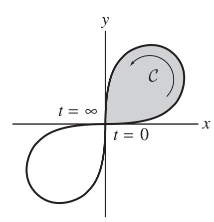
hence

$$y = tx = \frac{t^{3/2}}{1 + t^2}.$$

We obtain the parametrization

$$x = \frac{t^{1/2}}{1 + t^2}, \quad y = \frac{t^{3/2}}{1 + t^2}.$$

One loop is traced as $0 \le t < \infty$.



The area enclosed by one loop is given by the following line integral:

$$A = \frac{1}{2} \int_{\mathcal{C}} x\,dy - y\,dx \tag{1}$$

In Exercise 19 we showed the relation $t = \frac{y}{x}$ implies that

$$x\,dy - y\,dx = x^2\,dt$$

Now $x = \frac{t^{1/2}}{1+t^2}$, hence

$$x\,dy - y\,dx = \frac{t}{(1 + t^2)^2}\,dt$$

We substitute in (1) and compute the resulting improper integral using the substitution $u = 1 + t^2$, $du = 2t\,dt$. We get

$$A = \frac{1}{2} \int_{\mathcal{C}} x\,dy - y\,dx = \frac{1}{2} \int_0^{\infty} \frac{t}{(1 + t^2)^2}\,dt = \frac{1}{2} \lim_{R \to \infty} \int_0^R \frac{t\,dt}{(1 + t^2)^2} = \frac{1}{2} \lim_{R \to \infty} \int_1^{1+R^2} \frac{\frac{1}{2}\,du}{u^2}\,du$$
$$= \frac{1}{4} \lim_{R \to \infty} -\frac{1}{u}\bigg|_{u=1}^{1+R^2} = \frac{1}{4} \lim_{R \to \infty} \left(1 - \frac{1}{1 + R^2}\right) = \frac{1}{4}(1 - 0) = \frac{1}{4}$$

21. The Centroid via Boundary Measurements The centroid (see Section 15.5) of a domain $\mathcal{D}$ enclosed by a simple closed curve $\mathcal{C}$ is the point with coordinates $(\overline{x}, \overline{y}) = (M_y/M, M_x/M)$, where M is the area of $\mathcal{D}$ and the moments are defined by

$$M_x = \iint_{\mathcal{D}} y\, dA, \qquad M_y = \iint_{\mathcal{D}} x\, dA$$

Show that $M_x = \oint_{\mathcal{C}} xy\, dy$. Find a similar expression for M_y.

SOLUTION Consider the moment $M_x = \iint_{\mathcal{D}} y\, dA$, we know from Green's Theorem:

$$\iint_{\mathcal{D}} \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right) dA = \oint_{\mathcal{C}} F_1 dx + F_2 dy$$

So then we need

$$\frac{\partial F_2}{dx} - \frac{\partial F_1}{\partial y} = y$$

If we set $F_2 = xy$ and $F_1 = 0$, then $\frac{\partial F_2}{dx} - \frac{\partial F_1}{\partial y} = y$ and

$$M_x = \iint_{\mathcal{D}} y\, dA = \oint_{\mathcal{C}} xy\, dy$$

Similarly, consider the moment $M_y = \iint_{\mathcal{D}} x\, dA$. We will now use Green's Theorem, stated above. Here we need

$$\frac{\partial F_2}{dx} - \frac{\partial F_1}{\partial y} = x$$

If we set $F_1 = -xy$ and $F_2 = 0$ then $\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} = x$ and

$$M_y = \iint_{\mathcal{D}} x\, dA = \oint_{\mathcal{C}} -xy\, dx$$

22. Use the result of Exercise 21 to compute the moments of the semicircle $x^2 + y^2 = R^2$, $y \geq 0$ as line integrals. Verify that the centroid is $(0, 4R/(3\pi))$.

SOLUTION Firstly, let us compute M which is the area of the semicircular region, here $\frac{1}{2}\pi R^2$. Then computing M_x and M_y as line integrals we must first parametrize the semicircle from $(1, 0)$ to $(-1, 0)$ as:

$$\mathbf{r}(\theta) = \langle R\cos\theta, R\sin\theta \rangle, \quad 0 \leq \theta \leq \pi$$

and the line segment from $(-1, 0)$ to $(1, 0)$ as:

$$\mathbf{r}(t) = \langle 2t - 1, 0 \rangle, \quad 0 \leq t \leq 1$$

Thus we have

$$\begin{aligned} M_x &= \oint_{\mathcal{C}} xy\, dy \\ &= \int_0^{\pi} (R\cos\theta)(R\sin\theta)(R\cos\theta)\, d\theta + \int_0^1 (2t-1)\cdot(0)\cdot(0)\, dt \\ &= \int_0^{\pi} R^3 \cos^2\theta \sin\theta\, d\theta \\ &= -\frac{R^3\cos^3\theta}{3}\bigg|_0^{\pi} = \frac{R^3}{3} + \frac{R^3}{3} = \frac{2}{3}R^3 \end{aligned}$$

and

$$\begin{aligned} M_y &= \oint_{\mathcal{C}} -xy\, dx \\ &= \int_0^{\pi} -(R\cos\theta)(R\sin\theta)(-R\sin\theta)\, d\theta + \int_0^1 (2t-1)\cdot(0)\cdot(2)\, dt \\ &= \int_0^{\pi} R^3 \cos\theta \sin^2\theta\, d\theta \\ &= \frac{R^3\sin^3\theta}{3}\bigg|_0^{\pi} = 0 \end{aligned}$$

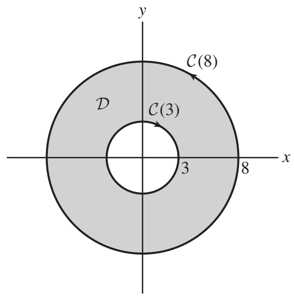
Now to compute the coordinates of the centroid we have:

$$\overline{x} = \frac{M_y}{M} = 0, \quad \overline{y} = \frac{M_x}{M} = \frac{2R^3/3}{\pi R^2/2} = \frac{2R^3}{3} \cdot \frac{2}{\pi R^2} = \frac{4R}{3\pi}$$

Thus the centroid is $(\overline{x}, \overline{y}) = (0, 4R/(3\pi))$.

23. Let $\mathcal{C}_R$ be the circle of radius R centered at the origin. Use the general form of Green's Theorem to determine $\oint_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s}$, where $\mathbf{F}$ is a vector field such that $\oint_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = 9$ and $\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} = x^2 + y^2$ for (x, y) in the annulus $1 \le x^2 + y^2 \le 4$.

SOLUTION We use Green's Theorem for the annulus $\mathcal{D}$ between the circles $\mathcal{C}_1$ and $\mathcal{C}_2$ oriented as shown in the figure.



That is,

$$\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} - \int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right) dx\,dy$$

Substituting the given information, we get

$$\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} - 9 = \iint_{\mathcal{D}} (x^2 + y^2)\,dx\,dy$$

or

$$\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = 9 + \iint_{\mathcal{D}} (x^2 + y^2)\,dx\,dy$$

We compute the double integral by converting it to polar coordinates:

$$\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = 9 + \int_0^{2\pi} \int_1^2 r^2 \cdot r\,dr\,d\theta = 9 + 2\pi \int_1^2 r^3\,dr = 9 + 2\pi \cdot \left.\frac{r^4}{4}\right|_1^2 = 9 + 2\pi \left(\frac{2^4 - 1^4}{4} \right) = 9 + \frac{15\pi}{2}$$

24. Referring to Figure 23, suppose that $\oint_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = 12$. Use Green's Theorem to determine $\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s}$, assuming that $\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial x} = -3$ in $\mathcal{D}$.

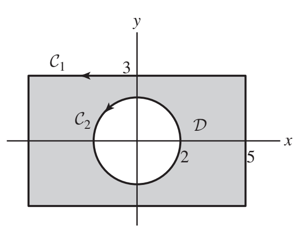


FIGURE 23

SOLUTION By Green's Theorem,

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} - \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \operatorname{curl}(\mathbf{F})\,dx\,dy$$

Substituting the given information gives

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} - 12 = \iint_{\mathcal{D}} -3\,dx\,dy = -3 \iint_{\mathcal{D}} 1\,dx\,dy = -3\,\text{Area}(\mathcal{D})$$

Hence,

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} - 12 = -3\,\text{Area}(\mathcal{D}) \tag{1}$$

We compute the area of $\mathcal{D}$ as the difference between the area of the rectangle and the area of the inner disk. That is,

$$\text{Area}(\mathcal{D}) = 6 \cdot 10 - \pi \cdot 2^2 = 60 - 4\pi$$

Substituting in (1) we get

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = 12 - 3(60 - 4\pi) = 12\pi - 168 \approx -130.3.$$

25. Referring to Figure 24, suppose that

$$\oint_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = 3\pi, \qquad \oint_{\mathcal{C}_3} \mathbf{F} \cdot d\mathbf{s} = 4\pi$$

Use Green's Theorem to determine the circulation of $\mathbf{F}$ around $\mathcal{C}_1$, assuming that $\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial x} = 9$ on the shaded region.

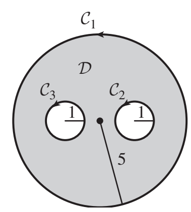

FIGURE 24

SOLUTION We must calculate $\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s}$. We use Green's Theorem for the region $\mathcal{D}$ between the three circles $\mathcal{C}_1$, $\mathcal{C}_2$, and $\mathcal{C}_3$. Because of orientation, the line integrals $\int_{-\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = -\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s}$ and $\int_{-\mathcal{C}_3} \mathbf{F} \cdot d\mathbf{s} = -\int_{\mathcal{C}_3} \mathbf{F} \cdot d\mathbf{s}$ must be used in applying Green's Theorem. That is,

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} - \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} - \int_{\mathcal{C}_3} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \text{curl}(\mathbf{F})\, dA$$

We substitute the given information to obtain

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} - 3\pi - 4\pi = \iint_{\mathcal{D}} 9\, dA = 9 \iint_{\mathcal{D}} 1 \cdot dA = 9\,\text{Area}(\mathcal{D}) \tag{1}$$

The area of $\mathcal{D}$ is computed as the difference of areas of discs. That is,

$$\text{Area}(\mathcal{D}) = \pi \cdot 5^2 - \pi \cdot 1^2 - \pi \cdot 1^2 = 23\pi$$

We substitute in (1) and compute the desired circulation:

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} - 7\pi = 9 \cdot 23\pi$$

or

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = 214\pi.$$

26. Let $\mathbf{F}$ be the vortex vector field

$$\mathbf{F} = \left\langle \frac{-y}{x^2 + y^2}, \frac{x}{x^2 + y^2} \right\rangle$$

In Section 16.3 we verified that $\int_{\mathcal{C}_R} \mathbf{F} \cdot d\mathbf{s} = 2\pi$, where $\mathcal{C}_R$ is the circle of radius R centered at the origin. Prove that $\oint_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = 2\pi$ for any simple closed curve $\mathcal{C}$ whose interior contains the origin (Figure 25). *Hint:* Apply the general form of Green's Theorem to the domain between $\mathcal{C}$ and $\mathcal{C}_R$, where R is so small that $\mathcal{C}_R$ is contained in $\mathcal{C}$.

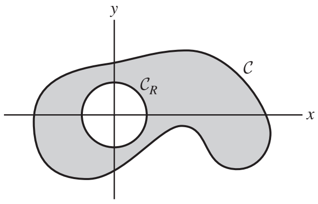

FIGURE 25

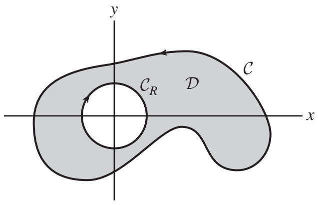
SOLUTION Let $R > 0$ be sufficiently small so that the circle $\mathcal{C}_R$ is contained in $\mathcal{C}$.



Let $\mathcal{D}$ denote the region between $\mathcal{C}_R$ and $\mathcal{C}$. We apply Green's Theorem to the region $\mathcal{D}$. The curve $\mathcal{C}$ is oriented counterclockwise and $\mathcal{C}_R$ is oriented clockwise. We have

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} + \int_{\mathcal{C}_R} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \text{curl}(\mathbf{F})\, dA \tag{1}$$

From Exercise 16.3.27 we know that $\int_{\mathcal{C}_R} \mathbf{F} \cdot d\mathbf{s} = -2\pi$. Since $\mathcal{D}$ does not contain the origin, we have by part (a) of Exercise 16.3.28, curl $(\mathbf{F}) = 0$ on $\mathcal{D}$. Substituting in (1) we obtain

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} - 2\pi = \iint_{\mathcal{D}} 0\, dA = 0$$

or

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = 2\pi.$$

In Exercises 27–30, refer to the Conceptual Insight that discusses the curl, defined by

$$\text{curl}_z(\mathbf{F}) = \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}$$

27. For the vector fields (A)–(D) in Figure 26, state whether the curl_z at the origin appears to be positive, negative, or zero.

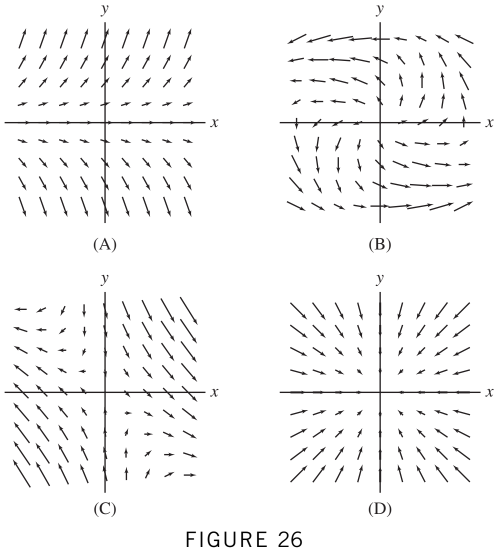


FIGURE 26

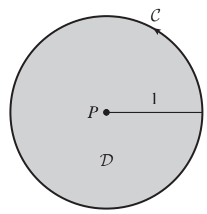
SOLUTION The vector field (A) does not have spirals, nor is it a "shear flow." Therefore, the curl appears to be zero. The vector field (B) rotates in the counterclockwise direction, hence we expect the curl to be positive. The vector field (C) rotates in a clockwise direction about the origin—we expect the curl to be negative. Finally, in the vector field (D), the fluid flows straight toward the origin without spiraling. We expect the curl to be zero.

28. Estimate the circulation of a vector field $\mathbf{F}$ around a circle of radius $R = 0.1$, assuming that $\text{curl}_z(\mathbf{F})$ takes the value 4 at the center of the circle.

SOLUTION We estimate the circulation by

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx \text{curl}(\mathbf{F})(P)\text{Area}(\mathcal{D}) \qquad (1)$$



We are given that $\text{curl}(\mathbf{F})(P) = 4$. The area of the disk of radius $R = 0.1$ is $\pi \cdot 0.1^2 = \pi/100$. Substituting in (1) gives the estimation

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx 4 \cdot \frac{\pi}{100} = \frac{\pi}{25}$$

29. Estimate $\oint_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$, where $\mathbf{F} = \left\langle x + 0.1y^2, y - 0.1x^2 \right\rangle$ and $\mathcal{C}$ encloses a small region of area 0.25 containing the point $P = (1, 1)$.

SOLUTION Use the following estimation:

$$\mathbf{F} \cdot d\mathbf{s} = \oint_{\mathcal{C}} F_1\,dx + F_2\,dy \approx \text{curl}_z(\mathbf{F})(P) \cdot \text{Area}(\mathcal{D})$$

First computing $\text{curl}\mathbf{F}$ we have:

$$\text{curl}\mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial x & \partial y & \partial z \\ x + 0.1y^2 & y - 0.1x^2 & 0 \end{vmatrix} = \langle 0, 0, -0.2x - 0.2y \rangle$$

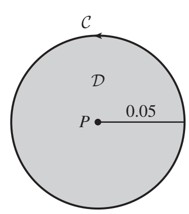
Thus $\text{curl}_z(\mathbf{F}) = -0.2x - 0.2y$ and $\text{curl}_z(\mathbf{F})(1, 1) = -0.2 - 0.2 = -0.4$. Also, we are given the area of the region is 0.25. Hence, we see:

$$\oint \mathbf{F} \cdot d\mathbf{s} \approx (-0.4)(0.25) = -0.10$$

30. Let $\mathbf{F}$ be the velocity field. Estimate the circulation of $\mathbf{F}$ around a circle of radius $R = 0.05$ with center P, assuming that $\text{curl}_z(\mathbf{F})(P) = -3$. In which direction would a small paddle placed at P rotate? How fast would it rotate (in radians per second) if $\mathbf{F}$ is expressed in meters per second?

SOLUTION We use the following estimation:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx \text{curl}(\mathbf{F})(P)\text{Area}(\mathcal{D}) \qquad (1)$$



We are given that $\text{curl}(\mathbf{F})(P) = -3$. Also, the area of the disk of radius $R = 0.05$ is $\pi \cdot 0.05^2 = 0.0025\pi$. Therefore, we obtain the following estimation:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx -3 \cdot 0.0025\pi \approx -0.024.$$

Since the curl is negative, the paddle would rotate in the clockwise direction. Using the formula $|\text{curl}(\mathbf{F})| = 2\omega$, we see that the angular speed is $\omega = 1.5$ radians per second.

31. Let $\mathcal{C}_R$ be the circle of radius R centered at the origin. Use Green's Theorem to find the value of R that maximizes $\oint_{\mathcal{C}_R} y^3\,dx + x\,dy$.

SOLUTION Using Green's Theorem we can write:

$$\oint_{\mathcal{C}_R} y^3\,dx + x\,dy = \iint_{\mathcal{D}} \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\,dA$$
$$= \iint_{\mathcal{D}} 1 - 3y^2\,dA$$

Then we have the following, using polar coordinates:

$$\begin{aligned}
\oint_{\mathcal{C}_R} y^3\,dx + x\,dy &= \iint_{\mathcal{D}} \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\,dA \\
&= \iint_{\mathcal{D}} 1 - 3y^2\,dA \\
&= \int_0^{2\pi}\int_0^R (1 - 3r^2\sin^2\theta)(r)\,dr\,d\theta \\
&= \int_0^{2\pi}\int_0^R r - 3r^3\sin^2\theta\,dr\,d\theta \\
&= \int_0^{2\pi} \frac{1}{2}r^2 - \frac{3}{4}r^4\sin^2\theta\Big|_0^R\,d\theta \\
&= \int_0^{2\pi} \frac{1}{2}R^2 - \frac{3}{8}R^4(1 - \cos 2\theta)\,dr\,d\theta \\
&= \int_0^{2\pi} \frac{3R^4}{8}(\cos 2\theta) + \frac{1}{2}R^2 - \frac{3}{8}R^4\,d\theta \\
&= \frac{3R^4}{16}\sin 2\theta + \left(\frac{1}{2}R^2 - \frac{3}{8}R^4\right)\theta\Big|_0^{2\pi} \\
&= 0 + 2\pi\left(\frac{1}{2}R^2 - \frac{3}{8}R^4\right) = \pi\left(R^2 - \frac{3}{4}R^4\right)
\end{aligned}$$

Now to maximize this quantity, we need to let $f(R) = \pi(R^2 - 3/4R^4)$ and take the first derivative.

$$f'(R) = \pi(2R - 3R^3) = 0 \quad \Rightarrow R = 0, \pm\sqrt{2/3}$$

This quantity is maximized when $R = \pm\sqrt{\frac{2}{3}}$ (that is, $R = 0$ is a minimum).

32. Area of a Polygon Green's Theorem leads to a convenient formula for the area of a polygon.

(a) Let $\mathcal{C}$ be the line segment joining (x_1, y_1) to (x_2, y_2). Show that

$$\frac{1}{2}\int_{\mathcal{C}} -y\,dx + x\,dy = \frac{1}{2}(x_1y_2 - x_2y_1)$$

(b) Prove that the area of the polygon with vertices $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$ is equal [where we set $(x_{n+1}, y_{n+1}) = (x_1, y_1)$] to

$$\frac{1}{2}\sum_{i=1}^{n}(x_iy_{i+1} - x_{i+1}y_i)$$

SOLUTION

(a) We parametrize the segment from (x_1, y_1) to (x_2, y_2) by

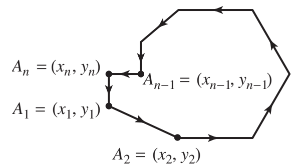
$$x = tx_2 + (1-t)x_1, \quad y = ty_2 + (1-t)y_1, \quad 0 \le t \le 1$$

Then, $dx = (x_2 - x_1)\,dt$ and $dy = (y_2 - y_1)\,dt$. Therefore,

$$\begin{aligned}
-y\,dx + x\,dy &= (-ty_2 - (1-t)y_1)(x_2 - x_1)\,dt + (tx_2 + (1-t)x_1)(y_2 - y_1)\,dt \\
&= (-ty_2x_2 + ty_2x_1 - y_1x_2(1-t) + (1-t)y_1x_1 + tx_2y_2 - tx_2y_1 + (1-t)x_1y_2 - (1-t)x_1y_1)\,dt \\
&= (x_1y_2 - x_2y_1)\,dt
\end{aligned}$$

We obtain the following integral:

$$\frac{1}{2}\int_{\mathcal{C}} -y\,dx + x\,dy = \frac{1}{2}\int_0^1 (x_1y_2 - x_2y_1)\,dt = \frac{1}{2}(x_1y_2 - x_2y_1)t\Big|_{t=0}^{1} = \frac{1}{2}(x_1y_2 - x_2y_1)$$



(b) Let $A_i = (x_i, y_i)$, $i = 1, 2, \ldots, n$, and let $\mathcal{C}$ be the closed curve determined by the polygon. By the formula for the area enclosed by a simple closed curve, the area of the polygon is

$$A = \frac{1}{2}\int_{\mathcal{C}} -y\,dx + x\,dy$$

We use additivity of line integrals and the result in part (a) to write the integral as follows:

$$\begin{aligned} A &= \frac{1}{2}\left(\sum_{i=1}^{n-1}\int_{\overline{A_iA_{i+1}}} -y\,dx + x\,dy + \int_{\overline{A_nA_1}} -y\,dx + x\,dy\right) \\ &= \frac{1}{2}\left(\sum_{i=1}^{n-1}(x_iy_{i+1} - x_{i+1}y_i) + (x_ny_1 - x_1y_n)\right) \\ &= \frac{1}{2}\sum_{i=1}^{n-1}(x_iy_{i+1} - x_{i+1}y_i) + \frac{1}{2}(x_ny_1 - x_1y_n) \end{aligned}$$

If we define $(x_{n+1}, y_{n+1}) = (x_1, y_1)$, we obtain the sum

$$A = \frac{1}{2}\sum_{i=1}^{n}(x_iy_{i+1} - x_{i+1}y_i).$$

33. Use the result of Exercise 32 to compute the areas of the polygons in Figure 27. Check your result for the area of the triangle in (A) using geometry.

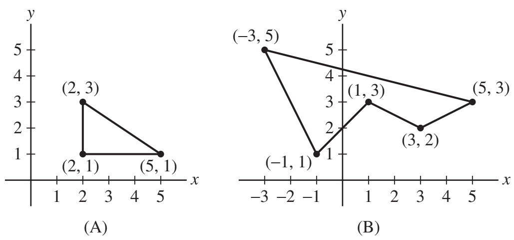


FIGURE 27

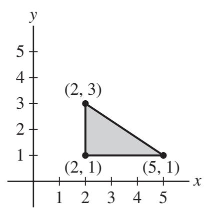
SOLUTION

(a) The vertices of the triangle are

$$(x_1, y_1) = (x_4, y_4) = (2, 1), \quad (x_2, y_2) = (5, 1), \quad (x_3, y_3) = (2, 3)$$



Using the formula obtained in Exercise 28, the area of the triangle is the following sum:

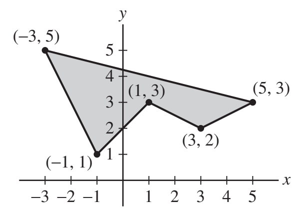
$$\begin{aligned} A &= \frac{1}{2}\big((x_1y_2 - x_2y_1) + (x_2y_3 - x_3y_2) + (x_3y_1 - x_1y_3)\big) \\ &= \frac{1}{2}\big((2\cdot 1 - 5\cdot 1) + (5\cdot 3 - 2\cdot 1) + (2\cdot 1 - 2\cdot 3)\big) = \frac{1}{2}(-3 + 13 - 4) = 3 \end{aligned}$$

We verify our result using the formula for the area of a triangle:

$$A = \frac{1}{2}bh = \frac{1}{2} \cdot (5-2) \cdot (3-1) = 3$$

(b) The vertices of the polygon are

$$(x_1, y_1) = (x_6, y_6) = (-1, 1)$$
$$(x_2, y_2) = (1, 3)$$
$$(x_3, y_3) = (3, 2)$$
$$(x_4, y_4) = (5, 3)$$
$$(x_5, y_5) = (-3, 5)$$



Using the formula in part (a), the area of the polygon is the following sum:

$$\begin{aligned} A &= \frac{1}{2}\big((x_1y_2 - x_2y_1) + (x_2y_3 - x_3y_2) + (x_3y_4 - x_4y) + (x_4y_5 - x_5y_4) + (x_5y_1 - x_1y_5)\big) \\ &= \frac{1}{2}\Big((-1\cdot 3 - 1\cdot 1) + (1\cdot 2 - 3\cdot 3) + (3\cdot 3 - 5\cdot 2) + \big(5\cdot 5 - (-3)\cdot 3\big) + \big(-3\cdot 1 - (-1)\cdot 5\big)\Big) \\ &= \frac{1}{2}(-4 - 7 - 1 + 34 + 2) = 12 \end{aligned}$$

Exercises 34–39: In Section 16.2, we defined the flux of $\mathbf{F}$ *across a curve* $\mathcal{C}$ *(Figure 28) as the integral of the normal component of* $\mathbf{F}$ *along* $\mathcal{C}$*, and we showed that if* $\mathbf{c}(t) = (x(t), y(t))$ *is a parametrization of* $\mathcal{C}$ *for* $a \le t \le b$*, then the flux is equal to*

$$\int_a^b \mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{n}(t)\, dt$$

where $\mathbf{n}(t) = \langle y'(t), -x'(t)\rangle$.

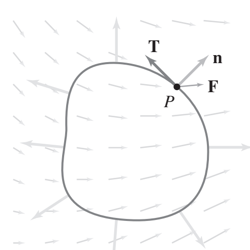


FIGURE 28 The flux of $\mathbf{F}$ is the integral of the normal component $\mathbf{F}\cdot\mathbf{n}$ around the curve.

34. Show that the flux of $\mathbf{F} = \langle P, Q\rangle$ across $\mathcal{C}$ is equal to $\oint_{\mathcal{C}} P\,dy - Q\,dx$.

SOLUTION First, let $\mathbf{F}^* = \langle Q, -P\rangle$. It is easy to show that $\mathbf{F}^*$ is a rotation of $\mathbf{F}$ by $\pi/2$ counterclockwise. The two are easily shown to be orthogonal since:

$$\mathbf{F}\cdot\mathbf{F}^* = \langle P, Q\rangle \cdot \langle Q, -P\rangle = 0$$

We must show that if $\mathcal{C}$ is a simple closed curve, then

$$\int_{\mathcal{C}} (\mathbf{F}\cdot\mathbf{n})d\mathbf{s} = \int_{\mathcal{C}} \mathbf{F}^* \cdot d\mathbf{s}$$

By the definition of the vector line integral, the line integral of the vector field $\mathbf{F}^*$ over $\mathcal{C}$ is

$$\int_{\mathcal{C}} \mathbf{F}^* \cdot d\mathbf{s} = \int_{\mathcal{C}} (\mathbf{F}^* \cdot \mathbf{T}) d\mathbf{s} \tag{1}$$

Since $\mathbf{F}^*$ is a rotation of $\mathbf{F}$ by $\frac{\pi}{2}$ counterclockwise, the angle between $\mathbf{F}^*$ and the tangent $\mathbf{T}$ is equal to the angle between $\mathbf{F}$ and the normal $\mathbf{n}$. Also, $\|\mathbf{F}^*\| = \|\mathbf{F}\|$. Hence,

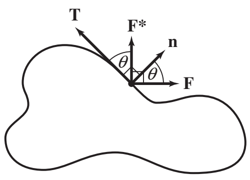
$$\mathbf{F}^* \cdot \mathbf{T} = \|\mathbf{F}^*\| \, \|\mathbf{T}\| \cos\theta = \|\mathbf{F}\| \cos\theta$$
$$\mathbf{F} \cdot \mathbf{n} = \|\mathbf{F}\| \|\mathbf{n}\| \cos\theta = \|\mathbf{F}\| \cos\theta$$

Since the dot products are equal, we conclude that

$$\int_{\mathcal{C}} (\mathbf{F}^* \cdot \mathbf{T}) d\mathbf{s} = \int_{\mathcal{C}} (\mathbf{F} \cdot \mathbf{n}) d\mathbf{s} \tag{2}$$

Combining (1) and (2) we obtain

$$\int_{\mathcal{C}} (\mathbf{F} \cdot \mathbf{n}) d\mathbf{s} = \int_{\mathcal{C}} \mathbf{F}^* \cdot d\mathbf{s} = \int_{\mathcal{C}} \langle Q, -P \rangle \cdot \langle dx, dy \rangle = \int_{\mathcal{C}} Q\, dx - P\, dy$$



35. Define $\text{div}(\mathbf{F}) = \dfrac{\partial P}{\partial x} + \dfrac{\partial Q}{\partial y}$. Use Green's Theorem to prove that for any simple closed curve $\mathcal{C}$,

$$\text{Flux across } \mathcal{C} = \iint_{\mathcal{D}} \text{div}(\mathbf{F})\, dA \tag{12}$$

where $\mathcal{D}$ is the region enclosed by $\mathcal{C}$. This is a two-dimensional version of the **Divergence Theorem** discussed in Section 17.3.

SOLUTION Since $\mathbf{F} = \langle P, Q \rangle$ and $\mathbf{F}^* = \langle -Q, P \rangle$, we have

$$\text{div}(\mathbf{F}) = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y}$$
$$\text{curl}(\mathbf{F}^*) = \frac{\partial P}{\partial x} - \frac{\partial}{\partial y}(-Q) = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y}$$

Therefore,

$$\text{div}(\mathbf{F}) = \text{curl}(\mathbf{F}^*) \tag{1}$$

Using Exercise 33, the flux of $\mathbf{F}$ across $\mathcal{C}$ is

$$\text{flux of } \mathbf{F} \text{ across } \mathcal{C} = \int_{\mathcal{C}} \mathbf{F}^* \cdot d\mathbf{s} \tag{2}$$

Green's Theorem and (1) imply that

$$\int_{\mathcal{C}} \mathbf{F}^* \cdot d\mathbf{s} = \iint_{\mathcal{D}} \text{curl}(\mathbf{F}^*)\, dA = \iint_{\mathcal{D}} \text{div}(\mathbf{F})\, dA \tag{3}$$

Combining (2) and (3) we have

$$\text{flux of } \mathbf{F} \text{ across } \mathcal{C} = \iint_{\mathcal{D}} \text{div}(\mathbf{F})\, dA.$$

36. Use Eq. (12) to compute the flux of $\mathbf{F} = \left\langle 2x + y^3, 3y - x^4 \right\rangle$ across the unit circle.

SOLUTION Using the result:

$$\text{flux} = \iint_{\mathcal{D}} \text{div}(\mathbf{F})\, dA$$

we can compute the divergence:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} = 2 + 3$$

Therefore,

$$\text{flux} = \iint_{\mathcal{D}} \operatorname{div}(\mathbf{F})\, dA = \iint_{\mathcal{D}} (2+3)\, dA = 5(\text{Area of the Region}) = 5\pi$$

37. Use Eq. (12) to compute the flux of $\mathbf{F} = \langle \cos y, \sin y \rangle$ across the square $0 \le x \le 2$, $0 \le y \le \frac{\pi}{2}$.

SOLUTION Using the result:

$$\text{flux} = \iint_{\mathcal{D}} \operatorname{div}(\mathbf{F})\, dA$$

we can compute the divergence:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} = 0 + \cos y$$

Therefore,

$$\begin{aligned}
\text{flux} &= \iint_{\mathcal{D}} \operatorname{div}(\mathbf{F})\, dA \\
&= \iint_{\mathcal{D}} (0 + \cos y)\, dA \\
&= \int_0^2 \int_0^{\pi/2} \cos y\, dy\, dx \\
&= (2-0)\left(\sin y \Big|_0^{\pi/2} \right) = 2
\end{aligned}$$

38. If $\mathbf{v}$ is the velocity field of a fluid, the flux of $\mathbf{v}$ across $\mathcal{C}$ is equal to the flow rate (amount of fluid flowing across $\mathcal{C}$ in m^2/s). Find the flow rate across the circle of radius 2 centered at the origin if $\operatorname{div}(\mathbf{v}) = x^2$.

SOLUTION Using the result:

$$\text{flux} = \iint_{\mathcal{D}} \operatorname{div}(\mathbf{F})\, dA$$

we have, using polar coordinates:

$$\begin{aligned}
\text{flux} &= \iint_{\mathcal{D}} \operatorname{div}(\mathbf{F})\, dA \\
&= \iint_{\mathcal{D}} x^2\, dA \\
&= \int_0^{2\pi} \int_0^2 (r\cos\theta)^2 (r)\, dr\, d\theta \\
&= \int_0^2 \int_0^{2\pi} r^3 \cos^2\theta\, dr\, d\theta \\
&= \int_0^2 r^3\, dr \cdot \int_0^{2\pi} \frac{1}{2}(1 + \cos 2\theta)\, d\theta \\
&= \frac{r^4}{4}\Big|_0^2 \cdot \frac{1}{2}\left(\theta + \frac{1}{2}\sin 2\theta\right)\Big|_0^{2\pi} \\
&= (4) \cdot \frac{1}{2}(2\pi) = 4\pi
\end{aligned}$$

39. A buffalo (Figure 29) stampede is described by a velocity vector field $\mathbf{F} = \left\langle xy - y^3, x^2 + y \right\rangle$ km/h in the region $\mathcal{D}$ defined by $2 \le x \le 3$, $2 \le y \le 3$ in units of kilometers (Figure 30). Assuming a density is $\rho = 500$ buffalo per square kilometer, use Eq. (12) to determine the net number of buffalo leaving or entering $\mathcal{D}$ per minute (equal to ρ times the flux of $\mathbf{F}$ across the boundary of $\mathcal{D}$).

FIGURE 29 Buffalo stampede.

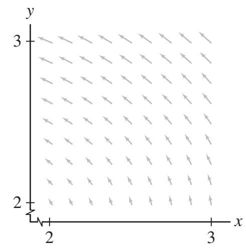


FIGURE 30 The vector field $\mathbf{F} = \left\langle xy - y^3, x^2 + y \right\rangle$.

SOLUTION The flux of $\mathbf{F}$ across the boundary ∂D has units of area per second. We multiply the buffalo density to obtain the number of buffalo per second crossing the boundary. Using Green's Theorem:

$$\begin{aligned}
\text{flux of buffalo} &= \int_{\partial D} 500\mathbf{F}\, d\mathbf{s} \\
&= 500 \int_{\partial D} \left\langle xy - y^3, x^2 + y \right\rangle d\mathbf{s} \\
&= 500 \int_2^3 \int_2^3 \operatorname{div}(\mathbf{F})\, dy\, dx \\
&= 500 \int_2^3 \int_2^3 (y+1)\, dy\, dx \\
&= 500 \int_2^3 dx \cdot \int_2^3 (y+1)\, dy \\
&= 500(3-2)\left(\frac{1}{2}y^2 + y\right)\Big|_2^3 \\
&= 500(1)\left(\frac{9}{2} + 3 - 2 - 2\right) \\
&= 500(3.5) \\
&= 1750 \text{ buffalos per second}
\end{aligned}$$

Further Insights and Challenges

In Exercises 40–43, the **Laplace operator** Δ *is defined by*

$$\Delta\varphi = \frac{\partial^2\varphi}{\partial x^2} + \frac{\partial^2\varphi}{\partial y^2} \qquad \boxed{13}$$

For any vector field $\mathbf{F} = \langle F_1, F_2\rangle$*, define the conjugate vector field* $\mathbf{F}^* = \langle -F_2, F_1\rangle$.

40. Show that if $\mathbf{F} = \nabla\varphi$, then $\operatorname{curl}_z(\mathbf{F}^*) = \Delta\varphi$.

SOLUTION For a vector field $\mathbf{F} = \langle P, Q\rangle$, the conjugate vector field is $\mathbf{F}^* = \langle -Q, P\rangle$. By the given information,

$$\mathbf{F} = \nabla\varphi = \left\langle \frac{\partial\varphi}{\partial x}, \frac{\partial\varphi}{\partial y} \right\rangle \quad \Rightarrow \quad \mathbf{F}^* = \left\langle -\frac{\partial\varphi}{\partial y}, \frac{\partial\varphi}{\partial x} \right\rangle$$

We compute the curl of $\mathbf{F}^*$:

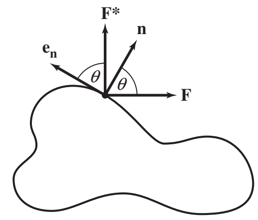
$$\operatorname{curl}(\mathbf{F}^*) = \frac{\partial}{\partial x}\left(\frac{\partial\varphi}{\partial x}\right) - \frac{\partial}{\partial y}\left(\frac{-\partial\varphi}{\partial y}\right) = \frac{\partial^2\varphi}{\partial x^2} + \frac{\partial^2\varphi}{\partial y^2} = \Delta\varphi$$

41. Let $\mathbf{n}$ be the outward-pointing unit normal vector to a simple closed curve $\mathcal{C}$. The **normal derivative** of a function φ, denoted $\frac{\partial\varphi}{\partial\mathbf{n}}$, is the directional derivative $D_{\mathbf{n}}(\varphi) = \nabla\varphi \cdot \mathbf{n}$. Prove that

$$\oint_{\mathcal{C}} \frac{\partial\varphi}{\partial\mathbf{n}}\, ds = \iint_{\mathcal{D}} \Delta\varphi\, dA$$

where $\mathcal{D}$ is the domain enclosed by a simple closed curve $\mathcal{C}$. *Hint:* Let $\mathbf{F} = \nabla\varphi$. Show that $\frac{\partial\varphi}{\partial\mathbf{n}} = \mathbf{F}^* \cdot \mathbf{T}$ where $\mathbf{T}$ is the unit tangent vector, and apply Green's Theorem.

SOLUTION In Exercise 34 we showed that for any vector field $\mathbf{F}$, $\mathbf{F}^*$ is a rotation of $\mathbf{F}$ by $\frac{\pi}{2}$ counterclockwise. The unit tangent $\mathbf{e}_n$ is a rotation of $\mathbf{n}$ by $\frac{\pi}{2}$ counterclockwise.



These properties imply that the angle θ between $\mathbf{F}$ and $\mathbf{n}$ is equal to the angle between $\mathbf{F}^*$ and $\mathbf{e}_n$, and $\|\mathbf{F}\| = \left\|\mathbf{F}^*\right\|$. Therefore,

$$\begin{aligned} \mathbf{F}\cdot\mathbf{n} &= \|\mathbf{F}\|\|\mathbf{n}\|\cos\theta = \|\mathbf{F}\|\cos\theta \\ \mathbf{F}^*\cdot\mathbf{e}_n &= \left\|\mathbf{F}^*\right\|\|\mathbf{e}_n\|\cos\theta = \|\mathbf{F}\|\cos\theta \end{aligned} \quad \Rightarrow \quad \mathbf{F}\cdot\mathbf{n} = \mathbf{F}^*\cdot\mathbf{e}_n$$

Now, if $\mathbf{F} = \nabla\varphi$, then

$$\frac{\partial\varphi}{\partial\mathbf{n}} = \nabla\varphi\cdot\mathbf{n} = \mathbf{F}\cdot\mathbf{n} = \mathbf{F}^*\cdot\mathbf{e}_n$$

By the definition of the vector line integral $\int_{\mathcal{C}} \mathbf{F}^*\cdot d\mathbf{s} = \int_{\mathcal{C}} (\mathbf{F}^*\cdot\mathbf{e}_n)\, ds$. Therefore,

$$\int_{\mathcal{C}} \frac{\partial\varphi}{\partial\mathbf{n}}\, ds = \int_{\mathcal{C}} (\mathbf{F}^*\cdot\mathbf{e}_n)\, ds = \int_{\mathcal{C}} \mathbf{F}^*\cdot d\mathbf{s}$$

Using Green's Theorem and the equality $\operatorname{curl}(\mathbf{F}^*) = \Delta\varphi$ obtained in Exercise 40, we get

$$\int_{\mathcal{C}} \frac{\partial\varphi}{\partial\mathbf{n}}\, ds = \int_{\mathcal{C}} \mathbf{F}^*\cdot d\mathbf{s} = \iint_{\mathcal{D}} \operatorname{curl}(\mathbf{F}^*)\, dA = \iint_{\mathcal{D}} \Delta\varphi\, dA.$$

42. Let $P = (a, b)$ and let $\mathcal{C}_r$ be the circle of radius r centered at P. The average value of a continuous function φ on $\mathcal{C}_r$ is defined as the integral

$$I_\varphi(r) = \frac{1}{2\pi}\int_0^{2\pi} \varphi(a + r\cos\theta, b + r\sin\theta)\, d\theta$$

(a) Show that

$$\frac{\partial\varphi}{\partial\mathbf{n}}(a + r\cos\theta, b + r\sin\theta) = \frac{\partial\varphi}{\partial r}(a + r\cos\theta, b + r\sin\theta)$$

(b) Use differentiation under the integral sign to prove that

$$\frac{d}{dr} I_\varphi(r) = \frac{1}{2\pi r}\int_{\mathcal{C}_r} \frac{\partial\varphi}{\partial\mathbf{n}}\, ds$$

(c) Use Exercise 41 to conclude that

$$\frac{d}{dr} I_\varphi(r) = \frac{1}{2\pi r}\iint_{\mathcal{D}(r)} \Delta\varphi\, dA$$

where $\mathcal{D}(r)$ is the interior of $\mathcal{C}_r$.

SOLUTION In this solution, $\varphi_r(a + r\cos\theta, b + r\sin\theta)$ denotes the partial derivative φ_r computed at $(a + r\cos\theta, b + r\sin\theta)$, whereas $\frac{\partial}{\partial r}\varphi(a + r\cos\theta, b + r\sin\theta)$ is the derivative of the composite function.

(a) Since $\frac{\partial\varphi}{\partial n} = \nabla\varphi\cdot\mathbf{n}$, we first express the gradient vector in terms of polar coordinates. We use the Chain Rule and the derivatives:

$$\theta_x = -\frac{\sin\theta}{r}, \quad \theta_y = \frac{\cos\theta}{r}, \quad r_x = \cos\theta, \quad r_y = \sin\theta$$

We get

$$\begin{aligned} \varphi_x &= \varphi_r r_x + \varphi_\theta\theta_x = \varphi_r\cos\theta + \varphi_\theta\left(-\frac{\sin\theta}{r}\right) \\ \varphi_y &= \varphi_r r_y + \varphi_\theta\theta_y = \varphi_r\sin\theta + \varphi_\theta\left(\frac{\cos\theta}{r}\right) \end{aligned} \tag{1}$$

Hence,

$$\nabla\varphi = \left\langle \varphi_r \cos\theta - \varphi_\theta \frac{\sin\theta}{r}, \varphi_r \sin\theta + \varphi_\theta \frac{\cos\theta}{r} \right\rangle$$

We use the following parametrization for $\mathcal{C}_r$:

$$\mathcal{C}_r : \mathbf{c}(\theta) = \langle a + r\cos\theta,\ b + r\sin\theta\rangle, \quad 0 \le \theta \le 2\pi$$

The unit normal vector is

$$\mathbf{n} = \langle \cos\theta, \sin\theta\rangle.$$

We compute the dot product:

$$\begin{aligned}\frac{\partial\varphi}{\partial\mathbf{n}} &= \nabla\varphi \cdot \mathbf{n} = \left\langle \varphi_r \cos\theta - \varphi_\theta \frac{\sin\theta}{r}, \varphi_r \sin\theta + \varphi_\theta \frac{\cos\theta}{r} \right\rangle \cdot \langle \cos\theta, \sin\theta\rangle \\ &= \varphi_r \cos^2\theta - \varphi_\theta \frac{\sin\theta\cos\theta}{r} + \varphi_r \sin^2\theta + \varphi_\theta \frac{\cos\theta\sin\theta}{r} = \varphi_r\left(\cos^2\theta + \sin^2\theta\right) = \varphi_r\end{aligned}$$

That is,

$$\frac{\partial\varphi}{\partial\mathbf{n}}(a + r\cos\theta, b + r\sin\theta) = \varphi_r(a + r\cos\theta, b + r\sin\theta) \tag{2}$$

(b) We compute the following derivative using the Chain Rule and (1):

$$\begin{aligned}\frac{\partial}{\partial r}\varphi(a + r\cos\theta, b + r\sin\theta) &= \varphi_x \frac{\partial}{\partial r}(a + r\cos\theta) + \varphi_y \frac{\partial}{\partial r}(b + r\sin\theta) \\ &= \left(\varphi_r\cos\theta - \varphi_\theta\frac{\sin\theta}{r}\right)\cos\theta + \left(\varphi_r\sin\theta + \varphi_\theta\frac{\cos\theta}{r}\right)\sin\theta \\ &= \varphi_r\cos^2\theta - \varphi_\theta\frac{\sin\theta\cos\theta}{r} + \varphi_r\sin^2\theta + \varphi_\theta\frac{\cos\theta\sin\theta}{r} \\ &= \varphi_r(a + r\cos\theta, b + r\sin\theta)\end{aligned} \tag{3}$$

We now differentiate $I_\varphi(r)$ under the integral sign, and use (3) and (2) to obtain

$$\begin{aligned}\frac{d}{dr}I_\varphi(r) &= \frac{1}{2\pi}\int_0^{2\pi} \frac{\partial}{\partial r}\varphi(a + r\cos\theta, b + r\sin\theta)\,d\theta = \frac{1}{2\pi}\int_0^{2\pi} \varphi_r(a + r\cos\theta, b + r\sin\theta)\,d\theta \\ &= \frac{1}{2\pi}\int_0^{2\pi} \frac{\partial\varphi}{\partial\mathbf{n}}(a + r\cos\theta, b + r\sin\theta)\,d\theta\end{aligned} \tag{4}$$

On the other hand, since $\mathbf{c}'(\theta) = \langle -r\sin\theta, r\cos\theta\rangle$, we have

$$\begin{aligned}\int_{\mathcal{C}_r} \frac{\partial\varphi}{\partial\mathbf{n}}\,ds &= \int_0^{2\pi} \frac{\partial\varphi}{\partial\mathbf{n}}(a + r\cos\theta, b + r\sin\theta)\left\|\mathbf{c}'(\theta)\right\|\,d\theta = \int_0^{2\pi} \frac{\partial\varphi}{\partial\mathbf{n}}(a + r\cos\theta, b + r\sin\theta) r\,d\theta \\ &= r\int_0^{2\pi} \frac{\partial\varphi}{\partial\mathbf{n}}(a + r\cos\theta, b + r\sin\theta)\,d\theta\end{aligned} \tag{5}$$

Combining (4) and (5) we get

$$\frac{d}{dr}I_\varphi(r) = \frac{1}{2\pi r}\int_{\mathcal{C}_r} \frac{\partial\varphi}{\partial\mathbf{n}}\,ds.$$

(c) We combine the result of part (b) and Exercise 36 to conclude

$$\frac{d}{dr}I_\varphi(r) = \frac{1}{2\pi r}\int_{\mathcal{C}_r} \frac{\partial\varphi}{\partial\mathbf{n}}\,ds = \frac{1}{2\pi r}\iint_{\mathcal{D}(r)} \Delta\varphi\,dA.$$

43. Prove that $m(r) \le I_\varphi(r) \le M(r)$, where $m(r)$ and $M(r)$ are the minimum and maximum values of φ on $\mathcal{C}_r$. Then use the continuity of φ to prove that $\lim_{r\to 0} I_\varphi(r) = \varphi(P)$.

SOLUTION $I_\varphi(r)$ is defined by

$$I_\varphi(r) = \frac{1}{2\pi}\int_0^{2\pi} \varphi(a + r\cos\theta, b + r\sin\theta)\,d\theta$$

The points on $\mathcal{C}_r$ have the form $(a + r\cos\theta, b + r\sin\theta)$. Therefore, since $m(r)$ and $M(r)$ are the minimum and maximum values of φ on $\mathcal{C}_r$, we have for all $0 \le \theta \le 2\pi$,

$$m(r) \le \varphi(a + r\cos\theta, b + r\sin\theta) \le M(r)$$

Using properties of integrals (Eq. (6) in Section 5.2), we conclude that

$$2\pi m(r) \le \int_0^{2\pi} \varphi(a + r\cos\theta + b + r\sin\theta) \le 2\pi M(r)$$

Dividing by 2π we obtain

$$m(r) \le I_\varphi(r) \le M(r) \tag{1}$$

Now, since φ is continuous and the functions $\sin\theta$ and $\cos\theta$ are bounded for all $0 \le \theta \le 2\pi$, the following holds:

$$\lim_{r\to 0} \varphi(a + r\cos\theta, b + r\sin\theta) = \varphi\left(\lim_{r\to 0}(a + r\cos\theta, b + r\sin\theta)\right) = \varphi(a, b)$$

which means that for $\epsilon > 0$ there exists $\delta > 0$ so that

$$|\varphi(a + r\cos\theta, b + r\sin\theta) - \varphi(a, b)| < \epsilon$$

for all $0 \le \theta \le 2\pi$, whenever $0 < r < \delta$. Hence also

$$\lim_{r\to 0} m(r) = \lim_{r\to 0} M(r) = \varphi(a, b) \tag{2}$$

Combining (1), (2), and the Squeeze Theorem, we obtain the following conclusion:

$$\lim_{r\to 0} I_\varphi(r) = \varphi(a, b).$$

In Exercises 44 and 45, let $\mathcal{D}$ be the region bounded by a simple closed curve $\mathcal{C}$. A function $\varphi(x, y)$ on $\mathcal{D}$ (whose second-order partial derivatives exist and are continuous) is called **harmonic** *if $\Delta\varphi = 0$, where $\Delta\varphi$ is the Laplace operator defined in Eq. (13).*

44. Use the results of Exercises 42 and 43 to prove the **mean-value property** of harmonic functions: If φ is harmonic, then $I_\varphi(r) = \varphi(P)$ for all r.

SOLUTION In Exercise 42 we showed that

$$\frac{d}{dr} I_\varphi(r) = \frac{1}{2\pi r} \iint_{\mathcal{D}} \Delta\varphi \, dA$$

If φ is harmonic, $\Delta\varphi = 0$. Therefore the right-hand side of the equality is zero, and we get

$$\frac{d}{dr} I_\varphi(r) = 0$$

We conclude that $I_\varphi(r)$ is constant, that is, $I_\varphi(r)$ has the same value for all r. The constant value is determined by the limit $\lim_{r\to 0} I_\varphi(r) = \varphi(P)$ obtained in Exercise 38. That is, $I_\varphi(r) = \varphi(P)$ for all r.

45. Show that $f(x, y) = x^2 - y^2$ is harmonic. Verify the mean-value property for $f(x, y)$ directly [expand $f(a + r\cos\theta, b + r\sin\theta)$ as a function of θ and compute $I_\varphi(r)$]. Show that $x^2 + y^2$ is not harmonic and does not satisfy the mean-value property.

SOLUTION We show that the function $f(x, y) = x^2 - y^2$ is harmonic by showing that $\Delta f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} = 0$. We have

$$\frac{\partial f}{\partial x} = 2x, \quad \frac{\partial f}{\partial y} = -2y$$

$$\frac{\partial^2 f}{\partial x^2} = 2, \quad \frac{\partial^2 f}{\partial y^2} = -2$$

Hence,

$$\Delta f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} = 2 - 2 = 0$$

We now verify the mean-value property for f. That is, we show that for all r,

$$I_f(r) = \frac{1}{2\pi} \int_0^{2\pi} f(a + r\cos\theta, b + r\sin\theta)\, d\theta = f(a, b)$$

We compute the integrand:

$$\begin{aligned} f(a + r\cos\theta, b + r\sin\theta) &= x^2 - y^2 = (a + r\cos\theta)^2 - (b + r\sin\theta)^2 \\ &= a^2 + 2ar\cos\theta + r^2\cos^2\theta - \left(b^2 + 2br\sin\theta + r^2\sin^2\theta\right) \\ &= a^2 - b^2 + 2r(a\cos\theta - b\sin\theta) + r^2\cos 2\theta \end{aligned}$$

We compute the integral:

$$\begin{aligned} 2\pi I_f(r) &= \int_0^{2\pi} \left(a^2 - b^2 + 2r(a\cos\theta - b\sin\theta) + r^2\cos 2\theta\right) d\theta \\ &= (a^2 - b^2)\theta + 2ar\sin\theta + 2br\cos\theta + \frac{r^2}{2}\sin 2\theta\Big|_{\theta=0}^{2\pi} = 2\pi(a^2 - b^2) \end{aligned}$$

Hence,

$$I_f(r) = a^2 - b^2$$

However, we have $f(a, b) = a^2 - b^2$. Hence, for all r, $I_f(r) = f(a, b)$, which proves the mean-value property for f. For $g(x, y) = x^2 + y^2$ we have

$$g_{xx} = 2, \quad g_{yy} = 2, \quad \text{and} \quad \Delta g = 2 + 2 = 4 \neq 0.$$

We check the mean value property:

$$\begin{aligned} I_g(r) &= \frac{1}{2\pi}\int_0^{2\pi} g(a + r\cos\theta, b + r\sin\theta)\, d\theta = \frac{1}{2\pi}\int_0^{2\pi} (a + r\cos\theta)^2 + (b + r\sin\theta)^2\, d\theta \\ &= \frac{1}{2\pi}\int_0^{2\pi} a^2 + b^2 + 2r(a\cos\theta + b\sin\theta) + r^2\, d\theta = a^2 + b^2 + r^2 \neq a^2 + b^2 = \varphi(a, b) \end{aligned}$$

The mean value property does not hold for g.

17.2 Stokes' Theorem (LT Section 18.2)

Preliminary Questions

1. Indicate with an arrow the boundary orientation of the boundary curves of the surfaces in Figure 14, oriented by the outward-pointing normal vectors.

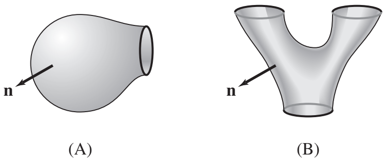


FIGURE 14

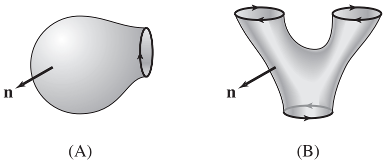
SOLUTION The indicated orientation is defined so that if the normal vector is moving along the boundary curve, the surface lies to the left. Since the surfaces are oriented by the outward-pointing normal vectors, the induced orientation is as shown in the figure:



2. Let $\mathbf{F} = \text{curl}(\mathbf{A})$. Which of the following are related by Stokes' Theorem?

(a) The circulation of $\mathbf{A}$ and flux of $\mathbf{F}$.

(b) The circulation of $\mathbf{F}$ and flux of $\mathbf{A}$.

SOLUTION Stokes' Theorem states that the circulation of $\mathbf{A}$ is equal to the flux of $\mathbf{F}$. The correct answer is (a).

3. What is the definition of a vector potential?

SOLUTION A vector field $\mathbf{A}$ such that $\mathbf{F} = \text{curl}(\mathbf{A})$ is a vector potential for $\mathbf{F}$.

4. Which of the following statements is correct?

(a) The flux of curl(**A**) through every oriented surface is zero.

(b) The flux of curl(**A**) through every closed, oriented surface is zero.

SOLUTION Statement (b) is the correct statement. The flux of curl(**F**) through an oriented surface is not necessarily zero, unless the surface is closed.

5. Which condition on **F** guarantees that the flux through $\mathcal{S}_1$ is equal to the flux through $\mathcal{S}_2$ for any two oriented surfaces $\mathcal{S}_1$ and $\mathcal{S}_2$ with the same oriented boundary?

SOLUTION If **F** has a vector potential **A**, then by a corollary of Stokes' Theorem,

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}} \mathbf{A} \cdot d\mathbf{s}$$

Therefore, if two oriented surfaces $\mathcal{S}_1$ and $\mathcal{S}_2$ have the same oriented boundary curve, $\mathcal{C}$, then

$$\iint_{\mathcal{S}_1} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}} \mathbf{A} \cdot d\mathbf{s} \quad \text{and} \quad \iint_{\mathcal{S}_2} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}} \mathbf{A} \cdot d\mathbf{s}$$

Hence,

$$\iint_{\mathcal{S}_1} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}_2} \mathbf{F} \cdot d\mathbf{s}$$

Exercises

In Exercises 1–4, calculate curl(**F**).

1. $\mathbf{F} = \langle z - y^2, x + z^3, y + x^2 \rangle$

SOLUTION We have

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ z - y^2 & x + z^3 & y + x^2 \end{vmatrix} = (1 - 3z^2)\mathbf{i} - (2x - 1)\mathbf{j} + (1 + 2y)\mathbf{k} = \langle 1 - 3z^2, 1 - 2x, 1 + 2y \rangle$$

2. $\mathbf{F} = \left\langle \frac{y}{x}, \frac{y}{z}, \frac{z}{x} \right\rangle$

SOLUTION The curl is the following vector:

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{y}{x} & \frac{y}{z} & \frac{z}{x} \end{vmatrix} = \left(0 - \frac{-y}{z^2}\right)\mathbf{i} - \left(-\frac{z}{x^2} - 0\right)\mathbf{j} + \left(0 - \frac{1}{x}\right)\mathbf{k} = \left\langle \frac{y}{z^2}, \frac{z}{x^2}, -\frac{1}{x} \right\rangle$$

3. $\mathbf{F} = \langle e^y, \sin x, \cos x \rangle$

SOLUTION We have

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ e^y & \sin x & \cos x \end{vmatrix} = 0\mathbf{i} - (-\sin x)\mathbf{j} + (\cos x - e^y)\mathbf{k} = \langle 0, \sin x, \cos x - e^y \rangle$$

4. $\mathbf{F} = \left\langle \frac{x}{x^2 + y^2}, \frac{y}{x^2 + y^2}, 0 \right\rangle$

SOLUTION

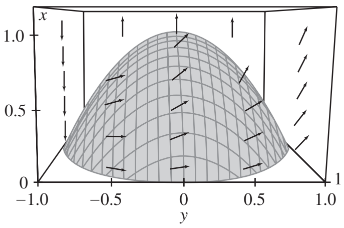
$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{x}{x^2 + y^2} & \frac{y}{x^2 + y^2} & 0 \end{vmatrix} = 0\mathbf{i} - 0\mathbf{j} + \left(\frac{-2xy}{(x^2 + y^2)^2} + \frac{2xy}{(x^2 + y^2)^2}\right)\mathbf{k} = \mathbf{0}$$

In Exercises 5–8, verify Stokes' Theorem for the given vector field and surface, oriented with an upward-pointing normal.

5. $\mathbf{F} = \langle 2xy, x, y+z \rangle$, the surface $z = 1 - x^2 - y^2$ for $x^2 + y^2 \le 1$

SOLUTION We must show that

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{S}$$



Step 1. Compute the line integral around the boundary curve. The boundary curve $\mathcal{C}$ is the unit circle oriented in the counterclockwise direction. We parametrize $\mathcal{C}$ by

$$\gamma(t) = (\cos t, \sin t, 0), \quad 0 \le t \le 2\pi$$

Then,

$$\begin{aligned}
\mathbf{F}(\gamma(t)) &= \langle 2\cos t \sin t, \cos t, \sin t \rangle \\
\gamma'(t) &= \langle -\sin t, \cos t, 0 \rangle \\
\mathbf{F}(\gamma(t)) \cdot \gamma'(t) &= \langle 2\cos t \sin t, \cos t, \sin t \rangle \cdot \langle -\sin t, \cos t, 0 \rangle = -2\cos t \sin^2 t + \cos^2 t
\end{aligned}$$

We obtain the following integral:

$$\int_{\mathcal{C}} \mathbf{F}\, d\mathbf{s} = \int_0^{2\pi} \left(-2\cos t \sin^2 t + \cos^2 t\right) dt = -\frac{2\sin^3 t}{3} + \frac{t}{2} + \frac{\sin 2t}{4}\Bigg|_0^{2\pi} = \pi \tag{1}$$

Step 2. Compute the flux of the curl through the surface. We parametrize the surface by

$$\Phi(\theta, t) = \left(t\cos\theta, t\sin\theta, 1 - t^2\right), \quad 0 \le t \le 1, \quad 0 \le \theta \le 2\pi$$

We compute the normal vector:

$$\begin{aligned}
\mathbf{T}_\theta &= \frac{\partial \Phi}{\partial \theta} = \langle -t\sin\theta, t\cos\theta, 0 \rangle \\
\mathbf{T}_t &= \frac{\partial \Phi}{\partial t} = \langle \cos\theta, \sin\theta, -2t \rangle \\
\mathbf{T}_\theta \times \mathbf{T}_t &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -t\sin\theta & t\cos\theta & 0 \\ \cos\theta & \sin\theta & -2t \end{vmatrix} = (-2t^2\cos\theta)\mathbf{i} - (2t^2\sin\theta)\mathbf{j} - t(\sin^2\theta + \cos^2\theta)\mathbf{k} \\
&= (-2t^2\cos\theta)\mathbf{i} - (2t^2\sin\theta)\mathbf{j} - t\mathbf{k}
\end{aligned}$$

Since the normal is always supposed to be pointing upward, the z-coordinate of the normal vector must be positive. Therefore, the normal vector is

$$\mathbf{n} = \left\langle 2t^2\cos\theta, 2t^2\sin\theta, t \right\rangle$$

We compute the curl:

$$\text{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ 2xy & x & y+z \end{vmatrix} = \mathbf{i} + (1-2x)\mathbf{k} = \langle 1, 0, 1-2x \rangle$$

We compute the curl in terms of the parameters:

$$\text{curl}(\mathbf{F}) = \langle 1, 0, 1 - 2t\cos\theta \rangle$$

Hence,

$$\text{curl}(\mathbf{F}) \cdot \mathbf{n} = \langle 1, 0, 1 - 2t\cos\theta \rangle \cdot \left\langle 2t^2\cos\theta, 2t^2\sin\theta, t \right\rangle = 2t^2\cos\theta + t - 2t^2\cos\theta = t$$

The surface integral is thus

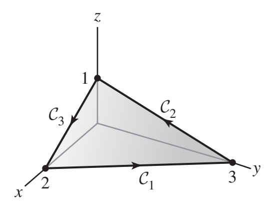
$$\iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^1 t\,dt\,d\theta = 2\pi \int_0^1 t\,dt = 2\pi \cdot \left.\frac{t^2}{2}\right|_0^1 = \pi \tag{2}$$

The values of the integrals in (1) and (2) are equal, as stated in Stokes' Theorem.

6. $\mathbf{F} = \langle yz, 0, x \rangle$, the portion of the plane $\frac{x}{2} + \frac{y}{3} + z = 1$ where $x, y, z \geq 0$

SOLUTION

Step 1. Compute the integral around the boundary curve. The boundary curve $\mathcal{C}$ consists of the segments $\mathcal{C}_1$, $\mathcal{C}_2$, and $\mathcal{C}_3$ shown in the figure:



We parametrize the segments by

$$\mathcal{C}_1 : \gamma_1(t) = (2 - 2t, 3t, 0), \quad t \text{ from 0 to 1}$$
$$\mathcal{C}_2 : \gamma_2(t) = (0, 3 - 3t, t), \quad t \text{ from 0 to 1}$$
$$\mathcal{C}_3 : \gamma_3(t) = (2t, 0, 1 - t), \quad t \text{ from 0 to 1}$$

We compute the following values:

$$\mathbf{F}(\gamma_1(t)) = \langle yz, 0, x \rangle = \langle 0, 0, 2 - 2t \rangle, \quad \gamma_1'(t) = \langle -2, 3, 0 \rangle$$
$$\mathbf{F}(\gamma_2(t)) = \langle yz, 0, x \rangle = \left\langle 3t - 3t^2, 0, 0 \right\rangle, \quad \gamma_2'(t) = \langle 0, -3, 1 \rangle$$
$$\mathbf{F}(\gamma_3(t)) = \langle yz, 0, x \rangle = \langle 0, 0, 2t \rangle, \quad \gamma_3'(t) = \langle 2, 0, -1 \rangle$$

Hence,

$$\mathbf{F}(\gamma_1(t)) \cdot \gamma_1'(t) = \langle 0, 0, 2 - 2t \rangle \cdot \langle -2, 3, 0 \rangle = 0$$
$$\mathbf{F}(\gamma_2(t)) \cdot \gamma_2'(t) = \left\langle 3t - 3t^2, 0, 0 \right\rangle \cdot \langle 0, -3, 1 \rangle = 0$$
$$\mathbf{F}(\gamma_3(t)) \cdot \gamma_3'(t) = \langle 0, 0, 2t \rangle \cdot \langle 2, 0, -1 \rangle = -2t$$

We obtain the following integral:

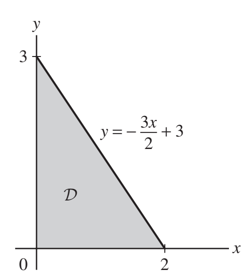
$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} + \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} + \int_{\mathcal{C}_3} \mathbf{F} \cdot d\mathbf{s} = 0 + 0 + \int_0^1 -2t\,dt = -t^2\Big|_0^1 = -1 \tag{1}$$

Step 2. Compute the curl.

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ yz & 0 & x \end{vmatrix} = -(1 - y)\mathbf{j} + (0 - z)\mathbf{k} = \langle 0, y - 1, -z \rangle$$

Step 3. Compute the flux of the curl through the surface. We parametrize the portion of the plane by

$$\Phi(x, y) = \left(x, y, 1 - \frac{x}{2} - \frac{y}{3}\right) \quad \text{for } (x, y) \in \mathcal{D}$$



We find the normal vector:

$$\mathbf{T}_x = \frac{\partial \Phi}{\partial x} = \left\langle 1, 0, -\frac{1}{2} \right\rangle$$

$$\mathbf{T}_y = \frac{\partial \Phi}{\partial y} = \left\langle 0, 1, -\frac{1}{3} \right\rangle$$

$$\mathbf{T}_x \times \mathbf{T}_y = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -\frac{1}{2} \\ 0 & 1 & -\frac{1}{3} \end{vmatrix} = \frac{1}{2}\mathbf{i} + \frac{1}{3}\mathbf{j} + \mathbf{k} = \left\langle \frac{1}{2}, \frac{1}{3}, 1 \right\rangle$$

The upward pointing normal is

$$\mathbf{n} = \left\langle \frac{1}{2}, \frac{1}{3}, 1 \right\rangle.$$

We compute the curl($\mathbf{F}$) in terms of the parameters x and y:

$$\text{curl}(\mathbf{F}) = \left\langle 0, y-1, -\left(1 - \frac{x}{2} - \frac{y}{3}\right) \right\rangle = \left\langle 0, y-1, \frac{x}{2} + \frac{y}{3} - 1 \right\rangle$$

We obtain the following integral:

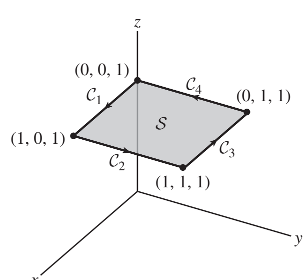
$$\begin{aligned} \iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} &= \iint_{\mathcal{D}} \left\langle 0, y-1, \frac{x}{2} + \frac{y}{3} - 1 \right\rangle \cdot \left\langle \frac{1}{2}, \frac{1}{3}, 1 \right\rangle dA = \iint_{\mathcal{D}} \left(\frac{x}{2} + \frac{2y}{3} - \frac{4}{3} \right) dA \\ &= \int_0^2 \int_0^{-3x/2+3} \left(\frac{x}{2} + \frac{2y}{3} - \frac{4}{3} \right) dy\, dx = \int_0^2 \frac{xy}{2} + \frac{y^2}{3} - \frac{4y}{3} \bigg|_{y=0}^{-3x/2+3} dx \\ &= \int_0^2 \left(\frac{x}{2} - 1 \right) dx = \frac{x^2}{4} - x \bigg|_0^2 = -1 \end{aligned} \tag{2}$$

The integrals in (1) and (2) are equal as stated in Stokes' Theorem.

7. $\mathbf{F} = \langle e^{y-z}, 0, 0 \rangle$, the square with vertices (1, 0, 1), (1, 1, 1), (0, 1, 1), and (0, 0, 1)

SOLUTION

Step 1. Compute the integral around the boundary curve. The boundary consists of four segments $\mathcal{C}_1$, $\mathcal{C}_2$, $\mathcal{C}_3$, and $\mathcal{C}_4$ shown in the figure:



We parametrize the segments by

$$\begin{aligned} \mathcal{C}_1 &: \gamma_1(t) = (t, 0, 1), \quad 0 \le t \le 1 \\ \mathcal{C}_2 &: \gamma_2(t) = (1, t, 1), \quad 0 \le t \le 1 \\ \mathcal{C}_3 &: \gamma_3(t) = (1-t, 1, 1), \quad 0 \le t \le 1 \\ \mathcal{C}_4 &: \gamma_4(t) = (0, 1-t, 1), \quad 0 \le t \le 1 \end{aligned}$$

We compute the following values:

$$\begin{aligned} \mathbf{F}(\gamma_1(t)) &= \langle e^{y-z}, 0, 0 \rangle = \left\langle e^{-1}, 0, 0 \right\rangle \\ \mathbf{F}(\gamma_2(t)) &= \langle e^{y-z}, 0, 0 \rangle = \left\langle e^{t-1}, 0, 0 \right\rangle \\ \mathbf{F}(\gamma_3(t)) &= \langle e^{y-z}, 0, 0 \rangle = \langle 1, 0, 0 \rangle \\ \mathbf{F}(\gamma_4(t)) &= \langle e^{y-z}, 0, 0 \rangle = \left\langle e^{-t-1}, 0, 0 \right\rangle \end{aligned}$$

Hence,

$$\mathbf{F}(\gamma_1(t)) \cdot \gamma_1'(t) = \left\langle e^{-1}, 0, 0 \right\rangle \cdot \langle 1, 0, 0 \rangle = e^{-1}$$
$$\mathbf{F}(\gamma_2(t)) \cdot \gamma_2'(t) = \left\langle e^{t-1}, 0, 0 \right\rangle \cdot \langle 0, 1, 0 \rangle = 0$$
$$\mathbf{F}(\gamma_3(t)) \cdot \gamma_3'(t) = \langle 1, 0, 0 \rangle \cdot \langle -1, 0, 0 \rangle = -1$$
$$\mathbf{F}(\gamma_4(t)) \cdot \gamma_4'(t) = \left\langle e^{-t-1}, 0, 0 \right\rangle \cdot \langle 0, -1, 0 \rangle = 0$$

We obtain the following integral:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \sum_{i=1}^{4} \int_{\mathcal{C}_i} \mathbf{F} \cdot d\mathbf{s} = \int_0^1 e^{-1}\, dt + 0 + \int_0^1 (-1)\, dt + 0 = e^{-1} - 1$$

Step 2. Compute the curl.

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ e^{y-z} & 0 & 0 \end{vmatrix} = -e^{y-z}\ \mathbf{j}\ - e^{y-z}\ \mathbf{k}\ = \left\langle 0, -e^{y-z}, -e^{y-z} \right\rangle$$

Step 3. Compute the flux of the curl through the surface. We parametrize the surface by

$$\Phi(x, y) = (x, y, 1), \quad 0 \le x,\ y \le 1$$

The upward pointing normal is $\mathbf{n} = \langle 0, 0, 1 \rangle$. We express curl($\mathbf{F}$) in terms of the parameters x and y:

$$\operatorname{curl}(\mathbf{F})\,(\Phi(x, y)) = \left\langle 0, -e^{y-1}, -e^{y-1} \right\rangle$$

Hence,

$$\operatorname{curl}(\mathbf{F}) \cdot \mathbf{n} = \left\langle 0, -e^{y-1}, -e^{y-1} \right\rangle \cdot \langle 0, 0, 1 \rangle = -e^{y-1}$$

The surface integral is thus

$$\iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot\, d\mathbf{S} = \iint_{\mathcal{D}} -e^{y-1}\, dA = \int_0^1 \int_0^1 -e^{y-1}\, dy\, dx = \int_0^1 -e^{y-1}\, dy = -e^{y-1}\Big|_0^1$$
$$= -1 + e^{-1} = e^{-1} - 1 \tag{1}$$

We see that the integrals in (1) and (2) are equal.

8. $\mathbf{F} = \left\langle y, x, x^2 + y^2 \right\rangle$, the upper hemisphere $x^2 + y^2 + z^2 = 1$, $z \ge 0$

SOLUTION

Step 1. Compute the integral around the boundary curve. The boundary curve is the unit circle oriented in the counterclockwise direction. We use the parametrization $\gamma(t) = \langle \cos t, \sin t, 0 \rangle$, $0 \le t \le 2\pi$. Then,

$$\mathbf{F}(\gamma(t)) \cdot \gamma'(t) = \langle \sin t, \cos t, 1 \rangle \cdot \langle -\sin t, \cos t, 0 \rangle = -\sin^2 t + \cos^2 = \cos 2t$$

The line integral is

$$\int_{\mathcal{C}} \mathbf{F} \cdot\, d\mathbf{s} = \int_0^{2\pi} (\cos^2 t - \sin^2 t)\, dt = \int_0^{2\pi} \cos 2t\, dt = \frac{1}{2} \sin 2t\Big|_0^{2\pi} = 0$$

Step 2. Compute the curl.

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & x & x^2 + y^2 \end{vmatrix} = \langle 2y, -2x, 0 \rangle$$

Step 3. Compute the flux of the curl through the surface. We parametrize the surface by

$$G(\phi, \theta) = \langle \cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi \rangle, \quad 0 \le \theta \le 2\pi, \quad 0 \le \phi \le \frac{\pi}{2}$$

We compute the normal to the surface:

$$G_\theta = \langle -\sin\theta\sin\phi, \cos\theta\sin\phi, 0\rangle$$
$$G_\phi = \langle \cos\theta\cos\phi, \sin\theta\cos\phi, -\sin\phi\rangle$$
$$G_\theta \times G_\phi = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin\theta\sin\phi & \cos\theta\sin\phi & 0 \\ \cos\theta\cos\phi & \sin\theta\cos\phi & -\sin\phi \end{vmatrix}$$
$$= \left\langle -\cos\theta\ \sin^2\phi, -\sin\theta\ \sin^2\phi, -\frac{\sin^2\theta\sin 2\phi}{2} - \frac{\cos^2\theta\sin 2\phi}{2}\right\rangle$$

Since $\mathbf{n}$ points upward, we take $\mathbf{n} = -G_\theta \times G_\phi$. Thus,

$$\mathbf{n} = \sin\phi\,\langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle$$

We express curl($\mathbf{F}$) in terms of $G(\phi, \theta)$:

$$\mathrm{curl}(\mathbf{F})(G(\phi,\theta)) = \langle 2\sin\theta\sin\phi, -2\cos\theta\sin\phi, 0\rangle$$

Then we obtain:

$$\mathrm{curl}(\mathbf{F})\cdot\mathbf{n} = \langle 2\sin\theta\sin\phi, -2\cos\theta\sin\phi, 0\rangle\cdot\sin\phi\,\langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle$$
$$= \sin\phi(2\sin\theta\cos\theta\sin^2\phi - 2\sin\theta\cos\theta\sin^2\phi + 0) = 0$$

Therefore, the line integral around the unit circle is

$$\iint_{\mathcal{S}} \mathrm{curl}(\mathbf{F})\cdot d\mathbf{S} = \iint_{\mathcal{D}} 0\,dA = 0.$$

In Exercises 9 and 10, calculate curl($\mathbf{F}$) *and then use Stokes' Theorem to compute the flux of* curl($\mathbf{F}$) *through the given surface as a line integral.*

9. $\mathbf{F} = \left\langle e^{z^2} - y, e^{z^3} + x, \cos(xz)\right\rangle$, the upper hemisphere $x^2 + y^2 + z^2 = 1$, $z \ge 0$ with outward-pointing normal

SOLUTION

Step 1. Compute the curl.

$$\mathrm{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial x & \partial y & \partial z \\ e^{z^2} - y & e^{z^3} + x & \cos(xz) \end{vmatrix} = \left\langle -3z^2e^{z^3}, 2ze^{z^3} + z\sin(xz), 2\right\rangle$$

Step 2. Compute the flux of the curl through the surface. We will use Stokes' Theorem and compute the line integral around the boundary curve. The boundary curve is the unit circle oriented in the counterclockwise direction. We use the parametrization $\gamma(t) = \langle\cos t, \sin t, 0\rangle$, $0 \le t \le 2\pi$. Then

$$\mathbf{F}(\gamma(t))\cdot\gamma'(t) = \left\langle e^0 - \sin t, e^0 + \cos t, \cos(0)\right\rangle\cdot\langle -\sin t, \cos t, 0\rangle$$
$$= \langle 1 - \sin t, 1 + \cos t, 1\rangle\cdot\langle -\sin t, \cos t, 0\rangle$$
$$= -\sin t(1 - \sin t) + \cos t(1 + \cos t) + 0$$
$$= -\sin t + \sin^2 t + \cos t + \cos^2 t$$
$$= 1 - \sin t + \cos t$$

The line integral is:

$$\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} = \int_0^{2\pi}(1 - \sin t + \cos t)\,dt = t + \cos t + \sin t\Big|_0^{2\pi} = 2\pi$$

10. $\mathbf{F} = \left\langle x + y, z^2 - 4, x\sqrt{y^2 + 1} \right\rangle$, surface of the wedge-shaped box in Figure 15 (bottom included, top excluded) with outward pointing normal.

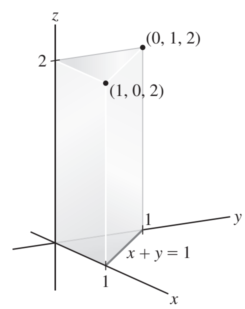


FIGURE 15

SOLUTION We are asked to calculate the flux of curl($\mathbf{F}$) through the walls of the wedge-shaped box (bottom included, top excluded) with outward pointing normal. The oriented boundary of this surface is the triangle at height $z = 2$, oriented clockwise (when viewed from above). By Stokes' Theorem, the flux of curl($\mathbf{F}$) is equal to the line integral of $\mathbf{F}$ around the oriented boundary. The restriction of $\mathbf{F}$ to the boundary, where $z = 2$ is

$$\mathbf{F} = \left\langle x + y, 0, x\sqrt{y^2 + 1} \right\rangle$$

We parametrize the three sides of this triangle for $0 \le t \le 1$:

$$\langle 1 - t, 0, 0 \rangle, \quad \langle 0, t, 0 \rangle, \quad \langle t, 1 - t, 0 \rangle$$

Thus $d\mathbf{s}$ on the three sides is

$$\langle -1, 0, 0 \rangle \; dt, \quad \langle 0, 1, 0 \rangle \; dt, \quad \langle 1, -1, 0 \rangle \; dt$$

and the dot products are (the z-component of $\mathbf{F}$ is not relevant because $d\mathbf{s}$ has zero z-component):

$$\begin{aligned}
\mathbf{F} \cdot d\mathbf{s} &= \langle 1 - t, 0, \star \rangle \cdot \langle -1, 0, 0 \rangle \; dt = (t - 1) \; dt \\
\mathbf{F} \cdot d\mathbf{s} &= \langle t, 0, \star \rangle \cdot \langle 0, 1, 0 \rangle \; dt = 0 \\
\mathbf{F} \cdot d\mathbf{s} &= \langle 1, 0, \star \rangle \cdot \langle 1, -1, 0 \rangle \; dt = \; dt
\end{aligned}$$

Therefore, the line integral around the oriented boundary is equal to

$$\int_0^1 (t - 1) \, dt + 0 + \int_0^1 \; dt = -\frac{1}{2} + 0 + 1 = \frac{1}{2}$$

Thus, the flux of curl($\mathbf{F}$) through the surface is $\frac{1}{2}$.

11. Let $\mathcal{S}$ be the surface of the cylinder (not including the top and bottom) of radius 2 for $1 \le z \le 6$, oriented with outward-pointing normal (Figure 16).

(a) Indicate with an arrow the orientation of $\partial\mathcal{S}$ (the top and bottom circles).

(b) Verify Stokes' Theorem for $\mathcal{S}$ and $\mathbf{F} = \left\langle yz^2, 0, 0 \right\rangle$.

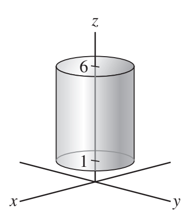

FIGURE 16

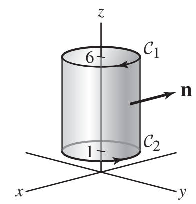
SOLUTION

(a) The induced orientation is defined so that as the normal vector travels along the boundary curve, the surface lies to its left. Therefore, the boundary circles on top and bottom have opposite orientations, which are shown in the figure.



(b) We verify Stokes' Theorem for $\mathcal{S}$ and $\mathbf{F} = \left\langle yz^2, 0, 0 \right\rangle$.

Step 1. Compute the integral around the boundary circles. We use the following parametrizations:

$$\mathcal{C}_1 : \gamma_1(t) = (2\cos t, 2\sin t, 6), \quad t \text{ from } 2\pi \text{ to } 0$$
$$\mathcal{C}_2 : \gamma_2(t) = (2\cos t, 2\sin t, 1), \quad t \text{ from } 0 \text{ to } 2\pi$$

We compute the following values:

$$\begin{aligned}
\mathbf{F}(\gamma_1(t)) &= \left\langle yz^2, 0, 0 \right\rangle = \langle 72\sin t, 0, 0 \rangle, \\
\gamma_1'(t) &= \langle -2\sin t, 2\cos t, 0 \rangle \\
\mathbf{F}(\gamma_1(t)) \cdot \gamma_1'(t) &= \langle 72\sin t, 0, 0 \rangle \cdot \langle -2\sin t, 2\cos t, 0 \rangle = -144\sin^2 t \\
\mathbf{F}(\gamma_2(t)) &= \left\langle yz^2, 0, 0 \right\rangle = \langle 2\sin t, 0, 0 \rangle, \\
\gamma_2'(t) &= \langle -2\sin t, 2\cos t, 0 \rangle \\
\mathbf{F}(\gamma_2(t)) \cdot \gamma_2'(t) &= \langle 2\sin t, 0, 0 \rangle \cdot \langle -2\sin t, 2\cos t, 0 \rangle = -4\sin^2 t
\end{aligned}$$

The line integral is thus

$$\begin{aligned}
\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} &= \int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} + \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = \int_{2\pi}^{0} (-144\sin^2 t)\, dt + \int_0^{2\pi} (-4\sin^2 t)\, dt \\
&= \int_0^{2\pi} 140\sin^2 t\, dt = 140 \int_0^{2\pi} \frac{1 - \cos 2t}{2}\, dt = 70 \cdot 2\pi - \left.\frac{70\sin 2t}{2}\right|_0^{2\pi} = 140\pi
\end{aligned}$$

Step 2. Compute the curl

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ yz^2 & 0 & 0 \end{vmatrix} = (2yz)\mathbf{j} - z^2\mathbf{k} = \left\langle 0, 2yz, -z^2 \right\rangle$$

Step 3. Compute the flux of the curl through the surface. We parametrize $\mathcal{S}$ by

$$\Phi(\theta, z) = (2\cos\theta, 2\sin\theta, z), \quad 0 \le \theta \le 2\pi, \quad 1 \le z \le 6$$

In Example 2 in the text, it is shown that the outward pointing normal is

$$\mathbf{n} = \langle 2\cos\theta, 2\sin\theta, 0 \rangle$$

We compute the dot product:

$$\operatorname{curl}(\mathbf{F})(\Phi(\theta, z)) \cdot \mathbf{n} = \left\langle 0, 4z\sin\theta, -z^2 \right\rangle \cdot \langle 2\cos\theta, 2\sin\theta, 0 \rangle = 8z\sin^2\theta$$

We obtain the following integral (and use the integral we computed before):

$$\iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} = \int_1^6 \int_0^{2\pi} 8z\sin^2\theta\, d\theta\, dz = \left(\int_1^6 8z\, dz \right) \left(\int_0^{2\pi} \sin^2\theta\, d\theta \right) = \left. 4z^2 \right|_1^6 \cdot \pi = 140\pi$$

The line integral and the flux have the same value. This verifies Stokes' Theorem.

12. Let $\mathcal{S}$ be the portion of the plane $z = x$ contained in the half-cylinder of radius R depicted in Figure 17. Use Stokes' Theorem to calculate the circulation of $\mathbf{F} = \langle z, x, y + 2z \rangle$ around the boundary of $\mathcal{S}$ (a half-ellipse) in the counterclockwise direction when viewed from above. *Hint:* Show that curl($\mathbf{F}$) is orthogonal to the normal vector to the plane.

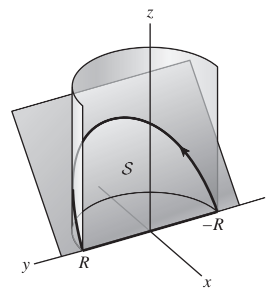


FIGURE 17

SOLUTION By Stokes' Theorem,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{S}$$

We compute the curl:

$$\text{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ z & x & y+2z \end{vmatrix} = \mathbf{i} + \mathbf{j} + \mathbf{k} = \langle 1, 1, 1 \rangle$$

The outward pointing vector of the plane $z = x$, or $x - z = 0$, is $\mathbf{n} = \langle -1, 0, 1 \rangle$. Therefore,

$$\text{curl}(\mathbf{F}) \cdot \mathbf{n} = \langle 1, 1, 1 \rangle \cdot \langle -1, 0, 1 \rangle = -1 + 0 + 1 = 0$$

We conclude that

$$\iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{s} = \iint_{\mathcal{D}} 0 \, dA = 0$$

This equation, along with Stokes' Theorem, allows us to conclude that the circulation of **F** around $\mathcal{C}$ is zero.

13. Let I be the flux of $\mathbf{F} = \left\langle e^y, 2xe^{x^2}, z^2 \right\rangle$ through the upper hemisphere $\mathcal{S}$ of the unit sphere.

(a) Let $\mathbf{G} = \left\langle e^y, 2xe^{x^2}, 0 \right\rangle$. Find a vector field **A** such that $\text{curl}(\mathbf{A}) = \mathbf{G}$.
(b) Use Stokes' Theorem to show that the flux of **G** through $\mathcal{S}$ is zero. *Hint:* Calculate the circulation of **A** around $\partial\mathcal{S}$.
(c) Calculate I. *Hint:* Use (b) to show that I is equal to the flux of $\left\langle 0, 0, z^2 \right\rangle$ through $\mathcal{S}$.

SOLUTION

(a) We search for a vector field **A** so that $\mathbf{G} = \text{curl}(\mathbf{A})$. That is,

$$\left\langle \frac{\partial \mathbf{A}_3}{\partial y} - \frac{\partial \mathbf{A}_2}{\partial z}, \frac{\partial \mathbf{A}_1}{\partial z} - \frac{\partial \mathbf{A}_3}{\partial x}, \frac{\partial \mathbf{A}_2}{\partial x} - \frac{\partial \mathbf{A}_1}{\partial y} \right\rangle = \left\langle e^y, 2xe^{x^2}, 0 \right\rangle$$

We note that the third coordinate of this curl vector must be zero; this can be satisfied if $\mathbf{A}_1 = 0$ and $\mathbf{A}_2 = 0$. With this in mind, we let $\mathbf{A} = \left\langle 0, 0, e^y - e^{x^2} \right\rangle$. The vector field $\mathbf{A} = \left\langle 0, 0, e^y - e^{x^2} \right\rangle$ satisfies this equality. Indeed,

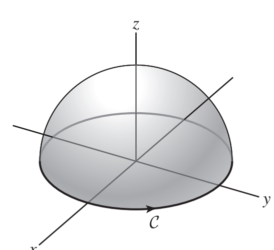
$$\frac{\partial \mathbf{A}_3}{\partial y} - \frac{\partial \mathbf{A}_2}{\partial z} = e^y, \quad \frac{\partial \mathbf{A}_1}{\partial z} - \frac{\partial \mathbf{A}_3}{\partial x} = 2xe^{x^2}, \quad \frac{\partial \mathbf{A}_2}{\partial x} - \frac{\partial \mathbf{A}_1}{\partial y} = 0$$

(b) We found that $\mathbf{G} = \text{curl}(\mathbf{A})$, where $\mathbf{A} = \left\langle 0, 0, e^y - e^{x^2} \right\rangle$. We compute the flux of **G** through $\mathcal{S}$. By Stokes' Theorem,

$$\iint_{\mathcal{S}} \mathbf{G} \cdot d\mathbf{S} = \iint_{\mathcal{S}} \text{curl}(\mathbf{A}) \cdot d\mathbf{S} = \int_{\mathcal{C}} \mathbf{A} \cdot d\mathbf{s}$$

The boundary $\mathcal{C}$ is the circle $x^2 + y^2 = 1$, parametrized by

$$\gamma(t) = (\cos t, \sin t, 0), \quad 0 \le t \le 2\pi$$



We compute the following values:

$$\mathbf{A}(\gamma(t)) = \left\langle 0, 0, e^y - e^{x^2} \right\rangle = \left\langle 0, 0, e^{\sin t} - e^{\cos^2 t} \right\rangle$$
$$\gamma'(t) = \langle -\sin t, \cos t, 0 \rangle$$
$$\mathbf{A}(\gamma(t)) \cdot \gamma'(t) = \left\langle 0, 0, e^{\sin t} - e^{\cos^2 t} \right\rangle \cdot \langle -\sin t, \cos t, 0 \rangle = 0$$

Therefore,

$$\int_{\mathcal{C}} \mathbf{A} \cdot d\mathbf{s} = \int_0^{2\pi} 0\, dt = 0$$

(c) We rewrite the vector field $\mathbf{F} = \left\langle e^y, 2xe^{x^2}, z^2 \right\rangle$ as

$$\mathbf{F} = \left\langle e^y, 2xe^{x^2}, z^2 \right\rangle = \left\langle e^y, 2xe^{x^2}, 0 \right\rangle + \left\langle 0, 0, z^2 \right\rangle = \operatorname{curl}(\mathbf{A}) + \left\langle 0, 0, z^2 \right\rangle$$

Therefore,

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{S}} \operatorname{curl}(\mathbf{A}) \cdot d\mathbf{S} + \iint_{\mathcal{S}} \left\langle 0, 0, z^2 \right\rangle \cdot d\mathbf{S} \tag{1}$$

In part (b) we showed that the first integral on the right-hand side is zero. Therefore,

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{S}} \left\langle 0, 0, z^2 \right\rangle \cdot d\mathbf{S} \tag{2}$$

The upper hemisphere is parametrized by

$$\Phi(\theta, \phi) = (\cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi), \quad 0 \le \theta \le 2\pi, \quad 0 \le \phi \le \frac{\pi}{2}.$$

with the outward pointing normal

$$\mathbf{n} = \sin\phi \, \langle \cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi \rangle$$

See Example 4, Section 17.4. We have

$$\left\langle 0, 0, \cos^2\phi \right\rangle \cdot \mathbf{n} = \sin\phi \cos^3\phi$$

Therefore,

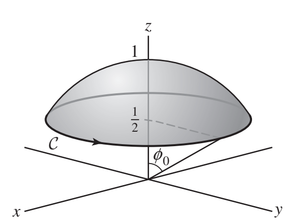
$$\iint_{\mathcal{S}} \left\langle 0, 0, z^2 \right\rangle \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^{\pi/2} \sin\phi \, \cos^3\phi \, d\phi \, d\theta = 2\pi \int_0^{\pi/2} \sin\phi \, \cos^3\phi \, d\phi$$
$$= 2\pi \left. \frac{-\cos^4\phi}{4} \right|_0^{\pi/2} = -\frac{\pi}{2}(0 - 1) = \frac{\pi}{2}$$

Combining with (2) we obtain the solution

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \frac{\pi}{2}.$$

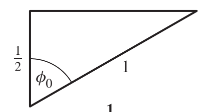
14. Let $\mathbf{F} = \langle 0, -z, 1 \rangle$. Let $\mathcal{S}$ be the spherical cap $x^2 + y^2 + z^2 \le 1$, where $z \ge \frac{1}{2}$. Evaluate $\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S}$ directly as a surface integral. Then verify that $\mathbf{F} = \operatorname{curl}(\mathbf{A})$, where $\mathbf{A} = (0, x, xz)$ and evaluate the surface integral again using Stokes' Theorem.

SOLUTION



We first compute the surface integral directly. The spherical cap is parametrized by

$$\Phi(\theta,\phi)=(\cos\theta\sin\phi,\sin\theta\sin\phi,\cos\phi),\quad 0\le\theta\le 2\pi,\quad 0\le\phi\le\frac{\pi}{3}$$



$$\cos\phi_0=\frac{1}{2}\Rightarrow\phi_0=\frac{\pi}{3}$$

The outward pointing normal is

$$\mathbf{n}=\sin\phi(\cos\theta\sin\phi,\sin\theta\sin\phi,\cos\phi)$$

See Example 4, Section 17.4. Hence,

$$\mathbf{F}\left(\Phi(\theta,\phi)\right)\cdot\mathbf{n}=\langle 0,-\cos\phi,1\rangle\cdot\mathbf{n}=-\sin\theta\sin^2\phi\cos\phi+\sin\phi\cos\phi$$

We obtain the following integral:

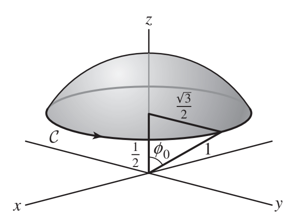
$$\begin{aligned}\iint_{\mathcal{S}}\mathbf{F}\cdot d\mathbf{S}&=\int_0^{2\pi}\int_0^{\pi/3}\left(-\sin\theta\sin^2\phi\cos\phi+\sin\phi\cos\phi\right)\,d\phi\,d\theta\\&=\left(\int_0^{2\pi}-\sin\theta\,d\theta\right)\left(\int_0^{\pi/3}\sin^2\phi\cos\phi\,d\phi\right)+2\pi\int_0^{\pi/3}\sin\phi\cos\phi\,d\phi\\&=0+\pi\int_0^{\pi/3}\sin 2\phi\,d\phi=\pi\left(-\frac{\cos 2\phi}{2}\right)\Bigg|_0^{\pi/3}=\frac{3\pi}{4}\end{aligned}\tag{1}$$

We now evaluate the flux using Stokes' Theorem. We first notice that $\mathbf{F}=\mathrm{curl}(\mathbf{A})$, where $\mathbf{A}=\langle 0,x,xz\rangle$. We verify it:

$$\begin{aligned}\frac{\partial A_3}{\partial y}-\frac{\partial A_2}{\partial z}&=0-0=0\\\frac{\partial A_1}{\partial z}-\frac{\partial A_3}{\partial x}&=0-z=-z\\\frac{\partial A_2}{\partial x}-\frac{\partial A_1}{\partial y}&=1-0=1\end{aligned}$$

Indeed, we see that $\mathrm{curl}(\mathbf{A})=\mathbf{F}$. Applying Stokes' Theorem, we have

$$\iint_{\mathcal{S}}\mathbf{F}\cdot d\mathbf{S}=\iint_{\mathcal{S}}\mathrm{curl}(\mathbf{A})\cdot d\mathbf{S}=\int_{\mathcal{C}}\mathbf{A}\cdot d\mathbf{s}\tag{2}$$



To compute the line integral, we notice that the boundary curve is the circle $x^2+y^2=\frac{3}{4}$ in the plane $z=\frac{1}{2}$. We parametrize $\mathcal{C}$ by

$$\gamma(t)=\left(\frac{\sqrt{3}}{2}\cos t,\frac{\sqrt{3}}{2}\sin t,\frac{1}{2}\right),\quad 0\le t\le 2\pi$$

We compute the following values:

$$\begin{aligned}\mathbf{A}\left(\gamma(t)\right)&=\langle 0,x,xz\rangle=\left\langle 0,\frac{\sqrt{3}}{2}\cos t,\frac{\sqrt{3}}{4}\cos t\right\rangle\\\gamma'(t)&=\left\langle -\frac{\sqrt{3}}{2}\sin t,\frac{\sqrt{3}}{2}\cos t,0\right\rangle\\\mathbf{A}\left(\gamma(t)\right)\cdot\gamma'(t)&=\left\langle 0,\frac{\sqrt{3}}{2}\cos t,\frac{\sqrt{3}}{4}\cos t\right\rangle\cdot\left\langle -\frac{\sqrt{3}}{2}\sin t,\frac{\sqrt{3}}{2}\cos t,0\right\rangle=\frac{3}{4}\cos^2 t\end{aligned}$$

We obtain the following line integral:

$$\int_{\mathcal{C}} \mathbf{A} \cdot d\mathbf{s} = \int_0^{2\pi} \frac{3}{4}\cos^2 t\, dt = \int_0^{2\pi} \left(\frac{3}{8} + \frac{3}{8}\cos 2t\right) dt = \frac{3t}{8} + \frac{3}{16}\sin 2t\Big|_0^{2\pi} = \frac{3\pi}{4} \tag{3}$$

Combining with (2), we obtain

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \frac{3\pi}{4}$$

This values agrees with the solution obtained in (1), as expected.

15. Let **A** be the vector potential and **B** the magnetic field of the infinite solenoid of radius R in Example 6. Use Stokes' Theorem to compute:

(a) The flux of **B** through a circle in the xy-plane of radius $r < R$

(b) The circulation of **A** around the boundary $\mathcal{C}$ of a surface lying outside the solenoid

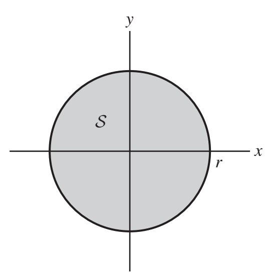
SOLUTION

(a) In Example 6 it is shown that $\mathbf{B} = \text{curl}(\mathbf{A})$, where

$$\mathbf{A} = \begin{cases} \frac{1}{2}R^2 B \left\langle -\frac{y}{r^2}, \frac{x}{r^2}, 0 \right\rangle & \text{if} \quad r > R \\ \frac{1}{2} B \langle -y, x, 0 \rangle & \text{if} \quad r < R \end{cases} \tag{1}$$

Therefore, using Stokes' Theorem, we have ($\mathcal{S}$ is the disk of radius r in the xy-plane)

$$\iint_{\mathcal{S}} \mathbf{B} \cdot d\mathbf{S} = \iint_{\mathcal{S}} \text{curl}(\mathbf{A}) \cdot d\mathbf{S} = \int_{\partial \mathcal{S}} \mathbf{A} \cdot d\mathbf{s} \tag{2}$$



We parametrize the circle $\mathcal{C} = \partial\mathcal{S}$ by $\mathbf{c}(t) = \langle r\cos t, r\sin t, 0\rangle$, $0 \le t \le 2\pi$. Then

$$\mathbf{c}'(t) = \langle -r\sin t, r\cos t, 0\rangle$$

By (1) for $r < R$,

$$\mathbf{A}\left(\mathbf{c}(t)\right) = \frac{1}{2}B\langle -r\sin t, r\cos t, 0\rangle$$

Hence,

$$\mathbf{A}\left(\mathbf{c}(t)\right) \cdot \mathbf{c}'(t) = \frac{1}{2}B\langle -r\sin t, r\cos t, 0\rangle \cdot \langle -r\sin t, r\cos t, 0\rangle = \frac{1}{2}B\left(r^2\sin^2 t + r^2\cos^2 t\right) = \frac{1}{2}r^2 B$$

Now, by (2) we get

$$\iint_{\mathcal{S}} \mathbf{B} \cdot d\mathbf{S} = \int_{\partial\mathcal{S}} \mathbf{A} \cdot d\mathbf{S} = \int_0^{2\pi} \frac{1}{2}r^2\mathbf{B}\, dt = \frac{1}{2}r^2\mathbf{B}\int_0^{2\pi} dt = r^2\mathbf{B}\pi$$

(b) Outside the solenoid **B** is the zero field, hence $\mathbf{B} = \mathbf{0}$ on every domain lying outside the solenoid. Therefore, Stokes' Theorem implies that

$$\int_{\partial\mathcal{S}} \mathbf{A} \cdot d\mathbf{S} = \iint_{\mathcal{S}} \text{curl}(\mathbf{A}) \cdot d\mathbf{S} = \iint_{\mathcal{S}} \mathbf{B} \cdot d\mathbf{S} = \iint_{\mathcal{S}} \mathbf{0} \cdot d\mathbf{S} = 0.$$

16. The magnetic field $\mathbf{B}$ due to a small current loop (which we place at the origin) is called a **magnetic dipole** (Figure 18). Let $\rho = (x^2 + y^2 + z^2)^{1/2}$. For ρ large, $\mathbf{B} = \text{curl}(\mathbf{A})$, where

$$\mathbf{A} = \left\langle -\frac{y}{\rho^3}, \frac{x}{\rho^3}, 0 \right\rangle$$

(a) Let $\mathcal{C}$ be a horizontal circle of radius R with center $(0, 0, c)$, where c is large. Show that $\mathbf{A}$ is tangent to $\mathcal{C}$.

(b) Use Stokes' Theorem to calculate the flux of $\mathbf{B}$ through $\mathcal{C}$.

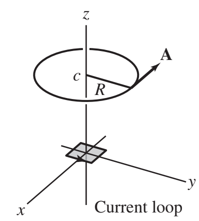


FIGURE 18

SOLUTION

(a) We parametrize $\mathcal{C}$ by

$$\mathbf{c}(t) = (R\cos t, R\sin t, c), \quad 0 \le t \le 2\pi$$

Then, the tangent to $\mathbf{c}(t)$ is in the direction of

$$\mathbf{c}'(t) = \langle -R\sin t, R\cos t, 0\rangle$$

We write $\mathbf{A} = \left\langle -\frac{y}{\rho^3}, \frac{x}{\rho^3}, 0 \right\rangle$ in terms of the parameter t:

$$\mathbf{A}(\mathbf{c}(t)) = \left\langle -\frac{R\sin t}{\rho^3}, \frac{R\cos t}{\rho^3}, 0 \right\rangle$$

$\mathbf{A}(\mathbf{c}(t)) = \frac{1}{\rho^3}\mathbf{c}'(t)$. Therefore, $\mathbf{A}$ is parallel to $\mathbf{c}'(t)$. We conclude that $\mathbf{A}$ is tangent to $\mathcal{C}$.

(b) Let $\mathcal{S}$ be the disc enclosed in $\mathcal{C}$. By Stokes' Theorem the flux of $\mathbf{B}$ through $\mathcal{S}$ is

$$\iint_{\mathcal{S}} \mathbf{B} \cdot d\mathbf{S} = \iint_{\mathcal{S}} \text{curl}(\mathbf{A}) \cdot d\mathbf{S} = \int_{\mathcal{C}} \mathbf{A} \cdot d\mathbf{s}$$

We compute the line integral. Since $\mathbf{A}$ and $\mathbf{c}'(t)$ are parallel, we have

$$\mathbf{A}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \|\mathbf{A}(\mathbf{c}(t))\| \left\|\mathbf{c}'(t)\right\| = \sqrt{\frac{R^2\sin^2 t}{\rho^6} + \frac{R^2\cos^2 t}{\rho^6}}\sqrt{R^2\sin^2 t + R^2\cos^2 t}$$

$$= \frac{R}{\rho^3} \cdot R = \frac{R^2}{\rho^3} = \frac{R^2}{\left(R^2\cos^2 t + R^2\sin^2 t + c^2\right)^{3/2}}$$

$$= \frac{R^2}{\left(R^2\left(\cos^2 t + \sin^2 t + \left(\frac{c}{R}\right)^2\right)\right)^{3/2}} = \frac{1}{R\left(1 + \left(\frac{c}{R}\right)^2\right)^{3/2}}$$

Hence,

$$\iint_{\mathcal{S}} \mathbf{B} \cdot d\mathbf{S} = \int_{\mathcal{C}} \mathbf{A} \cdot d\mathbf{s} = \int_0^{2\pi} \frac{dt}{R\left(1 + \left(\frac{c}{R}\right)^2\right)^{3/2}} = \frac{2\pi}{R\left(1 + \left(\frac{c}{R}\right)^2\right)^{3/2}}$$

17. A uniform magnetic field $\mathbf{B}$ has constant strength b in the z-direction [that is, $\mathbf{B} = \langle 0, 0, b\rangle$].

(a) Verify that $\mathbf{A} = \frac{1}{2}\mathbf{B} \times \mathbf{r}$ is a vector potential for $\mathbf{B}$, where $\mathbf{r} = \langle x, y, 0\rangle$.

(b) Calculate the flux of $\mathbf{B}$ through the rectangle with vertices A, B, C, and D in Figure 19.

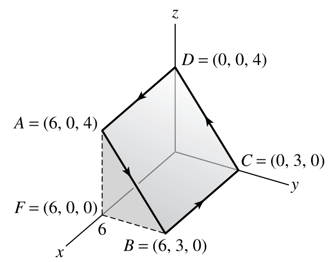

FIGURE 19

SOLUTION

(a) We compute the vector $\mathbf{A} = \frac{1}{2}\mathbf{B} \times \mathbf{r}$. Since $\mathbf{B} = b\mathbf{k}$ and $\mathbf{r} = x\mathbf{i} + y\mathbf{j}$, we have

$$\mathbf{A} = \frac{1}{2}\mathbf{B} \times \mathbf{r} = \frac{1}{2}b\mathbf{k} \times (x\mathbf{i} + y\mathbf{j}) = \frac{1}{2}b(x\mathbf{k} \times \mathbf{i} + y\mathbf{k} \times \mathbf{j}) = \frac{1}{2}b(x\mathbf{j} - y\mathbf{i}) = \left\langle -\frac{by}{2}, \frac{bx}{2}, 0 \right\rangle$$

We now show that $\text{curl}(\mathbf{A}) = \mathbf{B}$. We compute the curl of $\mathbf{A}$:

$$\text{curl}\,(\mathbf{A}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ -\frac{by}{2} & \frac{bx}{2} & 0 \end{vmatrix} = \left\langle 0, 0, \frac{b}{2} + \frac{b}{2} \right\rangle = \langle 0, 0, b \rangle = \mathbf{B}$$

Therefore, $\mathbf{A}$ is a vector potential for $\mathbf{B}$.

(b) Let $\mathcal{S}$ be the rectangle $\square ABCD$ and let $\mathcal{C}$ be the boundary of $\mathcal{S}$. Since $\mathbf{B} = \text{Curl}(\mathbf{A})$, we see that $\mathbf{B}$ has a vector potential. It follows, as explained in this section, that the flux of $\mathbf{B}$ through rectangle $\mathcal{S}$ is equal to the flux of $\mathbf{B}$ through any surface with the same boundary $\mathcal{C}$. Let $\mathcal{S}'$ be the wedge-shaped box with four sides and open top. Since the boundary of $\mathcal{S}'$ is also $\mathcal{C}$, we have

$$\iint_{\mathcal{S}} \mathbf{B} \cdot d\mathbf{S} = \iint_{\mathcal{S}'} \mathbf{B} \cdot d\mathbf{S}$$

The vector field $\mathbf{B}$ points in the $\mathbf{k}$ direction, so it has zero flux through the three vertical sides of $\mathcal{S}'$. On the other hand, the unit normal vector to the bottom face of $\mathcal{S}'$ is $\mathbf{k}$, so the normal component of $\mathbf{B}$ along the bottom face is equal to b. We obtain

$$\iint_{\mathcal{S}'} \mathbf{B} \cdot d\mathbf{S} = \iint_{\text{Bottom Face of } \mathcal{S}'} b\,dA$$

$$= b(\text{Area of Bottom Face of } \mathcal{S}') = 18b$$

18. Let $\mathbf{F} = \langle -x^2y, x, 0 \rangle$. Referring to Figure 19, let $\mathcal{C}$ be the closed path $ABCD$. Use Stokes' Theorem to evaluate $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$ in two ways. First, regard $\mathcal{C}$ as the boundary of the rectangle with vertices A, B, C, and D. Then treat $\mathcal{C}$ as the boundary of the wedge-shaped box with open top.

SOLUTION Let $\mathcal{S}_1$ be the rectangle whose boundary is $\mathcal{C}$, and let $\mathcal{S}_2$ denote the wedge-shaped box. Then by Stokes' Theorem,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}_1} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} \tag{1}$$

and:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}_2} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} \tag{2}$$

We find the curl of $\mathbf{F} = \left\langle -x^2y, x, 0 \right\rangle$:

$$\text{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ -x^2y & x & 0 \end{vmatrix} = \left\langle 0, 0, 1 + x^2 \right\rangle$$

We first compute the line integral via the surface integral in (1). To find a parametrization for $\mathcal{S}_1$, we compute the equation of the plane through $A = (6, 0, 4)$, $C = (0, 3, 0)$, $D = (0, 0, 4)$. A normal to the plane is

$$\begin{aligned}\overrightarrow{AD} \times \overrightarrow{AC} &= \langle -6, 0, 0\rangle \times \langle -6, 3, -4\rangle = -6\mathbf{i} \times (-6\mathbf{i} + 3\mathbf{j} - 4\mathbf{k}) = -18\mathbf{k} - 24\mathbf{j}\\ &= \langle 0, -24, -18\rangle = -6\,\langle 0, 4, 3\rangle\end{aligned}$$

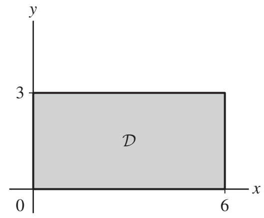
We use the point-normal equation of the plane:

$$\begin{aligned}0(x-0) + 4(y-3) + 3(z-0) &= 0\\ 4y - 12 + 3z = 0 \quad &\Rightarrow \quad z = 4 - \frac{4}{3}y\end{aligned}$$

We parametrize $\mathcal{S}_1$ by

$$\Phi(x, y) = \left(x, y, 4 - \frac{4y}{3}\right)$$

With the parameter domain, $\mathcal{D} = [0, 6] \times [0, 3]$ in the xy-plane.



Then

$$\frac{\partial \Phi}{\partial x} \times \frac{\partial \Phi}{\partial y} = \langle 1, 0, 0\rangle \times \left\langle 0, 1, -\frac{4}{3}\right\rangle = \mathbf{i} \times (\mathbf{j} - \frac{4}{3}\mathbf{k}) = \mathbf{k} + \frac{4}{3}\mathbf{j} = \left\langle 0, \frac{4}{3}, 1\right\rangle$$

The upward pointing normal is

$$\mathbf{n} = \left\langle 0, \frac{4}{3}, 1\right\rangle$$

Also,

$$\operatorname{curl}(\mathbf{F})\,(\Phi(x, y)) = \left\langle 0, 0, 1 + x^2\right\rangle$$

Hence,

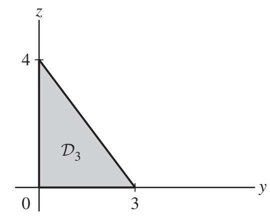
$$\operatorname{curl}(\mathbf{F}) \cdot \mathbf{n} = \left\langle 0, 0, 1 + x^2\right\rangle \cdot \left\langle 0, \frac{4}{3}, 1\right\rangle = 1 + x^2$$

The integral in (1) is thus

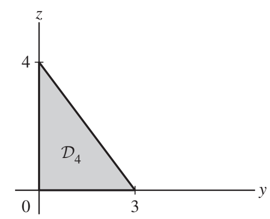
$$\begin{aligned}\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} &= \iint_{\mathcal{S}_1} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} = \iint_{\mathcal{D}} (1 + x^2)\, dA = \int_0^3 \int_0^6 (1 + x^2)\, dx\, dy = 3\int_0^6 (1 + x^2)\, dx\\ &= 3\left(x + \frac{x^3}{3}\bigg|_0^6\right) = 234 \qquad (3)\end{aligned}$$

We now compute the line integral via the surface integral (2). The surface $\mathcal{S}_2$ consists of two rectangles R_1 and R_2 and two triangles T_1 and T_2, parametrized by

$$\begin{aligned}R_1 :\ \Phi_1(x, z) &= (x, 0, z), \quad 0 \le x \le 6, \quad 0 \le z \le 4\\ n_1 &= \langle 0, 1, 0\rangle\\ R_2 :\ \Phi_2(x, y) &= (x, y, 0), \quad 0 \le x \le 6, \quad 0 \le y \le 3\\ n_2 &= \langle 0, 0, 1\rangle\\ T_1 :\ \Phi_3(y, z) &= (6, y, z), \quad (y, z) \in \mathcal{D}_3\\ n_3 &= \langle -1, 0, 0\rangle\end{aligned}$$



$$T_2: \ \Phi_4(y,z) = (0, y, z), \quad (y,z) \in \mathcal{D}_4$$
$$n_4 = \langle 1, 0, 0 \rangle$$



We compute each one of the surface integrals.

$$\begin{aligned}
\text{curl}(\mathbf{F})\,(\Phi_1(x,z)) \cdot \mathbf{n}_1 &= \left\langle 0, 0, 1 + x^2 \right\rangle \cdot \langle 0, 1, 0 \rangle = 0 \\
\text{curl}(\mathbf{F})\,(\Phi_2(x,y)) \cdot \mathbf{n}_2 &= \left\langle 0, 0, 1 + x^2 \right\rangle \cdot \langle 0, 0, 1 \rangle = 1 + x^2 \\
\text{curl}(\mathbf{F})\,(\Phi_3(x,y)) \cdot \mathbf{n}_3 &= \left\langle 0, 0, 1 + 6^2 \right\rangle \cdot \langle -1, 0, 0 \rangle = 0 \\
\text{curl}(\mathbf{F})\,(\Phi_4(y,z)) \cdot \mathbf{n}_4 &= \left\langle 0, 0, 1 + 0^2 \right\rangle \cdot \langle 1, 0, 0 \rangle = 0
\end{aligned}$$

Therefore the only nonzero integral is through R_2. We obtain

$$\begin{aligned}
\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} &= \iint_{\mathcal{S}_2} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} \\
&= \iint_{R_1} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} + \iint_{R_2} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} + \iint_{T_1} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} + \iint_{T_2} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} \\
&= \iint_{R_2} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} = \int_0^3 \int_0^6 (1 + x^2)\, dx\, dy = 3 \int_0^6 (1 + x^2)\, dx \\
&= 3 \left(x + \frac{x^3}{3} \right) \Big|_0^6 = 234
\end{aligned} \tag{4}$$

The values in (3) and (4) match as expected.

19. Let $\mathbf{F} = \langle y^2, 2z + x, 2y^2 \rangle$. Use Stokes' Theorem to find a plane with equation $ax + by + cz = 0$ (where a, b, c are not all zero) such that $\oint_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = 0$ for every closed $\mathcal{C}$ lying in the plane. *Hint:* Choose a, b, c so that curl($\mathbf{F}$) lies in the plane.

SOLUTION Since we are interested in $\oint_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$, we can also consider $\iint \text{curl}\mathbf{F} \cdot d\mathbf{S}$, by Stokes' Theorem. The curl is $\langle 4y - 2, 0, 1 - 2y \rangle$ and the normal to the plane is $\mathbf{n} = \langle a, b, c \rangle$. They are orthogonal if

$$\langle 4y - 2, 0, 1 - 2y \rangle \cdot \langle a, b, c \rangle = a(4y - 2) + c(1 - 2y) = 0$$

which means:

$$4ay - 2a + c - 2cy = 0 \quad \Rightarrow \quad (4a - 2c) = 0, (c - 2a) = 0$$

This yields $c = 2a$ and b is arbitrary.

20. Let $\mathbf{F} = \left\langle -z^2, 2zx, 4y - x^2 \right\rangle$ and let $\mathcal{C}$ be a simple closed curve in the plane $x + y + z = 4$ that encloses a region of area 16 (Figure 20). Calculate $\oint_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$, where $\mathcal{C}$ is oriented in the counterclockwise direction (when viewed from above the plane).

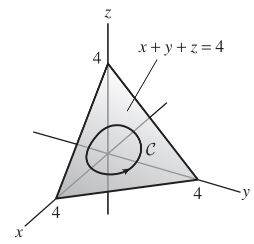


FIGURE 20

SOLUTION We denote by $\mathcal{S}$ the region enclosed by $\mathcal{C}$. Then by Stokes' Theorem,

$$\int_c \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{s} \tag{1}$$

We compute the curl of $\mathbf{F} = \left\langle -z^2, 2zx, 4y - x^2 \right\rangle$:

$$\text{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ -z^2 & 2zx & 4y - x^2 \end{vmatrix} = \langle 4 - 2x, 2x - 2z, 2z \rangle$$

The plane $x + y + z = 4$ has the parametrization

$$\Phi(x, y) = \langle x, y, 4 - x - y \rangle$$

Hence,

$$\frac{\partial \Phi}{\partial x} \times \frac{\partial \Phi}{\partial y} = \langle 1, 0, -1 \rangle \times \langle 0, 1, -1 \rangle = (\mathbf{i} - \mathbf{k})(\mathbf{j} - \mathbf{k}) = \mathbf{k} + \mathbf{j} + \mathbf{i} = \langle 1, 1, 1 \rangle$$

The normal determined by the induced orientation is

$$\mathbf{n} = \langle 1, 1, 1 \rangle$$

Let $\mathcal{D}$ be the parameter domain in the parametrization $\Phi(x, y) = (x, y, 4 - x - y)$ of $\mathcal{S}$; that is, $\mathcal{D}$ will be the base triangle in the xy plane that lies underneath the pyramid in the picture. To compute the surface integral in (1) we compute the values

$$\text{curl}(\mathbf{F})\,(\Phi(x, y)) = \langle 4 - 2x, 2x - 2(4 - x - y), 2(4 - x - y) \rangle = \langle 4 - 2x, -8 + 4x + 2y, 8 - 2x - 2y \rangle$$

$$\text{curl}(\mathbf{F}) \cdot \mathbf{n} = \langle 4 - 2x, -8 + 4x + 2y, 8 - 2x - 2y \rangle \cdot \langle 1, 1, 1 \rangle = 4 - 2x - 8 + 4x + 2y + 8 - 2x - 2y = 4$$

Therefore, using (1) and (2) we obtain

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} = \iint_{\mathcal{D}} 4\, dA = 4\text{Area}(\mathcal{D}) = 4 \cdot \frac{16}{2} = 32$$

21. Let $\mathbf{F} = \left\langle y^2, x^2, z^2 \right\rangle$. Show that

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s}$$

for any two closed curves lying on a cylinder whose central axis is the z-axis (Figure 21).

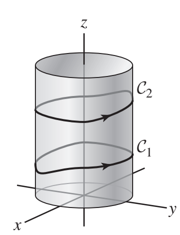

FIGURE 21

SOLUTION We denote by $\mathcal{S}$ the part of the cylinder for which $\mathcal{C}_1$ and $\mathcal{C}_2$ are boundary curves. Using Stokes' Theorem (notice that $\mathcal{C}_1$ and $\mathcal{C}_2$ have the same orientations), we have

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} - \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} \tag{1}$$

We compute the curl:

$$\operatorname{curl}(\mathbf{F}) = \left\langle \frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}, \frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}, \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right\rangle = \langle 0, 0, 2x - 2y \rangle$$

We parametrize $\mathcal{S}$ by

$$\Phi(\theta, z) = \langle R\cos\theta,\ R\sin\theta, z\rangle$$

where (θ, z) varies in a certain parameter domain $\mathcal{D}$. The outward-pointing normal is

$$\mathbf{n} = \langle R\cos\theta,\ R\sin\theta, 0\rangle$$

We compute curl($\mathbf{F}$) in terms of the parameters:

$$\operatorname{curl}(\mathbf{F}) = \langle 0, 0, 2x - 2y\rangle = \langle 0, 0, 2R\cos\theta - 2R\sin\theta\rangle$$

We compute the dot product:

$$\operatorname{curl}(\mathbf{F}) \cdot \mathbf{n} = 2R\,\langle 0, 0, \cos\theta - \sin\theta\rangle \cdot R\,\langle \cos\theta, \sin\theta, 0\rangle = 2R^2(0 + 0 + 0) = 0$$

Combining with (1) gives

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} - \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} = \iint_{\mathcal{D}} 0\, d\theta\, dr = 0$$

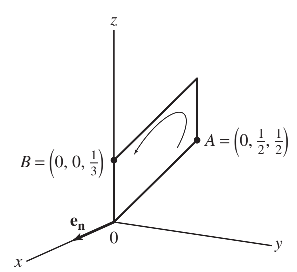
or

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s}.$$

22. The curl of a vector field $\mathbf{F}$ at the origin is $\mathbf{v}_0 = \langle 3, 1, 4\rangle$. Estimate the circulation around the small parallelogram spanned by the vectors $\mathbf{A} = \left\langle 0, \frac{1}{2}, \frac{1}{2}\right\rangle$ and $\mathbf{B} = \left\langle 0, 0, \frac{1}{3}\right\rangle$.

SOLUTION We use the following approximation, relying on Stokes' Theorem:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx (\mathbf{v}_0 \cdot \mathbf{e}_n) A(P) \tag{1}$$



The unit normal vector in the positive x-direction is

$$\mathbf{e}_n = \langle 1, 0, 0\rangle \tag{2}$$

We compute the area of the parallelogram spanned by the vectors $\overrightarrow{OA} = \left\langle 0, \frac{1}{2}, \frac{1}{2}\right\rangle$ and $\overrightarrow{OB} = \left\langle 0, 0, \frac{1}{3}\right\rangle$:

$$\overrightarrow{OA} \times \overrightarrow{OB} = \frac{1}{2}(\mathbf{j} + \mathbf{k}) \times \frac{1}{3}\mathbf{k} = \frac{1}{6}(\mathbf{j} \times \mathbf{k} + \mathbf{k} \times \mathbf{k}) = \frac{1}{6}\mathbf{i}$$

$$A(P) = \left\| \frac{1}{6}\mathbf{i} \right\| = \frac{1}{6} \tag{3}$$

We now substitute $\mathbf{v}_0 = \langle 3, 1, 4\rangle$, (2), and (3) in (1) to obtain the approximation

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx \langle 3, 1, 4\rangle \cdot \langle 1, 0, 0\rangle \cdot \frac{1}{6} = 3 \cdot \frac{1}{6} = \frac{1}{2}$$

23. You know two things about a vector field $\mathbf{F}$:

(i) $\mathbf{F}$ has a vector potential $\mathbf{A}$ (but $\mathbf{A}$ is unknown).

(ii) The circulation of $\mathbf{A}$ around the unit circle (oriented counterclockwise) is 25.

Determine the flux of $\mathbf{F}$ through the surface $\mathcal{S}$ in Figure 22, oriented with upward pointing normal.

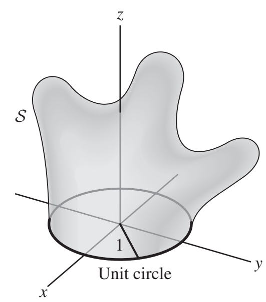


FIGURE 22 Surface $\mathcal{S}$ whose boundary is the unit circle.

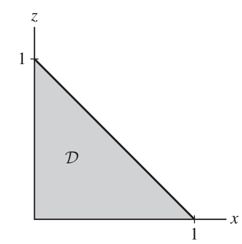
SOLUTION Since $\mathbf{F}$ has a vector potential—that is, $\mathbf{F}$ is the curl of a vector field—the flux of $\mathbf{F}$ through a surface depends only on the boundary curve $\mathcal{C}$. Now, the surface $\mathcal{S}$ and the unit disc $\mathcal{S}_1$ in the xy-plane share the same boundary $\mathcal{C}$. Therefore,

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \iint_{\mathcal{S}_1} \mathbf{F}\cdot d\mathbf{S} \tag{1}$$



We compute the flux of $\mathbf{F}$ through $\mathcal{S}_1$, using the parametrization

$$\mathcal{S}_1:\ \Phi(r,\theta) = (r\cos\theta, r\sin\theta, 0), \quad 0\le r\le 1, \quad 0\le\theta\le 2\pi$$
$$\mathbf{n} = \langle 0,0,1\rangle$$

By the given information, we have

$$\mathbf{F}(\Phi(r,\theta)) = \mathbf{F}(r\cos\theta, r\sin\theta, 0) = \langle 0,0,1\rangle$$

Hence,

$$\mathbf{F}(\Phi(r,\theta))\cdot\mathbf{n} = \langle 0,0,1\rangle\cdot\langle 0,0,1\rangle = 1$$

We obtain the following integral:

$$\iint_{\mathcal{S}_1} \mathbf{F}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^1 \mathbf{F}(\Phi(r,\theta))\cdot\mathbf{n}\,dr\,d\theta = \int_0^{2\pi}\int_0^1 1\,dr\,d\theta = 2\pi$$

Combining with (1) we obtain

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = 2\pi$$

24. Suppose that $\mathbf{F}$ has a vector potential and that $\mathbf{F}(x,y,0) = \mathbf{k}$. Find the flux of $\mathbf{F}$ through the surface $\mathcal{S}$ in Figure 22, oriented with upward pointing normal.

SOLUTION The flux is equal to the flux through the lower hemisphere with outward pointing normal, and this is

$$\int_{\theta=0}^{2\pi}\int_{\phi=0}^{\pi} \sin\phi\,d\theta\,d\phi$$

25. Prove that $\mathrm{curl}(f\mathbf{a}) = \nabla f \times \mathbf{a}$, where f is a differentiable function and $\mathbf{a}$ is a constant vector.

SOLUTION Let us first write $\mathbf{a}$ as a constant vector $\mathbf{a} = \langle a_1, a_2, a_3\rangle$ and $f = f(x, y, z)$. Then consider the following:

$$\mathrm{curl}(f\mathbf{a}) = \mathrm{curl}(f(x,y,z)\langle a_1,a_2,a_3\rangle) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ a_1 f(x,y,z) & a_2 f(x,y,z) & a_3 f(x,y,z) \end{vmatrix}$$

$$= \left\langle \frac{\partial}{\partial y}(a_3 f) - \frac{\partial}{\partial z}(a_2 f), -\frac{\partial}{\partial z}(a_1 f) + \frac{\partial}{\partial x}(a_3 f), \frac{\partial}{\partial x}(a_2 f) - \frac{\partial}{\partial y}(a_1 f) \right\rangle$$

$$= \langle a_3 f_y - a_2 f_z, a_3 f_x - a_1 f_z, a_2 f_x - a_1 f_y \rangle$$

And now consider the following:

$$\nabla f \times \mathbf{a} = \langle f_x, f_y, f_z\rangle \times \langle a_1, a_2, a_3\rangle$$

$$= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ f_x & f_y & f_z \\ a_1 & a_2 & a_3 \end{vmatrix}$$

$$= \langle a_3 f_y - a_2 f_z, a_3 f_x - a_1 f_z, a_2 f_x - a_1 f_y \rangle$$

Since the two expressions above are equal, we conclude

$$\mathrm{curl}(f\mathbf{a}) = \nabla f \times \mathbf{a}$$

26. Show that $\mathrm{curl}(\mathbf{F}) = \mathbf{0}$ if $\mathbf{F}$ is **radial**, meaning that $\mathbf{F} = f(\rho)\langle x, y, z\rangle$ for some function $f(\rho)$, where $\rho = \sqrt{x^2+y^2+z^2}$. *Hint:* It is enough to show that one component of $\mathrm{curl}(\mathbf{F})$ is zero, because it will then follow for the other two components by symmetry.

SOLUTION Let $\mathbf{v} = \langle x, y, z\rangle$. We must show that $\mathrm{curl}(\mathbf{F}) = \mathrm{curl}(f\mathbf{v}) = \mathbf{0}$. We compute the curl of $\mathbf{v}$:

$$\mathrm{curl}(f\mathbf{v}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ x \cdot f & y \cdot f & z \cdot f \end{vmatrix}$$

$$= \left\langle \frac{\partial}{\partial y}(z\cdot f) - \frac{\partial}{\partial z}(y\cdot f), -\frac{\partial}{\partial z}(x\cdot f) + \frac{\partial}{\partial x}(z\cdot f), \frac{\partial}{\partial x}(y\cdot f) - \frac{\partial}{\partial y}(x\cdot f) \right\rangle$$

$$= \left\langle z\frac{\partial f}{\partial y} - y\frac{\partial f}{\partial z}, z\frac{\partial f}{\partial x} - x\frac{\partial f}{\partial z}, y\frac{\partial f}{\partial x} - x\frac{\partial f}{\partial y} \right\rangle$$

We now must prove that the cross product is zero. To compute the first order partials for f, we use the derivatives

$$\frac{\partial \rho}{\partial x} = \frac{2x}{2\sqrt{x^2+y^2+z^2}} = \frac{x}{\rho}$$

$$\frac{\partial \rho}{\partial y} = \frac{2y}{2\sqrt{x^2+y^2+z^2}} = \frac{y}{\rho}$$

$$\frac{\partial \rho}{\partial z} = \frac{2z}{2\sqrt{x^2+y^2+z^2}} = \frac{z}{\rho}$$

By the Chain Rule we get

$$\frac{\partial f}{\partial x} = \frac{df}{d\rho}\frac{\partial \rho}{\partial x} = \frac{df}{d\rho}\cdot\frac{x}{\rho}$$

$$\frac{\partial f}{\partial y} = \frac{df}{d\rho}\frac{\partial \rho}{\partial y} = \frac{df}{d\rho}\cdot\frac{y}{\rho}$$

$$\frac{\partial f}{\partial z} = \frac{df}{d\rho}\frac{\partial \rho}{\partial z} = \frac{df}{d\rho}\cdot\frac{z}{\rho}$$

Therefore,

$$\mathrm{curl}(f\mathbf{v}) = \left\langle z\frac{\partial f}{\partial y} - y\frac{\partial f}{\partial z}, z\frac{\partial f}{\partial x} - x\frac{\partial f}{\partial z}, y\frac{\partial f}{\partial x} - x\frac{\partial f}{\partial y} \right\rangle$$

$$= \left\langle \frac{df}{d\rho}\cdot\frac{yz}{\rho} - \frac{df}{d\rho}\cdot\frac{yz}{\rho}, \frac{df}{d\rho}\cdot\frac{xz}{\rho} - \frac{df}{d\rho}\cdot\frac{xz}{\rho}, \frac{df}{d\rho}\cdot\frac{xy}{\rho} - \frac{df}{d\rho}\cdot\frac{xy}{\rho} \right\rangle$$

$$= \mathbf{0}$$

Hence, we have shown, $\mathrm{curl}(\mathbf{F}) = \mathrm{curl}(f\mathbf{v}) = \mathbf{0}$.

27. Prove the following Product Rule:

$$\operatorname{curl}(f\mathbf{F}) = f\operatorname{curl}(\mathbf{F}) + \nabla f \times \mathbf{F}$$

SOLUTION We evaluate the curl of $f\mathbf{F}$. Since $f\mathbf{F} = \langle fF_1, fF_2, fF_3\rangle$, using the Product Rule for scalar functions we have

$$\begin{aligned}
\operatorname{curl}(f\mathbf{F}) &= \left\langle \frac{\partial}{\partial y}(fF_3) - \frac{\partial}{\partial z}(fF_2), \frac{\partial}{\partial z}(fF_1) - \frac{\partial}{\partial x}(fF_3), \frac{\partial}{\partial x}(fF_2) - \frac{\partial}{\partial y}(fF_1)\right\rangle \\
&= \left\langle \frac{\partial f}{\partial y}F_3 + f\frac{\partial F_3}{\partial y} - \frac{\partial f}{\partial z}F_2 - f\frac{\partial F_2}{\partial z}, \frac{\partial f}{\partial z}F_1 + f\frac{\partial F_1}{\partial z} - \frac{\partial f}{\partial x}F_3 - f\frac{\partial F_3}{\partial x},\right. \\
&\qquad \left. \frac{\partial f}{\partial x}F_2 + f\frac{\partial F_2}{\partial x} - \frac{\partial f}{\partial y}F_1 - f\frac{\partial F_1}{\partial y}\right\rangle \\
&= f\left\langle \frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}, \frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}, \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right\rangle \\
&\quad + \left\langle \frac{\partial f}{\partial y}F_3 - \frac{\partial f}{\partial z}F_2, \frac{\partial f}{\partial z}F_1 - \frac{\partial f}{\partial x}F_3, \frac{\partial f}{\partial x}F_2 - \frac{\partial f}{\partial y}F_1\right\rangle \qquad (1)
\end{aligned}$$

The vector in the first term is $\operatorname{curl}(\mathbf{F})$. We show that the second term is the cross product $\nabla f \times \mathbf{F}$. We compute the cross product:

$$\begin{aligned}
\nabla f \times \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial f}{\partial x} & \frac{\partial f}{\partial y} & \frac{\partial f}{\partial z} \\ F_1 & F_2 & F_3 \end{vmatrix} = \left(\frac{\partial f}{\partial y}F_3 - \frac{\partial f}{\partial z}F_2\right)\mathbf{i} - \left(\frac{\partial f}{\partial x}F_3 - \frac{\partial f}{\partial z}F_1\right)\mathbf{j} + \left(\frac{\partial f}{\partial x}F_2 - \frac{\partial f}{\partial y}F_1\right)\mathbf{k} \\
&= \left\langle \frac{\partial f}{\partial y}F_3 - \frac{\partial f}{\partial z}F_2, \frac{\partial f}{\partial z}F_1 - \frac{\partial f}{\partial x}F_3, \frac{\partial f}{\partial x}F_2 - \frac{\partial f}{\partial y}F_1\right\rangle
\end{aligned}$$

Therefore, (1) gives

$$\operatorname{curl}(f\mathbf{F}) = f\operatorname{curl}(\mathbf{F}) + \nabla f \times \mathbf{F}$$

28. Assume that f and g have continuous partial derivatives of order 2. Prove that

$$\oint_{\partial\mathcal{S}} f\nabla(g)\cdot d\mathbf{s} = \iint_{\mathcal{S}} \nabla(f)\times\nabla(g)\cdot d\mathbf{s}$$

SOLUTION By Stokes' Theorem, we have

$$\int_{\partial\mathcal{S}} f\nabla(g)\cdot d\mathbf{s} = \iint_{\mathcal{S}} \operatorname{curl}(f\nabla g)\cdot d\mathbf{S}$$

We now use Eq.(8) to evaluate the curl of $f\nabla g$. That is,

$$\begin{aligned}
\int_{\partial\mathcal{S}} f\nabla(g)\cdot d\mathbf{s} &= \iint_{\mathcal{S}} (f\operatorname{curl}(\nabla g) + \nabla f\times\nabla g)\cdot d\mathbf{S} \\
&= \iint_{\mathcal{S}} f\operatorname{curl}(\nabla g)\cdot d\mathbf{S} + \iint_{\mathcal{S}} \nabla(g)\times\nabla(g)\cdot d\mathbf{S} \qquad (1)
\end{aligned}$$

Now, since the gradient field ∇f is conservative, this field satisfies the cross-partials condition. In other words,

$$\operatorname{curl}(\nabla f) = \mathbf{0}$$

Combining with (1) we obtain

$$\int_{\partial\mathcal{S}} f(\nabla g)\cdot d\mathbf{s} = \iint_{\mathcal{S}} \mathbf{0}\cdot d\mathbf{S} + \iint_{\mathcal{S}} \nabla(f)\times\nabla(g)\cdot d\mathbf{S} = \iint_{\mathcal{S}} \nabla(f)\times\nabla(g)\cdot d\mathbf{S}$$

29. Verify that $\mathbf{B} = \operatorname{curl}(\mathbf{A})$ for $r > R$ in the setting of Example 6.

SOLUTION As observed in the example,

$$\operatorname{curl}(\langle f, g, 0\rangle) = \langle -g_z, f_z, g_x - f_y\rangle$$

and recall $r = x^2 + y^2$. For $r > R$, this yields

$$\operatorname{curl}(\mathbf{A}) = \frac{1}{2}R^2 B\left\langle 0, 0, \frac{\partial}{\partial x}(xr^{-2}) - \frac{\partial}{\partial y}(-yr^{-2})\right\rangle$$

The z-component on the right is also zero:

$$\frac{\partial}{\partial x}(xr^{-2}) + \frac{\partial}{\partial y}(yr^{-2}) = \frac{\partial}{\partial x}\left(\frac{x}{x^2+y^2}\right) + \frac{\partial}{\partial y}\left(\frac{y}{x^2+y^2}\right)$$
$$= \frac{(x^2+y^2) - x(2x)}{(x^2+y^2)^2} + \frac{(x^2+y^2) - y(2y)}{(x^2+y^2)^2}$$
$$= 0$$

Thus, $\text{curl}(\mathbf{A}) = \mathbf{0}$ when $r > R$ as required.

30. Explain carefully why Green's Theorem is a special case of Stokes' Theorem.

SOLUTION Let $\mathcal{C}$ be a simple closed curve enclosing a region $\mathcal{D}$ oriented counterclockwise in the xy-plane. We must show, using Stokes' Theorem, that for $\mathbf{F} = \langle F_1, F_2 \rangle$,

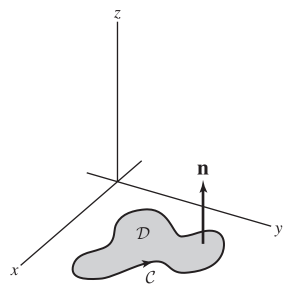
$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right) dA$$

We consider $\mathcal{D}$ as a surface in three-space with parametrization

$$\Phi(x, y) = (x, y, 0), \quad (x, y) \in \mathcal{D}$$

The normal vector is

$$\mathbf{n} = \langle 0, 0, 1 \rangle$$



We compute the curl of $\mathbf{F} = \langle F_1, F_2, 0 \rangle$. Since $F_1 = F_1(x, y)$, $F_2 = F_2(x, y)$, and $F_3 = 0$, the curl of $\mathbf{F}$ is the vector

$$\text{curl}(\mathbf{F}) = \left\langle \frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}, \frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}, \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right\rangle = \left\langle 0, 0, \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right\rangle$$

Hence,

$$\text{curl}(\mathbf{F}) \cdot \mathbf{n} = \left\langle 0, 0, \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right\rangle \cdot \langle 0, 0, 1 \rangle = \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}$$

By Stokes' Theorem we have

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} = \iint_{\mathcal{D}} \text{curl}(\mathbf{F}) \cdot \mathbf{n}\, dA = \iint_{\mathcal{D}} \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right) dA$$

We thus showed that Green's Theorem is a special case of Stokes' Theorem for two dimensions.

Further Insights and Challenges

31. In this exercise, we use the notation of the proof of Theorem 1 and prove

$$\oint_{\mathcal{C}} F_3(x, y, z)\mathbf{k} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \text{curl}(F_3(x, y, z)\mathbf{k}) \cdot d\mathbf{S} \qquad \boxed{11}$$

In particular, $\mathcal{S}$ is the graph of $z = f(x, y)$ over a domain $\mathcal{D}$, and $\mathcal{C}$ is the boundary of $\mathcal{S}$ with parametrization $(x(t), y(t), f(x(t), y(t)))$.

(a) Use the Chain Rule to show that

$$F_3(x, y, z)\mathbf{k} \cdot d\mathbf{s} = F_3(x(t), y(t), f(x(t), y(t)))\left(f_x(x(t), y(t))x'(t) + f_y(x(t), y(t))y'(t)\right) dt$$

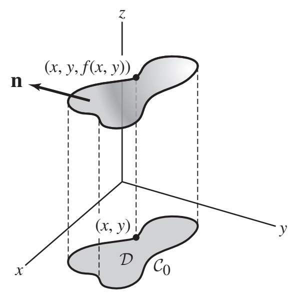
and verify that

$$\oint_{\mathcal{C}} F_3(x, y, z)\mathbf{k} \cdot d\mathbf{s} = \oint_{\mathcal{C}_0} \left\langle F_3(x, y, z) f_x(x, y), F_3(x, y, z) f_y(x, y) \right\rangle \cdot d\mathbf{s}$$

where $\mathcal{C}_0$ has parametrization $(x(t), y(t))$.

(b) Apply Green's Theorem to the line integral over $\mathcal{C}_0$ and show that the result is equal to the right-hand side of Eq. (11).

SOLUTION Let $(x(t), y(t))$, $a \le t \le b$ be a parametrization of the boundary curve $\mathcal{C}_0$ of the domain $\mathcal{D}$.



The boundary curve $\mathcal{C}$ of $\mathcal{S}$ projects on $\mathcal{C}_0$ and has the parametrization

$$\gamma(t) = (x(t), y(t), f(x(t), y(t))), \quad a \le t \le b$$

Let

$$\mathbf{F} = \langle 0, 0, F_3(x, y, z)\rangle$$

We must show that

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} \tag{1}$$

We first compute the surface integral, using the parametrization

$$\mathcal{S} : \Phi(x, y) = (x, y, f(x, y))$$

The normal vector is

$$\mathbf{n} = \frac{\partial \Phi}{\partial x} \times \frac{\partial \Phi}{\partial y} = \langle 1, 0, f_x(x, y)\rangle \times \left\langle 0, 1, f_y(x, y)\right\rangle = (\mathbf{i} + f_x(x, y)\mathbf{k}) \times \left(\mathbf{j} + f_y(x, y)\mathbf{k}\right)$$
$$= -f_y(x, y)\mathbf{j} - f_x(x, y)\mathbf{i} + \mathbf{k} = \left\langle -f_x(x, y), -f_y(x, y), 1\right\rangle$$

We compute the curl of $\mathbf{F}$:

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ 0 & 0 & F_3(x, y, z) \end{vmatrix} = \left\langle \frac{\partial F_3(x, y, z)}{\partial y}, -\frac{\partial F_3(x, y, z)}{\partial x}, 0\right\rangle$$

Hence,

$$\operatorname{curl}(\mathbf{F})\,(\Phi(x, y)) \cdot \mathbf{n} = \left\langle \frac{\partial F_3}{\partial y}\,(x, y, f(x, y)) - \frac{\partial F_3}{\partial x}\,(x, y, f(x, y))\,, 0\right\rangle \cdot \left\langle -f_x(x, y), -f_y(x, y), 1\right\rangle$$
$$= -\frac{\partial F_3\,(x, y, f(x, y))}{\partial y} f_x(x, y) + \frac{\partial F_3\,(x, y, f(x, y))}{\partial x} f_y(x, y)$$

The surface integral is thus

$$\iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} = \iint_{\mathcal{D}} \left(-\frac{\partial F_3\,(x, y, f(x, y))}{\partial y} f_x(x, y) + \frac{\partial F_3\,(x, y, f(x, y))}{\partial x} f_y(x, y)\right) dx\,dy \tag{2}$$

We now evaluate the line integral in (1). We have

$$\mathbf{F}\big(\gamma(t)\big) \cdot \gamma'(t) = \left\langle 0, 0, \mathbf{F}_3\Big(x(t), y(t), f\big(x(t), y(t)\big)\Big)\right\rangle \cdot \left\langle x'(t), y'(t), \frac{d}{dt} f\big(x(t), y(t)\big)\right\rangle$$
$$= \mathbf{F}_3\Big(x(t), y(t), f\big(x(t), y(t)\big)\Big) \frac{d}{dt} f\big(x(t), y(t)\big) \tag{3}$$

Using the Chain Rule gives

$$\frac{d}{dt} f\big(x(t), y(t)\big) = f_x\big(x(t), y(t)\big)x'(t) + f_y\big(x(t), y(t)\big)y'(t)$$

Substituting in (3), we conclude that the line integral is

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_a^b \Big(F_3\Big(x(t), y(t), f\big(x(t), y(t)\big)\Big) \cdot \Big(f_x\big(x(t), y(t)\big)x'(t) + f_y\big(x(t), y(t)\big)y'(t)\Big)\Big)\, dt \tag{4}$$

We consider the following vector field:

$$\mathbf{G}(x, y) = \big\langle F_3\big(x, y, f(x, y)\big) f_x(x, y), F_3\big(x, y, f(x, y)\big) f_y(x, y)\big\rangle$$

Then the integral in (4) is the line integral of the planar vector field $\mathbf{G}$ over $\mathcal{C}_0$. That is,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}_0} \mathbf{G} \cdot d\mathbf{s}$$

Therefore, we may apply Green's Theorem and write

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_{\mathcal{C}_0} \mathbf{G} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial}{\partial x}\Big(F_3\big(x, y, f(x, y)\big) f_y(x, y)\Big) - \frac{\partial}{\partial y}\Big(F_3\big(x, y, f(x, y)\big) f_x(x, y)\Big)\right) dx\, dy \tag{5}$$

We use the Product Rule to evaluate the integrand:

$$\frac{\partial F_3}{\partial x}(x, y, f(x, y))\, f_y(x, y) + F_3\big(x, y, f(x, y)\big) f_{yx}(x, y) - \frac{\partial F_3}{\partial y}\big(x, y, f(x, y)\big) f_x(x, y) - F_3\big(x, y, f(x, y)\big) f_{xy}(x, y)$$

$$= \frac{\partial F_3}{\partial x}\big(x, y, f(x, y)\big) f_y(x, y) - \frac{\partial F_3}{\partial y}\big(x, y, f(x, y)\big) f_x(x, y)$$

Substituting in (5) gives

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} \left(\frac{\partial F_3\,(x, y, f(x, y))}{\partial x} f_y(x, y) - \frac{\partial F_3\,(x, y, f(x, y))}{\partial y} f_x(x, y)\right) dx\, dy \tag{6}$$

Equations(2) and(6) give the same result, hence

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{s}$$

for

$$\mathbf{F} = \langle 0, 0, F_3(x, y, z)\rangle$$

32. Let $\mathbf{F}$ be a continuously differentiable vector field in $\mathbf{R}^3$, Q a point, and $\mathcal{S}$ a plane containing Q with unit normal vector $\mathbf{e}$. Let $\mathcal{C}_r$ be a circle of radius r centered at Q in $\mathcal{S}$, and let $\mathcal{S}_r$ be the disk enclosed by $\mathcal{C}_r$. Assume $\mathcal{S}_r$ is oriented with unit normal vector $\mathbf{e}$.

(a) Let $m(r)$ and $M(r)$ be the minimum and maximum values of $\operatorname{curl}(\mathbf{F}(P)) \cdot \mathbf{e}$ for $P \in \mathcal{S}_r$. Prove that

$$m(r) \le \frac{1}{\pi r^2} \iint_{\mathcal{S}_r} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} \le M(r)$$

(b) Prove that

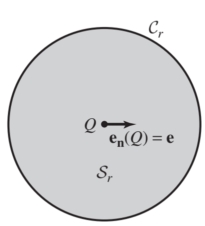
$$\operatorname{curl}(\mathbf{F}(Q)) \cdot \mathbf{e} = \lim_{r \to 0} \frac{1}{\pi r^2} \int_{\mathcal{C}_r} \mathbf{F} \cdot d\mathbf{s}$$

This proves that $\operatorname{curl}(\mathbf{F}(Q)) \cdot \mathbf{e}$ is the circulation per unit area in the plane $\mathcal{S}$.

SOLUTION

(a) We may assume that the circle lies on the xy-plane, and parametrize $\mathcal{S}_r$ by

$$\mathcal{S}_r : \Phi(x, y, z) = (x, y, 0), \quad (x, y) \in \mathcal{S}_r$$



Then, $\mathbf{n}$ is a unit vector and we have

$$\iint_{\mathcal{S}_r} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} = \iint_{\mathcal{S}_r} \text{curl}(\mathbf{F})(P) \cdot \mathbf{e}_n(P)\, dA \tag{1}$$

We use the given information $m(r) \le \text{curl}(\mathbf{F})(P) \cdot \mathbf{e}_n(P) \le M(r)$ for $P \in \mathcal{S}_r$ and properties of the double integral to write

$$A(\mathcal{S}_r)m(r) \le \iint_{\mathcal{S}_r} \text{curl}(\mathbf{F})(P) \cdot \mathbf{e}_n(P)\, dA \le A(\mathcal{S}_r) \cdot M(r)$$

The area of the disk is $A(\mathcal{S}_r) = \pi r^2$. Therefore,

$$\pi r^2 m(r) \le \iint_{\mathcal{S}_r} \text{curl}(\mathbf{F})(P) \cdot \mathbf{e}_n(P)\, dA \le \pi r^2 M(r)$$

or

$$m(r) \le \frac{1}{\pi r^2} \iint_{\mathcal{S}_r} \text{curl}(\mathbf{F})(P) \cdot \mathbf{e}_n(P)\, dA \le M(r)$$

Combining with (1) we get

$$m(r) \le \frac{1}{\pi r^2} \iint_{\mathcal{S}_r} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} \le M(r)$$

(b) By Stokes' Theorem,

$$\int_{\mathcal{C}_r} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}_r} \text{curl}(\mathbf{F}) \cdot d\mathbf{S}$$

By part(a) we have

$$m(r) \le \frac{1}{\pi r^2} \int_{\mathcal{C}_r} \mathbf{F} \cdot d\mathbf{s} \le M(r) \tag{2}$$

We take the limit over the circles of radius r centered at Q, as $r \to 0$. As $r \to 0$, the regions $\mathcal{S}_r$ are approaching the center Q. The continuity of the curl implies that

$$\lim_{r\to 0} m(r) = \lim_{r\to 0} M(r) = \text{curl}(\mathbf{F})(Q) \cdot \mathbf{e}_n(Q) = \text{curl}(\mathbf{F})(Q) \cdot \mathbf{e}$$

Therefore,

$$\lim_{r\to 0} m(r) \le \lim_{r\to 0} \frac{1}{\pi r^2} \int_{\mathcal{C}_r} \mathbf{F} \cdot d\mathbf{s} \le \lim_{r\to 0} M(r)$$

$$\text{curl}(\mathbf{F})(Q) \cdot \mathbf{e} \le \lim_{r\to 0} \frac{1}{\pi r^2} \int_{\mathcal{C}_r} \mathbf{F} \cdot d\mathbf{s} \le \text{curl}(\mathbf{F})(Q) \cdot \mathbf{e}$$

Hence,

$$\lim_{r\to 0} \frac{1}{\pi r^2} \int_{\mathcal{C}_r} \mathbf{F} \cdot d\mathbf{s} = \text{curl}(\mathbf{F})(Q) \cdot \mathbf{e}$$

17.3 Divergence Theorem (LT Section 18.3)

Preliminary Questions

1. What is the flux of $\mathbf{F} = \langle 1, 0, 0 \rangle$ through a closed surface?

SOLUTION The divergence of $\mathbf{F} = \langle 1, 0, 0 \rangle$ is $\text{div}(\mathbf{F}) = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z} = 0$, therefore the Divergence Theorem implies that the flux of $\mathbf{F}$ through a closed surface $\mathcal{S}$ is

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \text{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} 0\, dV = 0$$

2. Justify the following statement: The flux of $\mathbf{F} = \langle x^3, y^3, z^3 \rangle$ through every closed surface is positive.

SOLUTION The divergence of $\mathbf{F} = \left\langle x^3, y^3, z^3 \right\rangle$ is

$$\text{div}(\mathbf{F}) = 3x^2 + 3y^2 + 3z^2$$

Therefore, by the Divergence Theorem, the flux of **F** through a closed surface $\mathcal{S}$ is

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} (3x^2 + 3y^2 + 3z^2)\, dV$$

Since the integrand is positive for all $(x, y, z) \neq (0, 0, 0)$, the triple integral, hence also the flux, is positive.

3. Which of the following expressions are meaningful (where **F** is a vector field and f is a function)? Of those that are meaningful, which are automatically zero?

(a) $\operatorname{div}(\nabla f)$ **(b)** $\operatorname{curl}(\nabla f)$ **(c)** $\nabla\operatorname{curl}(f)$

(d) $\operatorname{div}(\operatorname{curl}(\mathbf{F}))$ **(e)** $\operatorname{curl}(\operatorname{div}(\mathbf{F}))$ **(f)** $\nabla(\operatorname{div}(\mathbf{F}))$

SOLUTION

(a) The divergence is defined on vector fields. The gradient is a vector field, hence $\operatorname{div}(\nabla\varphi)$ is defined. It is not automatically zero since for $\varphi = x^2 + y^2 + z^2$ we have

$$\operatorname{div}(\nabla\varphi) = \operatorname{div}\langle 2x, 2y, 2z\rangle = 2 + 2 + 2 = 6 \neq 0$$

(b) The curl acts on vector valued functions, and $\nabla\varphi$ is such a function. Therefore, $\operatorname{curl}(\nabla\varphi)$ is defined. Since the gradient field $\nabla\varphi$ is conservative, the cross partials of $\nabla\varphi$ are equal, or equivalently, $\operatorname{curl}(\nabla\varphi)$ is the zero vector.

(c) The curl is defined on vector fields rather than on scalar functions. Therefore, $\operatorname{curl}(\varphi)$ is undefined. Obviously, $\nabla\operatorname{curl}(\varphi)$ is also undefined.

(d) The curl is defined on the vector field **F** and the divergence is defined on the vector field $\operatorname{curl}(\mathbf{F})$. Therefore the expression $\operatorname{div}(\operatorname{curl}(\mathbf{F}))$ is meaningful. We show that this vector is automatically zero:

$$\begin{aligned}
\operatorname{div}(\operatorname{curl}(\mathbf{F})) &= \operatorname{div}\left\langle \frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}, \frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}, \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right\rangle \\
&= \frac{\partial}{\partial x}\left(\frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}\right) + \frac{\partial}{\partial y}\left(\frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}\right) + \frac{\partial}{\partial z}\left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right) \\
&= \frac{\partial^2 F_3}{\partial x\partial y} - \frac{\partial^2 F_2}{\partial x\partial z} + \frac{\partial^2 F_1}{\partial y\partial z} - \frac{\partial^2 F_3}{\partial y\partial x} + \frac{\partial^2 F_2}{\partial z\partial x} - \frac{\partial^2 F_1}{\partial z\partial y} \\
&= \left(\frac{\partial^2 F_3}{\partial x\partial y} - \frac{\partial^2 F_3}{\partial y\partial x}\right) + \left(\frac{\partial^2 F_2}{\partial z\partial x} - \frac{\partial^2 F_2}{\partial x\partial z}\right) + \left(\frac{\partial^2 F_1}{\partial y\partial z} - \frac{\partial^2 F_1}{\partial z\partial y}\right) \\
&= 0 + 0 + 0 = 0
\end{aligned}$$

(e) The curl acts on vector valued functions, whereas $\operatorname{div}(\mathbf{F})$ is a scalar function. Therefore the expression $\operatorname{curl}(\operatorname{div}(\mathbf{F}))$ has no meaning.

(f) $\operatorname{div}(\mathbf{F})$ is a scalar function, hence $\nabla(\operatorname{div}\mathbf{F})$ is meaningful. It is not necessarily the zero vector as shown in the following example:

$$\begin{aligned}
\mathbf{F} &= \left\langle x^2, y^2, z^2\right\rangle \\
\operatorname{div}(\mathbf{F}) &= 2x + 2y + 2z \\
\nabla(\operatorname{div}\mathbf{F}) &= \langle 2, 2, 2\rangle \neq \langle 0, 0, 0\rangle
\end{aligned}$$

4. Which of the following statements is correct (where **F** is a continuously differentiable vector field defined everywhere)?

(a) The flux of $\operatorname{curl}(\mathbf{F})$ through all surfaces is zero.

(b) If $\mathbf{F} = \nabla\varphi$, then the flux of **F** through all surfaces is zero.

(c) The flux of $\operatorname{curl}(\mathbf{F})$ through all closed surfaces is zero.

SOLUTION

(a) This statement holds only for conservative fields. If **F** is not conservative, there exist closed curves such that $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \neq 0$, hence by Stokes' Theorem $\iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} \neq 0$.

(b) This statement is false. Consider the unit sphere $\mathcal{S}$ in the three-dimensional space and the function $\varphi(x, y, z) = x^2 + y^2 + z^2$. Then $\mathbf{F} = \nabla\varphi = \langle 2x, 2y, 2z\rangle$ and $\operatorname{div}(\mathbf{F}) = 2 + 2 + 2 = 6$. Using the Divergence Theorem, we have ($\mathcal{W}$ is the unit ball in R^3)

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} 6\, dV = 6\iiint_{\mathcal{W}} dV = 6\,\operatorname{Vol}(\mathcal{W})$$

(c) This statement is correct, as stated in the corollary of Stokes' Theorem in section 18.2.

5. How does the Divergence Theorem imply that the flux of $\mathbf{F} = \langle x^2, y - e^z, y - 2zx \rangle$ through a closed surface is equal to the enclosed volume?

SOLUTION By the Divergence Theorem, the flux is

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} (2x + 1 - 2x)\, dV = \iiint_{\mathcal{W}} 1\, dV = \text{Volume}(\mathcal{W})$$

Therefore the statement is true.

Exercises

In Exercises 1–4, compute the divergence of the vector field.

1. $\mathbf{F} = \langle xy, yz, y^2 - x^3 \rangle$

SOLUTION The divergence of $\mathbf{F}$ is

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(xy) + \frac{\partial}{\partial y}(yz) + \frac{\partial}{\partial z}(y^2 - x^3) = y + z + 0 = y + z$$

2. $x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$

SOLUTION

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = 1 + 1 + 1 = 3$$

3. $\mathbf{F} = \langle x - 2zx^2, z - xy, z^2x^2 \rangle$

SOLUTION

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x - 2zx^2) + \frac{\partial}{\partial y}(z - xy) + \frac{\partial}{\partial z}(z^2x^2) = (1 - 4zx) + (-x) + (2zx^2) = 1 - 4zx - x + 2zx^2$$

4. $\sin(x + z)\mathbf{i} - ye^{xz}\mathbf{k}$

SOLUTION

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}\sin(x + z) + \frac{\partial}{\partial z}(-ye^{xz}) = \cos(x + z) - yxe^{xz}$$

5. Find a constant c for which the velocity field

$$\mathbf{v} = (cx - y)\mathbf{i} + (y - z)\mathbf{j} + (3x + 4cz)\mathbf{k}$$

of a fluid is incompressible [meaning that $\operatorname{div}(\mathbf{v}) = 0$].

SOLUTION We compute the divergence of $\mathbf{v}$:

$$\operatorname{div}(\mathbf{v}) = \frac{\partial}{\partial x}(cx - y) + \frac{\partial}{\partial y}(y - z) + \frac{\partial}{\partial z}(3x + 4cz) = c + 1 + 4c = 5c + 1$$

Therefore, $\operatorname{div}(\mathbf{v}) = 0$ if $5c + 1 = 0$ or $c = -\frac{1}{5}$.

6. Verify the identity $\operatorname{div}(\operatorname{curl}(\mathbf{F})) = 0$ where $\mathbf{F} = \langle F_1, F_2, F_3 \rangle$. Assume that the components F_j have continuous second-order derivatives.

SOLUTION Let $\mathbf{F} = \langle F_1(x, y, z), F_2(x, y, z), F_3(x, y, z) \rangle$. We compute the curl of $\mathbf{F}$:

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ F_1 & F_2 & F_3 \end{vmatrix} = \left\langle \frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}, \frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}, \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right\rangle$$

The divergence of $\operatorname{curl}(\mathbf{F})$ is thus

$$\begin{aligned} \operatorname{div}(\operatorname{curl}(\mathbf{F})) &= \frac{\partial}{\partial x}\left(\frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}\right) + \frac{\partial}{\partial y}\left(\frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}\right) + \frac{\partial}{\partial z}\left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right) \\ &= \frac{\partial^2 F_3}{\partial x \partial y} - \frac{\partial^2 F_2}{\partial x \partial z} + \frac{\partial^2 F_1}{\partial y \partial z} - \frac{\partial^2 F_3}{\partial y \partial x} + \frac{\partial^2 F_2}{\partial z \partial x} - \frac{\partial^2 F_1}{\partial z \partial y} \end{aligned}$$

$$= \left(\frac{\partial^2 F_3}{\partial x \partial y} - \frac{\partial^2 F_3}{\partial y \partial x}\right) + \left(\frac{\partial^2 F_2}{\partial z \partial x} - \frac{\partial^2 F_2}{\partial x \partial z}\right) + \left(\frac{\partial^2 F_1}{\partial y \partial z} - \frac{\partial^2 F_1}{\partial z \partial y}\right)$$

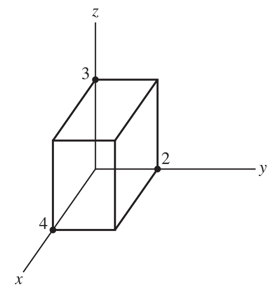
Since the second-order partials are continuous, the mixed partials are equal. Therefore,

$$\text{div}\,(\text{curl}(\mathbf{F})) = 0$$

In Exercises 7–10, verify the Divergence Theorem for the vector field and region.

7. $\mathbf{F} = \langle z, x, y \rangle$, the box $[0, 4] \times [0, 2] \times [0, 3]$

SOLUTION Let $\mathcal{S}$ be the surface of the box and $\mathcal{R}$ the region enclosed by $\mathcal{S}$.



We first compute the surface integral in the Divergence Theorem:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{R}} \text{div}(\mathbf{F})\, dV \tag{1}$$

We denote by $\mathcal{S}_i$, $i = 1, \dots, 6$, the faces of the box, starting at the face on the xz-plane and moving counterclockwise, then moving to the bottom and the top. We use parametrizations

$$\begin{aligned}
\mathcal{S}_1:\ & \Phi_1(x, z) = (x, 0, z), \quad 0 \le x \le 4, \quad 0 \le z \le 3 \\
& \mathbf{n} = \langle 0, -1, 0 \rangle \\
\mathcal{S}_2:\ & \Phi_2(y, z) = (0, y, z), \quad 0 \le y \le 2, \quad 0 \le z \le 3 \\
& \mathbf{n} = \langle -1, 0, 0 \rangle \\
\mathcal{S}_3:\ & \Phi_3(x, z) = (x, 2, z), \quad 0 \le x \le 4, \quad 0 \le z \le 3 \\
& \mathbf{n} = \langle 0, 1, 0 \rangle \\
\mathcal{S}_4:\ & \Phi_4(y, z) = (4, y, z), \quad 0 \le y \le 2, \quad 0 \le z \le 3 \\
& \mathbf{n} = \langle 1, 0, 0 \rangle \\
\mathcal{S}_5:\ & \Phi_5(x, y) = (x, y, 0), \quad 0 \le x \le 4, \quad 0 \le y \le 2 \\
& \mathbf{n} = \langle 0, 0, -1 \rangle \\
\mathcal{S}_6:\ & \Phi_6(x, y) = (x, y, 3), \quad 0 \le x \le 4, \quad 0 \le y \le 2 \\
& \mathbf{n} = \langle 0, 0, 1 \rangle
\end{aligned}$$

Then,

$$\begin{aligned}
\iint_{\mathcal{S}_1} \mathbf{F} \cdot d\mathbf{S} &= \int_0^3 \int_0^4 \mathbf{F}\,(\Phi_1(x, z)) \cdot \langle 0, -1, 0 \rangle\, dx\, dz = \int_0^3 \int_0^4 \langle z, x, 0 \rangle \cdot \langle 0, -1, 0 \rangle\, dx\, dz \\
&= \int_0^3 \int_0^4 -x\, dx\, dz = 3 \frac{-x^2}{2}\bigg|_0^4 = -24 \\
\iint_{\mathcal{S}_2} \mathbf{F} \cdot d\mathbf{S} &= \int_0^3 \int_0^2 \mathbf{F}\,(\Phi_2(y, z)) \cdot \langle -1, 0, 0 \rangle\, dy\, dz = \int_0^3 \int_0^2 \langle z, 0, y \rangle \cdot \langle -1, 0, 0 \rangle\, dy\, dz \\
&= \int_0^3 \int_0^2 -z\, dy\, dz = 2 \cdot \frac{-z^2}{2}\bigg|_0^3 = -9 \\
\iint_{\mathcal{S}_3} \mathbf{F} \cdot d\mathbf{S} &= \int_0^3 \int_0^4 \mathbf{F}\,(\Phi_3(x, z)) \cdot \langle 0, 1, 0 \rangle\, dx\, dz = \int_0^3 \int_0^4 \langle z, x, 2 \rangle \cdot \langle 0, 1, 0 \rangle\, dx\, dz
\end{aligned}$$

$$= \int_0^3 \int_0^4 x\,dx\,dz = 3 \cdot \frac{x^2}{2}\Big|_0^4 = 24$$

$$\iint_{\mathcal{S}_4} \mathbf{F} \cdot d\mathbf{S} = \int_0^3 \int_0^2 \mathbf{F}\left(\Phi_4(y,z)\right) \cdot \langle 1,0,0\rangle\,dy\,dz = \int_0^3 \int_0^2 \langle z,4,y\rangle \cdot \langle 1,0,0\rangle\,dy\,dz$$

$$= \int_0^3 \int_0^2 z\,dy\,dz = 2 \cdot \frac{z^2}{2}\Big|_0^3 = 9$$

$$\iint_{\mathcal{S}_5} \mathbf{F} \cdot d\mathbf{S} = \int_0^2 \int_0^4 \mathbf{F}\left(\Phi_5(x,y)\right) \cdot \langle 0,0,-1\rangle\,dx\,dy = \int_0^2 \int_0^4 \langle 0,x,y\rangle \cdot \langle 0,0,-1\rangle\,dx\,dy$$

$$= \int_0^2 \int_0^4 -y\,dx\,dy = 4 \cdot \frac{-y^2}{2}\Big|_0^2 = -8$$

$$\iint_{\mathcal{S}_6} \mathbf{F} \cdot d\mathbf{S} = \int_0^2 \int_0^4 \mathbf{F}\left(\Phi_6(x,y)\right) \cdot \mathbf{n}\,dx\,dy = \int_0^2 \int_0^4 \langle 3,x,y\rangle \cdot \langle 0,0,1\rangle\,dx\,dy$$

$$= \int_0^2 \int_0^4 y\,dx\,dy = 4 \cdot \frac{y^2}{2}\Big|_0^2 = 8$$

We add the integrals to obtain the surface integral

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \sum_{i=1}^{6} \iint_{\mathcal{S}_i} \mathbf{F} \cdot d\mathbf{S} = -24 - 9 + 24 + 9 - 8 + 8 = 0 \qquad (2)$$

We now evaluate the triple integral in (1). We compute the divergence of $\mathbf{F} = \langle z, x, y\rangle$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(z) + \frac{\partial}{\partial y}(x) + \frac{\partial}{\partial z}(y) = 0$$

Hence,

$$\iiint_{\mathcal{R}} \operatorname{div}(\mathbf{F})\,dV = \iiint_{\mathcal{R}} 0\,dV = 0 \qquad (3)$$

The equality of the integrals in (2) and (3) verifies the Divergence Theorem.

8. $\mathbf{F} = \langle y, x, z\rangle$, the region $x^2 + y^2 + z^2 \le 4$

SOLUTION Let $\mathcal{S}$ be the surface of the sphere and $\mathcal{R}$ the ball enclosed by $\mathcal{S}$. We compute both sides of the Divergence Theorem:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{R}} \operatorname{div}(\mathbf{F})\,dV \qquad (1)$$

Step 1. Integral over sphere. We use the parametrization

$$\mathcal{S}: \Phi(\theta,\phi) = (2\cos\theta\sin\phi, 2\sin\theta\sin\phi, 2\cos\phi), \quad 0 \le \theta \le 2\pi, \quad 0 \le \phi \le \pi$$

$$\mathbf{n} = 4\sin\phi\,\langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle$$

Then,

$$\mathbf{F}\left(\Phi(\theta,\phi)\right) \cdot \mathbf{n} = 2\,\langle\sin\theta\sin\phi, \cos\theta\sin\phi, \cos\phi\rangle \cdot 4\sin\phi\,\langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle$$

$$= 8\left(\sin\theta\cos\theta\sin^3\phi + \cos\theta\sin\theta\sin^3\phi + \cos^2\phi\sin\phi\right)$$

$$= 8\sin 2\theta\sin^3\phi + 8\cos^2\phi\sin\phi$$

The surface integral is thus

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \int_0^{\pi} \int_0^{2\pi} \mathbf{F}\left(\Phi(\theta,\phi)\right) \cdot \mathbf{n}\,d\theta\,d\phi = \int_0^{\pi} \int_0^{2\pi} \left(8\sin 2\theta\,\sin^3\phi + 8\,\cos^2\phi\sin\phi\right)\,d\theta\,d\phi$$

$$= \left(8\int_0^{2\pi} \sin 2\theta\,d\theta\right)\left(\int_0^{\pi} \sin^3\phi d\phi\right) + 16\pi\int_0^{\pi} \cos^2\phi\sin\phi\,d\phi$$

$$= 0 + 16\pi\left(-\frac{\cos^3\phi}{3}\Big|_0^{\pi}\right) = -\frac{16\pi}{3}(-1-1) = \frac{32\pi}{3}$$

We compute the triple integral in (1):

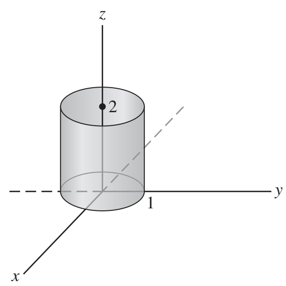
$$\operatorname{div}\mathbf{F} = \operatorname{div}\langle y, x, z\rangle = \frac{\partial}{\partial x}(y) + \frac{\partial}{\partial y}(x) + \frac{\partial}{\partial z}(z) = 1$$

$$\iiint_{\mathcal{R}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{R}} 1\, dV = \text{Volume}(\mathcal{R}) = \frac{4\pi \cdot 2^3}{3} = \frac{32\pi}{3} \tag{2}$$

The equality of the integrals in (2) and (3) verifies the Divergence Theorem.

9. $\mathbf{F} = \langle 2x, 3z, 3y\rangle$, the region $x^2 + y^2 \le 1, 0 \le z \le 2$

SOLUTION



Let $\mathcal{S}$ be the surface of the cylinder and $\mathcal{R}$ the region enclosed by $\mathcal{S}$. We compute the two sides of the Divergence Theorem:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{R}} \operatorname{div}(\mathbf{F})\, dV \tag{1}$$

We first calculate the surface integral.

Step 1. Integral over the side of the cylinder. The side of the cylinder is parametrized by

$$\Phi(\theta, z) = (\cos\theta, \sin\theta, z), \quad 0 \le \theta \le 2\pi, \quad 0 \le z \le 2$$
$$\mathbf{n} = \langle \cos\theta, \sin\theta, 0\rangle$$

Then,

$$\mathbf{F}(\Phi(\theta, z)) \cdot \mathbf{n} = \langle 2\cos\theta, 3z, 3\sin\theta\rangle \cdot \langle \cos\theta, \sin\theta, 0\rangle = 2\cos^2\theta + 3z\sin\theta$$

We obtain the integral

$$\iint_{\text{side}} \mathbf{F} \cdot d\mathbf{S} = \int_0^2 \int_0^{2\pi} \left(2\cos^2\theta + 3z\sin\theta\right) d\theta\, dz = 4\int_0^{2\pi} \cos^2\theta\, d\theta + \left(\int_0^2 3z\, dz\right)\left(\int_0^{2\pi} \sin\theta\, d\theta\right)$$
$$= 4 \cdot \left(\frac{\theta}{2} + \frac{\sin 2\theta}{4}\bigg|_0^{2\pi}\right) + 0 = 4\pi$$

Step 2. Integral over the top of the cylinder. The top of the cylinder is parametrized by

$$\Phi(x, y) = (x, y, 2)$$

with parameter domain $\mathcal{D} = \left\{(x, y) : x^2 + y^2 \le 1\right\}$. The upward pointing normal is

$$\mathbf{n} = \mathbf{T}_x \times \mathbf{T}_y = \langle 1, 0, 0\rangle \times \langle 0, 1, 0\rangle = \mathbf{i} \times \mathbf{j} = \mathbf{k} = \langle 0, 0, 1\rangle$$

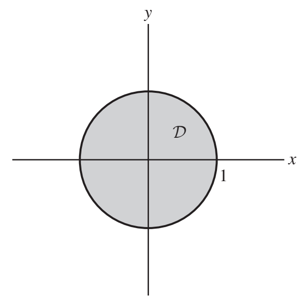
Also,

$$\mathbf{F}(\Phi(x, y)) \cdot \mathbf{n} = \langle 2x, 6, 3y\rangle \cdot \langle 0, 0, 1\rangle = 3y$$

Hence,

$$\iint_{\text{top}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} 3y\, dA = 0$$

The last integral is zero due to symmetry.



Step 3. Integral over the bottom of the cylinder. We parametrize the bottom by

$$\Phi(x, y) = (x, y, 0), \quad (x, y) \in \mathcal{D}$$

The downward pointing normal is $\mathbf{n} = \langle 0, 0, -1\rangle$. Then

$$\mathbf{F}(\Phi(x, y)) \cdot \mathbf{n} = \langle 2x, 0, 3y\rangle \cdot \langle 0, 0, -1\rangle = -3y$$

We obtain the following integral, which is zero due to symmetry:

$$\iint_{\text{bottom}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} -3y\, dA = 0$$

Adding the integrals we get

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\text{side}} \mathbf{F} \cdot d\mathbf{S} + \iint_{\text{top}} \mathbf{F} \cdot d\mathbf{S} + \iint_{\text{bottom}} \mathbf{F} \cdot d\mathbf{S} = 4\pi + 0 + 0 = 4\pi \tag{2}$$

Step 4. Compare with integral of divergence.

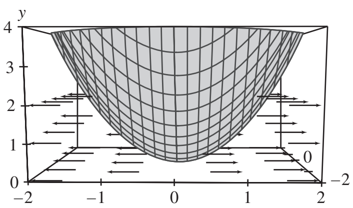
$$\operatorname{div}(\mathbf{F}) = \operatorname{div}\langle 2x, 3z, 3y\rangle = \frac{\partial}{\partial x}(2x) + \frac{\partial}{\partial y}(3z) + \frac{\partial}{\partial z}(3y) = 2$$

$$\iiint_{\mathcal{R}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{R}} 2\, dV = 2\iiint_{\mathcal{R}} dV = 2\,\mathrm{Vol}(\mathcal{R}) = 2 \cdot \pi \cdot 2 = 4\pi \tag{3}$$

The equality of (2) and (3) verifies the Divergence Theorem.

10. $\mathbf{F} = \langle x, 0, 0\rangle$, the region $x^2 + y^2 \le z \le 4$

SOLUTION



Let $\mathcal{S}$ be the surface enclosing the given region $\mathcal{R}$. We must verify the equality

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{R}} \operatorname{div}(\mathbf{F})\, dV \tag{1}$$

We first compute the surface integral on the left-hand side.

Step 1. Integral over the side of the surface. The side of the surface is parametrized by

$$\Phi(\theta, t) = \left(t\cos\theta, t\sin\theta, t^2\right), \quad 0 \le t \le 2, \quad 0 \le \theta \le 2\pi$$

The outward pointing normal is

$$\mathbf{n} = \mathbf{T}_\theta \times \mathbf{T}_t = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -t\sin\theta & t\cos\theta & 0 \\ \cos\theta & \sin\theta & 2t \end{vmatrix} = \left\langle 2t^2\cos\theta, 2t^2\sin\theta, -t\right\rangle$$

Also,

$$\mathbf{F}(\Phi(\theta, t)) \cdot \mathbf{n} = \langle t\cos\theta, 0, 0\rangle \cdot \left\langle 2t^2\cos\theta, 2t^2\sin\theta, -t\right\rangle = 2t^3\cos^2\theta$$

The surface integral over the side is

$$\iint_{\text{side}} \mathbf{F} \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^2 2t^3 \cos^2\theta \, dt \, d\theta = \left(\int_0^{2\pi} \cos^2\theta \, d\theta\right)\left(\int_0^2 2t^3 \, dt\right)$$

$$= \left(\frac{\theta}{2} + \frac{\sin 2\theta}{4}\Big|_{\theta=0}^{2\pi}\right)\left(\frac{t^4}{2}\Big|_{t=0}^{2}\right) = 8\pi \tag{2}$$

Step 2. Integral over the top of the surface. The top of the surface is parametrized by $\Phi(x, y) = (x, y, 4)$ with parameter domain $\mathcal{D} = \left\{(x, y) : x^2 + y^2 \le 2\right\}$. The upward pointing normal vector is

$$\mathbf{n} = \mathbf{T}_x \times \mathbf{T}_y = \langle 1, 0, 0\rangle \times \langle 0, 1, 0\rangle = \mathbf{i} \times \mathbf{j} = \mathbf{k} = \langle 0, 0, 1\rangle$$

Also,

$$\mathbf{F}\left(\Phi(x, y)\right) \cdot \mathbf{n} = \langle x, 0, 0\rangle \cdot \langle 0, 0, 1\rangle = 0$$

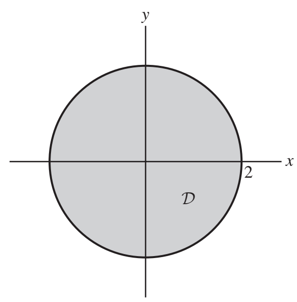
Hence,

$$\iint_{\text{top}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} 0 \, dA = 0 \tag{3}$$

Adding the surface integrals (2) and (3) we get

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\text{side}} \mathbf{F} \cdot d\mathbf{S} + \iint_{\text{top}} \mathbf{F} \cdot d\mathbf{S} = 8\pi + 0 = 8\pi$$

Step 3. Compare with integral of divergence.



We compute the divergence:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(0) + \frac{\partial}{\partial z}(0) = 1$$

We obtain the following triple integral:

$$\iiint_{\mathcal{R}} \operatorname{div}(\mathbf{F}) \cdot dV = \iiint_{\mathcal{R}} 1 \, dV = \iint_{\mathcal{D}} \left(\int_{x^2+y^2}^{4} dz\right) dx\, dy = \iint_{\mathcal{D}} \left(4 - (x^2 + y^2)\right) dx\, dy$$

$$= \int_0^{2\pi} \int_0^2 (4 - r^2) r \, dr \, d\theta = 2\pi \int_0^2 \left(4r - r^3\right) dr = 2\pi \left(2r^2 - \frac{r^4}{4}\Big|_0^2\right)$$

$$= 2\pi \cdot 4 = 8\pi \tag{4}$$

The equality of (2) and (4) verifies the Divergence Theorem.

In Exercises 11–18, use the Divergence Theorem to evaluate the flux $\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S}$.

11. $\mathbf{F} = \left\langle 0, 0, z^3/3\right\rangle$, $\mathcal{S}$ is the sphere $x^2 + y^2 + z^2 = 1$.

SOLUTION We compute the divergence of $\mathbf{F} = \left\langle 0, 0, z^3/3\right\rangle$:

$$\operatorname{div}\mathbf{F} = \frac{\partial}{\partial x}(0) + \frac{\partial}{\partial y}(0) + \frac{\partial}{\partial z}(z^3/3) = z^2$$

Hence, by the Divergence Theorem ($\mathcal{W}$ is the unit ball),

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\,dV = \iiint_{\mathcal{W}} z^2\,dV$$

Computing this integral we see:

$$\begin{aligned}
\iiint_{\mathcal{W}} z^2\,dV &= \int_0^{2\pi}\int_0^{\pi}\int_0^1 \rho^2\cos^2\phi\cdot\rho^2\sin\phi\,d\rho\,d\phi\,d\theta \\
&= \int_0^{2\pi} d\theta\cdot\int_0^{\pi}\cos^2\phi\sin\phi\,d\phi\cdot\int_0^1\rho^4\,d\rho \\
&= (2\pi)\cdot\left(-\frac{\cos^3\phi}{3}\bigg|_0^{\pi}\right)\cdot\left(\frac{\rho^5}{5}\bigg|_0^1\right) \\
&= 2\pi\left(-\frac{1}{3}(-1-1)\right)\left(\frac{1}{5}\right) \\
&= 2\pi\left(\frac{2}{3}\right)\left(\frac{1}{5}\right) = \frac{4\pi}{15}
\end{aligned}$$

12. $\mathbf{F} = \langle y, z, x\rangle$, $\mathcal{S}$ is the sphere $x^2+y^2+z^2=1$.

SOLUTION We compute the divergence of $\mathbf{F} = \langle y, z, x\rangle$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(y) + \frac{\partial}{\partial y}(z) + \frac{\partial}{\partial z}(x) = 0+0+0 = 0$$

Hence, by the Divergence Theorem ($\mathcal{W}$ is the unit ball),

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\,dV = \iiint_{\mathcal{W}} 0\,dV = 0$$

13. $\mathbf{F} = \left\langle x^3, 0, z^3\right\rangle$, $\mathcal{S}$ is the octant of the sphere $x^2+y^2+z^2=4$, in the first octant $x\ge 0$, $y\ge 0$, $z\ge 0$.

SOLUTION We compute the divergence of $\mathbf{F} = \left\langle x^3, 0, z^3\right\rangle$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x^3) + \frac{\partial}{\partial y}(0) + \frac{\partial}{\partial z}(z^3) = 3x^2+3z^2 = 3(x^2+z^2)$$

Using the Divergence Theorem we obtain ($\mathcal{W}$ is the region inside the sphere)

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\,dV = \iiint_{\mathcal{W}} 3(x^2+z^2)\,dV$$

We convert the integral to spherical coordinates. We have

$$\begin{aligned}
x^2+z^2 &= \rho^2\cos^2\theta\sin^2\phi + \rho^2\cos^2\phi = \rho^2\cos^2\theta\sin^2\phi + \rho^2(1-\sin^2\phi) \\
&= -\rho^2\sin^2\phi(1-\cos^2\theta) + \rho^2 = -\rho^2\sin^2\phi\sin^2\theta + \rho^2 = \rho^2(1-\sin^2\phi\sin^2\theta)
\end{aligned}$$

We obtain the following integral:

$$\begin{aligned}
\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} &= 3\int_0^{2\pi}\int_0^{\pi/2}\int_0^2 \rho^2(1-\sin^2\phi\sin^2\theta)\cdot\rho^2\sin\phi\,d\rho\,d\phi\,d\theta \\
&= 3\int_0^{2\pi}\int_0^{\pi/2}\int_0^2 \rho^4(\sin\phi - \sin^3\phi\sin^2\theta)d\rho\,d\phi\,d\theta \\
&= 3\int_0^{2\pi}\int_0^{\pi/2}\int_0^2 \rho^4\sin\phi\,d\rho\,d\phi\,d\theta - 3\int_0^{2\pi}\int_0^{\pi/2}\int_0^2 \rho^4\sin^3\phi\sin^2\theta\,d\rho\,d\phi\,d\theta \\
&= 6\pi\left(\int_0^{\pi/2}\sin\phi\,d\phi\right)\left(\int_0^2\rho^4\,d\rho\right) - 3\left(\int_0^{2\pi}\sin^2\theta\,d\theta\right)\left(\int_0^{\pi/2}\sin^3\phi\,d\phi\right)\left(\int_0^2\rho^4\,d\rho\right) \\
&= 6\pi\left(-\cos\phi\bigg|_{\phi=0}^{\pi/2}\right)\left(\frac{\rho^5}{5}\bigg|_{\rho=0}^{2}\right)\left(-3\frac{\theta}{2} - \frac{\sin 2\theta}{4}\bigg|_{\theta=0}^{2\pi}\right)\cdot\left(-\frac{\sin^2\phi\cos\phi}{3} - \frac{2}{3}\cos\phi\bigg|_{\phi=0}^{\pi/2}\right)\left(\frac{\rho^5}{5}\bigg|_{\rho=0}^{2}\right) \\
&= 6\pi\cdot\frac{32}{5} - 3\pi\cdot\frac{2}{3}\cdot\frac{32}{5} = \frac{128\pi}{5}
\end{aligned}$$

14. $\mathbf{F} = \langle e^{x+y}, e^{x+z}, e^{x+y} \rangle$, $\mathcal{S}$ is the boundary of the unit cube $0 \le x \le 1$, $0 \le y \le 1$, $0 \le z \le 1$.

SOLUTION Let $\mathcal{W}$ denote the box $[0,1] \times [0,1] \times [0,1]$. By the Divergence Theorem,

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV$$

We compute the divergence of $\mathbf{F} = \langle e^{x+y}, e^{x+z}, e^{x+y} \rangle$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(e^{x+y}) + \frac{\partial}{\partial y}(e^{x+z}) + \frac{\partial}{\partial z}(e^{x+y}) = e^{x+y} + 0 + 0 = e^{x+y}$$

By the Divergence Theorem we have

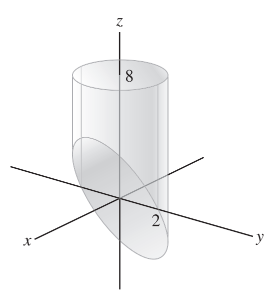
$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} e^{x+y}\, dV$$

We compute the triple integral:

$$\begin{aligned} \iiint_{\mathcal{W}} e^{x+y}\, dV &= \int_0^1 \int_0^1 \int_0^1 e^x \cdot e^y \, dx\,dy\,dz \\ &= \int_0^1 dz \cdot \int_0^1 e^x\, dx \cdot \int_0^1 e^y\, dy \\ &= (1) \cdot e^x \Big|_0^1 \cdot e^y \Big|_0^1 = (e-1)^2 \end{aligned}$$

15. $\mathbf{F} = \langle x, y^2, z+y \rangle$, $\mathcal{S}$ is the boundary of the region contained in the cylinder $x^2 + y^2 = 4$ between the planes $z = x$ and $z = 8$.

SOLUTION Let $\mathcal{W}$ be the region enclosed by $\mathcal{S}$.



We compute the divergence of $\mathbf{F} = \langle x, y^2, z+y \rangle$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y^2) + \frac{\partial}{\partial z}(z+y) = 1 + 2y + 1 = 2 + 2y.$$

By the Divergence Theorem we have

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} (2+2y)\, dV$$

We compute the triple integral. Denoting by $\mathcal{D}$ the disk $x^2 + y^2 \le 4$ in the xy-plane, we have

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}} \int_x^8 (2+2y)\, dz\, dx\, dy = \iint_{\mathcal{D}} (2+2y) z \Big|_{z=x}^{8} dx\, dy = \iint_{\mathcal{D}} (2+2y)(8-x)\, dx\, dy$$

We convert the integral to polar coordinates:

$$\begin{aligned} \iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} &= \int_0^{2\pi} \int_0^2 (2 + 2r\sin\theta)(8 - r\cos\theta) r\, dr\, d\theta \\ &= \int_0^{2\pi} \int_0^2 \left(16r + 2r^2(8\sin\theta - \cos\theta) - r^3 \sin 2\theta\right) dr\, d\theta \\ &= \int_0^{2\pi} 8r^2 + \frac{2}{3} r^3 (8\sin\theta - \cos\theta) - \frac{r^4}{4} \sin 2\theta \Big|_{r=0}^{2} d\theta \end{aligned}$$

$$= \int_0^{2\pi} \left(32 + \frac{16}{3}(8\sin\theta - \cos\theta) - 4\sin 2\theta \right) d\theta$$

$$= 64\pi + \frac{128}{3}\int_0^{2\pi} \sin\theta\, d\theta - \frac{16}{3}\int_0^{2\pi} \cos\theta\, d\theta - \int_0^{2\pi} 4\sin 2\theta\, d\theta = 64\pi$$

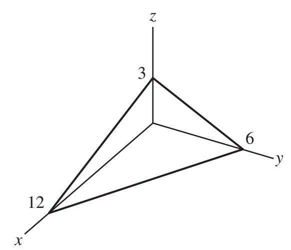
16. $\mathbf{F} = \left\langle x^2 - z^2, e^{z^2} - \cos x, y^3 \right\rangle$, $\mathcal{S}$ is the boundary of the region bounded by $x + 2y + 4z = 12$ and the coordinate planes in the first octant.

SOLUTION We compute the divergence of $\mathbf{F} = \left\langle x^2 - z^2, e^{z^2} - \cos x, y^3 \right\rangle$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x^2 - z^2) + \frac{\partial}{\partial y}\left(e^{z^2} - \cos x\right) + \frac{\partial}{\partial z}(y^3) = 2x.$$

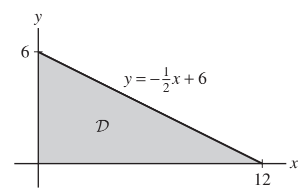
By the Divergence Theorem,

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} 2x\, dV.$$



To compute the triple integral, we describe the region $\mathcal{W}$ by the inequalities

$$0 \le x \le 12, \quad 0 \le y \le -\frac{x}{2} + 6, \quad 0 \le z \le 3 - \frac{y}{2} - \frac{x}{4}.$$



Thus,

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \int_0^{12} \int_0^{-x/2+6} \int_0^{3-\frac{y}{2}-\frac{x}{4}} 2x\, dz\, dy\, dx = \int_0^{12} \int_0^{-x/2+6} 2xz \Big|_{z=0}^{3-\frac{y}{2}-\frac{x}{4}} dy\, dx$$

$$= \int_0^{12} \int_0^{-x/2+6} 2x\left(3 - \frac{y}{2} - \frac{x}{4}\right) dy\, dx = \int_0^{12} 2x \left(3y - \frac{y^2}{4} - \frac{xy}{4}\right) \Big|_{y=0}^{-x/2+6} dx$$

$$= \int_0^{12} 2x \left(\left(3 - \frac{x}{4}\right)\left(6 - \frac{x}{2}\right) - \frac{\left(6 - \frac{x}{2}\right)^2}{4} \right) dx$$

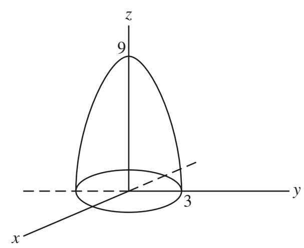
We let $u = 6 - \frac{x}{2}$ and $du = -\frac{1}{2}\, dx$:

$$\int_0^{12} 2x \cdot \frac{\left(6 - \frac{x}{2}\right)^2}{4}\, dx = \int_0^6 2(6-u)u^2\, du = 4u^3 - \frac{1}{2}u^4 \Big|_0^6 = 216.$$

17. $\mathbf{F} = \langle x + y, z, z - x \rangle$, $\mathcal{S}$ is the boundary of the region between the paraboloid $z = 9 - x^2 - y^2$ and the xy-plane.

SOLUTION We compute the divergence of $\mathbf{F} = \langle x + y, z, z - x \rangle$,

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x + y) + \frac{\partial}{\partial y}(z) + \frac{\partial}{\partial z}(z - x) = 1 + 0 + 1 = 2.$$

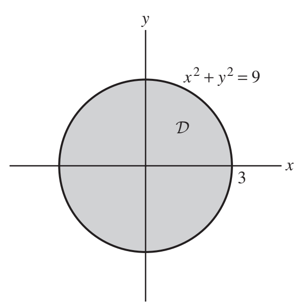


Using the Divergence Theorem we have

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\,dV = \iiint_{\mathcal{W}} 2\,dV$$

We compute the triple integral:

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}} 2\,dV = \iint_{\mathcal{D}} \int_0^{9-x^2-y^2} 2\,dz\,dx\,dy = \iint_{\mathcal{D}} 2z\Big|_0^{9-x^2-y^2}\,dx\,dy$$
$$= \iint_{\mathcal{W}} 2(9-x^2-y^2)\,dx\,dy$$



We convert the integral to polar coordinates:

$$x = r\cos\theta, \quad y = r\sin\theta, \quad 0 \le r \le 3, \quad 0 \le \theta \le 2\pi$$

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^3 2\left(9-r^2\right) r\,dr\,d\theta = 4\pi\int_0^3 (9r-r^3)\,dr = 4\pi\left(\frac{9r^2}{2} - \frac{r^4}{4}\Big|_0^3\right) = 81\pi$$

18. $\mathbf{F} = \left\langle e^{z^2}, 2y+\sin(x^2z), 4z+\sqrt{x^2+9y^2}\right\rangle$, $\mathcal{S}$ is the region $x^2+y^2 \le z \le 8-x^2-y^2$.

SOLUTION First, let us solve for the boundary (or intersection) of the two surfaces:

$$8-x^2-y^2 = x^2+y^2$$
$$8 = 2x^2+2y^2$$
$$x^2+y^2 = 4$$

The intersection of the two surfaces is a circle of radius 2 centered at the origin.

We compute the divergence of $\mathbf{F} = \left\langle e^{z^2}, 2y+\sin(x^2z), 4z+\sqrt{x^2+9y^2}\right\rangle$:

$$\operatorname{div}\mathbf{F} = \frac{\partial}{\partial x}(e^{z^2}) + \frac{\partial}{\partial y}(2y+\sin(x^2z)) + \frac{\partial}{\partial z}(4z+\sqrt{x^2+9y^2}) = 0+2+4 = 6$$

Using the Divergence Theorem we have

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\,dV = \iiint_{\mathcal{W}} 6\,dV$$

We compute the triple integral:

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}} 6\,dV = \iint_{\mathcal{D}} \int_{x^2+y^2}^{8-x^2-y^2} 6\,dz\,dx\,dy$$

We convert this triple integral to cylindrical coordinates:

$$x = r\cos\theta, \quad y = r\sin\theta, \quad 0 \le r \le 2, 0 \le \theta \le 2\pi$$

$$\begin{aligned}
\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} &= 6 \int_0^{2\pi} \int_0^2 \int_{r^2}^{8-r^2} r\, dz\, dr\, d\theta \\
&= 6 \int_0^{2\pi} d\theta \cdot \int_0^2 r[(8-r^2) - r^2]\, dr \\
&= 6(2\pi) \int_0^2 8r - 2r^3\, dr = 12\pi \left(4r^2 - \frac{1}{2} r^4 \Big|_0^2 \right) \\
&= 12\pi(16-8) = 96\pi
\end{aligned}$$

19. Calculate the flux of the vector field $\mathbf{F} = 2xy\mathbf{i} - y^2\mathbf{j} + \mathbf{k}$ through the surface $\mathcal{S}$ in Figure 18. *Hint:* Apply the Divergence Theorem to the closed surface consisting of $\mathcal{S}$ and the unit disk.

SOLUTION From the diagram in the book, $\mathcal{S}$ is the surface in question bounded by the unit circle. Let T be the union of $\mathcal{S}$ and the unit disk D. Then T is a closed surface, and we may apply the Divergence Theorem:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} + \iint_D \mathbf{F} \cdot d\mathbf{S} = \iint_T \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F}) \cdot d\mathbf{S}$$

where $\mathcal{W}$ is the region enclosed by T. Now we observe that $\mathbf{F} = \left\langle 2xy, -y^2, 1 \right\rangle$ and we compute the divergence of $\mathbf{F}$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(2xy) + \frac{\partial}{\partial y}(-y^2) + \frac{\partial}{\partial z}(1) = 2y - 2y + 0 = 0$$

Therefore, the triple integral is zero and we obtain:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = -\iint_D \mathbf{F} \cdot d\mathbf{S} \tag{1}$$

where D is oriented with a downward pointing normal. Let $\Phi(r, \theta) = (r\cos\theta, r\sin\theta, 0)$ be the parametrization of D with polar coordinates. Then

$$\mathbf{F}(\Phi(r,\theta)) = \left\langle 2r^2 \cos\theta \sin\theta, -r^2 \sin^2\theta, 1 \right\rangle$$

Furthermore,

$$\Phi_r(r,\theta) = \langle \cos\theta, \sin\theta, 0 \rangle, \quad \Phi_\theta(r,\theta) = \langle -r\sin\theta, r\cos\theta, 0 \rangle$$

and $\Phi_r \times \Phi_\theta = \langle 0, 0, r \rangle$ is an upward pointing normal. Finally,

$$\mathbf{F} \cdot d\mathbf{S} = \mathbf{F}(\Phi(r,\theta)) \cdot (\Phi_r \times \Phi_\theta)\, dr\, d\theta = r\, dr\, d\theta$$

The integral on the right in (1) uses a downward pointing normal, so we may drop the minus sign and use the upward-pointing normal to obtain:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^1 r\, dr\, d\theta = \pi$$

20. Let $\mathcal{S}_1$ be the closed surface consisting of $\mathcal{S}$ in Figure 18 together with the unit disk. Find the volume enclosed by $\mathcal{S}_1$, assuming that

$$\iint_{\mathcal{S}_1} \langle x, 2y, 3z \rangle \cdot d\mathbf{S} = 72$$

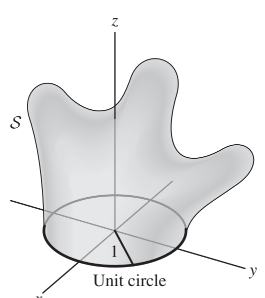


FIGURE 18 Surface $\mathcal{S}$ whose boundary is the unit circle.

SOLUTION First, let $\mathbf{F} = \langle x, 2y, 3z \rangle$. By the Divergence Theorem we can conclude

$$\iint_{\mathcal{S}_1} \langle x, 2y, 3z \rangle \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \text{div}\mathbf{F}\, dV$$

where

$$\text{div}\mathbf{F} = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(2y) + \frac{\partial}{\partial z}(3z) = 1 + 2 + 3 = 6$$

So then

$$72 = \iint_{\mathcal{S}_1} \langle x, 2y, 3z \rangle \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \text{div}\mathbf{F}\, dV = \iiint_{\mathcal{W}} 6\, dV = 6 \cdot \text{Volume}(\mathcal{W})$$

Therefore, Volume($\mathcal{W}$) = 12.

21. Let $\mathcal{S}$ be the half-cylinder $x^2 + y^2 = 1, x \geq 0, 0 \leq z \leq 1$. Assume that $\mathbf{F}$ is a horizontal vector field (the z-component is zero) such that $\mathbf{F}(0, y, z) = zy^2\mathbf{i}$. Let $\mathcal{W}$ be the solid region enclosed by $\mathcal{S}$, and assume that

$$\iiint_{\mathcal{W}} \text{div}(\mathbf{F})\, dV = 4$$

Find the flux of $\mathbf{F}$ through the curved side of $\mathcal{S}$.

SOLUTION The flux through the top and bottom of the surface are zero. The flux through the flat side (with outward normal $-\mathbf{i}$) is

$$-\int_{z=0}^{1} \int_{y=-1}^{1} zy^2\, dy dz = -\frac{1}{2}\left(\frac{2}{3}\right) = -\frac{1}{3}$$

The flux through the curved side is $4 + \frac{1}{3} = \frac{13}{3}$.

22. Volume as a Surface Integral Let $\mathbf{F} = \langle x, y, z \rangle$. Prove that if $\mathcal{W}$ is a region $\mathbf{R}^3$ with a smooth boundary $\mathcal{S}$, then

$$\text{Volume}(\mathcal{W}) = \frac{1}{3} \iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} \qquad \boxed{10}$$

SOLUTION Using the volume as a triple integral we have

$$\text{Volume}(\mathcal{W}) = \iiint_{\mathcal{W}} 1\, dV \qquad (1)$$

We compute the surface integral of $\mathbf{F}$ over $\mathcal{S}$, using the Divergence Theorem. Since $\text{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = 3$, we get

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \text{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} 3\, dV = 3 \iiint_{\mathcal{W}} 1\, dV \qquad (2)$$

We combine (1) and (2) to obtain

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = 3 \cdot \text{volume}(\mathcal{W})$$

or

$$\text{Volume}(\mathcal{W}) = \frac{1}{3} \iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S}$$

23. Use Eq. (10) to calculate the volume of the unit ball as a surface integral over the unit sphere.

SOLUTION Let $\mathcal{S}$ be the unit sphere and $\mathcal{W}$ is the unit ball. By Eq. (10) we have

$$\text{Volume}(\mathcal{W}) = \frac{1}{3} \iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S},\ \mathbf{F} = \langle x, y, z \rangle$$

To compute the surface integral, we parametrize $\mathcal{S}$ by

$$\Phi(\theta, \phi) = (\cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi), \quad 0 \leq \theta \leq 2\pi, \quad 0 \leq \phi \leq \pi$$

$$\mathbf{n} = \sin\phi \langle \cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi \rangle$$

Then

$$\mathbf{F}(\Phi(\theta,\phi))\cdot\mathbf{n} = \langle\cos\theta\sin\phi, \sin\theta\sin\phi, \cos\phi\rangle\cdot\left\langle\cos\theta\sin^2\phi, \sin\theta\sin^2\phi, \cos\phi\sin\phi\right\rangle$$
$$= \cos^2\theta\sin^3\phi + \sin^2\theta\sin^3\phi + \cos^2\phi\sin\phi = \sin^3\phi(\cos^2\theta+\sin^2\theta) + \cos^2\phi\sin\phi$$
$$= \sin^3\phi + \cos^2\phi\sin\phi = \sin^3\phi + (1-\sin^2\phi)\sin\phi = \sin\phi$$

We obtain the following integral:

$$\text{Volume}(\mathcal{W}) = \frac{1}{3}\int_0^{2\pi}\int_0^{\pi}\sin\phi\,d\phi\,d\theta = \frac{1}{3}\cdot 2\pi\int_0^{\pi}\sin\phi\,d\phi = \frac{2\pi}{3}\left(-\cos\phi\Big|_0^{\pi}\right) = \frac{2\pi}{3}(1+1) = \frac{4\pi}{3}$$

24. Verify that Eq. (10) applied to the box $[0,a]\times[0,b]\times[0,c]$ yields the volume $V = abc$.

SOLUTION Recall the result

$$\begin{aligned}\text{Volume}(\mathcal{W}) &= \frac{1}{3}\iint_{\mathcal{S}}\mathbf{F}\cdot d\mathbf{S}\\ &= \frac{1}{3}\iiint_{\mathcal{W}}\operatorname{div}(\mathbf{F})\,dV\\ &= \frac{1}{3}\iiint_{\mathcal{W}}(1+1+1)\,dV = \iiint_{\mathcal{W}}dV\\ &= \int_0^c\int_0^b\int_0^a dV = abc\end{aligned}$$

25. Let $\mathcal{W}$ be the region in Figure 19 bounded by the cylinder $x^2+y^2=4$, the plane $z=x+1$, and the xy-plane. Use the Divergence Theorem to compute the flux of $\mathbf{F}=\left\langle z, x, y+z^2\right\rangle$ through the boundary of $\mathcal{W}$.

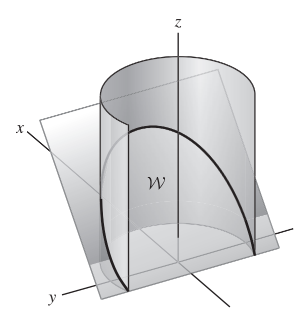

FIGURE 19

SOLUTION We compute the divergence of $\mathbf{F}=\left\langle z, x, y+z^2\right\rangle$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(z) + \frac{\partial}{\partial y}(x) + \frac{\partial}{\partial z}(y+z^2) = 2z$$

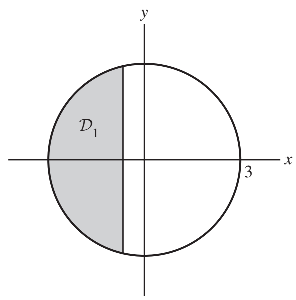
By the Divergence Theorem we have

$$\iint_{\mathcal{S}}\mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}}\operatorname{div}(\mathbf{F})\,dV = \iiint_{\mathcal{W}}2\,dV$$

To compute the triple integral, we identify the projection $\mathcal{D}$ of the region on the xy-plane. $\mathcal{D}$ is the region in the xy plane enclosed by the circle $x^2+y^2=4$ and the line $0=x+1$ or $x=-1$. We obtain the following integral:

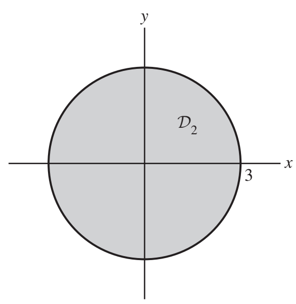
$$\iint_{\mathcal{S}}\mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}}2z\,dV = \iint_{\mathcal{D}}\int_0^{x+1}2z\,dz\,dx\,dy = \iint_{\mathcal{D}}z^2\Big|_{z=0}^{x+1}dx\,dy = \iint_{\mathcal{D}}(x+1)^2\,dx\,dy$$

We compute the double integral as the difference of two integrals: the integral over the disk $\mathcal{D}_2$ of radius 2, and the integral over the part $\mathcal{D}_1$ of the disk, shown in the figure.



We obtain

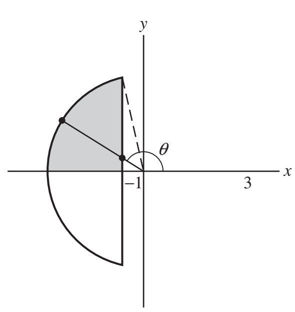
$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{D}_2} (x+1)^2\, dx\, dy - \iint_{\mathcal{D}_1} (x+1)^2\, dx\, dy$$



We compute the first integral, converting to polar coordinates:

$$\begin{aligned}
\iint_{\mathcal{D}_2} (x+1)^2\, dx\, dy &= \int_0^{2\pi} \int_0^2 (r\cos\theta + 1)^2 r\, dr\, d\theta \\
&= \int_0^{2\pi} \int_0^2 r^3 \cos^2\theta + 2r^2\cos\theta + r\, dr\, d\theta \\
&= \int_0^{2\pi} \frac{r^4}{4}\cos^2\theta + \frac{2}{3}r^3\cos\theta + \frac{1}{2}r^2 \Big|_0^2\, d\theta \\
&= \int_0^{2\pi} 4\cos^2\theta + \frac{16}{3}\cos\theta + 2\, d\theta \\
&= \int_0^{2\pi} 2\cos 2\theta + \frac{16}{3}\cos\theta + 4\, d\theta \\
&= \sin 2\theta + \frac{16}{3}\sin\theta + 4\theta \Big|_0^{2\pi} = 8\pi
\end{aligned}$$

We compute the second integral over the upper part of $\mathcal{D}_1$. Due to symmetry, this integral is equal to half of the integral over $\mathcal{D}_1$.



We describe the region in polar coordinates:

$$\frac{2\pi}{3} \le \theta \le \pi, \quad \frac{-1}{\cos\theta} \le r \le 2$$

Then

$$\begin{aligned}
\iint_{\mathcal{D}_1} (x+1)^2\,dx\,dy &= 2\int_{2\pi/3}^{\pi}\int_{-1/\cos\theta}^{2} (r\cos\theta+1)^2 r\,dr\,d\theta \\
&= \int_{2\pi/3}^{\pi}\int_{-1/\cos\theta}^{2} (r^3\cos^2\theta + 2r^2\cos\theta + r)\,dr\,d\theta \\
&= \int_{2\pi/3}^{\pi} \frac{r^4}{4}\cos^2\theta + \frac{2}{3}r^3\cos\theta + \frac{1}{2}r^2\Big|_{r=\frac{-1}{\cos\theta}}^{2}\,d\theta \\
&= 2\int_{2\pi/3}^{\pi} (4\cos^2\theta + \frac{16}{3}\cos\theta + 2) - \left(\frac{\cos^2\theta}{4\cos^4\theta} - \frac{2\cos\theta}{3\cos^3\theta} + \frac{1}{2\cos^2\theta}\right)d\theta \\
&= 2\int_{2\pi/3}^{\pi} 2\cos 2\theta + 4 + \frac{16}{3}\cos\theta - \frac{1}{4}\sec^2\theta + \frac{2}{3}\sec^2\theta - \frac{1}{2}\sec^2\theta\,d\theta \\
&= 2\int_{2\pi/3}^{\pi} 2\cos 2\theta + 4 + \frac{16}{3}\cos\theta - \frac{1}{12}\sec^2\theta\,d\theta \\
&= \sin 2\theta + 4\theta + \frac{16}{3}\sin\theta - \frac{1}{12}\tan\theta\Big|_{2\pi/3}^{\pi} \\
&= 2(4\pi) - 2\left(\sin\frac{4\pi}{3} + \frac{8\pi}{3} + \frac{16}{3}\sin\frac{2\pi}{3} - \frac{1}{12}\tan\frac{2\pi}{3}\right) \\
&= 8\pi - 2\left(-\frac{\sqrt{3}}{2} + \frac{8\pi}{3} + \frac{16\sqrt{3}}{6} + \frac{\sqrt{3}}{12}\right) \\
&= 8\pi + \sqrt{3} - \frac{16\pi}{3} - \frac{16\sqrt{3}}{3} - \frac{\sqrt{3}}{6} \\
&= \frac{8\pi}{3} + \sqrt{3}\left(1 - \frac{16}{3} - \frac{1}{6}\right) \\
&= \frac{8\pi}{3} - \frac{9}{2}\sqrt{3}
\end{aligned}$$

so we have

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = 8\pi - \iint_{\mathcal{D}_1} (x+1)^2\,dx\,dy \approx 8\pi - \left(\frac{8\pi}{3} - \frac{9}{2}\sqrt{3}\right) = \frac{16\pi}{3} + \frac{9}{2}\sqrt{3} \approx 24.550.$$

26. Let $I = \iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S}$, where

$$\mathbf{F} = \left\langle \frac{2yz}{r^2}, -\frac{xz}{r^2}, -\frac{xy}{r^2} \right\rangle$$

$(r = \sqrt{x^2+y^2+z^2})$ and $\mathcal{S}$ is the boundary of a region $\mathcal{W}$.

(a) Check that $\mathbf{F}$ is divergence-free.

(b) Show that $I = 0$ if $\mathcal{S}$ is a sphere centered at the origin. Explain, however, why the Divergence Theorem cannot be used to prove this.

SOLUTION

(a) To find $\mathrm{div}(\mathbf{F})$, we first compute the partial derivatives of $r = \sqrt{x^2+y^2+z^2}$:

$$\frac{\partial r}{\partial x} = \frac{2x}{2\sqrt{x^2+y^2+z^2}} = \frac{x}{r}, \quad \frac{\partial r}{\partial y} = \frac{2y}{2\sqrt{x^2+y^2+z^2}} = \frac{y}{r}, \quad \frac{\partial r}{\partial z} = \frac{2z}{2\sqrt{x^2+y^2+z^2}} = \frac{z}{r}$$

We compute the partial derivatives:

$$\begin{aligned}
\frac{\partial}{\partial x}\left(\frac{2yz}{r^2}\right) &= 2yz\frac{\partial}{\partial x}(r^{-2}) = 2yz\cdot(-2)r^{-3}\frac{\partial r}{\partial x} = -4yz\cdot r^{-3}\frac{x}{r} = -4xyzr^{-4} \\
\frac{\partial}{\partial y}\left(-\frac{xz}{r^2}\right) &= -xz\frac{\partial}{\partial y}(r^{-2}) = -xz\cdot(-2)r^{-3}\frac{\partial r}{\partial y} = 2zx\cdot r^{-3}\frac{y}{r} = 2xyzr^{-4} \\
\frac{\partial}{\partial z}\left(-\frac{xy}{r^2}\right) &= -xy\frac{\partial}{\partial z}(r^{-2}) = -xy\cdot(-2)r^{-3}\frac{\partial r}{\partial z} = 2xyr^{-3}\frac{z}{r} = 2xyzr^{-4}
\end{aligned}$$

The divergence of **F** is the sum of these partials. That is,

$$\operatorname{div}(\mathbf{F}) = -4xyzr^{-4} + 2xyzr^{-4} + 2xyzr^{-4} = 0$$

We conclude that **F** is divergence-free.

(b) We compute the flux of **F** over $\mathcal{S}$, using the following parametrization:

$$\mathcal{S} : \Phi(\theta, \phi) = (R\cos\theta\sin\phi, R\sin\theta\sin\phi, R\cos\phi), \quad 0 \le \theta \le 2\pi, \quad 0 \le \phi \le \pi$$
$$\mathbf{n} = R^2 \sin\phi\, \mathbf{e}_r \quad \text{where } \mathbf{e}_r = r^{-1}\langle x, y, z\rangle$$

We compute the dot product:

$$\mathbf{F} \cdot \mathbf{n} = \left\langle \frac{2yz}{r^2}, -\frac{xz}{r^2}, -\frac{xy}{r^2} \right\rangle \cdot \langle x, y, z\rangle\, r^{-1} \cdot R^2 \sin\phi = (2xyz - xyz - xyz)r^{-3} \cdot R^2 \sin\phi = 0$$

Therefore, $\mathbf{F}(\Phi(\theta, \phi)) \cdot \mathbf{n} = 0$, so we have

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^{\pi} \mathbf{F}(\Phi(\theta, \phi)) \cdot \mathbf{n}\, d\phi\, d\theta = \int_0^{2\pi} \int_0^{\pi} 0\, d\phi\, d\theta = 0$$

The Divergence Theorem cannot be used since **F** is not defined at the origin, which is inside the ball with the boundary $\mathcal{S}$.

27. The velocity field of a fluid **v** (in meters per second) has divergence $\operatorname{div}(\mathbf{v})(P) = 3$ at the point $P = (2, 2, 2)$. Estimate the flow rate out of the sphere of radius 0.5 centered at P.

SOLUTION

$$\text{flow rate through the box} \approx \operatorname{div}(\mathbf{v})(P) \cdot \left(\frac{4}{3}\pi(0.5)^3\right) = \frac{\pi}{2} \approx 1.57\ \text{m}^3/\text{s}$$

28. A hose feeds into a small screen box of volume 10 cm^3 that is suspended in a swimming pool. Water flows across the surface of the box at a rate of 12 cm^3/s. Estimate $\operatorname{div}(\mathbf{v})(P)$, where **v** is the velocity field of the water in the pool and P is the center of the box. What are the units of $\operatorname{div}(\mathbf{v})(P)$?

SOLUTION

$$\text{flow rate through the box} = 12 \approx \operatorname{div}(\mathbf{v})(P) \cdot (10)$$

Thus $\operatorname{div}(\mathbf{v})(P) \approx 1.2\ \text{sec}^{-1}$.

29. The electric field due to a unit electric dipole oriented in the **k**-direction is $\mathbf{E} = \nabla(z/r^3)$, where $r = (x^2 + y^2 + z^2)^{1/2}$ (Figure 20). Let $\mathbf{e}_r = r^{-1}\langle x, y, z\rangle$.

(a) Show that $\mathbf{E} = r^{-3}\mathbf{k} - 3zr^{-4}\mathbf{e}_r$.

(b) Calculate the flux of **E** through a sphere centered at the origin.

(c) Calculate $\operatorname{div}(\mathbf{E})$.

(d) Can we use the Divergence Theorem to compute the flux of **E** through a sphere centered at the origin?

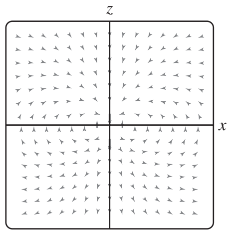


FIGURE 20 The dipole vector field restricted to the xz-plane.

SOLUTION

(a) We first compute the partial derivatives of r:

$$\frac{\partial r}{\partial x} = \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2} \cdot 2x = \frac{x}{r}$$
$$\frac{\partial r}{\partial y} = \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2} \cdot 2y = \frac{y}{r}$$
$$\frac{\partial r}{\partial z} = \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2} \cdot 2z = \frac{z}{r} \tag{1}$$

We compute the partial derivatives of $\frac{z}{r^3}$, using the Chain Rule and the partial derivatives in (1):

$$\frac{\partial}{\partial x}\left(\frac{z}{r^3}\right) = z\frac{\partial}{\partial x}(r^{-3}) = z\cdot(-3)r^{-4}\frac{\partial r}{\partial x} = -3z\cdot r^{-4}\frac{x}{r} = -\frac{3zx}{r^5} = -3zr^{-5}x$$

$$\frac{\partial}{\partial y}\left(\frac{z}{r^3}\right) = z\frac{\partial}{\partial y}(r^{-3}) = z\cdot(-3)r^{-4}\frac{\partial r}{\partial y} = -3z\cdot r^{-4}\frac{y}{r} = -3zr^{-5}y$$

$$\frac{\partial}{\partial z}\left(\frac{z}{r^3}\right) = \frac{\partial}{\partial z}(z\cdot r^{-3}) = 1\cdot r^{-3} + z\cdot(-3)r^{-4}\frac{\partial r}{\partial z} = r^{-3} - 3z\cdot r^{-4}\cdot\frac{z}{r} = r^{-3} - 3z^2r^{-5}$$

Therefore,

$$\begin{aligned}\mathbf{E} = \nabla\left(\frac{z}{r^3}\right) &= -3zr^{-5}x\mathbf{i} - 3zr^{-5}y\mathbf{j} + (r^{-3} - 3z^2r^{-5})\mathbf{k}\\ &= r^{-3}\mathbf{k} - 3zr^{-4}\cdot r^{-1}(x\mathbf{i} + y\mathbf{j} + z\mathbf{k}) = r^{-3}\mathbf{k} - 3zr^{-4}\mathbf{e}_r\end{aligned}$$

(b) To compute the flux $\iint_{\mathcal{S}}\mathbf{E}\cdot d\mathbf{S}$ we use the parametrization $\Phi(\theta,\phi) = (R\cos\theta\sin\phi, R\sin\theta\sin\phi, R\cos\phi)$, $0\le\theta\le 2\pi$, $0\le\phi\le\pi$:

$$\mathbf{n} = R^2\sin\phi\mathbf{e}_r$$

We compute $\mathbf{E}(\Phi(\theta,\phi))\cdot\mathbf{n}$. Since $r = R$ on $\mathcal{S}$, we get

$$\begin{aligned}\mathbf{E}(\Phi(\theta,\phi))\cdot\mathbf{n} &= \left(R^{-3}\mathbf{k} - 3zR^{-4}\mathbf{e}_r\right)\cdot R^2\sin\phi\mathbf{e}_r = R^{-1}\sin\phi\mathbf{k}\cdot\mathbf{e}_r - 3zR^{-2}\sin\phi\\ &= R^{-1}\sin\phi\mathbf{k}\cdot R^{-1}(x\mathbf{i} + y\mathbf{j} + z\mathbf{k}) - 3zR^{-2}\sin\phi\\ &= R^{-2}z\sin\phi - 3zR^{-2}\sin\phi = -2zR^{-2}\sin\phi\\ &= -2R\cos\phi\cdot R^{-2}\sin\phi = -R^{-1}\sin 2\phi\end{aligned}$$

Hence,

$$\iint_{\mathcal{S}}\mathbf{E}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^{\pi} -R^{-1}\sin 2\phi\,d\phi\,d\theta = -\frac{2\pi}{R}\int_0^{\pi}\sin 2\phi\,d\phi = \frac{\pi}{R}\cos 2\phi\Big|_{\phi=0}^{\pi} = 0$$

(c) We use part (a) to write the vector $\mathbf{E}$ componentwise:

$$\mathbf{E} = r^{-3}\mathbf{k} - 3zr^{-4}\mathbf{e}_r = r^{-3}\mathbf{k} - 3zr^{-4}r^{-1}\langle x, y, z\rangle = \left\langle -3zr^{-5}x, -3zr^{-5}y, -3z^2r^{-5} + r^{-3}\right\rangle$$

To find div($\mathbf{E}$) we compute the following derivatives, using (1) and the laws of differentiation. This gives

$$\begin{aligned}\frac{\partial}{\partial x}(-3zr^{-5}x) &= -3z\frac{\partial}{\partial x}(r^{-5}x) = -3z\left(-5r^{-6}\frac{\partial r}{\partial x}x + r^{-5}\cdot 1\right)\\ &= -3z\left(-5r^{-6}x\frac{x}{r} + r^{-5}\right) = 3zr^{-7}(5x^2 - r^2)\end{aligned}$$

Similarly,

$$\frac{\partial}{\partial y}(-3zr^{-5}y) = 3zr^{-7}(5y^2 - r^2)$$

and

$$\begin{aligned}\frac{\partial}{\partial z}(-3z^2r^{-5} + r^{-3}) &= -6zr^{-5} - 3z^2(-5)r^{-6}\frac{\partial r}{\partial z} - 3r^{-4}\frac{\partial r}{\partial z}\\ &= -6zr^{-5} + 15z^2r^{-6}\frac{z}{r} - 3r^{-4}\frac{z}{r} = 3zr^{-7}(5z^2 - 3r^2)\end{aligned}$$

Hence,

$$\begin{aligned}\operatorname{div}(\mathbf{E}) &= 3zr^{-7}(5x^2 - r^2 + 5y^2 - r^2 + 5z^2 - 3r^2) = 15zr^{-7}(x^2 + y^2 + z^2 - r^2)\\ &= 15zr^{-7}(r^2 - r^2) = 0\end{aligned}$$

(d) Since $\mathbf{E}$ is not defined at the origin, which is inside the ball $\mathcal{W}$, we cannot use the Divergence Theorem to compute the flux of $\mathbf{E}$ through the sphere.

30. Let $\mathbf{E}$ be the electric field due to a long, uniformly charged rod of radius R with charge density δ per unit length (Figure 21). By symmetry, we may assume that $\mathbf{E}$ is everywhere perpendicular to the rod and its magnitude $E(d)$ depends only on the distance d to the rod (strictly speaking, this would hold only if the rod were infinite, but it is nearly true if the rod is long enough). Show that $E(d) = \delta/2\pi\epsilon_0 d$ for $d > R$. *Hint:* Apply Gauss's Law to a cylinder of radius R and of unit length with its axis along the rod.

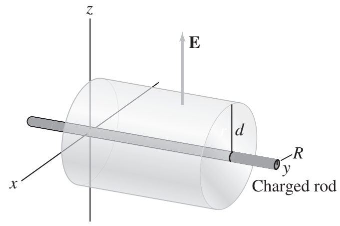

FIGURE 21

SOLUTION Gauss's Theorem asserts that if $\mathcal{S}$ is a closed surface, then the total charge Q enclosed by $\mathcal{S}$ is given by

$$Q = \iint_{\mathcal{S}} \epsilon_0 \mathbf{E} \cdot d\mathbf{S}$$

where ϵ_0 is the dielectric coefficient in vacuum. Here, we take $\mathcal{S}$ is a closed cylinder of radius d and unit length that encloses a charge $Q = \delta \cdot 1 = \delta$. By symmetry, $\mathbf{E}$ is directed radially outward from the rod and its magnitude depends only on the distance d:

$$\mathbf{E} = E(d)\,\langle \cos\theta, 0, \sin\theta\rangle$$

By Gauss's Theorem, for $d > R$,

$$\delta = \iint_{\mathcal{S}} \epsilon_0 \mathbf{E} \cdot d\mathbf{S} = \iint_{\text{integral cylinder}} \epsilon_0 \mathbf{E} \cdot d\mathbf{S} + \iint_{\text{bases}} \epsilon_0 \mathbf{E} \cdot d\mathbf{S}$$

The second integral is zero because $\mathbf{E}$ is perpendicular to the normal vectors of the two bases. To compute the surface integral over the side of the cylinder, we parametrize the side of $\mathcal{S}$ by $\Phi(y,\theta) = (d\cos\theta, y, d\sin\theta)$ for $0 \le y \le 1$ and $0 \le \theta \le 2\pi$. It can be checked that the normal vector in this parametrization is

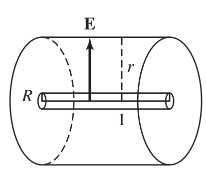
$$\mathbf{n} = \Phi_y \times \Phi_\theta = \langle d\cos\theta, 0, d\sin\theta\rangle$$

Therefore,

$$\mathbf{E} \cdot \mathbf{n} = dE(d)$$

and we

$$\delta = \iint_{\mathcal{S}} \epsilon_0 \mathbf{E} \cdot d\mathbf{S} = \int_0^{2\pi}\int_0^1 \epsilon_0\, dE(d)\, dy\, d\theta = 2\pi\epsilon_0\, dE(d) \tag{1}$$



We obtain

$$E(d) = \frac{\delta}{2\pi\epsilon_0 d}.$$

31. Let $\mathcal{W}$ be the region between the sphere of radius 4 and the cube of side 1, both centered at the origin. What is the flux through the boundary $\mathcal{S} = \partial\mathcal{W}$ of a vector field $\mathbf{F}$ whose divergence has the constant value $\mathrm{div}(\mathbf{F}) = -4$?

SOLUTION Recall,

$$\text{flux} = \iiint_{\mathcal{W}} \mathrm{div}(\mathbf{F})dV$$

Using this fact we see:

$$\text{flux} = \iiint_{\mathcal{W}} (-4)dV = -4 \cdot V(\mathcal{W}) = (-4)\left(\frac{256\pi}{3} - 1\right)$$

32. Let $\mathcal{W}$ be the region between the sphere of radius 3 and the sphere of radius 2, both centered at the origin. Use the Divergence Theorem to calculate the flux of $\mathbf{F} = x\mathbf{i}$ through the boundary $\mathcal{S} = \partial\mathcal{W}$.

SOLUTION We first calculate the divergence of $\mathbf{F} = \langle x, 0, 0\rangle$:

$$\text{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(0) + \frac{\partial}{\partial z}(0) = 1$$

Then to calculate flux, we use the Divergence Theorem:

$$\text{flux} = \iint_{\mathcal{W}} \text{div}(\mathbf{F})\, dV = \iint_{\mathcal{W}} 1\, dV = \text{Volume}(\mathcal{W}) = \frac{4}{3}\pi(3)^3 - \frac{4}{3}\pi(2)^3 = \frac{76\pi}{3}$$

33. Find and prove a Product Rule expressing $\text{div}(f\mathbf{F})$ in terms of $\text{div}(\mathbf{F})$ and ∇f.

SOLUTION Let $\mathbf{F} = \langle P, Q, R\rangle$. We compute $\text{div}(f\mathbf{F})$:

$$\text{div}(f\mathbf{F}) = \text{div}\,\langle fP, fQ, fR\rangle = \frac{\partial}{\partial x}(fP) + \frac{\partial}{\partial y}(fQ) + \frac{\partial}{\partial z}(fR)$$

Applying the product rule for scalar functions we obtain

$$\begin{aligned}\text{div}(f\mathbf{F}) &= \left(f\frac{\partial P}{\partial x} + \frac{\partial f}{\partial x}P\right) + \left(f\frac{\partial Q}{\partial y} + \frac{\partial f}{\partial y}Q\right) + \left(f\frac{\partial R}{\partial z} + \frac{\partial f}{\partial z}R\right)\\ &= f\left(\frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z}\right) + \frac{\partial f}{\partial x}P + \frac{\partial f}{\partial y}Q + \frac{\partial f}{\partial z}R = f\,\text{div}(\mathbf{F}) + \mathbf{F}\cdot\nabla f\end{aligned}$$

We thus proved the following identity:

$$\text{div}(f\mathbf{F}) = f\,\text{div}(\mathbf{F}) + \mathbf{F}\cdot\nabla f$$

34. Prove the identity

$$\text{div}(\mathbf{F}\times\mathbf{G}) = \text{curl}(\mathbf{F})\cdot\mathbf{G} - \mathbf{F}\cdot\text{curl}(\mathbf{G})$$

Then prove that the cross product of two irrotational vector fields is incompressible [$\mathbf{F}$ is called **irrotational** if $\text{curl}(\mathbf{F}) = 0$ and **incompressible** if $\text{div}(\mathbf{F}) = 0$].

SOLUTION We compute the left-hand side of the identity. For $F = \langle P, Q, R\rangle$ and $G = \langle S, T, U\rangle$ we have

$$\mathbf{F}\times\mathbf{G} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k}\\ P & Q & R\\ S & T & U\end{vmatrix} = (QU - RT)\mathbf{i} - (PU - RS)\mathbf{j} + (PT - QS)\mathbf{k}$$

$$\begin{aligned}\text{div}(\mathbf{F}\times\mathbf{G}) &= \frac{\partial}{\partial x}(QU - RT) - \frac{\partial}{\partial y}(PU - RS) + \frac{\partial}{\partial z}(PT - QS)\\ &= (Q_xU + QU_x - R_xT - RT_x) - \left(P_yU + PU_y - R_yS - RS_y\right) + (P_zT + PT_z - Q_zS - QS_z)\\ &= S(R_y - Q_z) + T(P_z - R_x) + U(Q_x - P_y) - P(U_y - T_z) - Q(S_z - U_x) - R(T_x - S_y)\end{aligned}$$

We compute the right hand side of the given identity. We have

$$\begin{aligned}\text{curl}(\mathbf{F}) &= \left\langle R_y - Q_z, P_z - R_x, Q_x - P_y\right\rangle\\ \text{curl}(\mathbf{G}) &= \left\langle U_y - T_z, S_z - U_x, T_x - S_y\right\rangle\end{aligned}$$

Thus,

$$\begin{aligned}\mathbf{G}\cdot\text{curl}(\mathbf{F}) - \mathbf{F}\cdot\text{curl}(\mathbf{G}) &= \langle S, T, U\rangle\cdot\left\langle R_y - Q_z, P_z - R_x, Q_x - P_y\right\rangle\\ &\quad - \langle P, Q, R\rangle\cdot\left\langle U_y - T_z, S_z - U_x, T_x - S_y\right\rangle\\ &= S(R_y - Q_z) + T(P_z - R_x) + U(Q_x - P_y)\\ &\quad - P(U_y - T_z) - Q(S_z - U_x) - R(T_x - S_y)\end{aligned}$$

This, with (1), proves the identity

$$\text{div}(\mathbf{F}\times\mathbf{G}) = \mathbf{G}\cdot\text{curl}(\mathbf{F}) - \mathbf{F}\cdot\text{curl}(\mathbf{G}).$$

Thus, if both $\mathbf{F}$ and $\mathbf{G}$ are irrotational (that is, with curl zero), then their cross product is source-free (that is, with divergence zero), as $\text{div}\,\mathbf{F}\times\mathbf{G} = \mathbf{G}\cdot\mathbf{0} - \mathbf{F}\cdot\mathbf{0} = 0$.

35. Prove that $\operatorname{div}(\nabla f \times \nabla g) = 0$.

SOLUTION We compute the cross product:

$$\nabla f \times \nabla g = \langle f_x, f_y, f_z \rangle \times \langle g_x, g_y, g_z \rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ f_x & f_y & f_z \\ g_x & g_y & g_z \end{vmatrix}$$
$$= \langle f_y g_z - f_z g_y, f_z g_x - f_x g_z, f_x g_y - f_y g_x \rangle$$

We now compute the divergence of this vector. Using the Product Rule for scalar functions and the equality of the mixed partials, we obtain

$$\begin{aligned}\operatorname{div}(\nabla f \times \nabla g) &= \frac{\partial}{\partial x}(f_y g_z - f_z g_y) + \frac{\partial}{\partial y}(f_z g_x - f_x g_z) + \frac{\partial}{\partial z}(f_x g_y - f_y g_x) \\ &= f_{yx} g_z + f_y g_{zx} - f_{zx} g_y - f_z g_{yx} + f_{zy} g_x + f_z g_{xy} - f_{xy} g_z - f_x g_{zy} + f_{xz} g_y + f_x g_{yz} \\ &\quad - f_{yz} g_x - f_y g_{xz} \\ &= (f_{yx} - f_{xy}) g_z + (g_{zx} - g_{xz}) f_y + (f_{xz} - f_{zx}) g_y + (g_{xy} - g_{yx}) f_z \\ &\quad + (f_{zy} - f_{yz}) g_x + (g_{yz} - g_{zy}) f_x = 0\end{aligned}$$

In Exercises 36–38, Δ denotes the Laplace operator defined by

$$\boxed{\Delta \varphi = \frac{\partial^2 \varphi}{\partial x^2} + \frac{\partial^2 \varphi}{\partial y^2} + \frac{\partial^2 \varphi}{\partial z^2}}$$

36. Prove the identity

$$\operatorname{curl}(\operatorname{curl}(\mathbf{F})) = \nabla(\operatorname{div}(\mathbf{F})) - \Delta \mathbf{F}$$

where $\Delta \mathbf{F}$ denotes $\langle \Delta F_1, \Delta F_2, \Delta F_3 \rangle$.

SOLUTION We compute the left-hand side of the identity. We have

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ F_1 & F_2 & F_3 \end{vmatrix} = \left\langle \frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}, \frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}, \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right\rangle$$

Hence,

$$\begin{aligned}\operatorname{curl}(\operatorname{curl}(\mathbf{F})) &= \left\langle \frac{\partial}{\partial y}\left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right) - \frac{\partial}{\partial z}\left(\frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}\right), \frac{\partial}{\partial z}\left(\frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}\right) - \frac{\partial}{\partial x}\left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right), \right. \\ &\quad \left. \frac{\partial}{\partial x}\left(\frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x}\right) - \frac{\partial}{\partial y}\left(\frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z}\right) \right\rangle \\ &= \left\langle \frac{\partial^2 F_2}{\partial y \partial x} - \frac{\partial^2 F_1}{\partial y^2} - \frac{\partial^2 F_1}{\partial z^2} + \frac{\partial^2 F_3}{\partial z \partial x}, \frac{\partial^2 F_3}{\partial z \partial y} - \frac{\partial^2 F_2}{\partial z^2} - \frac{\partial^2 F_2}{\partial x^2} + \frac{\partial^2 F_1}{\partial x \partial y}, \right. \\ &\quad \left. \frac{\partial^2 F_1}{\partial x \partial z} - \frac{\partial^2 F_3}{\partial x^2} - \frac{\partial^2 F_3}{\partial y^2} + \frac{\partial^2 F_2}{\partial y \partial z} \right\rangle \end{aligned} \tag{1}$$

We now compute the right-hand side of the given identity:

$$\begin{aligned}\nabla(\operatorname{div}(\mathbf{F})) &= \nabla\left(\frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z}\right) \\ &= \left\langle \frac{\partial}{\partial x}\left(\frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z}\right), \frac{\partial}{\partial y}\left(\frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z}\right), \frac{\partial}{\partial z}\left(\frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z}\right) \right\rangle \\ &= \left\langle \frac{\partial^2 F_1}{\partial x^2} + \frac{\partial^2 F_2}{\partial x \partial y} + \frac{\partial^2 F_3}{\partial x \partial z}, \frac{\partial^2 F_1}{\partial y \partial x} + \frac{\partial^2 F_2}{\partial y^2} + \frac{\partial^2 F_3}{\partial y \partial z}, \frac{\partial^2 F_1}{\partial z \partial x} + \frac{\partial^2 F_2}{\partial z \partial y} + \frac{\partial^2 F_3}{\partial z^2} \right\rangle\end{aligned}$$

Therefore,

$$\nabla(\operatorname{div}(\mathbf{F})) - \Delta \mathbf{F} = \nabla(\operatorname{div}(\mathbf{F})) - \left\langle \frac{\partial^2 F_1}{\partial x^2} + \frac{\partial^2 F_1}{\partial y^2} + \frac{\partial^2 F_1}{\partial z^2}, \frac{\partial^2 F_2}{\partial x^2} + \frac{\partial^2 F_2}{\partial y^2} + \frac{\partial^2 F_2}{\partial z^2}, \frac{\partial^2 F_3}{\partial x^2} + \frac{\partial^2 F_3}{\partial y^2} + \frac{\partial^2 F_3}{\partial z^2} \right\rangle$$

$$= \left\langle \frac{\partial^2 F_2}{\partial x \partial y} + \frac{\partial^2 F_3}{\partial x \partial z} - \frac{\partial^2 F_1}{\partial y^2} - \frac{\partial^2 F_1}{\partial z^2}, \frac{\partial^2 F_1}{\partial y \partial x} + \frac{\partial^2 F_3}{\partial y \partial z} - \frac{\partial^2 F_2}{\partial x^2} - \frac{\partial^2 F_2}{\partial z^2}, \right.$$

$$\left. \frac{\partial^2 F_1}{\partial z \partial x} + \frac{\partial^2 F_2}{\partial z \partial y} - \frac{\partial^2 F_3}{\partial x^2} - \frac{\partial^2 F_3}{\partial y^2} \right\rangle \qquad (2)$$

Since the mixed partials are equal, the expressions obtained in (1) and (2) are the same. This proves the desired identity.

37. A function φ satisfying $\Delta\varphi = 0$ is called **harmonic**.

(a) Show that $\Delta\varphi = \operatorname{div}(\nabla\varphi)$ for any function φ.

(b) Show that φ is harmonic if and only if $\operatorname{div}(\nabla\varphi) = 0$.

(c) Show that if **F** is the gradient of a harmonic function, then $\operatorname{curl}(F) = 0$ and $\operatorname{div}(F) = 0$.

(d) Show that $\mathbf{F} = \left\langle xz, -yz, \frac{1}{2}(x^2 - y^2)\right\rangle$ is the gradient of a harmonic function. What is the flux of **F** through a closed surface?

SOLUTION

(a) We compute the divergence of $\nabla\varphi$:

$$\operatorname{div}(\nabla\varphi) = \operatorname{div}\left(\left\langle \frac{\partial\varphi}{\partial x}, \frac{\partial\varphi}{\partial y}, \frac{\partial\varphi}{\partial z}\right\rangle\right) = \frac{\partial^2\varphi}{\partial x^2} + \frac{\partial^2\varphi}{\partial y^2} + \frac{\partial^2\varphi}{\partial z^2} = \Delta\varphi$$

(b) In part (a) we showed that $\Delta\varphi = \operatorname{div}(\nabla\varphi)$. Therefore $\Delta\varphi = 0$ if and only if $\operatorname{div}(\nabla\varphi) = 0$. That is, φ is harmonic if and only if $\nabla\varphi$ is divergence free.

(c) We are given that $\mathbf{F} = \nabla\varphi$, where $\Delta\varphi = 0$. In part (b) we showed that

$$\operatorname{div}(\mathbf{F}) = \operatorname{div}(\nabla\varphi) = 0$$

We now show that $\operatorname{curl}(\mathbf{F}) = 0$. We have

$$\operatorname{curl}(\mathbf{F}) = \operatorname{curl}(\nabla\varphi) = \operatorname{curl}\left\langle \varphi_x, \varphi_y, \varphi_z\right\rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \varphi_x & \varphi_y & \varphi_z \end{vmatrix}$$

$$= \left\langle \varphi_{zy} - \varphi_{yz}, \varphi_{xz} - \varphi_{zx}, \varphi_{yx} - \varphi_{xy}\right\rangle = \langle 0, 0, 0\rangle = \mathbf{0}$$

The last equality is due to the equality of the mixed partials.

(d) We first show that $\mathbf{F} = \left\langle xz, -yz, \frac{x^2-y^2}{2}\right\rangle$ is the gradient of a harmonic function. We let $\varphi = \frac{x^2 z}{2} - \frac{y^2 z}{2}$ such that $\mathbf{F} = \nabla\varphi$. Indeed,

$$\nabla\varphi = \left\langle \frac{\partial\varphi}{\partial x}, \frac{\partial\varphi}{\partial y}, \frac{\partial\varphi}{\partial z}\right\rangle = \left\langle xz, -yz, \frac{x^2 - y^2}{2}\right\rangle = \mathbf{F}$$

We show that φ is harmonic, that is, $\Delta\varphi = 0$. We compute the partial derivatives:

$$\frac{\partial\varphi}{\partial x} = xz \quad \Rightarrow \quad \frac{\partial^2\varphi}{\partial x^2} = z$$

$$\frac{\partial\varphi}{\partial y} = -yz \quad \Rightarrow \quad \frac{\partial^2\varphi}{\partial y^2} = -z$$

$$\frac{\partial\varphi}{\partial z} = \frac{x^2 - y^2}{2} \quad \Rightarrow \quad \frac{\partial^2\varphi}{\partial z^2} = 0$$

Therefore,

$$\Delta\varphi = \frac{\partial^2\varphi}{\partial x^2} + \frac{\partial^2\varphi}{\partial y^2} + \frac{\partial^2\varphi}{\partial z^2} = z - z + 0 = 0$$

Since **F** is the gradient of a harmonic function, we know by part (c) that $\operatorname{div}(\mathbf{F}) = 0$. Therefore, by the Divergence Theorem, the flux of **F** through a closed surface is zero:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} 0\, dV = 0$$

38. Let $\mathbf{F} = r^n \mathbf{e}_r$, where n is any number, $r = (x^2 + y^2 + z^2)^{1/2}$, and $\mathbf{e}_r = r^{-1} \langle x, y, z \rangle$ is the unit radial vector.

(a) Calculate $\operatorname{div}(\mathbf{F})$.

(b) Calculate the flux of $\mathbf{F}$ through the surface of a sphere of radius R centered at the origin. For which values of n is this flux independent of R?

(c) Prove that $\nabla(r^n) = n\, r^{n-1}\mathbf{e}_r$.

(d) Use (c) to show that $\mathbf{F}$ is conservative for $n \neq -1$. Then show that $\mathbf{F} = r^{-1}\mathbf{e}_r$ is also conservative by computing the gradient of $\ln r$.

(e) What is the value of $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$, where $\mathcal{C}$ is a closed curve that does not pass through the origin?

(f) Find the values of n for which the function $\varphi = r^n$ is harmonic.

SOLUTION

(a) $\mathbf{F}$ is the vector field:

$$\mathbf{F}(x, y, z) = r^n r^{-1} \langle x, y, z \rangle = (x^2 + y^2 + z^2)^{(n-1)/2} \langle x, y, z \rangle \tag{1}$$

Hence,

$$\begin{aligned}\frac{\partial F_1}{\partial x} &= \frac{\partial}{\partial x}\left((x^2+y^2+z^2)^{(n-1)/2}x\right) = \left(\frac{n-1}{2}\right)(x^2+y^2+z^2)^{(n-3)/2}\cdot 2x\cdot x + (x^2+y^2+z^2)^{(n-1)/2}\\ &= (x^2+y^2+z^2)^{(n-3)/2}\left((n-1)x^2 + x^2 + y^2 + z^2\right) = (x^2+y^2+z^2)^{(n-3)/2}(nx^2+y^2+z^2)\end{aligned}$$

Similarly,

$$\frac{\partial F_2}{\partial y} = \frac{\partial}{\partial y}\left((x^2+y^2+z^2)^{(n-1)/2}y\right) = (x^2+y^2+z^2)^{(n-3)/2}(x^2+ny^2+z^2)$$

and

$$\frac{\partial F_3}{\partial z} = \frac{\partial}{\partial z}\left((x^2+y^2+z^2)^{(n-1)/2}z\right) = (x^2+y^2+z^2)^{(n-3)/2}(x^2+y^2+nz^2)$$

The divergence of $\mathbf{F}$ is the sum

$$\begin{aligned}\operatorname{div}(\mathbf{F}) &= (x^2+y^2+z^2)^{(n-3)/2} = (nx^2+y^2+z^2+x^2+ny^2+z^2+x^2+y^2+nz^2)\\ &= (x^2+y^2+z^2)^{(n-3)/2}(n+2)(x^2+y^2+z^2) = (n+2)(x^2+y^2+z^2)^{(n-1)/2} = (n+2)r^{n-1}\end{aligned}$$

(b) Let $\mathcal{W}$ denote the ball inside the sphere of radius R. We may apply the Divergence Theorem when the components of $\mathbf{F}$ in (1) are defined and have continuous derivatives in $\mathcal{W}$, that is, when $\frac{n-1}{2} \geq 0$ and $\frac{n-3}{2} \geq 0$ or when $n \geq 3$. In this case, we have

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(F)\, dV = \iiint_{\mathcal{W}} (n+2)r^{n-1}\, dV$$

We compute the triple integral by converting it to spherical coordinates. Since $r = \rho$, we obtain

$$\begin{aligned}\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} &= \int_0^{2\pi}\int_0^{\pi}\int_0^{R}(n+2)r^{n-1}\rho^2\sin\phi\, d\rho\, d\phi\, d\theta = 2\pi(n+2)\int_0^{\pi}\int_0^{R}\rho^{n+1}\sin\phi\, d\rho\, d\phi\\ &= 2\pi(n+2)\left(\int_0^R \rho^{n+1}d\rho\right)\left(\int_0^{\pi}\sin\phi\, d\phi\right) = 2\pi(n+2)\left(-\cos\phi\Big|_{\phi=0}^{\pi}\right)\int_0^R\rho^{n+1}d\rho\\ &= 4\pi(n+2)\int_0^R\rho^{n+1}\, d\rho = 4\pi(n+2)\frac{\rho^{n+2}}{n+2}\Big|_{\rho=0}^{R} = 4\pi(n+2)\frac{R^{n+2}}{n+2} = 4\pi R^{n+2}\end{aligned}$$

That is,

$$\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S} = 4\pi R^{n+2}, \quad n \geq 3.$$

We now consider the case $n < 3$. We evaluate the surface integral directly, using the parametrization, $\Phi(\theta, \phi) = (R\cos\theta\sin\phi,\, R\sin\theta\sin\phi,\, R\cos\phi)$, $0 \leq \theta \leq 2\pi$, $0 \leq \phi \leq \pi$.

$$\mathbf{n} = R^2\sin\phi\mathbf{e}_r$$

Then,

$$\begin{aligned}\mathbf{F}\left(\Phi(\theta,\phi)\right)\cdot\mathbf{n} &= r^n\mathbf{e}_r\cdot R^2\sin\phi\mathbf{e}_r = \rho^n R^2\sin\phi\\ &= R^2\sin\phi\left(R^2\cos^2\theta\sin^2\phi + R^2\sin^2\theta\sin^2\phi + R^2\cos^2\phi\right)^{n/2} = R^{n+2}\sin\phi\end{aligned}$$

Hence,

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^{\pi} R^{n+2} \sin\phi \, d\phi \, d\theta = 2\pi R^{n+2} \left(-\cos\phi \Big|_0^{\pi} \right) = 4\pi R^{n+2}$$

We conclude that, for all values of n,

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = 4\pi R^{n+2}$$

The flux is independent of R when $n + 2 = 0$ or $n = -2$.

(c) We compute the gradient of r^n. We first compute the partial derivatives,

$$\frac{\partial r}{\partial x} = \frac{\partial}{\partial x}(x^2 + y^2 + z^2)^{1/2} = \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2} \cdot 2x = \frac{x}{(x^2 + y^2 + z^2)^{1/2}} = \frac{x}{r} \qquad (2)$$

Similarly,

$$\frac{\partial r}{\partial y} = \frac{y}{r} \quad \text{and} \quad \frac{\partial r}{\partial z} = \frac{z}{r}$$

Therefore,

$$\frac{\partial}{\partial x}(r^n) = nr^{n-1} \frac{\partial r}{\partial x} = nr^{n-1} \cdot \frac{x}{r} = nr^{n-2} x$$
$$\frac{\partial}{\partial y}(r^n) = nr^{n-1} \frac{\partial r}{\partial y} = nr^{n-1} \cdot \frac{y}{r} = nr^{n-2} y$$
$$\frac{\partial}{\partial z}(r^n) = nr^{n-1} \frac{\partial r}{\partial z} = nr^{n-1} \cdot \frac{z}{r} = nr^{n-2} z$$

The gradient of r^n is thus

$$\nabla(r^n) = \left\langle nr^{n-2}x, nr^{n-2}y, nr^{n-2}z \right\rangle = nr^{n-2} \langle x, y, z \rangle = nr^{n-1} \cdot r^{-1} \langle x, y, z \rangle = nr^{n-1} \mathbf{e}_r$$

(d) Replacing n by $n + 1$ in the equality of part (c), we have

$$\nabla(r^{n+1}) = (n+1) r^n \mathbf{e}_r = (n+1)\mathbf{F}$$

Therefore, if $n \neq -1$, then

$$\mathbf{F} = \nabla \left(\frac{r^{n+1}}{n+1} \right)$$

We now show that $\mathbf{F} = r^{-1}\mathbf{e}_r$ is also conservative. We compute the gradient of $\ln r$. Using the Chain Rule and the partial derivatives (1), we have

$$\frac{\partial}{\partial x}(\ln r) = \frac{1}{r} \frac{\partial r}{\partial x} = \frac{1}{r} \frac{x}{r} = \frac{x}{r^2}$$
$$\frac{\partial}{\partial y}(\ln r) = \frac{1}{r} \frac{\partial r}{\partial y} = \frac{1}{r} \frac{y}{r} = \frac{y}{r^2}$$
$$\frac{\partial}{\partial z}(\ln r) = \frac{1}{r} \frac{\partial r}{\partial z} = \frac{1}{r} \frac{z}{r} = \frac{z}{r^2}$$

Therefore, the gradient of $\ln r$ is

$$\nabla(\ln r) = \left\langle \frac{x}{r^2}, \frac{y}{r^2}, \frac{z}{r^2} \right\rangle = r^{-1} \cdot r^{-1} \langle x, y, z \rangle = r^{-1}\mathbf{e}_r = \mathbf{F}.$$

We conclude that $\mathbf{F}$ is conservative for all values of n.

(e) Since $\mathbf{F}$ is conservative, the line integral of $\mathbf{F}$ is zero over every closed curve in the domain of $\mathbf{F}$, that is, over every closed curve not passing through the origin.

(f) Using Exercise 37 part (b), $\varphi = r^n$ is harmonic if and only if

$$\operatorname{div}\left(\nabla(r^n)\right) = 0$$

That is, by part (c),

$$\operatorname{div}(nr^{n-1}\mathbf{e}_r) = n \operatorname{div}\left(r^{n-1}\mathbf{e}_r\right) = 0$$

or

$$\operatorname{div}(r^{n-1}\mathbf{e}_r) = 0 \quad \text{or} \quad n = 0$$

Using part (a) for n replaced by $n-1$, we have

$$\operatorname{div}(r^{n-1}\mathbf{e}_r) = (n+1)r^{n-2} = 0 \quad \Rightarrow \quad n = -1 \quad \text{or} \quad n = 0.$$

We conclude that $\varphi = r^n$ is harmonic for $n = -1$ or $n = 0$.

Further Insights and Challenges

39. Let $\mathcal{S}$ be the boundary surface of a region $\mathcal{W}$ in $\mathbf{R}^3$ and let $D_{\mathbf{e_n}}\varphi$ denote the directional derivative of φ, where $\mathbf{e_n}$ is the outward unit normal vector. Let Δ be the Laplace operator defined earlier.

(a) Use the Divergence Theorem to prove that

$$\iint_{\mathcal{S}} D_{\mathbf{e_n}}\varphi \, dS = \iiint_{\mathcal{W}} \Delta\varphi \, dV$$

(b) Show that if φ is a harmonic function (defined in Exercise 37), then

$$\iint_{\mathcal{S}} D_{\mathbf{e_n}}\varphi \, dS = 0$$

SOLUTION

(a) By the theorem on evaluating directional derivatives, $D_{\mathbf{e}_n}\varphi = \nabla\varphi \cdot \mathbf{e}_n$, hence,

$$\iint_{\mathcal{S}} D_{\mathbf{e}_n}\varphi \, dS = \iint_{\mathcal{S}} \nabla\varphi \cdot \mathbf{e}_n \, dS \tag{1}$$

By the definition of the vector surface integral, we have

$$\iint_{\mathcal{S}} \nabla\varphi \cdot d\mathbf{S} = \iint_{\mathcal{S}} (\nabla\varphi \cdot \mathbf{e}_n) \, dS$$

Combining with (1) gives

$$\iint_{\mathcal{S}} D_{\mathbf{e}_n}\varphi \, dS = \iint_{\mathcal{S}} \nabla\varphi \cdot d\mathbf{S}$$

We now apply the Divergence Theorem and the identity $\operatorname{div}(\nabla\varphi) = \Delta\varphi$ shown in part (a) of Exercise 27, to write

$$\iint_{\mathcal{S}} D_{\mathbf{e}_n}\varphi \, dS = \iint_{\mathcal{S}} \nabla\varphi \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\nabla\varphi) \, dV = \iiint_{\mathcal{W}} \Delta\varphi \, dV$$

(b) If φ is harmonic, then $\Delta\varphi = 0$; therefore, by the equality of part (a) we have

$$\iint_{\mathcal{S}} D_{\mathbf{e}_n}\varphi \, dS = \iiint_{\mathcal{W}} \Delta\varphi \cdot \, dV = \iiint_{\mathcal{W}} 0 \, dV = 0.$$

40. Assume that φ is harmonic. Show that $\operatorname{div}(\varphi\nabla\varphi) = \|\nabla\varphi\|^2$ and conclude that

$$\iint_{\mathcal{S}} \varphi D_{\mathbf{e_n}}\varphi \, dS = \iiint_{\mathcal{W}} \|\nabla\varphi\|^2 \, dV$$

SOLUTION In Exercise 33 we proved the following Product Rule:

$$\operatorname{div}(f\mathbf{F}) = \nabla f \cdot \mathbf{F} + f \operatorname{div}(\mathbf{F})$$

We use this rule for $f = \varphi$ and $\mathbf{F} = \nabla\varphi$ to obtain

$$\operatorname{div}(\varphi\nabla\varphi) = \nabla\varphi \cdot \nabla\varphi + \varphi \operatorname{div}(\nabla\varphi) = \|\nabla\varphi\|^2 + \varphi \operatorname{div}(\nabla\varphi) \tag{1}$$

By Exercise 37 part (a),

$$\operatorname{div}(\nabla\varphi) = \Delta\varphi \tag{2}$$

Also, since φ is harmonic,

$$\Delta\varphi = 0 \tag{3}$$

Combining (1), (2), and (3), we obtain

$$\operatorname{div}(\varphi\nabla\varphi) = \|\nabla\varphi\|^2 + \varphi\cdot 0 = \|\nabla\varphi\|^2 \tag{4}$$

Now, by the Theorem on evaluating directional derivatives,

$$D_{\mathbf{e}_n}\varphi = \nabla\varphi\cdot\mathbf{e}_n$$

Hence,

$$\iint_{\mathcal{S}} \varphi D_{\mathbf{e}_n}\varphi\, dS = \iint_{\mathcal{S}} (\varphi\nabla\varphi\cdot\mathbf{e}_n)\, dS \tag{5}$$

By the definition of the vector surface integral we have

$$\iint_{\mathcal{S}} \varphi\nabla\varphi\cdot d\mathbf{S} = \iint_{\mathcal{S}} (\varphi\nabla\varphi\cdot\mathbf{e}_n)\, dS \tag{6}$$

Combining (5) and (6) and using the Divergence Theorem and equality (4), we get

$$\iint_{\mathcal{S}} \varphi D_{\mathbf{e}_n}\varphi\, dS = \iint_{\mathcal{S}} \varphi\nabla\varphi\cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\varphi\nabla\varphi)\, dV = \iiint_{\mathcal{W}} \|\nabla\varphi\|^2\, dV$$

41. Let $\mathbf{F} = \langle P, Q, R\rangle$ be a vector field defined on $\mathbf{R}^3$ such that $\operatorname{div}(\mathbf{F}) = 0$. Use the following steps to show that $\mathbf{F}$ has a vector potential.

(a) Let $\mathbf{A} = \langle f, 0, g\rangle$. Show that

$$\operatorname{curl}(\mathbf{A}) = \left\langle \frac{\partial g}{\partial y}, \frac{\partial f}{\partial z} - \frac{\partial g}{\partial x}, -\frac{\partial f}{\partial y}\right\rangle$$

(b) Fix any value y_0 and show that if we define

$$f(x,y,z) = -\int_{y_0}^{y} R(x,t,z)\, dt + \alpha(x,z)$$
$$g(x,y,z) = \int_{y_0}^{y} P(x,t,z)\, dt + \beta(x,z)$$

where α and β are any functions of x and z, then $\partial g/\partial y = P$ and $-\partial f/\partial y = R$.

(c) It remains for us to show that α and β can be chosen so $Q = \partial f/\partial z - \partial g/\partial x$. Verify that the following choice works (for any choice of z_0):

$$\alpha(x,z) = \int_{z_0}^{z} Q(x, y_0, t)\, dt, \qquad \beta(x,z) = 0$$

Hint: You will need to use the relation $\operatorname{div}(\mathbf{F}) = 0$.

SOLUTION

(a) If $\mathbf{A} = \langle f, 0, g\rangle$, then the curl of $\mathbf{A}$ is the following vector field:

$$\operatorname{curl}(\mathbf{A}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ f & 0 & g \end{vmatrix} = \left(\frac{\partial g}{\partial y} - 0\right)\mathbf{i} - \left(\frac{\partial g}{\partial x} - \frac{\partial f}{\partial z}\right)\mathbf{j} + \left(0 - \frac{\partial f}{\partial y}\right)\mathbf{k} = \left\langle \frac{\partial g}{\partial y}, \frac{\partial f}{\partial z} - \frac{\partial g}{\partial x}, -\frac{\partial f}{\partial y}\right\rangle$$

(b) Using the Fundamental Theorem of Calculus, we have

$$\frac{\partial g}{\partial y}(x,y,z) = \frac{\partial}{\partial y}\int_{y_0}^{y} P(x,t,z)\, dt + \frac{\partial}{\partial y}\beta(x,z) = P(x,y,z) + 0 = P(x,y,z)$$
$$-\frac{\partial f}{\partial y}(x,y,z) = \frac{\partial}{\partial y}\int_{y_0}^{y} R(x,t,z)\, dt + \frac{\partial}{\partial y}\alpha(x,z) = R(x,y,z) + 0 = R(x,y,z)$$

(c) We verify that the functions

$$\alpha(x,z) = \int_{z_0}^{z} Q(x, y_0, t)\, dt, \quad \beta(x,z) = 0$$

satisfy the equality

$$Q = \frac{\partial f}{\partial z} - \frac{\partial g}{\partial x}$$

We differentiate to obtain

$$\frac{\partial f}{\partial z} - \frac{\partial g}{\partial x} = -\int_{y_0}^{y} R_z(x,t,z)\,dt + \alpha_z(x,z) - \int_{y_0}^{y} P_x(x,t,z)\,dz - \beta_x(x,z)$$
$$= -\int_{y_0}^{y} \left(P_x(x,t,z) + R_z(x,t,z)\right)\,dt + \alpha_z(x,z) \qquad (1)$$

By the Fundamental Theorem of Calculus,

$$\alpha_z(x,z) = \frac{\partial}{\partial z}\int_{z_0}^{z} Q(x,y_0,t)\,dt = Q(x,y_0,z) \qquad (2)$$

Also, since $\operatorname{div}(\mathbf{F}) = 0$, we have

$$\operatorname{div}(\mathbf{F}) = P_x + Q_y + R_z = 0 \quad \Rightarrow \quad P_x + R_z = -Q_y \qquad (3)$$

Substituting (2) and (3) in (1) gives

$$\frac{\partial f}{\partial z} - \frac{\partial g}{\partial x} = \int_{y_0}^{y} Q_y(x,t,z)\,dt + Q(x,y_0,z) = Q(x,y,z) - Q(x,y_0,z) + Q(x,y_0,z) = Q(x,y,z)$$

Parts (a)–(c) prove that $\mathbf{F} = \operatorname{curl}(\mathbf{A})$, or $\mathbf{A}$ is a vector potential for $\mathbf{F}$.

42. Show that

$$\mathbf{F} = \left\langle 2y - 1, 3z^2, 2xy \right\rangle$$

has a vector potential and find one.

SOLUTION Since $\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(2y-1) + \frac{\partial}{\partial y}(3z^2) + \frac{\partial}{\partial z}(2xy) = 0$, we know by Exercise 41 that $\mathbf{F}$ has a vector potential $\mathbf{A}$, which is

$$\mathbf{A} = \langle f, 0, g \rangle \qquad (1)$$
$$f(x,y,z) = -\int_{y_0}^{y} R(x,t,z)\,dt + \int_{z_0}^{z} Q(x,y_0,t)\,dt$$
$$g(x,y,z) = \int_{y_0}^{y} P(x,t,z)\,dt$$

Hence, $P(x,y,z) = 2y - 1$, $Q(x,y,z) = 3z^2$, and $R(x,y,z) = 2xy$. We choose $z_0 = y_0 = 0$ and find f and g:

$$f(x,y,z) = -\int_0^y 2xt\,dt + \int_0^z 3t^2\,dt = -xt^2\Big|_{t=0}^{y} + t^3\Big|_{t=0}^{z} = -xy^2 + z^3$$
$$g(x,y,z) = \int_0^y (2t-1)\,dt = t^2 - t\Big|_{t=0}^{y} = y^2 - y$$

Substituting in (1) we obtain the vector potential

$$\mathbf{A} = \left\langle z^3 - xy^2, 0, y^2 - y \right\rangle$$

43. Show that

$$\mathbf{F} = \left\langle 2ye^z - xy, y, yz - z \right\rangle$$

has a vector potential and find one.

SOLUTION As shown in Exercise 41, if $\mathbf{F}$ is divergence free, then $\mathbf{F}$ has a vector potential. We show that $\operatorname{div}(\mathbf{F}) = 0$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(2ye^z - xy) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(yz - z) = -y + 1 + y - 1 = 0$$

We find a vector potential $\mathbf{A}$, using the result in Exercise 41:

$$\mathbf{A} = \langle f, 0, g \rangle \qquad (1)$$

Using $z_0 = 0$, we have

$$f(x,y,z) = -\int_{y_0}^{y} R(x,t,z)\,dt + \int_0^z Q(x,y_0,t)\,dt$$

$$g(x, y, z) = \int_{y_0}^{y} P(x, t, z)\, dt$$

Hence, $P(x, y, z) = 2ye^z - xy$, $Q(x, y, z) = y$, and $R(x, y, z) = yz - z$. We choose $y_0 = 0$ and compute the functions f and g:

$$f(x, y, z) = -\int_0^y (tz - z)\, dt + \int_0^z 0\, dt = -\left(\frac{t^2 z}{2} - zt\right)\Bigg|_{t=0}^{y} = zy - \frac{y^2 z}{2} = z\left(y - \frac{y^2}{2}\right)$$

$$g(x, y, z) = \int_0^y (2te^z - xt)\, dt = t^2 e^z - \frac{xt^2}{2}\Bigg|_{t=0}^{y} = y^2 e^z - \frac{xy^2}{2} = y^2\left(e^z - \frac{x}{2}\right)$$

Substituting in (1) we obtain

$$\mathbf{A} = \left\langle z\left(y - \frac{y^2}{2}\right), 0, y^2\left(e^z - \frac{x}{2}\right)\right\rangle$$

44. In the text, we observed that although the inverse-square radial vector field $\mathbf{F} = \frac{\mathbf{e}_r}{r^2}$ satisfies $\mathrm{div}(\mathbf{F}) = 0$, $\mathbf{F}$ cannot have a vector potential on its domain $\{(x, y, z) \neq (0, 0, 0)\}$ because the flux of $\mathbf{F}$ through a sphere containing the origin is nonzero.

(a) Show that the method of Exercise 41 produces a vector potential $\mathbf{A}$ such that $\mathbf{F} = \mathrm{curl}(\mathbf{A})$ on the restricted domain $\mathcal{D}$ consisting of $\mathbf{R}^3$ with the y-axis removed.

(b) Show that $\mathbf{F}$ also has a vector potential on the domains obtained by removing either the x-axis or the z-axis from $\mathbf{R}^3$.

(c) Does the existence of a vector potential on these restricted domains contradict the fact that the flux of $\mathbf{F}$ through a sphere containing the origin is nonzero?

SOLUTION

(a) We have $\mathbf{F}(x, y, z) = \frac{\mathbf{e}_r}{r^2} = \frac{\langle x,y,z\rangle}{(x^2+y^2+z^2)^{3/2}}$, hence

$$P(x, y, z) = \frac{x}{(x^2 + y^2 + z^2)^{3/2}}$$

$$Q(x, y, z) = \frac{y}{(x^2 + y^2 + z^2)^{3/2}}$$

$$R(x, y, z) = \frac{z}{(x^2 + y^2 + z^2)^{3/2}}$$

In Exercise 41, we defined the functions (taking $y_0 = z_0 = 0$)

$$f(x, y, z) = -\int_0^y \frac{z}{(x^2 + t^2 + z^2)^{3/2}} dt + \int_0^z Q(x, 0, t)\, dt = -\int_0^y \frac{z}{(x^2 + t^2 + z^2)^{3/2}} dt$$

$$g(x, y, z) = \int_0^y \frac{x}{(x^2 + t^2 + z^2)^{3/2}} dt$$

We obtain

$$f(x, y, z) = -\frac{yz}{(x^2 + z^2)(x^2 + y^2 + z^2)^{1/2}}$$

$$g(x, y, z) = \frac{xy}{(x^2 + z^2)(x^2 + y^2 + z^2)^{1/2}}$$

We can check directly that $\mathbf{A} = \langle f, 0, g\rangle$ is a vector potential, without using the FTC.

These functions are defined for $(x, z) \neq (0, 0)$, since the points with $x = 0$ and $z = 0$ are on the y-axis. (Notice that for any fixed $(x, z) \neq (0, 0)$ the interval of integration do not intersect the y-axis, therefore they are contained in the domain $\mathcal{D}$.) For $(x, z) \neq (0, 0)$ we have by the Fundamental Theorem of Calculus

$$\frac{\partial g}{\partial y} = \frac{\partial}{\partial y}\int_0^y \frac{x}{(x^2 + t^2 + z^2)^{3/2}} dt = \frac{x}{(x^2 + y^2 + z^2)^{3/2}} = P(x, y, z)$$

$$\frac{\partial f}{\partial z} - \frac{\partial g}{\partial x} = -\int_0^y \frac{(x^2 + t^2 + z^2)^{3/2} - z \cdot \frac{3}{2}(x^2 + t^2 + z^2)^{1/2} \cdot 2z}{(x^2 + t^2 + z^2)^3} dt$$

$$-\int_0^y \frac{(x^2 + t^2 + z^2)^{3/2} - x \cdot \frac{3}{2}(x^2 + t^2 + z^2)^{1/2} \cdot 2x}{(x^2 + t^2 + z^2)^3} dt$$

$$= -\int_0^y \frac{(x^2+t^2+z^2)^{1/2}(x^2+t^2+z^2-3z^2)}{(x^2+t^2+z^2)^3}\,dt$$

$$-\int_0^y \frac{(x^2+t^2+z^2)^{1/2}(x^2+t^2+z^2-3x^2)}{(x^2+t^2+z^2)^3}\,dt$$

$$= -\int_0^y \frac{x^2+t^2-2z^2+t^2+z^2-2x^2}{(x^2+t^2+z^2)^{5/2}}\,dt$$

$$= \int_0^y \frac{x^2-2t^2+z^2}{(x^2+t^2+z^2)^{5/2}}\,dt = \frac{y}{(x^2+y^2+z^2)^{3/2}} = Q(x,y,z)$$

The last integral can be verified by showing that

$$\frac{\partial}{\partial y}\left(\frac{y}{(x^2+y^2+z^2)^{3/2}}\right) = \frac{x^2-2y^2+z^2}{(x^2+y^2+z^2)^{5/2}}$$

and

$$\frac{\partial f}{\partial y} = -\frac{\partial}{\partial y}\int_0^y \frac{z}{(x^2+t^2+z^2)^{3/2}}\,dt = -\frac{z}{(x^2+y^2+z^2)^{3/2}} = -R(x,y,z)$$

We conclude that the vector $\mathbf{A} = \langle f, 0, g\rangle$ is a vector potential of $\mathbf{F}$ in $\mathcal{D}$, since

$$\operatorname{curl}(\mathbf{A}) = \left\langle \frac{\partial g}{\partial y}, \frac{\partial f}{\partial z} - \frac{\partial g}{\partial x}, -\frac{\partial f}{\partial y}\right\rangle = \langle P, Q, R\rangle = \mathbf{F}.$$

(b) Suppose we remove the x-axis. In this case, we let

$$\mathbf{A} = \langle 0, f, g\rangle$$

$$g(x,y,z) = -\int_{x_0}^x Q(t,y,z)\,dt + \int_{y_0}^y P(x_0,t,z)\,dt$$

$$f(x,y,z) = \int_{x_0}^x R(t,y,z)\,dt$$

Using similar procedure to that in Exercise 41, one can show that

$$\mathbf{F} = \operatorname{curl}(\mathbf{A}).$$

In removing the z-axis the proof is similar, with corresponding modifications of the functions in Exercise 41.
(c) The ball inside any sphere containing the origin must intersect the x, y, and z axes; therefore, $\mathbf{F}$ does not have a vector potential in the ball, and the flux of $\mathbf{F}$ through the sphere may differ from zero, as in our example.

CHAPTER REVIEW EXERCISES

1. Let $\mathbf{F}(x,y) = \langle x+y^2, x^2-y\rangle$ and let $\mathcal{C}$ be the unit circle, oriented counterclockwise. Evaluate $\oint_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s}$ directly as a line integral and using Green's Theorem.

SOLUTION We parametrize the unit circle by $\mathbf{c}(t) = (\cos t, \sin t)$, $0 \le t \le 2\pi$. Then, $\mathbf{c}'(t) = \langle -\sin t, \cos t\rangle$ and $\mathbf{F}(\mathbf{c}(t)) = (\cos t + \sin^2 t, \cos^2 t - \sin t)$. We compute the dot product:

$$\mathbf{F}(\mathbf{c}(t))\cdot\mathbf{c}'(t) = \left\langle \cos t + \sin^2 t, \cos^2 t - \sin t\right\rangle \cdot \langle -\sin t, \cos t\rangle$$
$$= (-\sin t)(\cos t + \sin^2 t) + \cos t(\cos^2 t - \sin t)$$
$$= \cos^3 t - \sin^3 t - 2\sin t\cos t$$

The line integral is thus

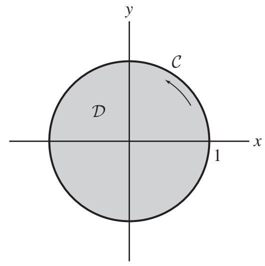
$$\int_{\mathcal{C}} \mathbf{F}(\mathbf{c}(t))\cdot\mathbf{c}'(t)\,dt = \int_0^{2\pi}\left(\cos^3 t - \sin^3 t - 2\sin t\cos t\right)dt$$
$$= \int_0^{2\pi}\cos^3 t\,dt - \int_0^{2\pi}\sin^3 t\,dt - \int_0^{2\pi}\sin 2t\,dt$$
$$= \frac{\cos^2 t\sin t}{3} + \frac{2\sin t}{3}\Big|_0^{2\pi} + \left(\frac{\sin^2 t\cos t}{3} + \frac{2\cos t}{3}\right)\Big|_0^{2\pi} + \frac{\cos 2t}{2}\Big|_0^{2\pi} = 0$$

We now compute the integral using Green's Theorem. We compute the curl of $\mathbf{F}$. Since $P = x + y^2$ and $Q = x^2 - y$, we have

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 2x - 2y$$

Thus,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{D}} (2x - 2y)\, dx\, dy$$



We compute the double integral by converting to polar coordinates. We get

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{2\pi} \int_0^1 (2r\cos\theta - 2r\sin\theta) r\, dr\, d\theta = \int_0^{2\pi} \int_0^1 2r^2(\cos\theta - \sin\theta)\, dr\, d\theta$$
$$= \left(\int_0^1 2r^2\, dr\right)\left(\int_0^{2\pi} (\cos\theta - \sin\theta)\, d\theta\right) = \left(\frac{2}{3}r^3\Big|_0^1\right)\left(\sin\theta + \cos\theta\Big|_0^{2\pi}\right) = \frac{2}{3}(1-1) = 0$$

2. Let $\partial\mathcal{R}$ be the boundary of the rectangle in Figure 1 and let $\partial\mathcal{R}_1$ and $\partial\mathcal{R}_2$ be the boundaries of the two triangles, all oriented counterclockwise.

(a) Determine $\oint_{\partial\mathcal{R}_1} \mathbf{F} \cdot d\mathbf{s}$ if $\oint_{\partial\mathcal{R}} \mathbf{F} \cdot d\mathbf{s} = 4$ and $\oint_{\partial\mathcal{R}_2} \mathbf{F} \cdot d\mathbf{s} = -2$.

(b) What is the value of $\oint_{\partial\mathcal{R}} \mathbf{F}\, d\mathbf{s}$ if $\partial\mathcal{R}$ is oriented clockwise?

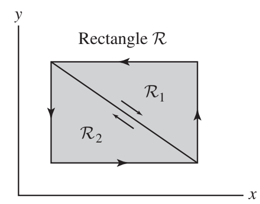


FIGURE 1

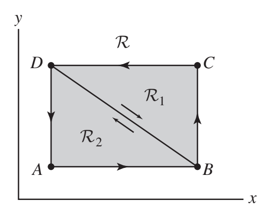
SOLUTION

(a) Since all boundaries are oriented counterclockwise, the segment $\overline{DB}$ is oriented in opposite directions as part of the boundaries ∂R_1 and ∂R_2.



Therefore, the contributions of this segment to the sum of the line integrals over ∂R_1 and ∂R_2 cancel each other and the following equality holds:

$$\int_{\partial R} \mathbf{F} \cdot d\mathbf{s} = \int_{\partial R_1} \mathbf{F} \cdot d\mathbf{s} + \int_{\partial R_2} \mathbf{F} \cdot d\mathbf{s}$$

Substituting the given information, we get

$$4 = \int_{\partial R_1} \mathbf{F} \cdot d\mathbf{s} - 2 \quad \text{or} \quad \int_{\partial R_1} \mathbf{F} \cdot d\mathbf{s} = 6.$$

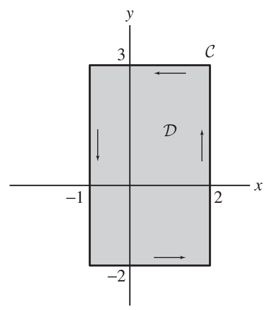
(b) Reversing the orientation of the curve gives the opposite integral. Therefore if ∂R is oriented clockwise, the line integral is the opposite of 4; that is,

$$\int_{\partial R} \mathbf{F} \cdot d\mathbf{s} = -4.$$

In Exercises 3–6, use Green's Theorem to evaluate the line integral around the given closed curve.

3. $\oint_{\mathcal{C}} xy^3\,dx + x^3y\,dy$, where $\mathcal{C}$ is the rectangle $-1 \le x \le 2$, $-2 \le y \le 3$, oriented counterclockwise.

SOLUTION



Since $P = xy^3$, $Q = x^3y$ the curl of $\mathbf{F}$ is

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 3x^2y - 3xy^2$$

By Green's Theorem we obtain

$$\int_{\mathcal{C}} xy^3\,dx + x^3y\,dy = \iint_{\mathcal{D}} (3x^2y - 3xy^2)\,dx\,dy = \int_{-2}^{3}\int_{-1}^{2} (3x^2y - 3xy^2)\,dx\,dy$$

$$= \int_{-2}^{3} x^3y - \frac{3x^2y^2}{2}\bigg|_{x=-1}^{2} dy = \int_{-2}^{3} \left((8y - 6y^2) - \left(-y - \frac{3y^2}{2}\right)\right) dy$$

$$= \int_{-2}^{3} \left(-\frac{9y^2}{2} + 9y\right) dy = -\frac{3y^3}{2} + \frac{9y^2}{2}\bigg|_{-2}^{3} = \left(-\frac{81}{2} + \frac{81}{2}\right) - (12 + 18) = -30$$

4. $\oint_{\mathcal{C}} (3x + 5y - \cos y)\,dx + x \sin y\,dy$, where $\mathcal{C}$ is any closed curve enclosing a region with area 4, oriented counterclockwise.

SOLUTION The components of $\mathbf{F}$ are $P = 3x + 5y - \cos y$ and $Q = x \sin y$. Therefore the curl of $\mathbf{F}$ is

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = \sin y - (5 + \sin y) = -5$$

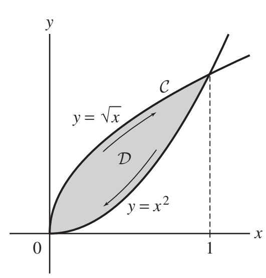
Using Green's Theorem we obtain

$$\int_{\mathcal{C}} P\,dx + Q\,dy = \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dA = \iint_{\mathcal{D}} (-5)\,dA$$

$$= -5 \iint_{\mathcal{D}} 1 \cdot dA = 5\text{Area}(A) = -5 \cdot 4 = -20$$

5. $\oint_{\mathcal{C}} y^2\,dx - x^2\,dy$, where $\mathcal{C}$ consists of the arcs $y = x^2$ and $y = \sqrt{x}$, $0 \le x \le 1$, oriented clockwise.

SOLUTION We compute the curl of $\mathbf{F}$.



We have $P = y^2$ and $Q = -x^2$, hence

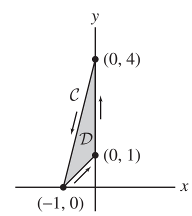
$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = -2x - 2y$$

We now compute the line integral using Green's Theorem. Since the curve is oriented clockwise, we consider the negative of the double integrals. We get

$$\begin{aligned}\int_{\mathcal{C}} y^2\,dx - x^2\,dy &= -\iint_{\mathcal{D}} (-2x-2y)\,dA = -\int_0^1 \int_{x^2}^{\sqrt{x}} (-2x-2y)\,dy\,dx \\ &= \int_0^1 2xy + y^2\Big|_{y=x^2}^{\sqrt{x}} dx = \int_0^1 \left(\left(2x\sqrt{x}+x\right) - (2x\cdot x^2 + x^4)\right) dx \\ &= \int_0^1 (-x^4 - 2x^3 + 2x^{3/2} + x)\,dx = -\frac{x^5}{5} - \frac{x^4}{2} + \frac{4x^{5/2}}{5} + \frac{x^2}{2}\Big|_0^1 \\ &= -\frac{1}{5} - \frac{1}{2} + \frac{4}{5} + \frac{1}{2} = \frac{3}{5}\end{aligned}$$

6. $\oint_{\mathcal{C}} ye^x\,dx + xe^y\,dy$, where $\mathcal{C}$ is the triangle with vertices $(-1, 0)$, $(0, 4)$, and $(0, 1)$, oriented counterclockwise.

SOLUTION

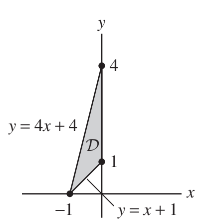


The components of the vector field are $P = ye^x$ and $Q = xe^y$, hence the flux is

$$\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = e^y - e^x.$$

Green's Theorem implies that

$$\begin{aligned}\int_{\mathcal{C}_0} ye^x\,dx + xe^y\,dy &= \iint_{\mathcal{D}} \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dA = \iint_{\mathcal{D}} (e^y - e^x)\,dA \\ &= \int_{-1}^0 \int_{x+1}^{4x+4} (e^y - e^x)\,dy\,dx = \int_{-1}^0 e^y - ye^x\Big|_{y=x+1}^{4x+4} dx \\ &= \int_{-1}^0 \left(\left(e^{4x+4} - (4x+4)e^x\right) - \left(e^{x+1} - (x+1)e^x\right)\right) dx \\ &= \int_{-1}^0 \left(e^{4x+4} - e^{x+1} - (3x+3)e^x\right) dx \\ &= \int_{-1}^0 (e^{4x+4} - e^{x+1} - 3e^x)\,dx - \int_{-1}^0 3xe^x\,dx\end{aligned}$$



The second integral is computed by parts. We obtain

$$\int_{\mathcal{C}} ye^x\,dx + xe^y\,dy = \frac{e^{4x+4}}{4} - e^{x+1} - 3e^x\Big|_{-1}^0 - 3e^x(x-1)\Big|_{-1}^0$$

$$= \left(\frac{e^4}{4} - e - 3\right) - \left(\frac{1}{4} - 1 - 3e^{-1}\right) - (-3 + 6e^{-1})$$

$$= \frac{e^4}{4} - e + \frac{3}{4} - 3e^{-1} \approx 10.58$$

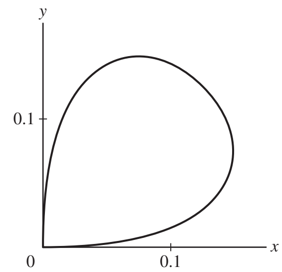
7. Let $\mathbf{c}(t) = \left(t^2(1-t), t(t-1)^2\right)$.

(a) $\boxed{\text{GU}}$ Plot the path $\mathbf{c}(t)$ for $0 \le t \le 1$.

(b) Calculate the area A of the region enclosed by $\mathbf{c}(t)$ for $0 \le t \le 1$ using the formula $A = \frac{1}{2}\oint_{\mathcal{C}} (x\,dy - y\,dx)$.

SOLUTION

(a) The path $\mathbf{c}(t)$ for $0 \le t \le 1$ is shown in the figure:



Note that the path is traced out clockwise as t goes from 0 to 1.

(b) We use the formula for the area enclosed by a closed curve,

$$A = \frac{1}{2}\int_{\mathcal{C}} (x\,dy - y\,dx)$$

We compute the line integral. Since $x = t^2(1-t)$ and $y = t(t-1)^2$, we have

$$dx = \left(2t(1-t) - t^2\right)\,dt = \left(2t - 3t^2\right)\,dt$$

$$dy = (t-1)^2 + t \cdot 2(t-1) = (t-1)(3t-1)\,dt$$

Therefore,

$$x\,dy - y\,dx = t^2(1-t)\cdot(t-1)(3t-1)\,dt - t(t-1)^2\cdot(2t-3t^2)\,dt = t^2(t-1)^2\,dt$$

We obtain the following integral (note that the path must be counterclockwise):

$$A = \frac{1}{2}\int_1^0 -t^2(t-1)^2\,dt = \frac{1}{2}\int_0^1 (t^4 - 2t^3 + t^2)\,dt = \frac{1}{2}\left(\frac{t^5}{5} - \frac{t^4}{2} + \frac{t^3}{3}\Big|_0^1\right) = \frac{1}{60}$$

8. In (a)–(d), state whether the equation is an identity (valid for all $\mathbf{F}$ or V). If it is not, provide an example in which the equation does not hold.

(a) $\mathrm{curl}(\nabla V) = 0$

(b) $\mathrm{div}(\nabla V) = 0$

(c) $\mathrm{div}(\mathrm{curl}(\mathbf{F})) = 0$

(d) $\nabla(\mathrm{div}(\mathbf{F})) = 0$

SOLUTION

(a) This equality is valid for all V since

$$\nabla V = \left\langle V_x, V_y, V_z\right\rangle$$

$$\mathrm{curl}(\nabla V) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ V_x & V_y & V_z \end{vmatrix} = (V_{zy} - V_{yz})\mathbf{i} - (V_{zx} - V_{xz})\mathbf{j} - (V_{yx} - V_{xy})\mathbf{k}$$

By the equality of the mixed partials, we conclude that $\mathrm{curl}(\nabla\varphi)$ is the zero vector.

(b) This equation is not an identity. Take $V(x, y, z) = x^2 + y + z$. Then $\nabla V = \langle 2x, 1, 1\rangle$ and

$$\mathrm{div}(\nabla V) = \frac{\partial}{\partial x}(2x) + \frac{\partial}{\partial y}(1) + \frac{\partial}{\partial z}(1) = 2 + 0 + 0 = 2 \ne 0.$$

(c) The equality div (curl($\mathbf{F}$)) = 0 is an identity. To prove it, we let $\mathbf{F} = \langle P, Q, R\rangle$. Then

$$\text{curl}\mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ P & Q & R \end{vmatrix} = (R_y - Q_z)\mathbf{i} - (R_x - P_z)\mathbf{j} + (Q_x - P_y)\mathbf{k}$$

$$\begin{aligned}\text{div}\,(\text{curl}(\mathbf{F})) &= \frac{\partial}{\partial x}(R_y - Q_z) - \frac{\partial}{\partial y}(R_x - P_z) + \frac{\partial}{\partial z}(Q_x - P_y) \\ &= R_{yx} - Q_{zx} - (R_{xy} - P_{zy}) + Q_{xz} - P_{yz} \\ &= (R_{yx} - R_{xy}) + (P_{zy} - P_{yz}) + (Q_{xz} - Q_{zx}) = 0\end{aligned}$$

The last equality is due the equality of the mixed partials.

(d) The equality $\nabla\,(\text{div}(\mathbf{F})) = \mathbf{0}$ is not an identity. Take $\mathbf{F} = \left\langle x^2, y, z\right\rangle$. Then

$$\text{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x^2) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = 2x + 2$$

$$\nabla\,(\text{div}(\mathbf{F})) = \left\langle \frac{\partial}{\partial x}(2x+2), \frac{\partial}{\partial y}(2x+2), \frac{\partial}{\partial z}(2x+2)\right\rangle = \langle 2, 0, 0\rangle \neq \mathbf{0}$$

In Exercises 9–12, calculate the curl and divergence of the vector field.

9. $\mathbf{F} = y\mathbf{i} - z\mathbf{k}$

SOLUTION We compute the curl of the vector field,

$$\begin{aligned}\text{curl}(\mathbf{F}) &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & 0 & -z \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(-z) - \frac{\partial}{\partial z}(0)\right)\mathbf{i} - \left(\frac{\partial}{\partial x}(-z) - \frac{\partial}{\partial z}(y)\right)\mathbf{j} + \left(\frac{\partial(0)}{\partial x} - \frac{\partial(y)}{\partial y}\right)\mathbf{k} \\ &= 0\mathbf{i} + 0\mathbf{j} - 1\mathbf{k} = -\mathbf{k}\end{aligned}$$

The divergence of $\mathbf{F}$ is

$$\text{div}(\mathbf{F}) = \frac{\partial}{\partial x}(y) + \frac{\partial}{\partial y}(0) + \frac{\partial}{\partial z}(-z) = 0 + 0 - 1 = -1.$$

10. $\mathbf{F} = \left\langle e^{x+y}, e^{y+z}, xyz\right\rangle$

SOLUTION The curl of $\mathbf{F} = \left\langle e^{x+y}, e^{y+z}, xyz\right\rangle$ is the following vector:

$$\begin{aligned}\text{curl}(F) = \nabla \times \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ e^{x+y} & e^{y+z} & xyz \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(xyz) - \frac{\partial}{\partial z}e^{y+z}\right)\mathbf{i} - \left(\frac{\partial}{\partial x}(xyz) - \frac{\partial}{\partial z}e^{x+y}\right)\mathbf{j} + \left(\frac{\partial}{\partial x}e^{y+z} - \frac{\partial}{\partial y}e^{x+y}\right)\mathbf{k} \\ &= (xz - e^{y+z})\mathbf{i} - (yz)\mathbf{j} - e^{x+y}\mathbf{k} = \left\langle xz - e^{y+z}, -yz, -e^{x+y}\right\rangle\end{aligned}$$

The divergence of $\mathbf{F}$ is

$$\text{div}\mathbf{F} = \frac{\partial}{\partial x}(e^{x+y}) + \frac{\partial}{\partial y}(e^{y+z}) + \frac{\partial}{\partial z}(xyz) = e^{x+y} + e^{y+z} + xy.$$

11. $\mathbf{F} = \nabla(e^{-x^2-y^2-z^2})$

SOLUTION In Exercise 8 we proved the identity $\text{curl}(\nabla\varphi) = \mathbf{0}$. Here, $\varphi = e^{-x^2-y^2-z^2}$, and we have $\text{curl}\left(\nabla\left(e^{-x^2-y^2-z^2}\right)\right) = \mathbf{0}$. To compute div $\mathbf{F}$, we first write $\mathbf{F}$ explicitly:

$$\mathbf{F} = \nabla\left(e^{-x^2-y^2-z^2}\right) = \left\langle -2xe^{-x^2-y^2-z^2}, -2ye^{-x^2-y^2-z^2}, -2ze^{-x^2-y^2-z^2}\right\rangle = \langle P, Q, R\rangle$$

$$\begin{aligned}\operatorname{div}(\mathbf{F}) &= \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z} \\ &= \left(-2e^{-x^2-y^2-z^2} + 4x^2e^{-x^2-y^2-z^2}\right) + \left(-2e^{-x^2-y^2-z^2} + 4y^2e^{-x^2-y^2-z^2}\right) \\ &\quad + \left(-2e^{-x^2-y^2-z^2} + 4z^2e^{-x^2-y^2-z^2}\right) \\ &= 2e^{-x^2-y^2-z^2}\left(2(x^2+y^2+z^2) - 3\right)\end{aligned}$$

12. $\mathbf{e}_r = r^{-1}\langle x, y, z\rangle \ \left(r = \sqrt{x^2+y^2+z^2}\right)$

SOLUTION It can be easily verified that $\mathbf{e}_r = \nabla\varphi$ for $\varphi(x, y, z) = \sqrt{x^2+y^2+z^2} = r$. Therefore, by the identity $\operatorname{curl}(\nabla\varphi) = \mathbf{0}$ (provided in Exercise 8), we have

$$\operatorname{curl}(\mathbf{e}_r) = \operatorname{curl}(\nabla\varphi) = \mathbf{0}$$

We compute the divergence of $\mathbf{e}_r$. Since $r_x = \frac{x}{r}$, $r_y = \frac{y}{r}$, $r_z = \frac{z}{r}$, we have

$$\begin{aligned}\operatorname{div}(\mathbf{e}_r) &= \frac{\partial}{\partial x}(xr^{-1}) + \frac{\partial}{\partial y}(yr^{-1}) + \frac{\partial}{\partial z}(zr^{-1}) = (r^{-1} - xr^{-2}r_x) + (r^{-1} - yr^{-2}r_y) + (r^{-1} - zr^{-2}r_z) \\ &= 3r^{-1} - r^{-2}(xr_x + yr_y + zr_z) = 3r^{-1} - r^{-2}\left(\frac{x^2}{r} + \frac{y^2}{r} + \frac{z^2}{r}\right) = 3r^{-1} - r^{-2}\cdot\frac{r^2}{r} = 2r^{-1}\end{aligned}$$

13. Recall that if F_1, F_2, and F_3 are differentiable functions of one variable, then

$$\operatorname{curl}\left(\langle F_1(x), F_2(y), F_3(z)\rangle\right) = \mathbf{0}$$

Use this to calculate the curl of

$$\mathbf{F} = \left\langle x^2+y^2, \ln y + z^2, z^3\sin(z^2)e^{z^3}\right\rangle$$

SOLUTION We use the linearity of the curl and the property mentioned in the exercise to compute the curl of $\mathbf{F}$:

$$\begin{aligned}\operatorname{curl}\mathbf{F} &= \operatorname{curl}\left(\left\langle x^2+y^2, \ln y + z^2, z^3\sin\left(z^2\right)e^{z^3}\right\rangle\right) = \operatorname{curl}\left(\left\langle x^2, \ln y, z^3\sin(z^2)e^{z^3}\right\rangle\right) + \operatorname{curl}\left(\left\langle y^2, z^2, 0\right\rangle\right) \\ &= 0 + \operatorname{curl}\left\langle y^2, z^2, 0\right\rangle = \left\langle \frac{\partial}{\partial y}(0) - \frac{\partial}{\partial z}z^2, \frac{\partial}{\partial z}y^2 - \frac{\partial}{\partial x}(0), \frac{\partial}{\partial x}z^2 - \frac{\partial}{\partial y}y^2\right\rangle = \langle -2z, 0, -2y\rangle\end{aligned}$$

14. Give an example of a nonzero vector field $\mathbf{F}$ such that $\operatorname{curl}(\mathbf{F}) = \mathbf{0}$ and $\operatorname{div}(\mathbf{F}) = 0$.

SOLUTION Let $\mathbf{F} = \langle x, -y, 0\rangle$. Then

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x & -y & 0 \end{vmatrix} = \left(\frac{\partial}{\partial y}(0) + \frac{\partial}{\partial z}(y)\right)\mathbf{i} - \left(\frac{\partial}{\partial x}(0) - \frac{\partial}{\partial z}(x)\right)\mathbf{j} + \left(\frac{\partial}{\partial x}(-y) - \frac{\partial}{\partial y}(x)\right)\mathbf{k} = \mathbf{0}$$

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(-y) + \frac{\partial}{\partial z}(0) = 1 - 1 + 0 = 0$$

15. Verify the identities of Exercises 6 and 34 in Section 17.3 for the vector fields $\mathbf{F} = \left\langle xz, ye^x, yz\right\rangle$ and $\mathbf{G} = \left\langle z^2, xy^3, x^2y\right\rangle$.

SOLUTION We first show $\operatorname{div}(\operatorname{curl}(\mathbf{F})) = 0$. Let $\mathbf{F} = \langle P, Q, R\rangle = \left\langle xz, ye^x, yz\right\rangle$. We compute the curl of $\mathbf{F}$:

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ P & Q & R \end{vmatrix} = \left\langle \frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z}, \frac{\partial P}{\partial z} - \frac{\partial R}{\partial x}, \frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right\rangle$$

Substituting in the appropriate values for P, Q, R and taking derivatives, we get

$$\operatorname{curl}(\mathbf{F}) = \left\langle z - 0, x - 0, ye^x - 0\right\rangle$$

Thus,

$$\operatorname{div}\left(\operatorname{curl}(\mathbf{F})\right) = (z)_x + (x)_y + (ye^x)_z = 0 + 0 + 0 = 0.$$

Likewise, for $\mathbf{G} = \langle P, Q, R\rangle = \left\langle z^2, xy^3x^2y\right\rangle$, we compute the curl of $\mathbf{G}$:

$$\text{curl}(\mathbf{G}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ P & Q & R \end{vmatrix} = \left\langle \frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z}, \frac{\partial P}{\partial z} - \frac{\partial R}{\partial x}, \frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right\rangle$$

Substituting in the appropriate values for P, Q, R and taking derivatives, we get

$$\text{curl}(\mathbf{G}) = \left\langle x^2 - 0, 2z - 2xy, y^3 - 0\right\rangle$$

Thus,

$$\text{div}\,(\text{curl}(\mathbf{G})) = (x^2)_x + (2z - 2xy)_y + (y^3)_z = 2x - 2x = 0.$$

We now work on the second identity. For $\mathbf{F} = \langle xz, ye^x, yz\rangle$ and $\mathbf{G} = \langle z^2, xy^3, x^2y\rangle$, it is easy to calculate

$$\mathbf{F} \times \mathbf{G} = \langle x^2y^2e^x - xy^4z, yz^3 - x^3yz, x^2y^3z - yz^2e^x\rangle$$

Thus,

$$\text{div}(\mathbf{F} \times \mathbf{G}) = (2xy^2e^x + x^2y^2e^x - y^4z) + (z^3 - x^3z) + (x^2y^3 - 2yze^x)$$

On the other hand, from our work above,

$$\text{curl}(\mathbf{F}) = \langle z, x, ye^x\rangle$$
$$\text{curl}(\mathbf{G}) = \left\langle x^2, 2z - 2xy, y^3\right\rangle$$

So, we calculate

$$\begin{aligned} \mathbf{G} \cdot \text{curl}(\mathbf{F} - \mathbf{F}) \cdot \text{curl}(\mathbf{G}) &= z^2 \cdot z + xy^3 \cdot x + x^2y \cdot ye^x - xz \cdot x^2 - ye^x \cdot (2z - 2xy) - yz \cdot y^3 \\ &= z^3 + x^2y^3 + x^2y^2e^x + 2xy^2e^x - x^3z - 2yze^x - y^4z \\ &= (2xy^2e^x + x^2y^2e^x - y^4z) + (z^3 - x^3z) + (x^2y^3 - 2yze^x) = \text{div}(\mathbf{F} \times \mathbf{G}) \end{aligned}$$

16. Suppose that $\mathcal{S}_1$ and $\mathcal{S}_2$ are surfaces with the same oriented boundary curve $\mathcal{C}$. Which of the following conditions guarantees that the flux of $\mathbf{F}$ through $\mathcal{S}_1$ is equal to the flux of $\mathbf{F}$ through $\mathcal{S}_2$?

(i) $\mathbf{F} = \nabla V$ for some function V

(ii) $\mathbf{F} = \text{curl}(\mathbf{G})$ for some vector field $\mathbf{G}$

SOLUTION If $\mathbf{F} = \text{curl}(\mathbf{G})$, then by the Theorem on Surface Independence for Curl Vector Fields, the flux of $\mathbf{F}$ through a surface $\mathcal{S}$ depends only the oriented boundary $\partial\mathcal{S}$. Since $\mathcal{S}_1$ and $\mathcal{S}_2$ have the same oriented boundary curve, we conclude that the flux of $\mathbf{F}$ through $\mathcal{S}_1$ is equal to the flux of $\mathbf{F}$ through $\mathcal{S}_2$. The condition in (i) that $\mathbf{F}$ is conservative does not guarantee that the flux of $\mathbf{F}$ through $\mathcal{S}_1$ is equal to the flux through $\mathcal{S}_2$.

17. Prove that if $\mathbf{F}$ is a gradient vector field, then the flux of $\text{curl}(\mathbf{F})$ through a smooth surface $\mathcal{S}$ (whether closed or not) is equal to zero.

SOLUTION If $\mathbf{F}$ is a gradient vector field, then $\mathbf{F}$ is conservative; therefore the line integral of $\mathbf{F}$ over any closed curve is zero. Combining with Stokes' Theorem yields

$$\iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} = \int_{\partial\mathcal{S}} \mathbf{F} \cdot d\mathbf{s} = 0$$

18. Verify Stokes' Theorem for $\mathbf{F} = \langle y, z - x, 0\rangle$ and the surface $z = 4 - x^2 - y^2$, $z \geq 0$, oriented by outward-pointing normals.

SOLUTION We begin by computing the line integral $\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s}$. The boundary curve is the circle $x^2 + y^2 = 4$ (in the xy plane) oriented in the counterclockwise direction. We use the parametrization

$$\mathcal{C} : r(t) = (2\cos t, 2\sin t, 0), \quad 0 \leq t \leq 2\pi$$

Then,

$$\begin{aligned} \mathbf{F}\,(r(t)) &= \langle 2\sin t, -2\cos t, 0\rangle \\ r'(t) &= \langle -2\sin t, 2\cos t, 0\rangle \\ \mathbf{F}\,(r(t)) \cdot r'(t) &= \langle 2\sin t, -2\cos t, 0\rangle \cdot \langle -2\sin t, 2\cos t, 0\rangle = -4\sin^2 t - 4\cos^2 t = -4 \end{aligned}$$

The line integral is thus

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{2\pi} -4\,dt = -8\pi \tag{1}$$

We now compute the integral $\iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{S}$. We find the curl of $\mathbf{F}$:

$$\text{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & z-x & 0 \end{vmatrix} = \left(0 - \frac{\partial}{\partial z}(z-x)\right)\mathbf{i} - \left(0 - \frac{\partial}{\partial z}y\right)\mathbf{j} + \left(\frac{\partial}{\partial x}(z-x) - \frac{\partial}{\partial y}y\right)\mathbf{k}$$
$$= -\mathbf{i} - 2\mathbf{k} = \langle -1, 0, -2\rangle$$

We parametrized the surface by

$$\Phi(u,v) = \left(u\cos v, u\sin v, 4-u^2\right), \quad 0 \le v < 2\pi, \quad 0 \le u \le 2.$$

Then,

$$\mathbf{T}_u = \frac{\partial \Phi}{\partial u} = \langle \cos v, \sin v, -2u\rangle$$
$$\mathbf{T}_v = \frac{\partial \Phi}{\partial v} = \langle -u\sin v, u\cos v, 0\rangle$$
$$\mathbf{T}_u \times \mathbf{T}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos v & \sin v & -2u \\ -u\sin v & u\cos v & 0 \end{vmatrix} = (2u^2\cos v)\mathbf{i} + (2u^2\sin v)\mathbf{j} + (u\cos^2 v + u\sin^2 v)\mathbf{k}$$
$$= \left\langle 2u^2\cos v, 2u^2\sin v, u\right\rangle$$

The surface is oriented outwards, hence the z-component of the normal vector is nonnegative. Therefore, the normal vector is (recall that $u \ge 0$)

$$\mathbf{n} = \left\langle 2u^2\cos v, 2u^2\sin v, u\right\rangle$$

We compute the dot product:

$$\text{curl}(\mathbf{F}) \cdot \mathbf{n} = \langle -1, 0, -2\rangle \cdot \left\langle 2u^2\cos v, 2u^2\sin v, u\right\rangle = -2u^2\cos v - 2u$$

We obtain the following integral:

$$\iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot \mathbf{n}\,ds = \int_0^{2\pi}\int_0^2 (-2u^2\cos v - 2u)\,du\,dv = \int_0^{2\pi} \left.\frac{-2u^3\cos v}{3} - u^2\right|_{u=0}^2 dv$$
$$= \int_0^{2\pi} \left(\frac{-16\cos v}{3} - 4\right) dv = \left.\frac{-16\sin v}{3} - 4v\right|_0^{2\pi} = -8\pi \tag{2}$$

By (1) and (2), both the line integral and the flux of the curl are equal to -8π. Thus, this example verifies Stokes' Theorem.

19. Let $\mathbf{F} = \left\langle z^2, x+z, y^2\right\rangle$ and let $\mathcal{S}$ be the upper half of the ellipsoid

$$\frac{x^2}{4} + y^2 + z^2 = 1$$

oriented by outward-pointing normals. Use Stokes' Theorem to compute $\iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{S}$.

SOLUTION We compute the curl of $\mathbf{F} = \left\langle z^2, x+z, y^2\right\rangle$:

$$\text{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ z^2 & x+z & y^2 \end{vmatrix} = (2y-1)\mathbf{i} - (0-2z)\mathbf{j} + (1-0)\mathbf{k} = \langle 2y-1, 2z, 1\rangle$$

Let $\mathcal{C}$ denote the boundary of $\mathcal{S}$, that is, the ellipse $\frac{x^2}{4} + y^2 = 1$ in the xy-plane, oriented counterclockwise. Then by Stoke's Theorem we have

$$\iint_{\mathcal{S}} \text{curl}(\mathbf{F}) \cdot d\mathbf{S} = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \tag{1}$$

We parametrize $\mathcal{C}$ by

$$\mathcal{C}: r(t) = (2\cos t, \sin t, 0), \quad 0 \le t \le 2\pi$$

Then

$$\mathbf{F}(r(t)) \cdot r'(t) = \left\langle 0, 2\cos t, \sin^2 t \right\rangle \cdot \langle -2\sin t, \cos t, 0\rangle = 2\cos^2 t$$

Combining with (1) gives

$$\iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{s} = \int_0^{2\pi} 2\cos^2 t\, dt = t + \frac{\sin 2t}{2}\bigg|_0^{2\pi} = 2\pi$$

20. Use Stokes' Theorem to evaluate $\oint_{\mathcal{C}} \langle y, z, x\rangle \cdot d\mathbf{s}$, where $\mathcal{C}$ is the curve in Figure 2.

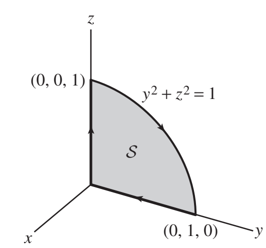


FIGURE 2

SOLUTION We compute the curl of $\mathbf{F} = \langle y, z, x\rangle$:

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & z & x \end{vmatrix} = -\mathbf{i} - \mathbf{j} - \mathbf{k} = \langle -1, -1, -1\rangle$$

By Stokes' Theorem, we have

$$\int_{\mathcal{C}} \langle y, z, x\rangle \cdot d\mathbf{s} = \iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} = \iint_{\mathcal{S}} (\operatorname{curl}(\mathbf{F}) \cdot \mathbf{e}_n)\, d\mathbf{S}$$

Since the boundary $\mathcal{C}$ of the quarter circle $\mathcal{S}$ is oriented clockwise, the induced orientation on $\mathcal{S}$ is normal pointing in the negative x direction. Thus,

$$\mathbf{e}_n = \langle -1, 0, 0\rangle.$$

Hence,

$$\operatorname{curl}(\mathbf{F}) \cdot \mathbf{e}_n = \langle -1, -1, -1\rangle \cdot \langle -1, 0, 0\rangle = 1.$$

Combining with (1) we get

$$\int_{\mathcal{C}} \langle y, z, x\rangle \cdot d\mathbf{s} = \iint_{\mathcal{S}} 1\, ds = \text{Area}(\mathcal{S}) = \frac{\pi}{4}$$

21. Let $\mathcal{S}$ be the side of the cylinder $x^2 + y^2 = 4$, $0 \le z \le 2$ (not including the top and bottom of the cylinder). Use Stokes' Theorem to compute the flux of $\mathbf{F} = \langle 0, y, -z\rangle$ through $\mathcal{S}$ (with outward pointing normal) by finding a vector potential $\mathbf{A}$ such that $\operatorname{curl}(\mathbf{A}) = \mathbf{F}$.

SOLUTION We can write $\mathbf{F} = \operatorname{curl}(\mathbf{A})$ where $\mathbf{A} = \langle yz, 0, 0\rangle$. The flux of $\mathbf{F}$ through $\mathcal{S}$ is equal to the line integral of A around the oriented boundary which consists of two circles of radius 2 with center on the z-axis (one at height $z = 0$ and one at height $z = 2$).

However, the line integrals of A about both circles are zero. This is clear for the circle at $z = 0$ because then $A = 0$, but it is also true at $z = 2$ because the vector field $A = \langle 2y, 0, 0\rangle$ integrates to zero around the circle.

22. Verify the Divergence Theorem for $\mathbf{F} = \langle 0, 0, z \rangle$ and the region $x^2 + y^2 + z^2 = 1$.

SOLUTION Let $\mathcal{S}$ be the boundary of the unit sphere $\mathcal{W}$. We calculate both sides of the equation:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV \tag{1}$$

We start with the surface integral. We parametrize $\mathcal{S}$ by

$$\Phi(\theta, \phi) = \langle \cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi \rangle, \quad 0 \le \theta < 2\pi, \quad 0 \le \phi \le \pi$$

Then (see Example 1 in Section 17.5)

$$\mathbf{n} = \sin\phi \langle \cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi \rangle$$

Hence,

$$\mathbf{F}(\Phi(\theta, \phi)) \cdot \mathbf{n} = \langle 0, 0, \cos\phi \rangle \cdot \sin\phi \langle \cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi \rangle = \cos^2\phi \sin\phi$$

We obtain the following integral:

$$\begin{aligned} \iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} &= \int_0^{2\pi} \int_0^{\pi} \mathbf{F}(\Phi(\theta, \phi)) \cdot \mathbf{n}\, d\phi\, d\theta = \int_0^{2\pi} \int_0^{\pi} \cos^2\phi \sin\phi\, d\phi\, d\theta \\ &= 2\pi \int_0^{\pi} \cos^2\phi \sin\phi\, d\phi = 2\pi \left(-\frac{\cos^3\phi}{3} \Big|_0^{\pi} \right) = 2\pi \left(\frac{1+1}{3} \right) = \frac{4\pi}{3} \end{aligned} \tag{2}$$

We now compute the triple integral in (1). We find the divergence of $\mathbf{F}$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(0) + \frac{\partial}{\partial y}(0) + \frac{\partial}{\partial z}(z) = 1$$

Hence,

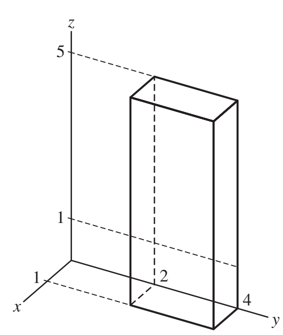
$$\iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F}) \cdot dV = \iiint_{\mathcal{W}} 1\, dV = \text{Volume}(\mathcal{W}) = \frac{4\pi}{3} \tag{3}$$

The integrals in (2) and (3) are equal, as follows from the Divergence Theorem.

In Exercises 23–26, use the Divergence Theorem to calculate $\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S}$ *for the given vector field and surface.*

23. $\mathbf{F} = \langle xy, yz, x^2z + z^2 \rangle$, $\mathcal{S}$ is the boundary of the box $[0, 1] \times [2, 4] \times [1, 5]$.

SOLUTION



We compute the divergence of $\mathbf{F} = \left\langle xy, yz, x^2z + z^2 \right\rangle$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x} xy + \frac{\partial}{\partial y} yz + \frac{\partial}{\partial z}(x^2z + z^2) = y + z + x^2 + 2z = x^2 + y + 3z$$

The Divergence Theorem gives

$$\begin{aligned} \iint_{\mathcal{S}} \left\langle xy, yz, x^2z + z^2 \right\rangle \cdot d\mathbf{S} &= \int_1^5 \int_2^4 \int_0^1 (x^2 + y + 3z)\, dx\, dy\, dz = \int_1^5 \int_2^4 \frac{x^3}{3} + (y + 3z)x \Big|_{x=0}^{1} dy\, dz \\ &= \int_1^5 \int_2^4 \left(\frac{1}{3} + y + 3z \right) dy\, dz = \int_1^5 \frac{1}{3}y + \frac{1}{2}y^2 + 3zy \Big|_{y=2}^{4} dz \end{aligned}$$

$$= \int_1^5 \left(\left(\frac{4}{3} + \frac{16}{2} + 12z \right) - \left(\frac{2}{3} + 2 + 6z \right) \right) dz = \int_1^5 \left(\frac{20}{3} + 6z \right) dz$$

$$= \frac{20z}{3} + \frac{3z^2}{2} \Big|_1^5 = \left(75 + \frac{100}{3} \right) - \left(3 + \frac{20}{3} \right) = \frac{296}{3}$$

24. $\mathbf{F} = \langle xy, yz, x^2z + z^2 \rangle$, $\mathcal{S}$ is the boundary of the unit sphere.

SOLUTION We use spherical coordinates:

$$x = \rho \cos\theta \sin\phi, \quad y = \rho \sin\theta \sin\phi, \quad z = \rho\cos\phi$$

with

$$0 \le \theta \le 2\pi, \quad 0 \le \phi \le \pi, \quad 0 \le \rho \le 1$$

We obtain

$$\iint_{\mathcal{S}} \left\langle xy, yz, x^2z + z^2 \right\rangle \cdot d\mathbf{S} = \iiint_V \operatorname{div}(\mathbf{F})\, dV = \iiint_V (x^2 + y + 3z)\, dV$$

$$= \int_0^{2\pi} \int_0^{\pi} \int_0^1 (\rho^2 \cos^2\theta \sin^2\phi + \rho \sin\theta \sin\phi + 3\rho\cos\phi) \cdot \rho^2 \sin\phi \, d\rho\, d\phi\, d\theta$$

$$= \left(\int_0^{2\pi} \cos^2\theta\, d\theta \right) \left(\int_0^{\pi} \sin^3\phi\, d\phi \right) \left(\int_0^1 \rho^4\, d\rho \right)$$

$$+ \left(\int_0^{2\pi} \sin\theta\, d\theta \right) \left(\int_0^{\pi} \sin^2\phi\, d\phi \right) \left(\int_0^1 \rho^3\, d\rho \right)$$

$$+ 6\pi \left(\int_0^{\pi} \cos\phi \sin\phi\, d\phi \right) \left(\int_0^1 \rho^3 d\rho \right)$$

$$= \pi \cdot \frac{4}{3} \cdot \frac{1}{5} + 0 + 0 = \frac{4\pi}{15}$$

25. $\mathbf{F} = \langle xyz + xy, \frac{1}{2}y^2(1 - z) + e^x, e^{x^2+y^2} \rangle$, $\mathcal{S}$ is the boundary of the solid bounded by the cylinder $x^2 + y^2 = 16$ and the planes $z = 0$ and $z = y - 4$.

SOLUTION We compute the divergence of $\mathbf{F}$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(xyz + xy) + \frac{\partial}{\partial y}\left(\frac{y^2}{2}(1 - z) + e^x \right) + \frac{\partial}{\partial z}(e^{x^2+y^2}) = yz + y + y(1 - z) = 2y$$

Let $\mathcal{S}$ denote the surface of the solid $\mathcal{W}$. The Divergence Theorem gives

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} 2y\, dV = \iint_{\mathcal{D}} \int_{y-4}^{0} 2y\, dz\, dx\, dy$$

$$= \iint_{\mathcal{D}} 2yz \Big|_{z=y-4}^{0} dx\, dy = \iint_{\mathcal{D}} 2y\,(0 - (y - 4))\, dx\, dy = \iint_{\mathcal{D}} (8y - 2y^2)\, dx\, dy$$

We convert the integral to polar coordinates:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^4 (8r\cos\theta - 2r^2\cos^2\theta) r\, dr\, d\theta$$

$$= 8 \left(\int_0^4 r^2\, dr \right) \left(\int_0^{2\pi} \cos\theta\, d\theta \right) - \left(\int_0^4 r^3\, dr \right) \left(\int_0^{2\pi} 2\cos^2\theta\, d\theta \right)$$

$$= 0 - \left(\frac{r^4}{4} \Big|_0^4 \right) \left(\theta + \frac{\sin 2\theta}{2} \Big|_0^{2\pi} \right) = -\frac{4^4}{4} \cdot 2\pi = -128\pi$$

26. $\mathbf{F} = \left\langle \sin(yz), \sqrt{x^2+z^4}, x\cos(x-y) \right\rangle$, $\mathcal{S}$ is any smooth closed surface that is the boundary of a region in $\mathbf{R}^3$.

SOLUTION We compute the divergence of $\mathbf{F}$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(\sin(yz)) + \frac{\partial}{\partial y}\left(\sqrt{x^2+z^4}\right) + \frac{\partial}{\partial z}(x\cos x(x-y)) = 0$$

Let $\mathcal{W}$ denote the solid inside $\mathcal{S}$. The Divergence Theorem gives

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV = \iiint_{\mathcal{W}} 0\, dV = 0$$

27. Find the volume of a region $\mathcal{W}$ if

$$\iint_{\partial \mathcal{W}} \left\langle x + xy + z, x + 3y - \frac{1}{2}y^2, 4z \right\rangle \cdot d\mathbf{S} = 16$$

SOLUTION Let $\mathbf{F} = \left\langle x + xy + z, x + 3y - \frac{1}{2}y^2, 4z \right\rangle$. We compute the divergence of $\mathbf{F}$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x + xy + z) + \frac{\partial}{\partial y}\left(x + 3y - \frac{1}{2}y^2\right) + \frac{\partial}{\partial z}(4z) = 1 + y + 3 - y + 4 = 8$$

Using the Divergence Theorem and the given information, we obtain

$$16 = \iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV = \iint_{\mathcal{W}} 8\, dV = 8 \iint_{\mathcal{W}} 1\, dV = 8 \text{ Volume } (\mathcal{W})$$

That is,

$$16 = 8 \text{ Volume } (\mathcal{W})$$

or

$$\text{Volume } (\mathcal{W}) = 2$$

28. Show that the circulation of $\mathbf{F} = \left\langle x^2, y^2, z(x^2+y^2) \right\rangle$ around any curve $\mathcal{C}$ on the surface of the cone $z^2 = x^2 + y^2$ is equal to zero (Figure 3).

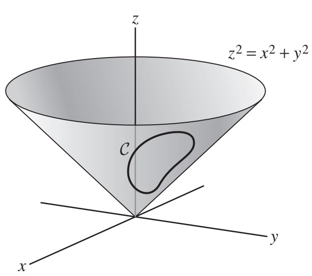


FIGURE 3

SOLUTION Let $\mathcal{S}$ be the part of the cone that is inside $\mathcal{C}$. Then by Stoke's Theorem, the circulation of $\mathbf{F}$ around $\mathcal{C}$ is

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} \tag{1}$$

We parametrize the cone by

$$\Phi(r, \theta) = (r\cos\theta, r\sin\theta, r)$$

Then,

$$\mathbf{T}_r = \frac{\partial \Phi}{\partial r} = \langle \cos\theta, \sin\theta, 1 \rangle$$

$$\mathbf{T}_\theta = \frac{\partial \Phi}{\partial \theta} = \langle -r\sin\theta, r\cos\theta, 0 \rangle$$

$$\mathbf{n} = \mathbf{T}_\theta \times \mathbf{T}_r = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -r\sin\theta & r\cos\theta & 0 \\ \cos\theta & \sin\theta & 1 \end{vmatrix} = \langle r\cos\theta, r\sin\theta, -r \rangle$$

We compute the curl of **F** and express it in terms of the parameters:

$$\text{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x^2 & y^2 & z(x^2+y^2) \end{vmatrix} = \langle 2yz, -2xz, 0\rangle$$

$$\text{curl}(\mathbf{F})\,(\Phi(r,\theta)) = \langle 2r\sin\theta\cdot r, -2r\cos\theta\cdot r, 0\rangle = \left\langle 2r^2\sin\theta, -2r^2\cos\theta, 0\right\rangle$$

The dot product is thus

$$\begin{aligned}\text{curl}(\mathbf{F})\big(\Phi(r,\theta)\big)\cdot\mathbf{n} &= \left\langle 2r^2\sin\theta, -2r^2\cos\theta, 0\right\rangle\cdot\langle r\cos\theta, r\sin\theta, -r\rangle \\ &= 2r^3\sin\theta\cos\theta - 2r^3\cos\theta\sin\theta + 0 = 0\end{aligned}$$

We see that curl(**F**) is tangent to the cone at all points on the cone, hence the surface integral in (1) is zero. We conclude that the circulation of **F** around any curve $\mathcal{C}$ on the cone is zero.

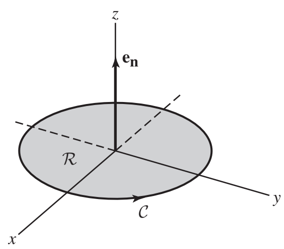
In Exercises 29–32, let **F** *be a vector field whose curl and divergence at the origin are*

$$\text{curl}(\mathbf{F})(0,0,0) = \langle 2,-1,4\rangle, \qquad \text{div}(\mathbf{F})(0,0,0) = -2$$

29. Estimate $\oint_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s}$, where $\mathcal{C}$ is the circle of radius 0.03 in the xy-plane centered at the origin.

SOLUTION We use the estimation

$$\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} \approx (\text{curl}(\mathbf{F})(\mathbf{0})\cdot\mathbf{e}_n)\,\text{Area}(\mathcal{R})$$



The unit normal vector to the disk $\mathcal{R}$ is $\mathbf{e}_n = \mathbf{k} = \langle 0,0,1\rangle$. The area of the disk is

$$\text{Area}\,(\mathcal{R}) = \pi\cdot 0.03^2 = 0.0009\pi.$$

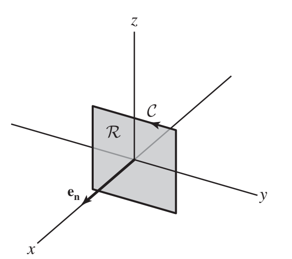
Using the given curl at the origin, we have

$$\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} \approx \langle 2,-1,4\rangle\cdot\langle 0,0,1\rangle\cdot 0.0009\pi = 4\cdot 0.0009\pi \approx 0.0113$$

30. Estimate $\oint_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s}$, where $\mathcal{C}$ is the boundary of the square of side 0.03 in the yz-plane centered at the origin. Does the estimate depend on how the square is oriented within the yz-plane? Might the actual circulation depend on how it is oriented?

SOLUTION We use the estimation

$$\int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} \approx (\text{curl}(\mathbf{F})(\mathbf{0})\cdot\mathbf{e}_n)\,\text{Area}\,(\mathcal{R}) \tag{1}$$



If we orient $\mathcal{C}$ counterclockwise, then the unit normal vector is

$$\mathbf{e}_n = \mathbf{i} = \langle 1, 0, 0 \rangle .$$

The area of the square is Area$(\mathcal{R}) = 0.03^2 = 0.0009$, and by the given information the curl at the origin is $\langle 2, -1, 4 \rangle$. Therefore (1) gives the estimation

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx \langle 2, -1, 4 \rangle \cdot \langle 1, 0, 0 \rangle \cdot 0.0009 = 2 \cdot 0.0009 = 0.0018$$

The estimate depend on curl$(\mathbf{F})$, $\mathbf{e}_n$ and the area of the square. Hence, if we flip the square over (such that $\mathbf{e}_n$ points along the negative x-axis), then we will get a different answer.

31. Suppose that $\mathbf{v}$ is the velocity field of a fluid and imagine placing a small paddle wheel at the origin. Find the equation of the plane in which the paddle wheel should be placed to make it rotate as quickly as possible.

SOLUTION The paddle wheel has the maximum spin when the circulation of the velocity field $\mathbf{v}$ around the wheel is maximum. The maximum circulation occurs when $\mathbf{e}_n$, and the curl of $\mathbf{v}$ at the origin (i.e., the vector $\langle 2, -1, 4 \rangle$) point in the same direction. Therefore, the plane in which the paddle wheel should be placed is the plane through the origin with the normal $\langle 2, -1, 4 \rangle$. This plane has the equation, $2x - y + 4z = 0$.

32. Estimate the flux of $\mathbf{F}$ through the box of side 0.5 in Figure 4. Does the result depend on how the box is oriented relative to the coordinate axes?

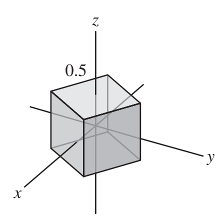


FIGURE 4

SOLUTION We use the following estimation:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} \approx \operatorname{div} \mathbf{F}(0) \text{ Volume } (\mathcal{W})$$

The volume of the box $\mathcal{W}$ is 0.5^3, and we are given that $\operatorname{div}(\mathbf{F})(0) = -2$. This gives the estimation

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} \approx -2 \cdot 0.5^3 = -0.25.$$

The negative sign shows that there is a net inflow across the box. Our estimation of the flux does not depend on the orientation of the box; rather, it depends on the magnitude of the divergence of $\mathbf{F}$.

33. The velocity vector field of a fluid (in meters per second) is

$$\mathbf{F} = \left\langle x^2 + y^2, 0, z^2 \right\rangle$$

Let $\mathcal{W}$ be the region between the hemisphere

$$\mathcal{S} = \left\{ (x, y, z) : x^2 + y^2 + z^2 = 1, \quad x, y, z \geq 0 \right\}$$

and the disk $\mathcal{D} = \left\{ (x, y, 0) : x^2 + y^2 \leq 1 \right\}$ in the xy-plane. Recall that the flow rate of a fluid across a surface is equal to the flux of $\mathbf{F}$ through the surface.

(a) Show that the flow rate across $\mathcal{D}$ is zero.

(b) Use the Divergence Theorem to show that the flow rate across $\mathcal{S}$, oriented with outward-pointing normal, is equal to $\iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F}) \, dV$. Then compute this triple integral.

SOLUTION

(a) To show that no fluid flows across $\mathcal{D}$, we show that the normal component of $\mathbf{F}$ at each point on $\mathcal{D}$ is zero. At each point $P = (x, y, 0)$ on the xy-plane,

$$\mathbf{F}(P) = \left\langle x^2 + y^2, 0, 0^2 \right\rangle = \left\langle x^2 + y^2, 0, 0 \right\rangle.$$

Moreover, the unit normal vector to the xy-plane is $\mathbf{e}_n = (0, 0, 1)$. Therefore,

$$\mathbf{F}(P) \cdot \mathbf{e}_n = \left\langle x^2 + y^2, 0, 0 \right\rangle \cdot \langle 0, 0, 1 \rangle = 0.$$

Since $\mathcal{D}$ is contained in the xy-plane, we conclude that the normal component of $\mathbf{F}$ at each point on $\mathcal{D}$ is zero. Therefore, no fluid flows across $\mathcal{D}$.

(b) By the Divergence Theorem and the linearity of the flux we have

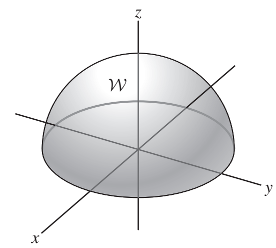
$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} + \iint_{\mathcal{D}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV$$

Since the flux through the disk $\mathcal{D}$ is zero, we have

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV \tag{1}$$

To compute the triple integral, we first compute $\operatorname{div}(\mathbf{F})$:

$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(x^2 + y^2) + \frac{\partial}{\partial y}(0) + \frac{\partial}{\partial z}(z^2) = 2x + 2z = 2(x + z).$$



Using spherical coordinates we get

$$\begin{aligned}
\iiint_{\mathcal{W}} \operatorname{div}(\mathbf{F})\, dV &= 2\int_0^{\pi/2}\int_0^{2\pi}\int_0^1 (\rho \sin\phi\cos\theta + \rho\cos\phi)\rho^2 \sin\phi\, d\rho\, d\phi \\
&= 2\int_0^1 \rho^3 d\rho \left(\left(\int_0^{\pi/2} \sin^2\phi\, d\phi\right)\left(\int_0^{2\pi} \cos\theta\, d\theta\right) + 2\pi \int_0^{\pi/2} \cos\phi \sin\phi\, d\rho\right) \\
&= \frac{1}{2}\left(0 + \pi \int_0^{\pi/2} \sin 2\phi\, d\phi\right) = \frac{\pi}{2}\left(-\frac{\cos 2\phi}{2}\right)\Bigg|_0^{\pi/2} = -\frac{\pi}{4}(-1-1) = \frac{\pi}{2}
\end{aligned}$$

Combining with (1) we obtain the flux:

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} = \frac{\pi}{2}$$

34. The velocity field of a fluid (in meters per second) is

$$\mathbf{F} = (3y - 4)\mathbf{i} + e^{-y(z+1)}\mathbf{j} + (x^2 + y^2)\mathbf{k}$$

(a) Estimate the flow rate (in cubic meters per second) through a small surface $\mathcal{S}$ around the origin if $\mathcal{S}$ encloses a region of volume 0.01 m^3.

(b) Estimate the circulation of $\mathbf{F}$ about a circle in the xy-plane of radius $r = 0.1$ m centered at the origin (oriented counterclockwise when viewed from above).

(c) Estimate the circulation of $\mathbf{F}$ about a circle in the yz-plane of radius $r = 0.1$ m centered at the origin (oriented counterclockwise when viewed from the positive x-axis).

SOLUTION

(a) We use the approximation

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} \approx \operatorname{div}(\mathbf{F})(\mathbf{0})\operatorname{Vol}(\mathcal{W}) \tag{1}$$

Here, $\operatorname{Vol}(\mathcal{W}) = 0.01\ \text{m}^3$. We compute the divergence at the origin:

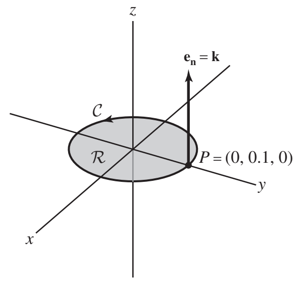
$$\operatorname{div}(\mathbf{F}) = \frac{\partial}{\partial x}(3y - 4) + \frac{\partial}{\partial y}e^{-y(z+1)} + \frac{\partial}{\partial z}(x^2 + y^2) = -(z+1)e^{-y(z+1)} \quad \Rightarrow \quad \operatorname{div}(\mathbf{F})(\mathbf{0}) = -1$$

Substituting in (1) gives the estimation

$$\iint_{\mathcal{S}} \mathbf{F} \cdot d\mathbf{S} \approx -1 \cdot 0.01 = -0.01\ \text{m}^3/\text{s}$$

(b) We use the estimation for the circulation using the point $P = (0, 0.1, 0)$:

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx (\operatorname{curl}(\mathbf{F})(P) \cdot \mathbf{e}_n) \text{ Area } (\mathcal{R}) \tag{2}$$



The unit normal vector to $\mathcal{R}$ is $\mathbf{e}_n = \langle 0, 0, 1\rangle = \mathbf{k}$ and the area of the disc is $\pi \cdot 0.1^2 = 0.01\pi$. We compute the curl at P:

$$\operatorname{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ (3y-4) & e^{-y(z+1)} & x^2+y^2 \end{vmatrix} = \left(2y - e^{-y(z+1)} \cdot (-y)\right)\mathbf{i} - (2x-0)\mathbf{j} + (0-3)\mathbf{k}$$

$$= \left(2y + ye^{-y(z+1)}\right)\mathbf{i} - 2x\mathbf{j} - 3\mathbf{k}$$

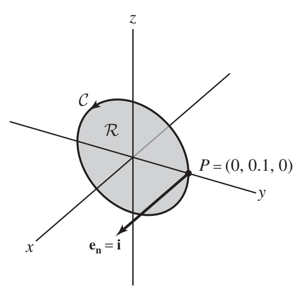
Hence,

$$\operatorname{curl}(\mathbf{F})(P) = (0.2 + 0.1e^{-0.1})\mathbf{i} - 3\mathbf{k}$$
$$D\operatorname{curl}(\mathbf{F})(P) \cdot \mathbf{e}_n = \left((0.2 + 0.1e^{-0.1})\mathbf{i} - 3\mathbf{k}\right) \cdot \mathbf{k} = -3$$

Combining with (2) gives the estimation

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx -3 \cdot 0.01\pi = -0.03\pi$$

(c) We use estimation (2), only that now the unit normal vector is $\mathbf{e}_n = \mathbf{i}$.



We get

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \approx \left(\left((0.2 + 0.1e^{-0.1})\mathbf{i} - 3\mathbf{k}\right) \cdot \mathbf{i}\right) 0.01\pi = (0.2 + 0.1e^{-0.1}) \cdot 0.01\pi = 0.009$$

35. Let $V(x, y) = x + \dfrac{x}{x^2 + y^2}$. The vector field $\mathbf{F} = \nabla V$ (Figure 5) provides a model in the plane of the velocity field of an incompressible, irrotational fluid flowing past a cylindrical obstacle (in this case, the obstacle is the unit circle $x^2 + y^2 = 1$).

(a) Verify that $\mathbf{F}$ is irrotational [by definition, $\mathbf{F}$ is irrotational if $\operatorname{curl}(\mathbf{F}) = \mathbf{0}$].

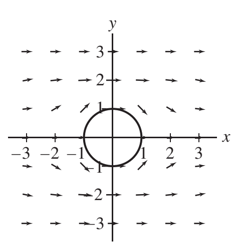


FIGURE 5 The vector field ∇V for $V(x, y) = x + \dfrac{x}{x^2 + y^2}$.

(b) Verify that $\mathbf{F}$ is tangent to the unit circle at each point along the unit circle except $(1, 0)$ and $(-1, 0)$ (where $\mathbf{F} = \mathbf{0}$).

(c) What is the circulation of $\mathbf{F}$ around the unit circle?

(d) Calculate the line integral of $\mathbf{F}$ along the upper and lower halves of the unit circle separately.

SOLUTION

(a) In Exercise 8, we proved the identity $\operatorname{curl}(\nabla\varphi) = \mathbf{0}$. Since $\mathbf{F}$ is a gradient vector field, it is irrotational; that is, $\operatorname{curl}(\mathbf{F}) = \mathbf{0}$ for $(x, y) \neq (0, 0)$, where $\mathbf{F}$ is defined.

(b) We compute $\mathbf{F}$ explicitly:

$$\mathbf{F} = \nabla\varphi = \left\langle \frac{\partial\varphi}{\partial x}, \frac{\partial\varphi}{\partial y} \right\rangle = \left\langle 1 + \frac{y^2 - x^2}{(x^2+y^2)^2}, -\frac{2xy}{(x^2+y^2)^2} \right\rangle$$

Now, using $x = \cos t$ and $y = \sin t$ as a parametrization of the circle, we see that

$$\mathbf{F} = \left\langle 1 + \sin^2 t - \cos^2 t, -2\cos t \sin t \right\rangle = \left\langle 2\sin^2 t, -2\cos t \sin t \right\rangle,$$

and so

$$\mathbf{F} = 2\sin t \langle \sin t, -\cos t \rangle = 2\sin t \langle y, -x \rangle,$$

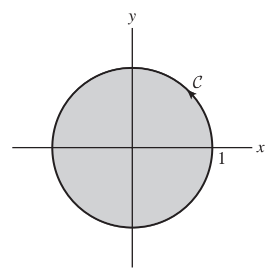
which is clearly perpendicular to the radial vector $\langle x, y \rangle$ for the circle.

(c) We use our expression of $\mathbf{F}$ from Part (b):

$$\mathbf{F} = \nabla\varphi = \left\langle 1 + \frac{y^2 - x^2}{(x^2+y^2)^2}, -\frac{2xy}{(x^2+y^2)^2} \right\rangle$$

Now, $\mathbf{F}$ is not defined at the origin and therefore we cannot use Green's Theorem to compute the line integral along the unit circle. We thus compute the integral directly, using the parametrization

$$\mathbf{c}(t) = (\cos t, \sin t), \quad 0 \le t \le 2\pi.$$



Then,

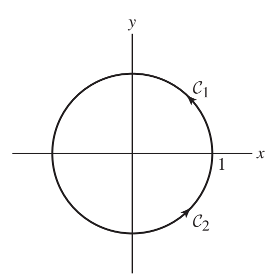
$$\begin{aligned}\mathbf{F}(\mathbf{c}(t)) \cdot c'(t) &= \left\langle 1 + \frac{\sin^2 t - \cos^2 t}{(\cos^2 t + \sin^2 t)^2}, -\frac{2\cos t \sin t}{(\cos^2 t + \sin^2 t)^2} \right\rangle \cdot \langle -\sin t, \cos t \rangle \\ &= \left\langle 1 + \sin^2 t - \cos^2 t, -2\cos t, \sin t \right\rangle \cdot \langle -\sin t, \cos t \rangle = \left\langle 2\sin^2 t, -2\cos t \sin t \right\rangle \cdot \langle -\sin t, \cos t \rangle \\ &= -2\sin^3 t - 2\cos^2 t \sin t = -2\sin t(\sin^2 t + \cos^2 t) = -2\sin t\end{aligned}$$

Hence,

$$\int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} = \int_0^{2\pi} -2\sin t \, dt = 0$$

(d) We denote by $\mathcal{C}_1$ and $\mathcal{C}_2$ the upper and lower halves of the unit circle. Using part (c) we have

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} + \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = 0 \quad \Rightarrow \quad \int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = -\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} \tag{1}$$



To compute the circulation along $\mathcal{C}_1$, we compute the integral as in part (c), only that the limits of integration are now $t = 0$ and $t = \pi$. Using the computations in part (c) we obtain

$$\int_{\mathcal{C}_1} \mathbf{F} \cdot d\mathbf{s} = \int_0^{\pi} -2\sin^2 t \, dt = -4$$

Therefore, by (1),

$$\int_{\mathcal{C}_2} \mathbf{F} \cdot d\mathbf{s} = 4.$$

36. Figure 6 shows the vector field $\mathbf{F} = \nabla V$, where

$$V(x, y) = \ln\left(x^2 + (y-1)^2\right) + \ln\left(x^2 + (y+1)^2\right)$$

which is the velocity field for the flow of a fluid with sources of equal strength at $(0, \pm 1)$ (note that V is undefined at these two points). Show that $\mathbf{F}$ is both irrotational and incompressible—that is, $\text{curl}_z(\mathbf{F}) = 0$ and $\text{div}(\mathbf{F}) = 0$ [in computing $\text{div}(\mathbf{F})$, treat $\mathbf{F}$ as a vector field in $\mathbf{R}^3$ with a zero z-component]. Is it necessary to compute $\text{curl}_z(\mathbf{F})$ to conclude that it is zero?

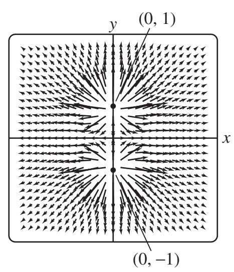


FIGURE 6 The vector field ∇V for $V(x, y) = \ln(x^2 + (y-1)^2) + \ln(x^2 + (y+1)^2)$.

SOLUTION Since $\mathbf{F}$ is a gradient field it is irrotational. This property was proved in Exercise 8, where we showed that $\text{curl}(\nabla\varphi) = \mathbf{0}$ for all φ. To show that $\mathbf{F}$ is incompressible, we first find $\mathbf{F}$ explicitly.

$$\begin{aligned}\mathbf{F}(x, y, z) &= \left\langle \frac{\partial\varphi}{\partial x}, \frac{\partial\varphi}{\partial y}, \frac{\partial\varphi}{\partial z} \right\rangle = \left\langle \frac{2x}{x^2 + (y-1)^2} + \frac{2x}{x^2 + (y+1)^2}, \frac{2(y-1)}{x^2 + (y-1)^2} + \frac{2(y+1)}{x^2 + (y+1)^2}, 0 \right\rangle \\ &= \langle F_1, F_2, F_3 \rangle\end{aligned}$$

Hence,

$$\begin{aligned}\text{div}\,\mathbf{F}(x, y, z) &= \frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z} \\ &= \frac{2\left(x^2 + (y-1)^2\right) - 2x \cdot 2x}{\left(x^2 + (y-1)^2\right)} + \frac{2\left(x^2 + (y+1)^2\right) - 2x \cdot 2x}{\left(x^2 + (y+1)^2\right)} \\ &\quad + \frac{2\left(x^2 + (y-1)^2\right) - 2(y-1) \cdot 2(y-1)}{\left(x^2 + (y-1)^2\right)} + \frac{2\left(x^2 + (y+1)^2\right) - 2 \cdot 2(y+1)^2}{\left(x^2 + (y+1)^2\right)} \\ &= 0 + 0 = 0\end{aligned}$$

Note that, again by Exercise 8, the divergence of $\nabla\varphi$ is zero, and hence so also is the divergence of $\mathbf{F}$.

37. In Section 17.1, we showed that if $\mathcal{C}$ is a simple closed curve, oriented counterclockwise, then the line integral is

$$\text{Area enclosed by } \mathcal{C} = \frac{1}{2} \oint_{\mathcal{C}} x\,dy - y\,dx \qquad \boxed{1}$$

Suppose that $\mathcal{C}$ is a path from P to Q that is not closed but has the property that every line through the origin intersects $\mathcal{C}$ in at most one point, as in Figure 7. Let $\mathcal{R}$ be the region enclosed by $\mathcal{C}$ and the two radial segments joining P and Q to the origin. Show that the line integral in Eq. (1) is equal to the area of $\mathcal{R}$. *Hint:* Show that the line integral of $\mathbf{F} = \langle -y, x \rangle$ along the two radial segments is zero and apply Green's Theorem.

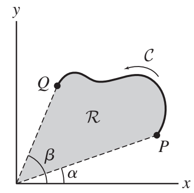

FIGURE 7

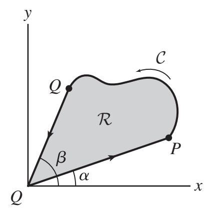
SOLUTION



Let $\mathbf{F} = \langle -y, x \rangle$. Then $P = -y$ and $Q = x$, and $\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} = 2$. By Green's Theorem, we have

$$\int_{\mathcal{C}} -y\,dx + x\,dy + \int_{\overline{QO}} -y\,dx + x\,dy + \int_{\overline{OP}} -y\,dx + x\,dy = \iint_{\mathcal{R}} 2\,dA = 2\iint_{\mathcal{R}} dA$$

Denoting by A the area of the region $\mathcal{R}$, we obtain

$$A = \frac{1}{2}\int_{\mathcal{C}} -y\,dx + x\,dy + \frac{1}{2}\int_{\overline{QO}} -y\,dx + x\,dy + \frac{1}{2}\int_{\overline{OP}} -y\,dx + x\,dy \tag{1}$$

We parametrize the two segments by

$$\begin{aligned} \overline{QO} &: \mathbf{c}(t) = (t, t\tan\beta) \\ \overline{OP} &: \mathbf{d}(t) = (t, t\tan\alpha) \end{aligned} \quad \Rightarrow \quad \begin{aligned} \mathbf{c}'(t) &= \langle 1, \tan\beta \rangle \\ \mathbf{d}'(t) &= \langle 1, \tan\alpha \rangle \end{aligned}$$

Then,

$$\mathbf{F}(\mathbf{c}(t)) \cdot \mathbf{c}'(t) = \langle -t\tan\beta, t \rangle \cdot \langle 1, \tan\beta \rangle = -t\tan\beta + t\tan\beta = 0$$
$$\mathbf{F}(\mathbf{d}(t)) \cdot \mathbf{d}'(t) = \langle -t\tan\alpha, t \rangle \cdot \langle 1, \tan\alpha \rangle = -t\tan\alpha + t\tan\alpha = 0$$

Therefore,

$$\int_{\overline{QO}} \mathbf{F} \cdot d\mathbf{s} = \int_{\overline{OP}} \mathbf{F} \cdot d\mathbf{s} = 0.$$

Combining with (1) gives

$$A = \frac{1}{2}\int_{\mathcal{C}} -y\,dx + x\,dy.$$

38. Suppose that the curve $\mathcal{C}$ in Figure 7 has the polar equation $r = f(\theta)$.

(a) Show that $\mathbf{c}(\theta) = (f(\theta)\cos\theta, f(\theta)\sin\theta)$ is a counterclockwise parametrization of $\mathcal{C}$.

(b) In Section 11.4, we showed that the area of the region $\mathcal{R}$ is given by the formula

$$\text{Area of } \mathcal{R} = \frac{1}{2}\int_{\alpha}^{\beta} f(\theta)^2\,d\theta$$

Use the result of Exercise 37 to give a new proof of this formula. *Hint:* Evaluate the line integral in Eq. (1) using $\mathbf{c}(\theta)$.

SOLUTION

(a) The curve $r = f(\theta)$ in polar coordinates can be parametrized using θ as a parameter. Since $x = r\cos\theta$ and $y = r\sin\theta$, we have

$$x = r\cos\theta = f(\theta)\cos\theta, \quad y = r\sin\theta = f(\theta)\sin\theta.$$

When θ varies from α to β, the path $\mathcal{C}$ is traversed counterclockwise.

(b) In Exercise 37 we showed that

$$\text{area of } \mathcal{R} = \frac{1}{2}\int_{\mathcal{C}} x\,dy - y\,dx \tag{1}$$

We evaluate the line integral using the parametrization in (a):

$$\mathbf{c}(\theta) = (f(\theta)\cos\theta, f(\theta)\sin\theta), \quad \alpha \le \theta \le \beta.$$

We have

$$\frac{dy}{d\theta} = f'(\theta)\sin\theta + f(\theta)\cos\theta \quad \Rightarrow \quad dy = \left(f'(\theta)\sin\theta + f(\theta)\cos\theta\right)d\theta$$
$$\frac{dx}{d\theta} = f'(\theta)\cos\theta - f(\theta)\sin\theta \quad \Rightarrow \quad dx = \left(f'(\theta)\cos\theta - f(\theta)\sin\theta\right)d\theta$$

Hence

$$\begin{aligned}\int_{\mathcal{C}} x\,dy - y\,dx &= \int_\alpha^\beta \left(f(\theta)\cos\theta\left(f'(\theta)\sin\theta + f(\theta)\cos\theta\right) - f(\theta)\sin\theta\left(f'(\theta)\cos\theta - f(\theta)\sin\theta\right)\right)d\theta\\ &= \int_\alpha^\beta \left(f(\theta)f'(\theta)\cos\theta\sin\theta + f^2(\theta)\cos^2\theta - f(\theta)f'(\theta)\sin\theta\cos\theta + f^2(\theta)\sin^2\theta\right)d\theta\\ &= \int_\alpha^\beta f^2(\theta)\left(\cos^2\theta + \sin^2\theta\right)d\theta = \int_\alpha^\beta f^2(\theta)\,d\theta\end{aligned}$$

Substituting in (1) we obtain

$$\text{area of } \mathcal{R} = \frac{1}{2}\int_\alpha^\beta f^2(\theta)\,d\theta$$

39. Prove the following generalization of Eq. (1). Let $\mathcal{C}$ be a simple closed curve in the plane (Figure 8)

$$\mathcal{S}: \quad ax + by + cz + d = 0$$

Then the area of the region R enclosed by $\mathcal{C}$ is equal to

$$\frac{1}{2\|\mathbf{n}\|}\oint_{\mathcal{C}} (bz - cy)\,dx + (cx - az)\,dy + (ay - bx)\,dz$$

where $\mathbf{n} = \langle a, b, c\rangle$ is the normal to $\mathcal{S}$, and $\mathcal{C}$ is oriented as the boundary of $\mathcal{R}$ (relative to the normal vector $\mathbf{n}$). *Hint:* Apply Stokes' Theorem to $\mathbf{F} = \langle bz - cy, cx - az, ay - bx\rangle$.

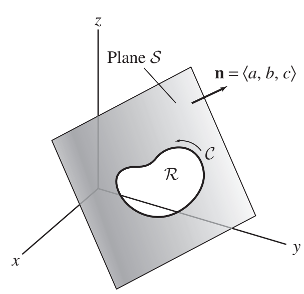


FIGURE 8

SOLUTION By Stokes' Theorem,

$$\iint_{\mathcal{S}} \text{curl}(\mathbf{F})\cdot d\mathbf{S} = \iint_{\mathcal{S}} (\text{curl}(\mathbf{F})\cdot \mathbf{e}_n)\;dS = \int_{\mathcal{C}} \mathbf{F}\cdot d\mathbf{s} \tag{1}$$

We compute the curl of $\mathbf{F}$:

$$\text{curl}(\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k}\\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z}\\ bz - cy & cx - az & ay - bx\end{vmatrix} = 2a\mathbf{i} + 2b\mathbf{j} + 2c\mathbf{k} = 2\langle a, b, c\rangle$$

The unit normal to the plane $ax + by + cz + d = 0$ is

$$\mathbf{e}_n = \frac{\langle a, b, c\rangle}{\sqrt{a^2 + b^2 + c^2}}$$

Therefore,

$$\begin{aligned}\operatorname{curl}(\mathbf{F}) \cdot \mathbf{e}_n &= 2\langle a, b, c\rangle \cdot \frac{1}{\sqrt{a^2+b^2+c^2}}\langle a, b, c\rangle \\ &= \frac{2}{\sqrt{a^2+b^2+c^2}}(a^2+b^2+c^2) = 2\sqrt{a^2+b^2+c^2}\end{aligned}$$

Hence,

$$\iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} = \iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot \mathbf{e}_n \, dS = \iint_{\mathcal{S}} 2\sqrt{a^2+b^2+c^2}\, dS = 2\sqrt{a^2+b^2+c^2} \iint_{\mathcal{S}} 1 \, dS \tag{2}$$

The sign of $\iint_S 1\, d\mathbf{S}$ is determined by the orientation of $\mathcal{S}$. Since the area is a positive value, we have

$$\left| \iint_{\mathcal{S}} 1 \, ds \right| = \text{Area}\,(\mathcal{S})$$

Therefore, (2) gives

$$\left| \iint_{\mathcal{S}} \operatorname{curl}(\mathbf{F}) \cdot d\mathbf{S} \right| = 2\sqrt{a^2+b^2+c^2}\, \text{Area}(S)$$

Combining with (1) we obtain

$$2\sqrt{a^2+b^2+c^2}\, \text{Area}(\mathcal{S}) = \left| \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{s} \right|$$

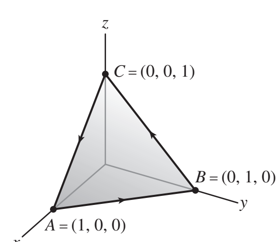
or

$$\text{Area}(\mathcal{S}) = \frac{1}{2\sqrt{a^2+b^2+c^2}} = \frac{1}{2\|\mathbf{n}\|} \cdot \left| \int_{\mathcal{C}} (bz - cy)\, dx + (cx - az)\, dy + (ay - bx)\, dz \right|$$

40. Use the result of Exercise 39 to calculate the area of the triangle with vertices (1, 0, 0), (0, 1, 0), and (0, 0, 1) as a line integral. Verify your result using geometry.

SOLUTION In Exercise 39 we showed that if $\mathcal{C}$ is a simple closed curve in the plane $ax + by + cz + d = 0$, then the area of the region $\mathcal{R}$ enclosed by $\mathcal{C}$ is equal to

$$\frac{1}{2\|\mathbf{n}\|} \int_{\mathcal{C}} (bz - cy)\, dx + (cx - az)\, dy + (ay - bx)\, dz, \ \mathbf{n} = \langle a, b, c\rangle \tag{1}$$



We use this formula where $\mathcal{C}$ is the triangle ABC parametrized counterclockwise. We compute the upward-pointing normal to the plane of the triangle:

$$\mathbf{n} = \overrightarrow{AB} \times \overrightarrow{AC} = (\mathbf{j} - \mathbf{i}) \times (\mathbf{k} - \mathbf{i}) = \mathbf{i} + \mathbf{k} + \mathbf{j} = \mathbf{i} + \mathbf{j} + \mathbf{k}.$$

We substitute $\|\mathbf{n}\| = \sqrt{1^2 + 1^2 + 1^2} = \sqrt{3}$ and $a = b = c = 1$ in (1) to obtain:

$$\text{area of } \mathcal{R} = \frac{1}{2\sqrt{3}} \int_{\mathcal{C}} (z - y)\, dx + (x - z)\, dy + (y - x)\, dz \tag{2}$$

We parametrized the oriented segments by

$$\begin{aligned}
\overline{AB} &: \mathbf{c}_1(t) = (1-t, t, 0), \quad 0 \le t \le 1 \quad \Rightarrow \quad dx = -dt, \quad dy = dt, \quad dz = 0 \\
\overline{BC} &: \mathbf{c}_2(t) = (0, 1-t, t), \quad 0 \le t \le 1 \quad \Rightarrow \quad dx = 0, \quad dy = -dt, \quad dz = dt \\
\overline{CA} &: \mathbf{c}_3(t) = (t, 0, 1-t), \quad 0 \le t \le 1 \quad \Rightarrow \quad dx = dt, \quad dy = 0, \quad dz = -dt
\end{aligned}$$

We compute the line integral along each segment separately:

$$\int_{\overline{AB}} (z-y)\,dx + (x-z)\,dy + (y-x)\,dz = \int_0^1 (0-t)(-dt) + (1-t-0)\,dt = \int_0^1 1\,dt = 1$$
$$\int_{\overline{BC}} (z-y)\,dx + (x-z)\,dy + (y-x)\,dz = \int_0^1 (0-t)(-dt) + (1-t-0)\,dt = \int_0^1 1\,dt = 1$$
$$\int_{\overline{CA}} (z-y)\,dx + (x-z)\,dy + (y-x)\,dz = \int_0^1 (1-t-0)\,dt + (0-t)(-dt) = \int_0^1 1\,dt = 1$$

The integral along $\mathcal{C}$ is the sum of these three integrals. That is,

$$\int_{\mathcal{C}} (z-c)\,dx + (x-z)\,dy + (y-x)\,dz = 1+1+1 = 3$$

We combine with (2) to obtain the following area of the triangle:

$$\text{area of } \mathcal{R} = \frac{1}{2\sqrt{3}} \cdot 3 = \frac{\sqrt{3}}{2}$$

We verify this solution geometrically. The triangle spanned by the vectors $\overrightarrow{AB} = \mathbf{j} - \mathbf{i}$ and $\overrightarrow{AC} = \mathbf{k} - \mathbf{i}$ has area

$$\frac{1}{2}\left\|\overrightarrow{AB} \times \overrightarrow{AC}\right\| = \frac{1}{2}\|\mathbf{i}+\mathbf{j}+\mathbf{k}\| = \frac{1}{2}\sqrt{3}.$$

The two answers match.

41. Show that $G(\theta,\phi) = (a\cos\theta\sin\phi, b\sin\theta\sin\phi, c\cos\phi)$ is a parametrization of the ellipsoid

$$\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 = 1$$

Then calculate the volume of the ellipsoid as the surface integral of $\mathbf{F} = \frac{1}{3}\langle x, y, z\rangle$ (this surface integral is equal to the volume by the Divergence Theorem).

SOLUTION For the given parametrization,

$$x = a\cos\theta\sin\phi, \quad y = b\sin\theta\sin\phi, \quad z = c\cos\phi \tag{1}$$

We show that it satisfies the equation of the ellipsoid

$$\begin{aligned}\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2 &= \left(\frac{a\cos\theta\sin\phi}{a}\right)^2 + \left(\frac{b\sin\theta\sin\phi}{b}\right)^2 + \left(\frac{c\cos\phi}{c}\right)^2 \\ &= \cos^2\theta\sin^2\phi + \sin^2\theta\sin^2\phi + \cos^2\phi \\ &= \sin^2\phi(\cos^2\theta + \sin^2\theta) + \cos^2\phi \\ &= \sin^2\phi + \cos^2\phi = 1\end{aligned}$$

Conversely, for each (x, y, z) on the ellipsoid, there exists θ and ϕ so that (1) holds. Therefore $\Phi(\theta,\phi)$ parametrizes the whole ellipsoid. Let $\mathcal{W}$ be the interior of the ellipsoid $\mathcal{S}$. Then by Eq. (10):

$$\text{Volume}(\mathcal{W}) = \frac{1}{3}\iint_{\mathcal{S}} \mathbf{F}\cdot d\mathbf{S}, \quad \mathbf{F} = \langle x, y, z\rangle$$

We compute the surface integral, using the given parametrization. We first compute the normal vector:

$$\begin{aligned}\frac{\partial\Phi}{\partial\theta} &= \langle -a\sin\theta\sin\phi, b\cos\theta\sin\phi, 0\rangle \\ \frac{\partial\Phi}{\partial\phi} &= \langle a\cos\theta\cos\phi, b\sin\theta\cos\phi, -c\sin\phi\rangle \\ \frac{\partial\Phi}{\partial\theta}\times\frac{\partial\Phi}{\partial\phi} &= -ab\sin^2\theta\sin\phi\cos\phi\mathbf{k} - ac\sin\theta\sin^2\phi\mathbf{j} - ab\cos^2\theta\sin\phi\cos\phi\mathbf{k} - bc\cos\theta\sin^2\phi\mathbf{i} \\ &= \left\langle -bc\cos\theta\sin^2\phi, -ac\sin\theta\sin^2\phi, -ab\sin\phi\cos\phi\right\rangle\end{aligned}$$

Hence, the outward pointing normal is

$$\mathbf{n} = \left\langle bc\cos\theta\sin^2\phi, ac\sin\theta\sin^2\phi, ab\sin\phi\cos\phi\right\rangle$$

$$\begin{aligned}
\mathbf{F}(\Phi(\theta,\phi))\cdot\mathbf{n} &= \langle a\cos\theta\sin\phi,\, b\sin\theta\sin\phi,\, c\cos\phi\rangle\cdot\left\langle bc\cos\theta\sin^2\phi,\, ac\sin\theta\sin^2\phi,\, ab\sin\phi\cos\phi\right\rangle\\
&= abc\cos^2\theta\sin^3\phi + abc\sin^2\theta\sin^3\phi + abc\sin\phi\cos^2\phi\\
&= abc\sin^3\phi(\cos^2\theta+\sin^2\theta) + abc\sin\phi\cos^2\phi\\
&= abc\sin^3\phi + abc\sin\phi\cos^2\phi = abc\sin^3\phi + abc\sin\phi(1-\sin^2\phi)\\
&= abc\sin\phi
\end{aligned}$$

We obtain the following integral:

$$\begin{aligned}
\text{Volume}(\mathcal{W}) &= \frac{1}{3}\iint_{\mathcal{S}}\mathbf{F}\cdot d\mathbf{S} = \frac{1}{3}\int_0^{2\pi}\int_0^{\pi} abc\sin\phi\,d\phi\,d\theta\\
&= \frac{2\pi abc}{3}\int_0^{\pi}\sin\phi\,d\varphi = \frac{2\pi abc}{3}\left(-\cos\phi\Big|_0^{\pi}\right) = \frac{4\pi abc}{3}
\end{aligned}$$
